9. Can you remember mapping properties of $w = \sin z$? $\cos z$? e^z?
10. What is a Riemann surface? Why was it introduced? Explain the simplest example.

11–16 MAPPING $w = z^2$

Find and sketch the image of the given curve or region under $w = z^2$.

11. $y = -1$, $y = 1$
12. $xy = -4$
13. $|z| = 4.5$, $|\arg z| < \pi/4$
14. $0 < y < 2$
15. $\frac{1}{2} < x < 1$
16. $\operatorname{Im} z > 0$

17–22 MAPPING $w = 1/z$

Find and sketch the image of the given curve or region under $w = 1/z$.

17. $x = -1$
18. $y = 1$

19. $|z - \frac{1}{2}| = \frac{1}{2}$ **20.** $|z| < \frac{1}{2}$, $y < 0$

21. $|\arg z| < \pi/4$ **22.** $|z| < 1$, $x < 0$, $y > 0$

23–28 FAILURE OF CONFORMALITY

Where is the mapping by the given function not conformal? (Give reason.)

23. $5z^7 + 7z^5$ **24.** $\cosh 2z$

25. $\sin 2z + \cos 2z$ **26.** $\cos \pi z^2$

27. $\exp(z^4 + z^2)$ **28.** $z + 1/z$ $(z \neq 0)$

29–34 LINEAR FRACTIONAL TRANSFORMATIONS (LFTs)

Find the LFT that maps

29. 0, 1, 2 onto 0, i, $2i$, respectively

30. -1, 1, 2 onto 0, 2, 3/2, respectively

31. 1, -1, $-i$ onto 1, -1, i, respectively

32. -1, $-i$, i onto $1 - i$, 2, 0, respectively

33. 0, ∞, -2 onto 0, 1, ∞, respectively

34. 0, i, $2i$ onto 0, ∞, $2i$

35–40 Fixed Points. Find all fixed points of

35. $w = \dfrac{z + 2}{z + 1}$ **36.** $w = \dfrac{2iz - 1}{z + 2i}$

37. $w = \dfrac{3z + 2}{z - 1}$ **38.** $w = \dfrac{iz + 5}{5z + i}$

39. $w = \dfrac{(2 + i)z + 1}{z - i}$ **40.** $w = z^4 + z - 81$

41–45 GIVEN REGIONS

Find an analytic function $w = f(z)$ that maps:

41. The infinite strip $0 < y < \pi/3$ onto the upper half-plane $v > 0$.

42. The interior of the unit circle $|z| = 1$ onto the exterior of the circle $|w + 1| = 5$.

43. The region $x > 0$, $y > 0$, $xy < k$ onto the strip $0 < v < 1$.

44. The semi-disk $|z| < 1$, $x > 0$ onto the exterior of the unit circle $|w| = 1$.

45. The sector $0 < \arg z < \pi/3$ onto the region $u < 1$.

SUMMARY OF CHAPTER 17
Conformal Mapping

A complex function $w = f(z)$ gives a **mapping** of its domain of definition in the complex z-plane onto its range of values in the complex w-plane. If $f(z)$ is *analytic*, this mapping is **conformal,** that is, angle-preserving: the images of any two intersecting curves make the same angle of intersection, in both magnitude and sense, as the curves themselves (Sec. 17.1). Exceptions are the points at which $f'(z) = 0$ (**"critical points,"** e.g. $z = 0$ for $w = z^2$).

For mapping properties of e^z, $\cos z$, $\sin z$, etc. see Secs. 17.1 and 17.4.

Linear fractional transformations, also called *Möbius transformations*

$$(1) \qquad w = \frac{az + b}{cz + d} \qquad \text{(Secs. 17.2, 17.3)}$$

$(ad - bc \neq 0)$ map the extended complex plane (Sec. 17.2) onto itself. They solve the problems of mapping half-planes onto half-planes or disks, and disks onto disks or half-planes. Prescribing the images of three points determines (1) uniquely.

Riemann surfaces (Sec. 17.5) consist of several sheets connected at certain points called *branch points.* On them, multivalued relations become single-valued, that is, functions in the usual sense. *Examples.* For $w = \sqrt{z}$ we need two sheets (with branch point 0) since this relation is doubly-valued. For $w = \ln z$ we need infinitely many sheets since this relation is infinitely many-valued (see Sec. 13.7).

CHAPTER 18

Complex Analysis and Potential Theory

Laplaces's equation $\nabla^2\Phi = 0$ is one of the most important PDEs in engineering mathematics, because it occurs in gravitation (Secs. 9.7, 12.10), electrostatics (Sec. 9.7), steady-state heat conduction (Sec. 12.5), incompressible fluid flow, etc. The theory of solutions of this equation is called **potential theory** (although "potential" is also used in a more general sense in connection with gradients; see Sec. 9.7).

In the "two-dimensional case" when Φ depends only on two Cartesian coordinates x and y, Laplace's equation becomes

$$\nabla^2\Phi = \Phi_{xx} + \Phi_{yy} = 0.$$

From Sec. 13.4 we know that then its solutions Φ are closely related to complex analytic functions $\Phi + i\,\Psi$. This relation is the main reason for the importance of complex analysis in physics and engineering. (We use the notation $\Phi + i\,\Psi$ since $u + iv$ will be needed in conformal mapping.)

In this chapter we shall consider this connection and its consequences in detail and illustrate it by modeling typical examples from electrostatics (Secs. 18.1, 18.2), heat conduction (Sec. 18.3), and hydrodynamics (Sec. 18.4). This will lead to **boundary value problems,** some of which involving functions whose mapping properties we have studied in Chap. 17. Further relating to that chapter, in Sec. 18.2 we explain conformal mapping as a method in potential theory.

In Sec. 18.5 we derive the important Poisson formula for potentials in a circular disk.

Finally, in Sec. 18.6 we show that results on analytic functions can be used to characterize *general* properties of **harmonic functions** (solutions of Laplace's equation whose second partial derivatives are continuous).

Prerequisite: Chaps. 13, 14, 17.
References and Answers to Problems: App. 1 Part D, App. 2.

18.1 Electrostatic Fields

The electrical force of attraction or repulsion between charged particles is governed by Coulomb's law. This force is the gradient of a function Φ, called the **electrostatic potential.** At any points free of charges, Φ is a solution of Laplace's equation

$$\nabla^2\Phi = 0.$$

The surfaces $\Phi = const$ are called **equipotential surfaces.** At each point P at which the gradient of Φ is not the zero vector, it is perpendicular to the surface $\Phi = const$ through P; that is, the electrical force has the direction perpendicular to the equipotential surface. (See also Secs. 9.7 and 12.10.)

The problems we shall discuss in this entire chapter are **two-dimensional** (for the reason just given in the chapter opening), that is, they model physical systems that lie in three-dimensional space (of course!), but are such that the potential Φ is independent of one of the space coordinates, so that Φ depends only on two coordinates, which we call x and y. Then **Laplace's equation** becomes

$$\nabla^2\Phi = \frac{\partial^2\Phi}{\partial x^2} + \frac{\partial^2\Phi}{\partial y^2} = 0. \tag{1}$$

Equipotential surfaces now appear as **equipotential lines** (curves) in the xy-plane.

Let us illustrate these ideas by a few simple basic examples.

EXAMPLE 1 Potential Between Parallel Plates

Find the potential Φ of the field between two parallel conducting plates extending to infinity (Fig. 393), which are kept at potentials Φ_1 and Φ_2, respectively.

Solution. From the shape of the plates it follows that Φ depends only on x, and Laplace's equation becomes $\Phi'' = 0$. By integrating twice we obtain $\Phi = ax + b$, where the constants a and b are determined by the given boundary values of Φ on the plates. For example, if the plates correspond to $x = -1$ and $x = 1$, the solution is

$$\Phi(x) = \tfrac{1}{2}(\Phi_2 - \Phi_1)x + \tfrac{1}{2}(\Phi_2 + \Phi_1).$$

The equipotential surfaces are parallel planes. ■

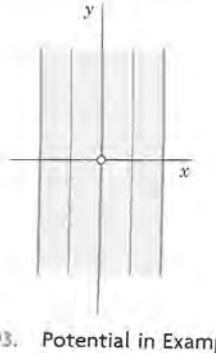

Fig. 393. Potential in Example 1

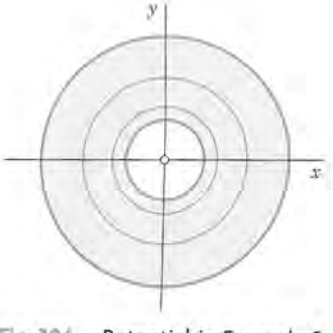

Fig. 394. Potential in Example 2

EXAMPLE 2 **Potential Between Coaxial Cylinders**

Find the potential Φ between two coaxial conducting cylinders extending to infinity on both ends (Fig. 394) and kept at potentials Φ_1 and Φ_2, respectively.

Solution. Here Φ depends only on $r = \sqrt{x^2 + y^2}$, for reasons of symmetry, and Laplace's equation $r^2 u_{rr} + r u_r + u_{\theta\theta} = 0$ [(5), Sec. 12.9] with $u_{\theta\theta} = 0$ and $u = \Phi$ becomes $r\Phi'' + \Phi' = 0$. By separating variables and integrating we obtain

$$\frac{\Phi''}{\Phi'} = -\frac{1}{r}, \qquad \ln \Phi' = -\ln r + \tilde{a}, \qquad \Phi' = \frac{a}{r}, \qquad \Phi = a \ln r + b$$

and a and b are determined by the given values of Φ on the cylinders. Although no infinitely extended conductors exist, the field in our idealized conductor will approximate the field in a long finite conductor in that part which is far away from the two ends of the cylinders. ■

EXAMPLE 3 **Potential in an Angular Region**

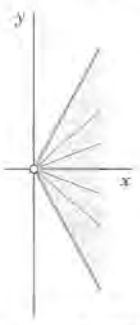

Fig. 395. Potential in Example 3

Find the potential Φ between the conducting plates in Fig. 395, which are kept at potentials Φ_1 (the lower plate) and Φ_2, and make an angle α, where $0 < \alpha \leqq \pi$. (In the figure we have $\alpha = 120° = 2\pi/3$.)

Solution. $\theta = \operatorname{Arg} z$ $(z = x + iy \neq 0)$ is constant on rays $\theta = const$. It is harmonic since it is the imaginary part of an analytic function, $\operatorname{Ln} z$ (Sec. 13.7). Hence the solution is

$$\Phi(x, y) = a + b \operatorname{Arg} z$$

with a and b determined from the two boundary conditions (given values on the plates)

$$a + b(-\tfrac{1}{2}\alpha) = \Phi_1, \qquad a + b(\tfrac{1}{2}\alpha) = \Phi_2.$$

Thus $a = (\Phi_2 + \Phi_1)/2$, $b = (\Phi_2 - \Phi_1)/\alpha$. The answer is

$$\Phi(x, y) = \frac{1}{2}(\Phi_2 + \Phi_1) + \frac{1}{\alpha}(\Phi_2 - \Phi_1)\theta, \qquad \theta = \arctan \frac{y}{x}. \quad ■$$

Complex Potential

Let $\Phi(x, y)$ be harmonic in some domain D and $\Psi(x, y)$ a harmonic conjugate of Φ in D. (See Sec. 13.4, where we wrote u and v, now needed in conformal mapping from the next section on; hence the change to Φ and Ψ.) Then

$$F(z) = \Phi(x, y) + i\Psi(x, y) \tag{2}$$

is an analytic function of $z = x + iy$. This function F is called the **complex potential** corresponding to the real potential Φ. Recall from Sec. 13.4 that for given Φ, a conjugate Ψ is uniquely determined except for an additive real constant. Hence we may say ***the*** complex potential, without causing misunderstandings.

The use of F has two advantages, a technical one and a physical one. Technically, F is easier to handle than real or imaginary parts, in connection with methods of complex analysis. Physically, Ψ has a meaning. By conformality, the curves $\Psi = const$ intersect the equipotential lines $\Phi = const$ in the xy-plane at right angles [except where $F'(z) = 0$]. Hence they have the direction of the electrical force and, therefore, are called **lines of force.** They are the paths of moving charged particles (electrons in an electron microscope, etc.).

EXAMPLE 4 **Complex Potential**

In Example 1, a conjugate is $\Psi = ay$. It follows that the complex potential is

$$F(z) = az + b = ax + b + iay.$$

and the lines of force are horizontal straight lines $y = const$ parallel to the x-axis. ■

EXAMPLE 5 Complex Potential

In Example 2 we have $\Phi = a \ln r + b = a \ln |z| + b$. A conjugate is $\Psi = a \operatorname{Arg} z$. Hence the complex potential is

$$F(z) = a \operatorname{Ln} z + b$$

and the lines of force are straight lines through the origin. $F(z)$ may also be interpreted as the complex potential of a source line (a wire perpendicular to the xy-plane) whose trace in the xy-plane is the origin. ■

EXAMPLE 6 Complex Potential

In Example 3 we get $F(z)$ by noting that $i \operatorname{Ln} z = i \ln |z| - \operatorname{Arg} z$, multiplying this by $-b$, and adding a:

$$F(z) = a - ib \operatorname{Ln} z = a + b \operatorname{Arg} z - ib \ln |z|.$$

We see from this that the lines of force are concentric circles $|z| = const$. Can you sketch them? ■

Superposition

More complicated potentials can often be obtained by superposition.

EXAMPLE 7 Potential of a Pair of Source Lines (a Pair of Charged Wires)

Determine the potential of a pair of oppositely charged source lines of the same strength at the points $z = c$ and $z = -c$ on the real axis.

Solution. From Examples 2 and 5 it follows that the potential of each of the source lines is

$$\Phi_1 = K \ln |z - c| \qquad \text{and} \qquad \Phi_2 = -K \ln |z + c|,$$

respectively. Here the real constant K measures the strength (amount of charge). These are the real parts of the complex potentials

$$F_1(z) = K \operatorname{Ln} (z - c) \qquad \text{and} \qquad F_2(z) = -K \operatorname{Ln} (z + c).$$

Hence the complex potential of the combination of the two source lines is

$$F(z) = F_1(z) + F_2(z) = K [\operatorname{Ln} (z - c) - \operatorname{Ln} (z + c)]. \tag{3}$$

The **equipotential lines** are the curves

$$\Phi = \operatorname{Re} F(z) = K \ln \left| \frac{z - c}{z + c} \right| = const, \qquad \text{thus} \qquad \left| \frac{z - c}{z + c} \right| = const.$$

These are circles, as you may show by direct calculation. The **lines of force** are

$$\Psi = \operatorname{Im} F(z) = K[\operatorname{Arg} (z - c) - \operatorname{Arg} (z + c)] = const.$$

We write this briefly (Fig. 396)

$$\Psi = K(\theta_1 - \theta_2) = const.$$

Now $\theta_1 - \theta_2$ is the angle between the line segments from z to c and $-c$ (Fig. 396). Hence the lines of force are the curves along each of which the line segment S: $-c \leqq x \leqq c$ appears under a constant angle. These curves are the totality of circular arcs over S, as is (or should be) known from elementary geometry. Hence the lines of force are circles. Figure 397 shows some of them together with some equipotential lines.

In addition to the interpretation as the potential of two source lines, this potential could also be thought of as the potential between two circular cylinders whose axes are parallel but do not coincide, or as the potential between two equal cylinders that lie outside each other, or as the potential between a cylinder and a plane wall. Explain this, using Fig. 397. ■

The idea of the complex potential as just explained is the key to a close relation of potential theory to complex analysis and will recur in heat flow and fluid flow.

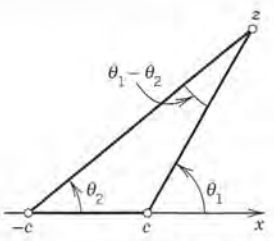

Fig. 396. Arguments in Example 7

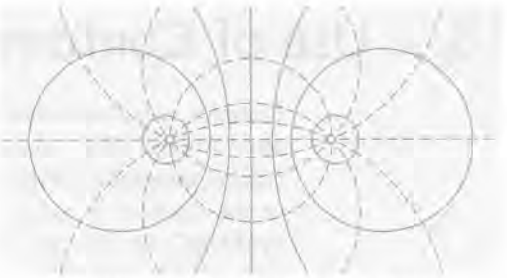

Fig. 397. Equipotential lines and lines of force (dashed) in Example 7

PROBLEM SET 18.1

1–4 POTENTIAL

Find and sketch the potential. Find the complex potential:

1. Between parallel plates at $x = -3$ and 3, potentials 140 V and 260 V, respectively
2. Between parallel plates at $x = -4$ and 10, potentials 4.4 kV and 10 kV, respectively
3. Between the axes (potential 110 V) and the hyperbola $xy = 1$ (potential 60 V)
4. Between parallel plates at $y = x$ and $x + k$, potentials 0 and 100 V, respectively

5–8 COAXIAL CYLINDERS

Find the potential between two infinite coaxial cylinders of radii r_1 and r_2 having potentials U_1 and U_2, respectively. Find the complex potential.

5. $r_1 = 0.5$, $r_2 = 2.0$, $U_1 = -110$ V, $U_2 = 110$ V
6. $r_1 = 1$, $r_2 = 10$, $U_1 = 100$ V, $U_2 = 1$ kV
7. $r_1 = 1$, $r_2 = 4$, $U_1 = 200$ V, $U_2 = 0$
8. $r_1 = 0.1$, $r_2 = 10$, $U_1 = 150$ V, $U_2 = 50$ V

9. Show that $\Phi = \theta/\pi = (1/\pi) \arctan(y/x)$ is harmonic in the upper half-plane and satisfies the boundary condition $\Phi(x, 0) = 1$ if $x < 0$ and 0 if $x > 0$, and the corresponding complex potential is $F(z) = -(i/\pi)\,\mathrm{Ln}\, z$.
10. Map the upper half z-plane onto the unit disk $|w| \leqq 1$ so that $0, \infty, -1$ are mapped onto $1, i, -i$, respectively. What are the boundary conditions on $|w| = 1$ resulting from the potential in Prob. 9? What is the potential at $w = 0$?
11. Verify by calculation that the equipotential lines in Example 7 are circles.
12. **CAS EXPERIMENT. Complex Potentials.** Graph the equipotential lines and lines of force in (a)–(d) (four graphs, Re $F(z)$ and Im $F(z)$ on the same axes). Then explore further complex potentials of your choice with the purpose of discovering configurations that might be of practical interest.
    (a) $F(z) = z^2$ **(b)** $F(z) = iz^2$
    (c) $F(z) = 1/z$ **(d)** $F(z) = i/z$

13–15 POTENTIALS FOR OTHER CONFIGURATIONS

13. Show that $F(z) = \arccos z$ (defined in Problem Set 13.7) gives the potential in Figs. 398 and 399.

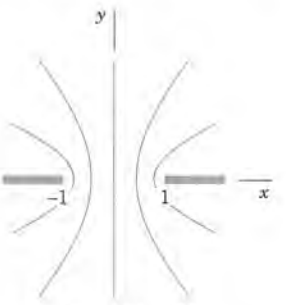

Fig. 398. Slit

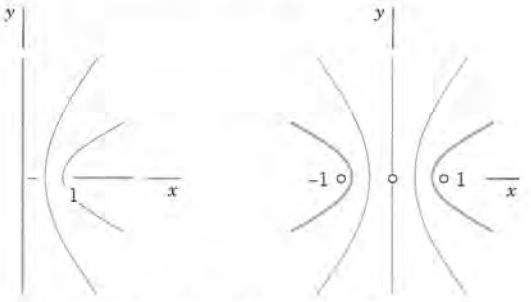

Fig. 399. Other apertures

14. Find the real and complex potentials in the sector $-\pi/6 \leqq \theta \leqq \pi/6$ between the boundary $\theta = \pm\pi/6$ (kept at 0) and the curve $x^3 - 3xy^2 = 1$, kept at 110 V.
15. Find the potential in the first quadrant of the xy-plane between the axes (having potential 220 V) and the hyperbola $xy = 1$ (having potential 110 V).

18.2 Use of Conformal Mapping. Modeling

Complex potentials relate potential theory closely to complex analysis, as we have just seen. Another close relation results from the use of conformal mapping in modeling and solving **boundary value problems** for the Laplace equation, that is, in finding a solution of the equation in some domain assuming given values on the boundary (**"Dirichlet problem"**; see also Sec. 12.5). Then conformal mapping is used to map a given domain onto one for which the solution is known or can be found more easily. This solution is then mapped back to the given domain. This is the idea. That it works is due to the fact that harmonic functions remain harmonic under conformal mapping:

THEOREM 1

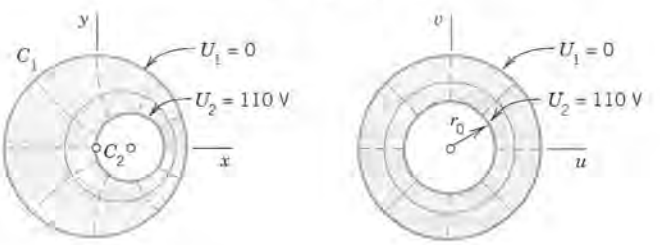
Harmonic Functions Under Conformal Mapping

Let Φ^* be harmonic in a domain D^* in the w-plane. Suppose that $w = u + iv = f(z)$ is analytic in a domain D in the z-plane and maps D conformally onto D^*. Then the function

$$\Phi(x, y) = \Phi^*(u(x, y), v(x, y)) \tag{1}$$

is harmonic in D.

PROOF The composite of analytic functions is analytic, as follows from the chain rule. Hence, taking a harmonic conjugate $\Psi^*(u, v)$ of Φ^*, as defined in Sec. 13.4, and forming the analytic function $F^*(w) = \Phi^*(u, v) + i\Psi^*(u, v)$, we conclude that $F(z) = F^*(f(z))$ is analytic in D. Hence its real part $\Phi(x, y) = \operatorname{Re} F(z)$ is harmonic in D. This completes the proof.



We mention without proof that if D^* is simply connected (Sec. 14.2), then a harmonic conjugate of Φ^* exists. Another proof of Theorem 1 without the use of a harmonic conjugate is given in App. 4. ■

EXAMPLE 1 **Potential Between Noncoaxial Cylinders**

Model the electrostatic potential between the cylinders C_1: $|z| = 1$ and C_2: $|z - 2/5| = 2/5$ in Fig. 400. Then give the solution for the case that C_1 is grounded, $U_1 = 0$ V, and C_2 has the potential $U_2 = 110$ V.

Solution. We map the unit disk $|z| = 1$ onto the unit disk $|w| = 1$ in such a way that C_2 is mapped onto some cylinder C_2^*: $|w| = r_0$. By (3), Sec. 17.3, a linear fractional transformation mapping the unit disk onto the unit disk is

$$w = \frac{z - b}{bz - 1} \tag{2}$$

(a) z-plane (b) w-plane

Fig. 400. Example 1

where we have chosen $b = z_0$ real without restriction. z_0 is of no immediate help here because centers of circles do not map onto centers of the images, in general. However, we now have two free constants b and r_0 and shall succeed by imposing two reasonable conditions, namely, that 0 and 4/5 (Fig. 400) should be mapped onto r_0 and $-r_0$, respectively. This gives by (2)

$$r_0 = \frac{0 - b}{0 - 1} = b, \qquad \text{and with this,} \qquad -r_0 = \frac{4/5 - b}{4b/5 - 1} = \frac{4/5 - r_0}{4r_0/5 - 1},$$

a quadratic equation in r_0 with solutions $r_0 = 2$ (no good because $r_0 < 1$) and $r_0 = 1/2$. Hence our mapping function (2) with $b = 1/2$ becomes that in Example 5 of Sec. 17.3,

$$w = f(z) = \frac{2z - 1}{z - 2}. \tag{3}$$

From Example 5 in Sec. 18.1, writing w for z we have as the complex potential in the w-plane the function $F^*(w) = a \operatorname{Ln} w + k$ and from this the real potential

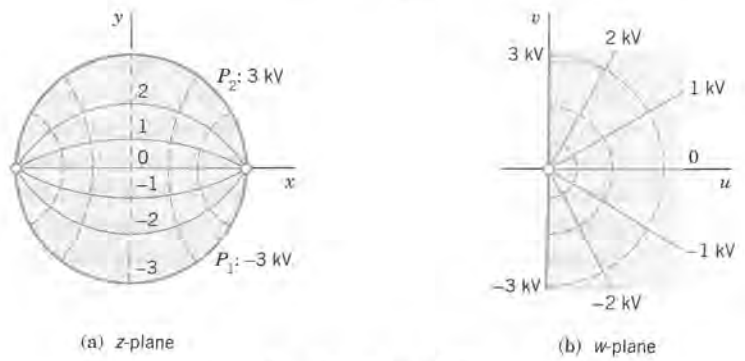
$$\Phi^*(u, v) = \operatorname{Re} F^*(w) = a \ln |w| + k.$$

This is our model. We now determine a and k from the boundary conditions. If $|w| = 1$, then $\Phi^* = a \ln 1 + k = 0$, hence $k = 0$. If $|w| = r_0 = 1/2$, then $\Phi^* = a \ln (1/2) = 110$, hence $a = 110/\ln (1/2) = -158.7$. Substitution of (3) now gives the desired solution in the given domain in the z-plane

$$F(z) = F^*(f(z)) = a \operatorname{Ln} \frac{2z - 1}{z - 2}.$$

The real potential is

$$\Phi(x, y) = \operatorname{Re} F(z) = a \ln \left| \frac{2z - 1}{z - 2} \right|, \qquad a = -158.7.$$



Can we "see" this result? Well, $\Phi(x, y) = const$ if and only if $|(2z - 1)/(z - 2)| = const$, that is, $|w| = const$ by (2) with $b = 1/2$. These circles are images of circles in the z-plane because the inverse of a linear fractional transformation is linear fractional (see (4), Sec. 17.2), and any such mapping maps circles onto circles (or straight lines), by Theorem 1 in Sec. 17.2. Similarly for the rays $\arg w = const$. Hence the equipotential lines $\Phi(x, y) = const$ are circles, and the lines of force are circular arcs (dashed in Fig. 400). These two families of curves intersect orthogonally, that is, at right angles, as shown in Fig. 400. ■

EXAMPLE 2 Potential Between Two Semicircular Plates

Model the potential between two semicircular plates P_1 and P_2 in Fig. 401a having potentials -3000 V and 3000 V, respectively. Use Example 3 in Sec. 18.1 and conformal mapping.

Solution. ***Step 1.*** We map the unit disk in Fig. 401a onto the right half of the w-plane (Fig. 401b) by using the linear fractional transformation in Example 3, Sec. 17.3:

$$w = f(z) = \frac{1 + z}{1 - z}.$$

(a) z-plane (b) w-plane

Fig. 401. Example 2

The boundary $|z| = 1$ is mapped onto the boundary $u = 0$ (the v-axis), with $z = -1, i, 1$ going onto $w = 0, i, \infty$, respectively, and $z = -i$ onto $w = -i$. Hence the upper semicircle of $|z| = 1$ is mapped onto the upper half, and the lower semicircle onto the lower half of the v-axis, so that the boundary conditions in the w-plane are as indicated in Fig. 401b.

Step 2. We determine the potential $\Phi^*(u, v)$ in the right half-plane of the w-plane. Example 3 in Sec. 18.1 with $\alpha = \pi$, $U_1 = -3000$, and $U_2 = 3000$ [with $\Phi^*(u, v)$ instead of $\Phi(x, y)$] yields

$$\Phi^*(u, v) = \frac{6000}{\pi}\varphi, \qquad \varphi = \arctan\frac{v}{u}.$$

On the positive half of the imaginary axis ($\varphi = \pi/2$), this equals 3000 and on the negative half -3000, as it should be. Φ^* is the real part of the complex potential

$$F^*(w) = -\frac{6000\,i}{\pi}\operatorname{Ln} w.$$

Step 3. We substitute the mapping function into F^* to get the complex potential $F(z)$ in Fig. 401a in the form

$$F(z) = F^*(f(z)) = -\frac{6000\,i}{\pi}\operatorname{Ln}\frac{1+z}{1-z}.$$

The real part of this is the potential we wanted to determine:

$$\Phi(x, y) = \operatorname{Re} F(z) = \frac{6000}{\pi}\operatorname{Im}\operatorname{Ln}\frac{1+z}{1-z} = \frac{6000}{\pi}\operatorname{Arg}\frac{1+z}{1-z}.$$

As in Example 1 we conclude that the equipotential lines $\Phi(x, y) = const$ are circular arcs because they correspond to $\operatorname{Arg}[(1+z)/(1-z)] = const$, hence to $\operatorname{Arg} w = const$. Also, $\operatorname{Arg} w = const$ are rays from 0 to ∞, the images of $z = -1$ and $z = 1$, respectively. Hence the equipotential lines all have -1 and 1 (the points where the boundary potential jumps) as their endpoints (Fig. 401a). The lines of force are circular arcs, too, and since they must be orthogonal to the equipotential lines, their centers can be obtained as intersections of tangents to the unit circle with the x-axis. (Explain!) ■

Further examples can easily be constructed. Just take any mapping $w = f(z)$ in Chap. 17, a domain D in the z-plane, its image D^* in the w-plane, and a potential Φ^* in D^*. Then (1) gives a potential in D. Make up some examples of your own, involving, for instance, linear fractional transformations.

Basic Comment on Modeling

We formulated the examples in this section as models on the electrostatic potential. It is quite important to realize that this is accidental. We could equally well have phrased everything in terms of (time-independent) heat flow; then instead of voltages we would have had temperatures, the equipotential lines would have become isotherms (= lines of constant temperature), and the lines of the electrical force would have become lines along which heat flows from higher to lower temperatures (more on this in the next section). Or we could have talked about fluid flow; then the electrostatic lines of force would have become streamlines (more on this in Sec. 18.4). What we again see here is the ***unifying power of mathematics:*** different phenomena and systems from different areas in physics having the same types of model can be treated by the same mathematical methods. What differs from area to area is just the kinds of problems that are of practical interest.

PROBLEM SET 18.2

1. Verify Theorem 1 for $\Phi^*(u, v) = u^2 - v^2$, $w = f(z) = e^z$ and any domain D.
2. Verify Theorem 1 for $\Phi^*(u, v) = uv$, $w = f(z) = e^z$, and D: $x \leqq 0$, $0 \leqq y \leqq \pi$. Sketch D and D^*.
3. Carry out all steps of the second proof of Theorem 1 (given in App. 4) in detail.
4. Derive (3) from (2).
5. Let D^* be the image of the rectangle D: $0 \leqq x \leqq \frac{1}{2}\pi$, $0 \leqq y \leqq 1$ under $w = \sin z$, and $\Phi^*(u, v) = u^2 - v^2$. Find the corresponding potential Φ in D and its boundary values.
6. What happens in Prob. 5 if you replace the potential by the conjugate $\Phi^* = 2uv$? Sketch or graph some of the equipotential lines $\Phi = const$.
7. **CAS PROJECT. Graphing Potential Fields.**
   (a) Graph equipotential lines in Probs. 1 and 2.
   (b) Graph equipotential lines if the complex potential is $F(z) = iz^2$, $F(z) = e^z$, $F(z) = ie^z$, $F(z) = e^{iz}$.
   (c) Graph equipotential surfaces corresponding to $F(z) = \ln z$ as cylinders in space.
8. **TEAM PROJECT. Noncoaxial Cylinders.** Find the potential between the cylinders C_1: $|z| = 1$ (potential $U_1 = 0$) and C_2: $|z - c| = c$ ($U_2 = 110$ V), where $0 < c < \frac{1}{2}$. Sketch or graph the equipotential curves and their orthogonal trajectories for $c = 0.1, 0.2, 0.3, 0.4$. Try to think of the further extension C_1: $|z| = 1$, C_2: $|z - c| = \rho \neq c$.
9. Find the potential Φ in the region R in the first quadrant of the z-plane bounded by the axes (having potential U_1) and the hyperbola $y = 1/x$ (having potential 0) in two ways, (i) directly, (ii) by mapping R onto a suitable infinite strip.
10. **(Extension of Example 2)** Find the linear fractional transformation $z = g(Z)$ that maps $|Z| \leqq 1$ onto $|z| \leqq 1$ with $Z = i/2$ being mapped onto $z = 0$. Show that $Z_1 = 0.6 + 0.8i$ is mapped onto $z = -1$ and $Z_2 = -0.6 + 0.8i$ onto $z = 1$, so that the equipotential lines of Example 2 look in $|Z| \leqq 1$ as shown in Fig. 402.

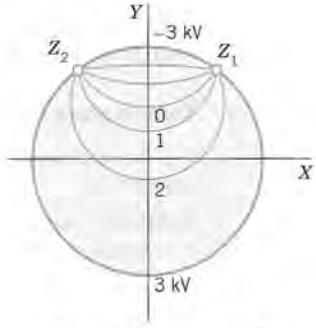


Fig. 402. Problem 10

11. The equipotential lines in Prob. 10 are circles. Why?
12. Show that in Example 2 the y-axis is mapped onto the unit circle in the w-plane.
13. Find the complex and real potentials in the upper half-plane with boundary values 0 if $x < 4$ and 10 kV if $x > 4$ on the x-axis.
14. **(Angular region)** Applying a suitable conformal mapping, obtain from Fig. 401b the potential Φ in the angular region $-\frac{1}{4}\pi < \text{Arg } z < \frac{1}{4}\pi$ such that $\Phi = -3$ kV if $\text{Arg } z = -\frac{1}{4}\pi$ and $\Phi = 3$ kV if $\text{Arg } z = \frac{1}{4}\pi$.
15. At $z = \pm 1$ in Fig. 401a the tangents to the equipotential lines shown make equal angles ($\pi/6$). Why?

18.3 Heat Problems

Laplace's equation also governs heat flow problems that are **steady,** that is, time-independent. Indeed, heat conduction in a body of homogeneous material is modeled by the **heat equation**

$$T_t = c^2 \nabla^2 T$$

where the function T is temperature, $T_t = \partial T/\partial t$, t is time, and c^2 is a positive constant (depending on the material of the body; see Sec. 12.5). Hence if a problem is steady, so that $T_t = 0$, and two-dimensional, then the heat equation reduces to the two-dimensional Laplace equation

$$\nabla^2 T = T_{xx} + T_{yy} = 0, \tag{1}$$

so that the problem can be treated by our present methods.

$T(x, y)$ is called the **heat potential.** It is the real part of the **complex heat potential**

$$F(z) = T(x, y) + i\Psi(x, y).$$

The curves $T(x, y) = const$ are called **isotherms** (= lines of constant temperature) and the curves $\Psi(x, y) = const$ **heat flow lines,** because along them, heat flows from higher to lower temperatures.

It follows that all the examples considered so far (Secs. 18.1, 18.2) can now be reinterpreted as problems on heat flow. The electrostatic equipotential lines $\Phi(x, y) = const$ now become isotherms $T(x, y) = const$, and the lines of electrical force become lines of heat flow, as in the following two problems.

EXAMPLE 1 Temperature Between Parallel Plates

Find the temperature between two parallel plates $x = 0$ and $x = d$ in Fig. 403 having temperatures 0 and 100°C, respectively.

Solution. As in Example 1 of Sec. 18.1 we conclude that $T(x, y) = ax + b$. From the boundary conditions, $b = 0$ and $a = 100/d$. The answer is

$$T(x, y) = \frac{100}{d}\, x \ [°\text{C}].$$

The corresponding complex potential is $F(z) = (100/d)z$. Heat flows horizontally in the negative x-direction along the lines $y = const$. ■

EXAMPLE 2 Temperature Distribution Between a Wire and a Cylinder

Find the temperature field around a long thin wire of radius $r_1 = 1$ mm that is electrically heated to $T_1 = 500$°F and is surrounded by a circular cylinder of radius $r_2 = 100$ mm, which is kept at temperature $T_2 = 60$°F by cooling it with air. See Fig. 404. (The wire is at the origin of the coordinate system.)

Solution. T depends only on r, for reasons of symmetry. Hence, as in Sec. 18.1 (Example 2),

$$T(x, y) = a \ln r + b.$$

The boundary conditions are

$$T_1 = 500 = a \ln 1 + b, \qquad T_2 = 60 = a \ln 100 + b.$$

Hence $b = 500$ (since $\ln 1 = 0$) and $a = (60 - b)/\ln 100 = -95.54$. The answer is

$$T(x, y) = 500 - 95.54 \ln r \ [°\text{F}].$$

The isotherms are concentric circles. Heat flows from the wire radially outward to the cylinder. Sketch T as a function of r. Does it look physically reasonable? ■

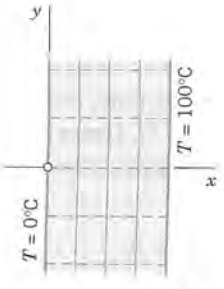

Fig. 403. Example 1

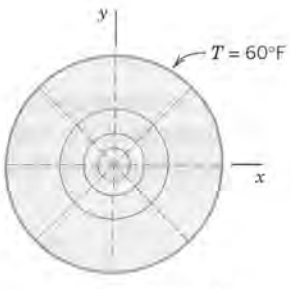

Fig. 404. Example 2

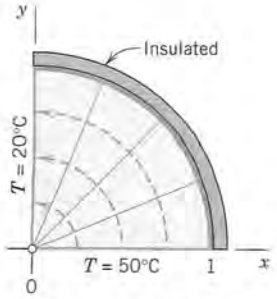

Fig. 405. Example 3

Mathematically the calculations remain the same in the transition to another field of application. Physically, new problems may arise, with boundary conditions that would make no sense physically or would be of no practical interest. This is illustrated by the next two examples.

EXAMPLE 3 A Mixed Boundary Value Problem

Find the temperature distribution in the region in Fig. 405 (cross section of a solid quarter-cylinder), whose vertical portion of the boundary is at 20°C, the horizontal portion at 50°C, and the circular portion is insulated.

Solution. The insulated portion of the boundary must be a heat flow line, since by the insulation, heat is prevented from crossing such a curve, hence heat must flow along the curve. Thus the isotherms must meet such a curve at right angles. Since T is constant along an isotherm, this means that

$$\frac{\partial T}{\partial n} = 0 \qquad \text{along an insulated portion of the boundary.} \tag{2}$$

Here $\partial T/\partial n$ is the **normal derivative** of T, that is, the directional derivative (Sec. 9.7) in the direction normal (perpendicular) to the insulated boundary. Such a problem in which T is prescribed on one portion of the boundary and $\partial T/\partial n$ on the other portion is called a **mixed boundary value problem.**

In our case, the normal direction to the insulated circular boundary curve is the radial direction toward the origin. Hence (2) becomes $\partial T/\partial r = 0$, meaning that along this curve the solution must not depend on r. Now $\operatorname{Arg} z = \theta$ satisfies (1), as well as this condition, and is constant (0 and $\pi/2$) on the straight portions of the boundary. Hence the solution is of the form

$$T(x, y) = a\theta + b.$$

The boundary conditions yield $a \cdot \pi/2 + b = 20$ and $a \cdot 0 + b = 50$. This gives

$$T(x, y) = 50 - \frac{60}{\pi}\,\theta, \qquad \theta = \arctan\frac{y}{x}.$$

The isotherms are portions of rays $\theta = const$. Heat flows from the x-axis along circles $r = const$ (dashed in Fig. 405) to the y-axis. ■

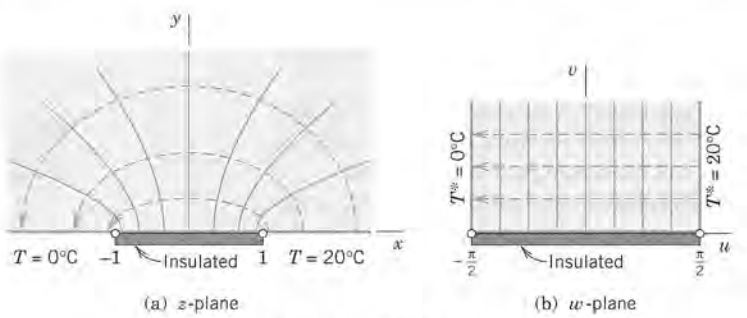

Fig. 406. Example 4

EXAMPLE 4 Another Mixed Boundary Value Problem in Heat Conduction

Find the temperature field in the upper half-plane when the x-axis is kept at $T = 0°C$ for $x < -1$, is insulated for $-1 < x < 1$, and is kept at $T = 20°C$ for $x > 1$ (Fig. 406a).

Solution. We map the half-plane in Fig. 406a onto the vertical strip in Fig. 406b, find the temperature $T^*(u, v)$ there, and map it back to get the temperature $T(x, y)$ in the half-plane.

The idea of using that strip is suggested by Fig. 388 in Sec. 17.4 with the roles of $z = x + iy$ and $w = u + iv$ interchanged. The figure shows that $z = \sin w$ maps our present strip onto our half-plane in Fig. 406a. Hence the inverse function

$$w = f(z) = \arcsin z$$

maps that half-plane onto the strip in the w-plane. This is the mapping function that we need according to Theorem 1 in Sec. 18.2.

The insulated segment $-1 < x < 1$ on the x-axis maps onto the segment $-\pi/2 < u < \pi/2$ on the u-axis. The rest of the x-axis maps onto the two vertical boundary portions $u = -\pi/2$ and $\pi/2$, $v > 0$, of the strip. This gives the transformed boundary conditions in Fig. 406b for $T^*(u, v)$, where on the insulated horizontal boundary, $\partial T^*/\partial n = \partial T^*/\partial v = 0$ because v is a coordinate normal to that segment.

Similarly to Example 1 we obtain

$$T^*(u, v) = 10 + \frac{20}{\pi} u$$

which satisfies all the boundary conditions. This is the real part of the complex potential $F^*(w) = 10 + (20/\pi)w$. Hence the complex potential in the z-plane is

$$F(z) = F^*(f(z)) = 10 + \frac{20}{\pi} \arcsin z$$

and $T(x, y) = \text{Re } F(z)$ is the solution. The isotherms are $u = const$ in the strip and the hyperbolas in the z-plane, perpendicular to which heat flows along the dashed ellipses from the 20°-portion to the cooler 0°-portion of the boundary, a physically very reasonable result. ■

This section and the last one show the usefulness of conformal mappings and complex potentials. The latter will also play a role in the next section on fluid flow.

PROBLEM SET 18.3

1. **CAS PROJECT. Isotherms.** Graph isotherms and lines of heat flow in Examples 2–4. Can you see from the graphs where the heat flow is very rapid?
2. Find the temperature and the complex potential in an infinite plate with edges $y = x - 2$ and $y = x + 2$ kept at -10°C and 20°C, respectively.
3. Find the temperature between two parallel plates $y = 0$ and $y = d$ kept at temperatures 0°C and 100°C, respectively. (i) Proceed directly. (ii) Use Example 1 and a suitable mapping.
4. Find the temperature T in the sector $0 \leqq \text{Arg } z \leqq \pi/3$, $|z| \leqq 1$ if $T = 20$°C on the x-axis, $T = 50$°C on $y = \sqrt{3}\, x$, and the curved portion is insulated.
5. Find the temperature in Fig. 405 if $T = -20$°C on the y-axis, $T = 100$°C on the x-axis, and the circular portion of the boundary is insulated as before.
6. Interpret Prob. 10 in Sec. 18.2 as a heat flow problem (with boundary temperatures, say, 20°C and 300°C). Along what curves does the heat flow?
7. Find the temperature and the complex potential in the first quadrant of the z-plane if the y-axis is kept at 100°C, the segment $0 < x < 1$ of the x-axis is insulated and the portion $x > 1$ of the x-axis is kept at 200°C. *Hint.* Use Example 4.
8. **TEAM PROJECT. Piecewise Constant Boundary Temperatures. (a) A basic building block** is shown in Fig. 407. Find the corresponding temperature and complex potential in the upper half-plane.

   (b) Conformal mapping. What temperature in the first quadrant of the z-plane is obtained from (a) by the mapping $w = a + z^2$ and what are the transformed boundary conditions?

   (c) Superposition. Find the temperature T^* and the complex potential F^* in the upper half-plane satisfying the boundary condition in Fig. 408.

   (d) Semi-infinite strip. Applying $w = \cosh z$ to (c), obtain the solution of the boundary value problem in Fig. 409.

18.4 Fluid Flow

Laplace's equation also plays a basic role in hydrodynamics, in steady nonviscous fluid flow under physical conditions discussed later in this section. In order that methods of complex analysis can be applied, our problems will be ***two-dimensional,*** so that the **velocity vector** V by which the motion of the fluid can be given depends only on two space variables x and y and the motion is the same in all planes parallel to the xy-plane.

Then we can use for the velocity vector V a complex function

$$V = V_1 + iV_2 \tag{1}$$

giving the magnitude $|V|$ and direction Arg V of the velocity at each point $z = x + iy$. Here V_1 and V_2 are the components of the velocity in the x and y directions. V is tangential to the path of the moving particles, called a **streamline** of the motion (Fig. 410).

We show that under suitable assumptions (explained in detail following the examples), for a given flow there exists an analytic function

$$F(z) = \Phi(x, y) + i\Psi(x, y), \tag{2}$$

called the **complex potential** of the flow, such that the streamlines are given by $\Psi(x, y) = const.$ and the velocity vector or, briefly, the **velocity** is given by

$$V = V_1 + iV_2 = \overline{F'(z)} \tag{3}$$

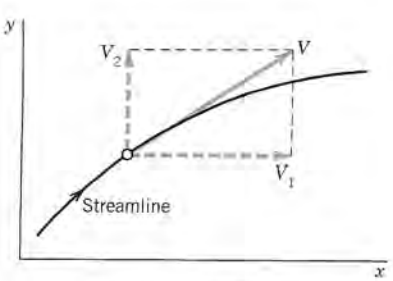

Fig. 410. Velocity

where the bar denotes the complex conjugate. Ψ is called the **stream function.** The function Φ is called the **velocity potential.** The curves $\Phi(x, y) = const$ are called **equipotential lines.** The velocity vector V is the **gradient** of Φ; by definition, this means that

$$(4) \qquad V_1 = \frac{\partial \Phi}{\partial x}, \qquad V_2 = \frac{\partial \Phi}{\partial y}.$$

Indeed, for $F = \Phi + i\Psi$, Eq. (4) in Sec. 13.4 is $F' = \Phi_x + i\Psi_x$ with $\Psi_x = -\Phi_y$ by the second Cauchy–Riemann equation. Together we obtain (3):

$$\overline{F'(z)} = \Phi_x - i\Psi_x = \Phi_x + i\Phi_y = V_1 + iV_2 = V.$$

Furthermore, since $F(z)$ is analytic, Φ and Ψ satisfy Laplace's equation

$$(5) \qquad \nabla^2\Phi = \frac{\partial^2 \Phi}{\partial x^2} + \frac{\partial^2 \Phi}{\partial y^2} = 0, \qquad \nabla^2\Psi = \frac{\partial^2 \Psi}{\partial x^2} + \frac{\partial^2 \Psi}{\partial y^2} = 0.$$

Whereas in electrostatics the boundaries (conducting plates) are equipotential lines, in fluid flow the boundaries across which fluid cannot flow must be streamlines. Hence in fluid flow the stream function is of particular importance.

Before discussing the conditions for the validity of the statements involving (2)–(5), let us consider two flows of practical interest, so that we first see what is going on from a practical point of view. Further flows are included in the problem set.

EXAMPLE 1 **Flow Around a Corner**

The complex potential $F(z) = z^2 = x^2 - y^2 + 2ixy$ models a flow with

Equipotential lines	$\Phi = x^2 - y^2 = const$	(Hyperbolas)
Streamlines	$\Psi = 2xy = const$	(Hyperbolas).

From (3) we obtain the velocity vector

$$V = 2\bar{z} = 2(x - iy), \qquad \text{that is,} \qquad V_1 = 2x, \qquad V_2 = -2y.$$

The speed (magnitude of the velocity) is

$$|V| = \sqrt{{V_1}^2 + {V_2}^2} = 2\sqrt{x^2 + y^2}.$$

The flow may be interpreted as the flow in a channel bounded by the positive coordinates axes and a hyperbola, say, $xy = 1$ (Fig. 411). We note that the speed along a streamline S has a minimum at the point P where the cross section of the channel is large. ■

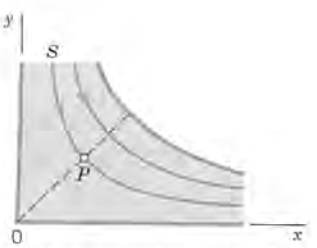

Fig. 411. Flow around a corner (Example 1)

EXAMPLE 2 **Flow Around a Cylinder**

Consider the complex potential

$$F(z) = \Phi(x, y) + i\Psi(x, y) = z + \frac{1}{z}.$$

Using the polar form $z = re^{i\theta}$, we obtain

$$F(z) = re^{i\theta} + \frac{1}{r}e^{-i\theta} = \left(r + \frac{1}{r}\right)\cos\theta + i\left(r - \frac{1}{r}\right)\sin\theta.$$

Hence the streamlines are

$$\Psi(x, y) = \left(r - \frac{1}{r}\right)\sin\theta = const.$$

In particular, $\Psi(x, y) = 0$ gives $r - 1/r = 0$ or $\sin\theta = 0$. Hence this streamline consists of the unit circle ($r = 1/r$ gives $r = 1$) and the x-axis ($\theta = 0$ and $\theta = \pi$). For large $|z|$ the term $1/z$ in $F(z)$ is small in absolute value, so that for these z the flow is nearly uniform and parallel to the x-axis. Hence we can interpret this as a flow around a long circular cylinder of unit radius that is perpendicular to the z-plane and intersects it in the unit circle $|z| = 1$ and whose axis corresponds to $z = 0$.

The flow has two **stagnation points** (that is, points at which the velocity V is zero), at $z = \pm 1$. This follows from (3) and

$$F'(z) = 1 - \frac{1}{z^2}, \quad \text{hence} \quad z^2 - 1 = 0. \qquad \text{(See Fig. 412.)}$$

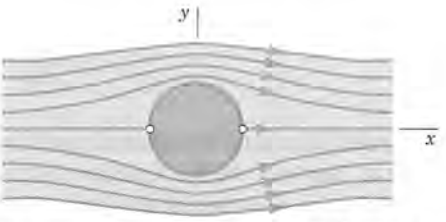

Fig. 412. Flow around a cylinder (Example 2)

Assumptions and Theory Underlying (2)–(5)

THEOREM 1 **Complex Potential of a Flow**

If the domain of flow is simply connected and the flow is irrotational and incompressible, then the statements involving (2)–(5) *hold. In particular, then the flow has a complex potential* $F(z)$*, which is an analytic function.* (Explanation of terms below.)

PROOF We prove this theorem, along with a discussion of basic concepts related to fluid flow.

(a) ***First Assumption: Irrotational.*** Let C be any smooth curve in the z-plane given by $z(s) = x(s) + iy(s)$, where s is the arc length of C. Let the real variable V_t be the component of the velocity V tangent to C (Fig. 413). Then the value of the real line integral

(6) $$\int_C V_t\, ds$$

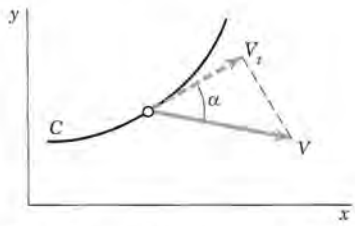

Fig. 413. Tangential component of the velocity with respect to a curve C

taken along C in the sense of increasing s is called the **circulation** of the fluid along C, a name that will be motivated as we proceed in this proof. Dividing the circulation by the length of C, we obtain the *mean velocity*[1] of the flow along the curve C. Now

$$V_t = |V| \cos \alpha \qquad \text{(Fig. 413).}$$

Hence V_t is the dot product (Sec. 9.2) of V and the tangent vector dz/ds of C (Sec. 17.1); thus in (6),

$$V_t\, ds = \left(V_1 \frac{dx}{ds} + V_2 \frac{dy}{ds}\right) ds = V_1\, dx + V_2\, dy.$$

The circulation (6) along C now becomes

$$\int_C V_t\, ds = \int_C (V_1\, dx + V_2\, dy). \tag{7}$$

As the next idea, let C be a ***closed curve*** satisfying the assumption as in Green's theorem (Sec. 10.4), and let C be the boundary of a simply connected domain D. Suppose further that V has continuous partial derivatives in a domain containing D and C. Then we can use Green's theorem to represent the circulation around C by a double integral,

$$\oint_C (V_1\, dx + V_2\, dy) = \iint_D \left(\frac{\partial V_2}{\partial x} - \frac{\partial V_1}{\partial y}\right) dx\, dy. \tag{8}$$

The integrand of this double integral is called the **vorticity** of the flow. The vorticity divided by 2 is called the **rotation**

$$\omega(x, y) = \frac{1}{2}\left(\frac{\partial V_2}{\partial x} - \frac{\partial V_1}{\partial y}\right), \tag{9}$$

---

[1] *Definitions:* $\dfrac{1}{b-a}\displaystyle\int_a^b f(x)\, dx =$ **mean value** of f on the interval $a \leqq x \leqq b$,

$$\frac{1}{L}\int_C f(s)\, ds = \textbf{mean value} \text{ of } f \text{ on } C \qquad (L = \text{length of } C),$$

$$\frac{1}{A}\iint_D f(x, y)\, dx\, dy = \textbf{mean value} \text{ of } f \text{ on } D \qquad (A = \text{area of } D).$$

We assume the flow to be **irrotational,** that is, $\omega(x, y) \equiv 0$ throughout the flow; thus,

$$\frac{\partial V_2}{\partial x} - \frac{\partial V_1}{\partial y} = 0. \tag{10}$$

To understand the physical meaning of vorticity and rotation, take for C in (8) a circle. Let r be the radius of C. Then the circulation divided by the length $2\pi r$ of C is the mean velocity of the fluid along C. Hence by dividing this by r we obtain the mean **angular velocity** ω_0 of the fluid about the center of the circle:

$$\omega_0 = \frac{1}{2\pi r^2} \iint_D \left(\frac{\partial V_2}{\partial x} - \frac{\partial V_1}{\partial y} \right) dx\, dy = \frac{1}{\pi r^2} \iint_D \omega(x, y)\, dx\, dy.$$

If we now let $r \to 0$, the limit of ω_0 is the value of ω at the center of C. Hence $\omega(x, y)$ is the limiting angular velocity of a circular element of the fluid as the circle shrinks to the point (x, y). Roughly speaking, *if a spherical element of the fluid were suddenly solidified and the surrounding fluid simultaneously annihilated, the element would rotate with the angular velocity* ω.

(b) ***Second Assumption: Incompressible.*** Our second assumption is that the fluid is incompressible. (Fluids include liquids, which are incompressible, and gases, such as air, which are compressible.) Then

$$\frac{\partial V_1}{\partial x} + \frac{\partial V_2}{\partial y} = 0 \tag{11}$$

in every region that is free of **sources** or **sinks,** that is, points at which fluid is produced or disappears, respectively. The expression in (11) is called the **divergence** of V and is denoted by div V. (See also (7) in Sec. 9.8.)

(c) ***Complex Velocity Potential.*** If the domain D of the flow is simply connected (Sec. 14.2) and the flow is irrotational, then (10) implies that the line integral (7) is independent of path in D (by Theorem 3 in Sec. 10.2, where $F_1 = V_1$, $F_2 = V_2$, $F_3 = 0$, and z is the third coordinate in space and has nothing to do with our present z). Hence if we integrate from a fixed point (a, b) in D to a variable point (x, y) in D, the integral becomes a function of the point (x, y), say, $\Phi(x, y)$:

$$\Phi(x, y) = \int_{(a, b)}^{(x, y)} (V_1\, dx + V_2\, dy). \tag{12}$$

We claim that the flow has a velocity potential Φ, which is given by (12). To prove this, all we have to do is to show that (4) holds. Now since the integral (7) is independent of path, $V_1\, dx + V_2\, dy$ is exact (Sec. 10.2), namely, the differential of Φ, that is,

$$V_1\, dx + V_2\, dy = \frac{\partial \Phi}{\partial x}\, dx + \frac{\partial \Phi}{\partial y}\, dy.$$

From this we see that $V_1 = \partial\Phi/\partial x$ and $V_2 = \partial\Phi/\partial y$, which gives (4).

That Φ is harmonic follows at once by substituting (4) into (11), which gives the first Laplace equation in (5).

We finally take a harmonic conjugate Ψ of Φ. Then the other equation in (5) holds. Also, since the second partial derivatives of Φ and Ψ are continuous, we see that the complex function

$$F(z) = \Phi(x, y) + i\Psi(x, y)$$

is analytic in D. Since the curves $\Psi(x, y) = const$ are perpendicular to the equipotential curves $\Phi(x, y) = const$ (except where $F'(z) = 0$), we conclude that $\Psi(x, y) = const$ are the streamlines. Hence Ψ is the stream function and $F(z)$ is the complex potential of the flow. This completes the proof of Theorem 1 as well as our discussion of the important role of complex analysis in compressible fluid flow. ■

PROBLEM SET 18.4

1–15 FLOW PATTERNS: STREAMLINES, COMPLEX POTENTIAL

These problems should encourage you to experiment with various functions $F(z)$, many of which model interesting flow patterns.

1. **(Parallel flow)** Show that $F(z) = -iKz$ (K positive real) describes a uniform flow upward, which can be interpreted as a uniform flow between two parallel lines (parallel planes in three-dimensional space). See Fig. 414. Find the velocity vector, the streamlines, and the equipotential lines.

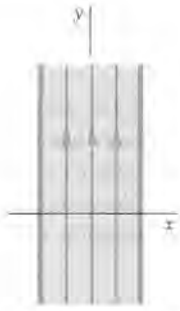

Fig. 414. Parallel flow in Problem 1

2. **(Conformal mapping)** Obtain the flow in Example 1 from that in Prob. 1 by a suitable conformal mapping.
3. Find the complex potential of a uniform flow parallel to the x-axis in the positive x-direction.
4. What happens to the flow in Prob. 1 if you replace z by $ze^{-i\alpha}$ with constant α, e.g., $\alpha = \pi/4$?
5. What is the complex potential of an upward parallel flow in the direction of $y = 2x$?
6. **(Extension of Example 1)** Sketch or graph the flow in Example 1 on the whole upper half-plane. Show that you can interpret it as as flow against a horizontal wall (the x-axis).
7. What $F(z)$ would be suitable in Example 1 if the angle of the corner were $\pi/3$?
8. Sketch or graph the streamlines and equipotential lines of $F(z) = iz^3$. Find V. Find all points at which V is parallel to the x-axis.
9. Find and graph the streamlines of $F(z) = z^2 + 2z$. Interpret the flow.
10. Show that $F(z) = iz^2$ models a flow around a corner. Sketch the streamlines and equipotential lines. Find V.
11. **(Potential $F(z) = 1/z$)** Show that the streamlines of $F(z) = 1/z$ are circles through the origin.
12. **(Cylinder)** What happens in Example 2 if you replace z by z^2? Sketch and interpret the resulting flow in the first quadrant.
13. Change $F(z)$ in Example 2 slightly to obtain a flow around a cylinder of radius r_0 that gives the flow in Example 2 if $r_0 \to 1$.
14. **(Aperture)** Show that $F(z) = \arccosh z$ gives confocal hyperbolas as streamlines, with foci at $z = \pm 1$, and the flow may be interpreted as a flow through an aperture (Fig. 415).
15. **(Elliptical cylinder)** Show that $F(z) = \arccos z$ gives confocal ellipses as streamlines, with foci at $z = \pm 1$, and that the flow circulates around an elliptic cylinder or a plate (the segment from -1 to 1 in Fig. 416).

16. TEAM PROJECT. Role of the Natural Logarithm in Modeling Flows. (a) Basic flows: Source and sink. Show that $F(z) = (c/2\pi) \ln z$ with constant positive real c gives a flow directed radially outward (Fig. 417), so that F models a **point source** at $z = 0$ (that is, a **source line** $x = 0$, $y = 0$ in space) at which fluid is produced. c is called the **strength** or **discharge** of the source. If c is negative real, show that the flow is directed radially inward, so that F models a **sink** at $z = 0$, a point at which fluid disappears. Note that $z = 0$ is the singular point of $F(z)$.

(b) Basic flows: Vortex. Show that $F(z) = -(Ki/2\pi) \ln z$ with positive real K gives a flow circulating counterclockwise around $z = 0$ (Fig. 418). $z = 0$ is called a **vortex.** Note that each time we travel around the vortex, the potential increases by K.

(c) Addition of flows. Show that addition of the velocity vectors of two flows gives a flow whose complex potential is obtained by adding the complex potentials of those flows.

(d) Source and sink combined. Find the complex potentials of a flow with a source of strength 1 at $z = -a$ and of a flow with a sink of strength 1 at $z = a$. Add both and sketch or graph the streamlines. Show that for small $|a|$ these lines look similar to those in Prob. 11.

(e) Flow with circulation around a cylinder. Add the potential in (b) to that in Example 2. Show that this gives a flow for which the cylinder wall $|z| = 1$ is a streamline. Find the speed and show that the stagnation points are

$$z = \frac{iK}{4\pi} \pm \sqrt{\frac{-K^2}{16\pi^2} + 1};$$

if $K = 0$ they are at ± 1; as K increases they move up on the unit circle until they unite at $z = i$ ($K = 4\pi$, see Fig. 419), and if $K > 4\pi$ they lie on the imaginary axis (one lies in the field of flow and the other one lies inside the cylinder and has no physical meaning).

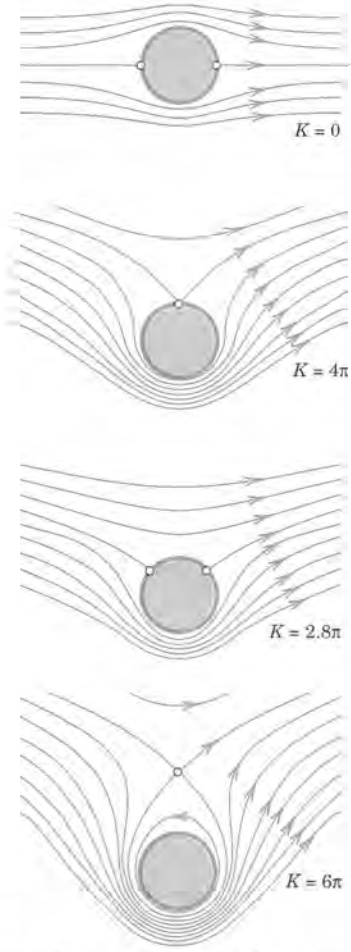

Fig. 419. Flow around a cylinder without circulation ($K = 0$) and with circulation

18.5 Poisson's Integral Formula for Potentials

So far in this chapter we have seen that complex analysis offers powerful methods for modeling and solving two-dimensional potential problems based on conformal mappings and complex potentials. A further method results from complex integration. As a most important result it yields Poisson's integral formula (5) for potentials in a standard domain (a circular disk) and from (5) a useful series (7) for these potentials. Hence we can solve problems for disks and then map solutions conformally onto other domains.

Poisson's formula will follow from Cauchy's integral formula (Sec. 14.3)

$$(1) \qquad F(z) = \frac{1}{2\pi i} \oint_C \frac{F(z^*)}{z^* - z}\, dz^*.$$

Here C is the circle $z^* = Re^{i\alpha}$ (counterclockwise, $0 \leqq \alpha \leqq 2\pi$), and we assume that $F(z^*)$ is analytic in a domain containing C and its full interior. Since $dz^* = iRe^{i\alpha}\, d\alpha = iz^*\, d\alpha$, we obtain from (1)

$$(2) \qquad F(z) = \frac{1}{2\pi} \int_0^{2\pi} F(z^*)\, \frac{z^*}{z^* - z}\, d\alpha \qquad (z^* = Re^{i\alpha},\ z = re^{i\theta}).$$

Now comes a little trick. If instead of z inside C we take a Z outside C, the integrals (1) and (2) are zero by Cauchy's integral theorem (Sec. 14.2). We choose $Z = z^*\bar{z}^*/\bar{z} = R^2/\bar{z}$, which is outside C because $|Z| = R^2/|z| = R^2/r > R$. From (2) we thus have

$$0 = \frac{1}{2\pi} \int_0^{2\pi} F(z^*)\, \frac{z^*}{z^* - Z}\, d\alpha = \frac{1}{2\pi} \int_0^{2\pi} F(z^*)\, \frac{z^*}{z^* - \dfrac{z^*\bar{z}^*}{\bar{z}}}\, d\alpha$$

and by straightforward simplification of the last expression on the right,

$$0 = \frac{1}{2\pi} \int_0^{2\pi} F(z^*)\, \frac{\bar{z}}{\bar{z} - \bar{z}^*}\, d\alpha.$$

We subtract this from (2) and use the following formula that you can verify by direct calculation ($\bar{z}z^*$ cancels):

$$(3) \qquad \frac{z^*}{z^* - z} - \frac{\bar{z}}{\bar{z} - \bar{z}^*} = \frac{z^*\bar{z}^* - z\bar{z}}{(z^* - z)(\bar{z}^* - \bar{z})}.$$

We then have

$$(4) \qquad F(z) = \frac{1}{2\pi} \int_0^{2\pi} F(z^*)\, \frac{z^*\bar{z}^* - z\bar{z}}{(z^* - z)(\bar{z}^* - \bar{z})}\, d\alpha.$$

From the polar representations of z and z^* we see that the quotient in the integrand is real and equal to

$$\frac{R^2 - r^2}{(Re^{i\alpha} - re^{i\theta})(Re^{-i\alpha} - re^{-i\theta})} = \frac{R^2 - r^2}{R^2 - 2Rr\cos(\theta - \alpha) + r^2}.$$

We now write $F(z) = \Phi(r, \theta) + i\Psi(r, \theta)$ and take the real part on both sides of (4). Then we obtain **Poisson's integral formula**[2]

$$\Phi(r, \theta) = \frac{1}{2\pi} \int_0^{2\pi} \Phi(R, \alpha) \frac{R^2 - r^2}{R^2 - 2Rr \cos(\theta - \alpha) + r^2} \, d\alpha. \tag{5}$$

This formula represents the harmonic function Φ in the disk $|z| \leqq R$ in terms of its values $\Phi(R, \alpha)$ on the boundary (the circle) $|z| = R$.

Formula (5) is still valid if the boundary function $\Phi(R, \alpha)$ is merely piecewise continuous (as is practically often the case; see Fig. 401 in Sec. 18.2 for an example). Then (5) gives a function harmonic in the open disk, and on the circle $|z| = R$ equal to the given boundary function, except at points where the latter is discontinuous. A proof can be found in Ref. [D1] in App. 1.

Series for Potentials in Disks

From (5) we may obtain an important series development of Φ in terms of simple harmonic functions. We remember that the quotient in the integrand of (5) was derived from (3). We claim that the right side of (3) is the real part of

$$\frac{z^* + z}{z^* - z} = \frac{(z^* + z)(\bar{z}^* - \bar{z})}{(z^* - z)(\bar{z}^* - \bar{z})} = \frac{z^*\bar{z}^* - z\bar{z} - z^*\bar{z} + z\bar{z}^*}{|z^* - z|^2}.$$

Indeed, the last denominator is real and so is $z^*\bar{z}^* - z\bar{z}$ in the numerator, whereas $-z^*\bar{z} + z\bar{z}^* = 2i \operatorname{Im}(z\bar{z}^*)$ in the numerator is pure imaginary. This verifies our claim. Now by the use of the geometric series we obtain (develop the denominator)

$$\frac{z^* + z}{z^* - z} = \frac{1 + (z/z^*)}{1 - (z/z^*)} = \left(1 + \frac{z}{z^*}\right) \sum_{n=0}^{\infty} \left(\frac{z}{z^*}\right)^n = 1 + 2\sum_{n=1}^{\infty} \left(\frac{z}{z^*}\right)^n. \tag{6}$$

Since $z = re^{i\theta}$ and $z^* = Re^{i\alpha}$, we have

$$\operatorname{Re}\left[\left(\frac{z}{z^*}\right)^n\right] = \operatorname{Re}\left[\frac{r^n}{R^n} e^{in\theta} e^{-in\alpha}\right] = \left(\frac{r}{R}\right)^n \cos(n\theta - n\alpha).$$

On the right, $\cos(n\theta - n\alpha) = \cos n\theta \cos n\alpha + \sin n\theta \sin n\alpha$. Hence from (6) we obtain

$$\begin{aligned} \operatorname{Re} \frac{z^* + z}{z^* - z} &= 1 + 2\sum_{n=1}^{\infty} \operatorname{Re}\left(\frac{z}{z^*}\right)^n \\ &= 1 + 2\sum_{n=1}^{\infty} \left(\frac{r}{R}\right)^n (\cos n\theta \cos n\alpha + \sin n\theta \sin n\alpha). \end{aligned} \tag{6*}$$

[2]SIMÉON DENIS POISSON (1781–1840), French mathematician and physicist, professor in Paris from 1809. His work includes potential theory, partial differential equations (Poisson equation, Sec. 12.1), and probability (Sec. 24.7).

This expression is equal to the quotient in (5), as we have mentioned before, and by inserting it into (5) and integrating term by term with respect to α from 0 to 2π we obtain

$$\Phi(r, \theta) = a_0 + \sum_{n=1}^{\infty} \left(\frac{r}{R}\right)^n (a_n \cos n\theta + b_n \sin n\theta) \tag{7}$$

where the coefficients are [the 2 in (6*) cancels the 2 in $1/(2\pi)$ in (5)]

$$a_0 = \frac{1}{2\pi} \int_0^{2\pi} \Phi(R, \alpha)\, d\alpha, \qquad a_n = \frac{1}{\pi} \int_0^{2\pi} \Phi(R, \alpha) \cos n\alpha\, d\alpha,$$
$$b_n = \frac{1}{\pi} \int_0^{2\pi} \Phi(R, \alpha) \sin n\alpha\, d\alpha, \qquad n = 1, 2, \cdots, \tag{8}$$

the Fourier coefficients of $\Phi(R, \alpha)$; see Sec. 11.1. Now for $r = R$ the series (7) becomes the Fourier series of $\Phi(R, \alpha)$. Hence the representation (7) will be valid whenever the given $\Phi(R, \alpha)$ on the boundary can be represented by a Fourier series.

EXAMPLE 1 **Dirichlet Problem for the Unit Disk**

Find the electrostatic potential $\Phi(r, \theta)$ in the unit disk $r < 1$ having the boundary values

$$\Phi(1, \alpha) = \begin{cases} -\alpha/\pi & \text{if } -\pi < \alpha < 0 \\ \alpha/\pi & \text{if } 0 < \alpha < \pi \end{cases} \qquad \text{(Fig. 420).}$$

Solution. Since $\Phi(1, \alpha)$ is even, $b_n = 0$, and from (8) we obtain $a_0 = \frac{1}{2}$ and

$$a_n = \frac{1}{\pi} \left[-\int_{-\pi}^{0} \frac{\alpha}{\pi} \cos n\alpha\, d\alpha + \int_0^{\pi} \frac{\alpha}{\pi} \cos n\alpha\, d\alpha \right] = \frac{2}{n^2\pi^2} (\cos n\pi - 1).$$

Hence, $a_n = -4/(n^2\pi^2)$ if n is odd, $a_n = 0$ if $n = 2, 4, \cdots$, and the potential is

$$\Phi(r, \theta) = \frac{1}{2} - \frac{4}{\pi^2} \left[r \cos\theta + \frac{r^3}{3^2} \cos 3\theta + \frac{r^5}{5^2} \cos 5\theta + \cdots \right].$$

Figure 421 shows the unit disk and some of the equipotential lines (curves $\Phi = const$). ■

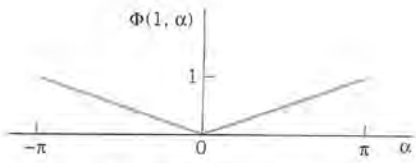

Fig. 420. Boundary values in Example 1

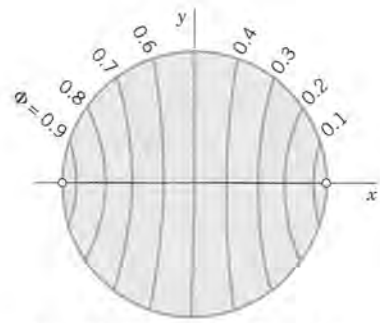

Fig. 421. Potential in Example 1

PROBLEM SET 18.5

1. Verify (3).
2. Show that every term in (7) is a harmonic function in the disk $r < R$.
3. Give the details of the derivation of the series (7) from the Poisson formula (5).

4–13 HARMONIC FUNCTIONS IN A DISK

Using (7), find the potential $\Phi(r, \theta)$ in the unit disk $r < 1$ having the given boundary values $\Phi(1, \theta)$. Using the sum of the first few terms of the series, compute some values of Φ and sketch a figure of the equipotential lines.

4. $\Phi(1, \theta) = \sin 2\theta$
5. $\Phi(1, \theta) = 2 \sin^2 \theta$
6. $\Phi(1, \theta) = \cos^2 5\theta$
7. $\Phi(1, \theta) = \theta$ if $-\pi < \theta < \pi$
8. $\Phi(1, \theta) = \theta$ if $0 < \theta < 2\pi$
9. $\Phi(1, \theta) = \sin^3 2\theta$
10. $\Phi(1, \theta) = \cos^4 \theta$
11. $\Phi(1, \theta) = \theta^2$ if $-\pi < \theta < \pi$
12. $\Phi(1, \theta) = 1$ if $-\frac{1}{2}\pi < \theta < \frac{1}{2}\pi$, $\Phi(1, \theta) = 0$ if $\frac{1}{2}\pi < \theta < \frac{3}{2}\pi$
13. $\Phi(1, \theta) = \theta$ if $-\frac{1}{2}\pi < \theta < \frac{1}{2}\pi$, $\Phi(1, \theta) = \pi - \theta$ if $\frac{1}{2}\pi < \theta < \frac{3}{2}\pi$
14. **TEAM PROJECT. Potential in a Disk. (a) Mean value property.** Show that the value of a harmonic function Φ at the center of a circle C equals the mean of the value of Φ on C (see Sec. 18.4, footnote 1, for definitions of mean values).

    (b) Separation of variables. Show that the terms of (7) appear as solutions in separating the Laplace equation in polar coordinates.

    (c) Harmonic conjugate. Find a series for a harmonic conjugate Ψ of Φ from (7).

    (d) Power series. Find a series for $F(z) = \Phi + i\Psi$.
15. **CAS EXPERIMENT. Series (7).** Write a program for series developments (7). Experiment on accuracy by computing values from partial sums and comparing them with values that you obtain from your CAS graph. Do this **(a)** for Example 1 and Fig. 421, **(b)** for Φ in Prob. 8 (which is discontinuous on the boundary!), **(c)** for a Φ of your choice with continuous boundary values, **(d)** for Φ with discontinuous boundary values.

18.6 General Properties of Harmonic Functions

General properties of harmonic functions can often be obtained from properties of analytic functions in a simple fashion. Specifically, important mean value properties of harmonic functions follow readily from those of analytic functions. The details are as follows.

THEOREM 1

Mean Value Property of Analytic Functions

Let $f(z)$ be analytic in a simply connected domain D. Then the value of $F(z)$ at a point z_0 in D is equal to the mean value of $F(z)$ on any circle in D with center at z_0.

PROOF In Cauchy's integral formula (Sec. 14.3)

$$F(z_0) = \frac{1}{2\pi i} \oint_C \frac{F(z)}{z - z_0}\, dz \tag{1}$$

we choose for C the circle $z = z_0 + re^{i\alpha}$ in D. Then $z - z_0 = re^{i\alpha}$, $dz = ire^{i\alpha}\, d\alpha$, and (1) becomes

$$F(z_0) = \frac{1}{2\pi} \int_0^{2\pi} F(z_0 + re^{i\alpha})\, d\alpha. \tag{2}$$

The right side is the mean value of F on the circle (= value of the integral divided by the length 2π of the interval of integration). This proves the theorem. ■

For harmonic functions, Theorem 1 implies

THEOREM 2

Two Mean Value Properties of Harmonic Functions

Let $\Phi(x, y)$ be harmonic in a simply connected domain D. Then the value of $\Phi(x, y)$ at a point (x_0, y_0) in D is equal to the mean value of $\Phi(x, y)$ on any circle in D with center at (x_0, y_0). This value is also equal to the mean value of $\Phi(x, y)$ on any circular disk in D with center (x_0, y_0). [See footnote 1 in Sec. 18.4.]

PROOF The first part of the theorem follows from (2) by taking the real parts on both sides,

$$\Phi(x_0, y_0) = \operatorname{Re} F(x_0 + iy_0) = \frac{1}{2\pi} \int_0^{2\pi} \Phi(x_0 + r\cos\alpha, y_0 + r\sin\alpha)\, d\alpha.$$

The second part of the theorem follows by integrating this formula over r from 0 to r_0 (the radius of the disk) and dividing by $r_0^2/2$,

$$\Phi(x_0, y_0) = \frac{1}{\pi r_0^2} \int_0^{r_0} \int_0^{2\pi} \Phi(x_0 + r\cos\alpha, y_0 + r\sin\alpha)\, r\, d\alpha\, dr. \tag{3}$$

The right side is the indicated mean value (integral divided by the area of the region of integration). ■

Returning to analytic functions, we state and prove another famous consequence of Cauchy's integral formula. The proof is indirect and shows quite a nice idea of applying the *ML*-inequality. (A *bounded region* is a region that lies entirely in some circle about the origin.)

THEOREM 3

Maximum Modulus Theorem for Analytic Functions

Let $F(z)$ be analytic and nonconstant in a domain containing a bounded region R and its boundary. Then the absolute value $|F(z)|$ cannot have a maximum at an interior point of R. Consequently, the maximum of $|F(z)|$ is taken on the boundary of R. If $F(z) \neq 0$ in R, the same is true with respect to the minimum of $|F(z)|$.

PROOF We assume that $|F(z)|$ has a maximum at an interior point z_0 of R and show that this leads to a contradiction. Let $|F(z_0)| = M$ be this maximum. Since $F(z)$ is not constant, $|F(z)|$ is not constant, as follows from Example 3 in Sec. 13.4. Consequently, we can find a circle C of radius r with center at z_0 such that the interior of C is in R and $|F(z)|$ is smaller than M at some point P of C. Since $|F(z)|$ is continuous, it will be smaller than M on an arc C_1 of C that contains P (see Fig. 422), say,

$$|F(z)| \leqq M - k \quad (k > 0) \qquad \text{for all } z \text{ on } C_1.$$

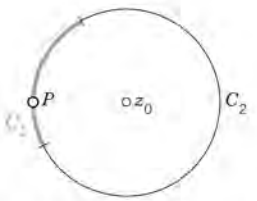

Fig. 422. Proof of Theorem 3

Let C_1 have the length L_1. Then the complementary arc C_2 of C has the length $2\pi r - L_1$. We now apply the ML-inequality (Sec. 14.1) to (1) and note that $|z - z_0| = r$. We then obtain (using straightforward calculation in the second line of the formula)

$$M = |F(z_0)| \leqq \frac{1}{2\pi}\left|\int_{C_1} \frac{F(z)}{z - z_0}\,dz\right| + \frac{1}{2\pi}\left|\int_{C_2} \frac{F(z)}{z - z_0}\,dz\right|$$

$$\leqq \frac{1}{2\pi}\left(\frac{M - k}{r}\right) L_1 + \frac{1}{2\pi}\left(\frac{M}{r}\right)(2\pi r - L_1) = M - \frac{kL_1}{2\pi r} < M$$

that is, $M < M$, which is impossible. Hence our assumption is false and the first statement is proved.

Next we prove the second statement. If $F(z) \neq 0$ in R, then $1/F(z)$ is analytic in R. From the statement already proved it follows that the maximum of $1/|F(z)|$ lies on the boundary of R. But this maximum corresponds to the minimum of $|F(z)|$. This completes the proof. ■

This theorem has several fundamental consequences for harmonic functions, as follows.

THEOREM 4

Harmonic Functions

Let $\Phi(x, y)$ be harmonic in a domain containing a simply connected bounded region R and its boundary curve C. Then:

(I) (Maximum principle) *If $\Phi(x, y)$ is not constant, it has neither a maximum nor a minimum in R. Consequently, the maximum and the minimum are taken on the boundary of R.*

(II) *If $\Phi(x, y)$ is constant on C, then $\Phi(x, y)$ is a constant.*

(III) *If $h(x, y)$ is harmonic in R and on C and if $h(x, y) = \Phi(x, y)$ on C, then $h(x, y) = \Phi(x, y)$ everywhere in R.*

PROOF **(I)** Let $\Psi(x, y)$ be a conjugate harmonic function of $\Phi(x, y)$ in R. Then the complex function $F(z) = \Phi(x, y) + i\Psi(x, y)$ is analytic in R, and so is $G(z) = e^{F(z)}$. Its absolute value is

$$|G(z)| = e^{\operatorname{Re} F(z)} = e^{\Phi(x, y)}.$$

From Theorem 3 it follows that $|G(z)|$ cannot have a maximum at an interior point of R. Since e^{Φ} is a monotone increasing function of the real variable Φ, the statement about the

maximum of Φ follows. From this, the statement about the minimum follows by replacing Φ by $-\Phi$.

(II) By (I) the function $\Phi(x, y)$ takes its maximum and its minimum on C. Thus, if $\Phi(x, y)$ is constant on C, its minimum must equal its maximum, so that $\Phi(x, y)$ must be a constant.

(III) If h and Φ are harmonic in R and on C, then $h - \Phi$ is also harmonic in R and on C, and by assumption, $h - \Phi = 0$ everywhere on C. By (II) we thus have $h - \Phi = 0$ everywhere in R, and (III) is proved. ∎

The last statement of Theorem 4 is very important. It means that a *harmonic function is uniquely determined in R by its values on the boundary of R.* Usually, $\Phi(x, y)$ is required to be harmonic in R and continuous on the boundary of R, that is,

$$\lim_{\substack{x \to x_0 \\ y \to y_0}} \Phi(x, y) = \Phi(x_0, y_0), \text{ where } (x_0, y_0) \text{ is on the boundary and } (x, y) \text{ is in } R.$$

Under these assumptions the maximum principle (I) is still applicable. The problem of determining $\Phi(x, y)$ when the boundary values are given is called the **Dirichlet problem** for the Laplace equation in two variables, as we know. From (III) we thus have, as a highlight of our discussion,

THEOREM 5

Uniqueness Theorem for the Dirichlet Problem

If for a given region and given boundary values the Dirichlet problem for the Laplace equation in two variables has a solution, the solution is unique.

PROBLEM SET 18.6

1. Integrate $|z|^2$ around the unit circle. Does your result contradict Theorem 1?

2–4 VERIFY THEOREM 1 for the given $F(z)$, z_0, and circle of radius 1.

2. $(z + 1)^3$, $z_0 = 2$

3. $(z - 2)^2$, $z_0 = \frac{1}{3}$

4. $10z^4$, $z_0 = 0$

5–7 VERIFY THEOREM 2 for the given $\Phi(x, y)$, (x_0, y_0) and circle of radius 1.

5. $(x - 2)(y - 2)$, $(4, -4)$

6. $x^2 - y^2$, $(3, 8)$

7. $x^3 - 3xy^2$, $(1, 1)$

8. Derive Theorem 2 from Poisson's integral formula.

9. CAS EXPERIMENT. Graphing Potentials. Graph the potentials in Probs. 5 and 7 and for three other functions of your choice as surfaces over a rectangle or a disk in the xy-plane. Find the locations of maxima and minima by inspecting these graphs.

10. TEAM PROJECT. Maximum Modulus of Analytic Functions. (a) Verify Theorem 3 for (i) $F(z) = z^2$ and the square $4 \leqq x \leqq 6$, $2 \leqq y \leqq 4$, (ii) $F(z) = e^{3z}$ and any bounded domain, (iii) $F(z) = \sin z$ and the unit disk.

(b) $F(x) = \cos x$ (x real) has a maximum 1 at 0. How does it follow that this cannot be a maximum of $|F(z)| = |\cos z|$ in a domain containing $z = 0$?

(c) $F(z) = 1 + |z|^2$ is not zero in the disk $|z| \leqq 4$ and has a minimum at an interior point. Does this contradict Theorem 3?

(d) If $F(z)$ is analytic and not constant in the closed unit disk D: $|z| \leqq 1$ and $|F(z)| = c = const$ on the unit circle, show that $F(z)$ must have a zero in D. Can you extend this to an arbitrary simple closed curve?

11–13 MAXIMUM MODULUS

Find the location and size of the maximum of $|F(z)|$ in the unit disk $|z| \leqq 1$.

11. $F(z) = z^2 - 1$

12. $F(z) = az + b$ (a, b complex)

13. $F(z) = \cos 2z$

14. Verify the maximum principle for $\Phi(x, y) = e^x \cos y$ and the rectangle $a \leqq x \leqq b$, $0 \leqq y \leqq 2\pi$.

15. (Conjugate) Do Φ and a harmonic conjugate Ψ of Φ in a region R have their maximum at the same point of R?

16. (Conformal mapping) Find the location (u_1, v_1) of the maximum of $\Phi^* = e^u \cos v$ in R^*: $|w| \leqq 1$, $v \geqq 0$, where $w = u + iv$. Find the region R that is mapped onto R^* by $w = f(z) = z^2$. Find the potential in R resulting from Φ^* and the location (x_1, y_1) of the maximum. Is (u_1, v_1) the image of (x_1, y_1)? If so, is this just by chance?

CHAPTER 18 REVIEW QUESTIONS AND PROBLEMS

1. Why can potential problems be modeled and solved by complex analysis? For what dimensions?

2. What is a harmonic function? A harmonic conjugate?

3. Give a few examples of potential problems considered in this chapter.

4. What is a complex potential? What does it give physically?

5. How can conformal mapping be used in connection with the Dirichlet problem?

6. What heat problems reduce to potential problems? Give a few examples.

7. Write a short essay on potential theory in fluid flow from memory.

8. What is a mixed boundary value problem? Where did it occur?

9. State Poisson's formula and its derivation from Cauchy's formula.

10. State the maximum modulus theorem and mean value theorems for harmonic functions.

11. Find the potential and complex potential between the plates $y = x$ and $y = x + 10$ kept at 10 V and 110 V, respectively.

12. Find the potential between the cylinders $|z| = 1$ cm having potential 0 and $|z| = 10$ cm having potential 20 kV.

13. Find the complex potential in Prob. 12.

14. Find the equipotential line $U = 0$ V between the cylinders $|z| = 0.25$ cm and $|z| = 4$ cm kept at -220 V and 220 V, respectively. (Guess first.)

15. Find the potential between the cylinders $|z| = 10$ cm and $|z| = 100$ cm kept at the potentials 10 kV and 0, respectively.

16. Find the potential in the angular region between the plates $\operatorname{Arg} z = \pi/6$, kept at 8 kV, and $\operatorname{Arg} z = \pi/3$, kept at 6 kV.

17. Find the equipotential lines of $F(z) = i \operatorname{Ln} z$.

18. Find and sketch the equipotential lines of $F(z) = (1 + i)/z$.

19. What is the complex potential in the upper half-plane if the negative half of the x-axis has potential 1 kV and the positive half is grounded?

20. Find the potential on the ray $y = x$, $x > 0$, and on the positive half of the x-axis if the positive half of the y-axis is at 1200 V and the negative half is grounded.

21. Interpret Prob. 20 as a problem in heat conduction.

22. Find the temperature in the upper half-plane if the portion $x > 2$ of the x-axis is kept at 50°C and the other portion at 0°C.

23. Show that the isotherms of $F(z) = -iz^2 + z$ are hyperbolas.

24. If the region between two concentric cylinders of radii 2 cm and 10 cm contains water and the outer cylinder is kept at 20°C, to what temperature must we heat the inner cylinder in order to have 30°C at distance 5 cm from the axis?

25. What are the streamlines of $F(z) = i/z$?

26. What is the complex potential of a flow around a cylinder of radius 4 without circulation?

27. Find the complex potential of a source at $z = 5$. What are the streamlines?

28. Find the temperature in the unit disk $|z| \leqq 1$ in the form of an infinite series if the left semicircle of $|z| = 1$ has the temperature of 50°C and the right semicircle has the temperature 0°C.

29. Same task as in Prob. 28 if the upper semicircle is at 40°C and the lower at 0°C.

30. Find a series for the potential in the unit disk with boundary values $\Phi(1, \theta) = \theta^2$ $(-\pi < \theta < \pi)$.

SUMMARY OF CHAPTER 18
Complex Analysis and Potential Theory

Potential theory is the theory of solutions of **Laplace's equation**

$$\nabla^2\Phi = 0. \tag{1}$$

Solutions whose second partial derivatives are ***continuous*** are called **harmonic functions.** Equation (1) is the most important PDE in physics, where it is of interest in two and three dimensions. It appears in electrostatics (Sec. 18.1), steady-state heat problems (Sec. 18.3), fluid flow (Sec. 18.4), gravity, etc. Whereas the three-dimensional case requires other methods (see Chap. 12), two-dimensional potential theory can be handled by complex analysis, since the real and imaginary parts of an analytic function are harmonic (Sec. 13.4). They remain harmonic under conformal mapping (Sec. 18.2), so that **conformal mapping** becomes a powerful tool in solving boundary value problems for (1), as is illustrated in this chapter. With a real potential Φ in (1) we can associate a **complex potential**

$$F(z) = \Phi + i\Psi \qquad \text{(Sec. 18.1).} \tag{2}$$

Then both families of curves $\Phi = const$ and $\Psi = const$ have a physical meaning. In electrostatics, they are equipotential lines and lines of electrical force (Sec. 18.1). In heat problems, they are isotherms (curves of constant temperature) and lines of heat flow (Sec. 18.3). In fluid flow, they are equipotential lines of the velocity potential and streamlines (Sec. 18.4).

For the disk, the solution of the Dirichlet problem is given by the **Poisson formula** (Sec. 18.5) or by a series that on the boundary circle becomes the Fourier series of the given boundary values (Sec. 18.5).

Harmonic functions, like analytic functions, have a number of general properties; particularly important are the **mean value property** and the **maximum modulus property** (Sec. 18.6), which implies the uniqueness of the solution of the Dirichlet problem (Theorem 5 in Sec. 18.6).

CHAPTER 19 Numerics in General

CHAPTER 20 Numeric Linear Algebra

CHAPTER 21 Numerics for ODEs and PDEs

Numeric analysis, more briefly also called **numerics,** concerns **numeric methods,** that is, methods for solving problems in terms of numbers or corresponding graphical representations. It also includes the investigation of the range of applicability and of the accuracy and stability of these methods.

Typical tasks for numerics are the evaluation of definite integrals, the solution of equations and linear systems, the solution of differential or integral equations for which there are no solution formulas, and the evaluation of experimental data for which we want to obtain, for example, an approximating polynomial.

Numeric methods then provide the transition from the mathematical model to an **algorithm,** which is a detailed stepwise recipe for solving a problem of the indicated kind to be programmed on your computer, using your CAS (computer algebra system) or other software, or on your programmable calculator.

In this and the next two chapters we explain and illustrate the most frequently used basic numeric methods in algorithmic form. Chapter 19 concerns numerics in general; Chap. 20 numeric linear algebra, in particular, methods for linear systems and matrix eigenvalue problems; and Chap. 21 numerics for ODEs and PDEs.

The algorithms are given in a form that seems best for showing how a method works. We suggest that you also make use of programs from public-domain or commercial software listed on pp. 778–779 or obtainable on the Internet.

Numerics has increased in importance to the engineer more than any other field of mathematics owing to the ongoing development of powerful software resulting from great research activity in numerics: new methods are invented, existing methods are improved and adapted, and old methods—impractical in precomputer times—are rediscovered. A main goal in these activities is the development of well-structured software. And in large-scale work—millions of equations or steps of iteration—even small algorithmic improvements may have a large effect on computing time, storage demand, accuracy, and stability.

On average this makes the algorithms used in practice more and more complicated. ***However, the more sophisticated modern software will become, the more important it will be to understand concepts and algorithms in a basic form that shows original motivating ideas of recent developments.***

To avoid misunderstandings: Various simple classical methods are still very useful in many routine situations and produce satisfactory results. In other words, not *everything* has become more sophisticated.

Software

See also http://www.wiley.com/college/kreyszig/

The following list will help you if you wish to find software. You may also obtain information on known and new software from magazines, such as *Byte Magazine* or *PC Magazine,* from articles published by the *American Mathematical Society* (see also their website at www.ams.org), the *Society for Industrial and Applied Mathematics* (SIAM, at www.siam.org), the *Association for Computing Machinery* (ACM, at www.acm.org), or the *Institute of Electrical and Electronics Engineers* (IEEE, at www.ieee.org). CHAPTER 19

Numerics in General

This first chapter on numerics begins with an explanation of some general concepts, such as floating point, roundoff errors, and general numeric errors and their propagation. In Sec. 19.2 we discuss methods for solving equations. Interpolation methods, including splines, follow in Secs. 19.3 and 19.4. The last section (19.5) concerns numeric integration and differentiation.

The purpose of this chapter is twofold. First, for all these tasks the student should become familiar with the most basic (but not too complicated) numeric solution methods. These are indispensable for the engineer, because for many problems there is no solution formula (think of a complicated integral or a polynomial of high degree or the interpolation of values obtained by measurements). In other cases a complicated solution formula may exist but may be practically useless.

Second, the student should learn to understand some basic ideas and concepts that are important throughout numerics, such as the practical form of algorithms, the estimation of errors, and the order of convergence.

Prerequisite: Elementary calculus
References and Answers to Problems: App. 1 Part E, App. 2

19.1 Introduction

Numeric methods are used to solve problems on computers or calculators by numeric calculations, resulting in a table of numbers and/or graphical representations (figures). The steps from a given situation (in engineering, economics, etc.) to the final answer are usually as follows.

1. **Modeling.** We set up a mathematical model of our problem, such as an integral, a system of equations, or a differential equation.
2. **Choosing a numeric method** and parameters (e.g., step size), perhaps with a preliminary error estimation.
3. **Programming.** We use the algorithm to write a corresponding program in a CAS, such as Maple, Mathematica, Matlab, or Mathcad, or, say, in Fortran, *C*, or C^{++}, selecting suitable routines from a software system as needed.
4. **Doing the computation.**
5. **Interpreting the results** in physical or other terms, also deciding to rerun if further results are needed.

Steps 1 and 2 are related. A slight change of the model may often admit of a more efficient method. To choose methods, we must first get to know them. Chapters 19–21 contain efficient algorithms for the most important classes of problems occurring frequently in practice.

In Step 3 the program consists of the given data and a sequence of instructions to be executed by the computer in a certain order for producing the answer in numeric or graphic form.

To create a good understanding of the nature of numeric work, we continue in this section with some simple general remarks.

Floating-Point Form of Numbers

We know that in decimal notation, every real number is represented by a finite or an infinite sequence of decimal digits. Now most computers have two ways of representing numbers, called *fixed point* and *floating point*. In a **fixed-point** system all numbers are given with a fixed number of decimals after the decimal point; for example, numbers given with 3 decimals are 62.358, 0.014, 1.000. In a text we would write, say, 3 decimals as 3D. Fixed-point representations are impractical in most scientific computations because of their limited range (explain!) and will not concern us.

In a **floating-point** system we write, for instance,

$$0.6247 \cdot 10^{3}, \qquad 0.1735 \cdot 10^{-13}, \qquad -0.2000 \cdot 10^{-1}$$

or sometimes also

$$6.247 \cdot 10^{2}, \qquad 1.735 \cdot 10^{-14}, \qquad -2.000 \cdot 10^{-2}.$$

We see that in this system the number of significant digits is kept fixed, whereas the decimal point is "floating." Here, a **significant digit** of a number c is any given digit of c, except possibly for zeros to the left of the first nonzero digit; these zeros serve only to fix the position of the decimal point. (Thus any other zero is a significant digit of c.) For instance, each of the numbers

$$1360, \quad 1.360, \quad 0.001360$$

has 4 significant digits. In a text we indicate, say, 4 significant digits, by 4S.

The use of exponents permits us to represent very large and very small numbers. Indeed, theoretically any nonzero number a can be written as

$$(1) \qquad a = \pm m \cdot 10^{n}, \qquad 0.1 \leqq |m| < 1, \qquad n \text{ integer.}$$

On the computer, m is limited to k digits (e.g., $k = 8$) and n is limited, giving representations (for finitely many numbers only!)

$$(2) \qquad \bar{a} = \pm \overline{m} \cdot 10^{n}, \qquad \overline{m} = 0.d_1 d_2 \cdots d_k, \qquad d_1 > 0.$$

These numbers $\bar{a}$ are often called *k-digit decimal machine numbers*. Their fractional part m (or $\overline{m}$) is called the *mantissa*. This has nothing to do with "mantissa" as used for logarithms. n is called the *exponent* of $\bar{a}$.

Underflow and Overflow. The range of exponents that a typical computer can handle is very large. The IEEE (Institute of Electrical and Electronics Engineers) floating-point standard for **single precision** (the usual number of digits in calculations) is about $-38 < n < 38$ (about $-125 < n^* < 125$ for the exponent in **binary representations,** i.e., representations in base 2). [For so-called **double precision** it is about $-308 < n < 308$ (about $-1020 < n^* < 1020$ for binary).] If in a computation a number outside that range occurs, this is called **underflow** when the number is smaller and **overflow** when it is larger. In the case of underflow the result is usually set to zero and computation continues. Overflow causes the computer to halt. Standard codes (by IMSL, NAG, etc.) are written to avoid overflow. Error messages on overflow may then indicate programming errors (incorrect input data, etc.).

Roundoff

An error is caused by **chopping** (= discarding all decimals from some decimal on) or **rounding.** This error is called **roundoff error,** regardless of whether we chop or round. The rule for rounding off a number to k decimals is as follows. (The rule for rounding off to k significant digits is the same, with "decimal" replaced by "significant digit.")

Roundoff Rule. Discard the $(k + 1)$th and all subsequent decimals. (a) If the number thus discarded is less than half a unit in the kth place, leave the kth decimal unchanged (*"rounding down"*). (b) If it is greater than half a unit in the kth place, add one to the kth decimal (*"rounding up"*). (c) If it is exactly half a unit, round off to the nearest *even* decimal. (Example: Rounding off 3.45 and 3.55 to 1 decimal gives 3.4 and 3.6, respectively.)

The last part of the rule is supposed to ensure that in discarding exactly half a decimal, rounding up and rounding down happens about equally often, on the average.

If we round off 1.2535 to 3, 2, 1 decimals, we get 1.254, 1.25, 1.3, but if 1.25 is rounded off to one decimal, without further information, we get 1.2.

Chopping is not recommended because the corresponding error can be larger than that in rounding, and is systematic. (Nevertheless, some computers use it because it is simpler and faster. On the other hand, some computers and calculators improve accuracy of results by doing intermediate calculations using one or more extra digits, called *guarding digits.*)

Error in Rounding. Let $\bar{a} = fl(a)$ in (2) be the floating-point computer approximation of a in (1) obtained by rounding, where fl suggests **floating.** Then the roundoff rule gives (by dropping exponents) $|m - \bar{m}| \leqq \frac{1}{2} \cdot 10^{-k}$. Since $|m| \geqq 0.1$, this implies (when $a \neq 0$)

$$\left| \frac{a - \bar{a}}{a} \right| \approx \left| \frac{m - \bar{m}}{m} \right| \leqq \frac{1}{2} \cdot 10^{1-k}. \tag{3}$$

The right side $u = \frac{1}{2} \cdot 10^{1-k}$ is called the **rounding unit.** If we write $\bar{a} = a(1 + \delta)$, we have by algebra $(\bar{a} - a)/a = \delta$, hence $|\delta| \leqq u$ by (3). *This shows that the rounding unit u is an error bound in rounding.*

Rounding errors may ruin a computation completely, even a small computation. In general, these errors become the more dangerous the more arithmetic operations (perhaps several millions!) we have to perform. It is therefore important to analyze computational programs for expected rounding errors and to find an arrangement of the computations such that the effect of rounding errors is as small as possible.

The arithmetic in a computer is not exact either and causes further errors; however, these will not be relevant to our discussion.

Accuracy in Tables. Although available software has rendered various tables of function values superfluous, some tables (of higher functions, of coefficients of integration formulas, etc.) will still remain in occasional use. If a table shows k significant digits, it is conventionally assumed that any value $\tilde{a}$ in the table deviates from the exact value a by at most $\pm\frac{1}{2}$ unit of the kth digit.

Algorithm. Stability

Numeric methods can be formulated as algorithms. An **algorithm** is a step-by-step procedure that states a numeric method in a form (a **"pseudocode"**) understandable to humans. (Turn pages to see what algorithms look like.) The algorithm is then used to write a program in a programming language that the computer can understand so that it can execute the numeric method. Important algorithms follow in the next sections. For routine tasks your CAS or some other software system may contain programs that you can use or include as parts of larger programs of your own.

Stability. To be useful, an algorithm should be **stable;** that is, small changes in the initial data should cause only small changes in the final results. However, if small changes in the initial data can produce large changes in the final results, we call the algorithm **unstable.**

This *"numeric instability,"* which in most cases can be avoided by choosing a better algorithm, must be distinguished from *"mathematical instability"* of a problem, which is called *"ill-conditioning,"* a concept we discuss in the next section.

Some algorithms are stable only for certain initial data, so that one must be careful in such a case.

Errors of Numeric Results

Final results of computations of unknown quantities generally are **approximations;** that is, they are not exact but involve errors. Such an error may result from a combination of the following effects. **Roundoff errors** result from rounding, as discussed on p. 782. **Experimental errors** are errors of given data (probably arising from measurements). **Truncating errors** result from truncating (prematurely breaking off), for instance, if we replace a Taylor series with the sum of its first few terms. These errors depend on the computational method used and must be dealt with individually for each method. ["Truncating" is sometimes used as a term for chopping off (see before), a terminology that is not recommended.]

Formulas for Errors. If $\tilde{a}$ is an approximate value of a quantity whose exact value is a, we call the difference

$$\epsilon = a - \tilde{a} \tag{4}$$

the **error** of $\tilde{a}$. Hence

$$a = \tilde{a} + \epsilon, \qquad \text{True value} = \text{Approximation} + \text{Error}. \tag{4*}$$

For instance, if $\tilde{a} = 10.5$ is an approximation of $a = 10.2$, its error is $\epsilon = -0.3$. The error of an approximation $\tilde{a} = 1.60$ of $a = 1.82$ is $\epsilon = 0.22$.

CAUTION! In the literature $|a - \tilde{a}|$ ("absolute error") or $\tilde{a} - a$ are sometimes also used as definitions of error.

The **relative error** ϵ_r of $\tilde{a}$ is defined by

$$\epsilon_r = \frac{\epsilon}{a} = \frac{a - \tilde{a}}{a} = \frac{\text{Error}}{\text{True value}} \qquad (a \neq 0). \tag{5}$$

This looks useless because a is unknown. But if $|\epsilon|$ is much less than $|\tilde{a}|$, then we can use $\tilde{a}$ instead of a and get

$$\epsilon_r \approx \frac{\epsilon}{\tilde{a}}. \tag{5'}$$

This still looks problematic because ϵ is unknown—if it were known, we could get $a = \tilde{a} + \epsilon$ from (4) and we would be done. But what one often can obtain in practice is an **error bound** for $\tilde{a}$, that is, a number β such that

$$|\epsilon| \leqq \beta, \qquad \text{hence} \qquad |a - \tilde{a}| \leqq \beta.$$

This tells us how far away from our computed $\tilde{a}$ the unknown a can at most lie. Similarly, for the relative error, an error bound is a number β_r such that

$$|\epsilon_r| \leqq \beta_r, \qquad \text{hence} \qquad \left|\frac{a - \tilde{a}}{a}\right| \leqq \beta_r.$$

Error Propagation

This is an important matter. It refers to how errors at the beginning and in later steps (roundoff, for example) propagate into the computation and affect accuracy, sometimes very drastically. We state here what happens to error bounds. Namely, bounds for the *error* add under addition and subtraction, whereas bounds for the *relative error* add under multiplication and division. You do well to keep this in mind.

THEOREM 1

Error Propagation

(a) *In addition and subtraction, an error bound for the results is given by the sum of the error bounds for the terms.*

(b) *In multiplication and division, an error bound for the relative error of the results is given (approximately) by the sum of the bounds for the relative errors of the given numbers.*

PROOF **(a)** We use the notations $x = \tilde{x} + \epsilon_1$, $y = \tilde{y} + \epsilon_2$, $|\epsilon_1| \leqq \beta_1$, $|\epsilon_2| \leqq \beta_2$. Then for the error ϵ of the *difference* we obtain

$$\begin{aligned} |\epsilon| &= |x - y - (\tilde{x} - \tilde{y})| \\ &= |x - \tilde{x} - (y - \tilde{y})| \\ &= |\epsilon_1 - \epsilon_2| \leqq |\epsilon_1| + |\epsilon_2| \leqq \beta_1 + \beta_2. \end{aligned}$$

The proof for the *sum* is similar and is left to the student.

(b) For the relative error ϵ_r of $\tilde{x}\tilde{y}$ we get from the relative errors ϵ_{r1} and ϵ_{r2} of $\tilde{x}$, $\tilde{y}$ and bounds β_{r1}, β_{r2}

$$|\epsilon_r| = \left|\frac{xy - \tilde{x}\tilde{y}}{xy}\right| = \left|\frac{xy - (x - \epsilon_1)(y - \epsilon_2)}{xy}\right| = \left|\frac{\epsilon_1 y + \epsilon_2 x - \epsilon_1\epsilon_2}{xy}\right|$$

$$\approx \left|\frac{\epsilon_1 y + \epsilon_2 x}{xy}\right| \leqq \left|\frac{\epsilon_1}{x}\right| + \left|\frac{\epsilon_2}{y}\right| = |\epsilon_{r1}| + |\epsilon_{r2}| \leqq \beta_{r1} + \beta_{r2}.$$

This proof shows what "approximately" means: we neglected $\epsilon_1\epsilon_2$ as small in absolute value compared to $|\epsilon_1|$ and $|\epsilon_2|$. The proof for the quotient is similar but slightly more tricky (see Prob. 15). ■

Basic Error Principle

Every numeric method should be accompanied by an error estimate. If such a formula is lacking, is extremely complicated, or is impractical because it involves information (for instance, on derivatives) that is not available, the following may help.

Error Estimation by Comparison. *Do a calculation twice with different accuracy. Regard the difference $\tilde{a}_2 - \tilde{a}_1$ of the results $\tilde{a}_1$, $\tilde{a}_2$ as a (perhaps crude) estimate of the error ϵ_1 of the inferior result $\tilde{a}_1$.* Indeed, $\tilde{a}_1 + \epsilon_1 = \tilde{a}_2 + \epsilon_2$ by formula (4*). This implies $\tilde{a}_2 - \tilde{a}_1 = \epsilon_1 - \epsilon_2 \approx \epsilon_1$ because $\tilde{a}_2$ is generally more accurate than $\tilde{a}_1$, so that $|\epsilon_2|$ is small compared to $|\epsilon_1|$.

Loss of Significant Digits

This means that a result of a calculation has fewer correct digits than the numbers from which it was obtained. This happens if we subtract two numbers of about the same size, for example, $0.1439 - 0.1426$ ("subtractive cancellation"). It may occur in simple problems, but it can be avoided in most cases by simple changes of the algorithm—if one is aware of it! Let us illustrate this with the following basic problem.

EXAMPLE 1 **Quadratic Equation. Loss of Significant Digits**

Find the roots of the equation

$$x^2 - 40x + 2 = 0,$$

using 4 significant digits (abbreviated 4S) in the computation.

Solution. A formula for the roots x_1, x_2 of a quadratic equation $ax^2 + bx + c = 0$ is

$$(6) \qquad x_1 = \frac{1}{2a}\left(-b + \sqrt{b^2 - 4ac}\right), \qquad x_2 = \frac{1}{2a}\left(-b - \sqrt{b^2 - 4ac}\right).$$

Furthermore, since $x_1x_2 = c/a$, another formula for those roots is

$$(7) \qquad x_1 \text{ as before.} \qquad x_2 = \frac{c}{ax_1}.$$

From (6) we obtain $x = 20 \pm \sqrt{398} = 20.00 \pm 19.95$. This gives $x_1 = 20.00 + 19.95 = 39.95$, involving no difficulty, whereas $x_2 = 20.00 - 19.95 = 0.05$ is poor because it involves loss of significant digits.

In contrast, (7) gives $x_1 = 39.95$, $x_2 = 2.000/39.95 = 0.05006$, in error by less than one unit of the last digit, as a computation with more digits shows. (The 10S-value is 0.0500 626 5674.)

Comment. To avoid misunderstandings: 4S was used for convenience; (7) is better than (6) regardless of the number of digits used. For instance, the 8S-computation by (6) is $x_1 = 39.949\,937$, $x_2 = 0.050\,063$, which is poor, and by (7) it is x_1 as before, $x_2 = 2/x_1 = 0.050\,062\,657$.

In a quadratic equation with real roots, if x_2 is absolutely largest (because $b > 0$), use (6) for x_2 and then $x_1 = c/(ax_2)$. ■

PROBLEM SET 19.1

1. **(Floating point)** Write 98.17, −100.987, 0.0057869, −13600 in floating-point form, rounded to 4S (4 significant digits).
2. Write −0.0286403, 11.25845, −31681.55 in floating-point form rounded to 6S.
3. **Small differences of large numbers** may be particularly strongly affected by rounding errors. Illustrate this by computing 0.36443/(17.862 − 17.798) as given with 5S, then rounding stepwise to 4S, 3S, and 2S, where "stepwise" means: round the *rounded* numbers, not the given ones.
4. Do the work in Prob. 3 with numbers of your choice that give even more drastically different results. How can you avoid such difficulties?
5. The quotient in Prob. 3 is of the form $a/(b - c)$. Write it as $a(b + c)/(b^2 - c^2)$. Compute it first with 5S, then rounding numerator 12.996 and denominator 2.28 stepwise as in Prob. 3. Compare and comment.
6. **(Quadratic equation)** Solve $x^2 - 20x + 1 = 0$ by (6) and by (7), using 6S in the computation. Compare and comment.
7. Do the computations in Prob. 6 with 4S and 2S.
8. Solve $x^2 + 100x + 2 = 0$ by (6) and (7) with 5S and compare.
9. Calculate $1/e = 0.367879$ (6S) from the partial sums of 5 to 10 terms of the Maclaurin series (a) of e^{-x} with $x = 1$, (b) of e^x with $x = 1$ and then taking the reciprocal. Which is more accurate?
10. Addition with a fixed number of significant digits depends on the order in which you add the numbers. Illustrate this with an example. Find an empirical rule for the best order.
11. **Approximations of π** $= 3.141\,592\,653\,589\,79 \cdots$ are 22/7 and 355/113. Determine the corresponding errors and relative errors to 3 significant digits.
12. Compute π by **Machin's approximation**
    $16 \arctan(1/5) - 4 \arctan(1/239)$ to 10S (which are correct). (In 1986, D. H. Bailey computed almost 30 million decimals of π on a CRAY-2 in less than 30 hours. The race for more and more decimals is continuing.)
13. **(Rounding and adding)** Let $a_1, \cdots, a_n$ be numbers with a_j correctly rounded to D_j decimals. In calculating the sum $a_1 + \cdots + a_n$, retaining $D = \min D_j$ decimals, is it essential that we first add and then round the result or that we first round each number to D decimals and then add?
14. **(Theorems on errors)** Prove Theorem 1(a) for addition.
15. Prove Theorem 1(b) for division.
16. Show that in Example 1 the absolute value of the error of $x_2 = 2.000/39.95 = 0.05006$ is less than 0.00001.
17. **Overflow and underflow** can sometimes be avoided by simple changes in a formula. Explain this in terms of $\sqrt{x^2 + y^2} = x\sqrt{1 + (y/x)^2}$ with $x^2 \geqq y^2$ and x so large that x^2 would cause overflow. Invent examples of your own.
18. **(Nested form)** Evaluate
    $$f(x) = x^3 - 7.5x^2 + 11.2x + 2.8$$
    $$= ((x - 7.5)x + 11.2)x + 2.8$$
    at $x = 3.94$ using 3S arithmetic and rounding, in both of the given forms. The latter, called the *nested form*, is usually preferable since it minimizes the number of operations and thus the effect of rounding.
19. **CAS EXPERIMENT. Chopping and Rounding.**
    (a) Let $x = 4/7$ and $y = 1/3$. Find the errors ϵ_{chop}, ϵ_{round} and the relative errors $\epsilon_{\text{r,ch}}$, $\epsilon_{\text{r,rd}}$ of $x + y$, $x - y$, xy, x/y in chopping and rounding to 5S. Experiment with other fractions of your choice.

    (b) Graph ϵ_{chop} and ϵ_{round} (for 5S) of $k/21$ as a function of $k = 1, 2, \cdots, 21$ on common axes. What average value can you read from the graph for ϵ_{chop}? For ϵ_{round}? Experiment with other integers that give similar graphs. Different types of graphs. Can you characterize the different types in terms of prime factors?

    (c) How does the situation in (b) change if you take 4S instead of 5S?

    (d) Write programs for the work in (a)–(c).
20. **WRITING PROJECT. Numerics.** In your own words write about the overall role of numeric methods in applied mathematics, why they are important, where and when they must be used or can be used, and how they are influenced by the use of the computer in engineering and other work.

19.2 Solution of Equations by Iteration

From here on, each section will be devoted to some basic kind of problem and corresponding solution methods. We begin with methods of finding solutions of a single equation

$$f(x) = 0 \tag{1}$$

where f is a given function. For this task there are practically no formulas (except in a few simple cases), so that one depends almost entirely on numeric algorithms. A **solution** of (1) is a number $x = s$ such that $f(s) = 0$. Here, s suggests "solution," but we shall also use other letters.

Examples are $x^3 + x = 1$, $\sin x = 0.5x$, $\tan x = x$, $\cosh x = \sec x$, $\cosh x \cos x = -1$, which can all be written in the form (1). The first concerns an **algebraic equation** because the corresponding f is a polynomial, and in this case the solutions are also called **roots** of the equation. The other equations are **transcendental equations** because they involve transcendental functions. Solving equations (1) is a task of prime importance because engineering applications abound: some occur in Chaps. 2, 4, 8 (characteristic equations), 6 (partial fractions), 12 (eigenvalues, zeros of Bessel functions), and 16 (integration), but there are many, many others.

To solve (1) when there is no formula for the exact solution, we can use an approximation method, in particular an **iteration method,** that is, a method in which we start from an initial guess x_0 (which may be poor) and compute step by step (in general better and better) approximations $x_1, x_2, \cdots$ of an unknown solution of (1). We discuss three such methods that are of particular practical importance and mention two others in the problem set. These methods and the underlying principles are basic for understanding the diverse methods in software packages.

In general, iteration methods are easy to program because the computational operations are the same in each step—just the data change from step to step—and, more important, if in a concrete case a method converges, it is stable (see Sec. 19.1) in general.

Fixed-Point Iteration for Solving Equations $f(x) = 0$

Our present use of the word "fixed point" has absolutely nothing to do with that in the last section.

In one way or another we transform (1) *algebraically* into the form

$$x = g(x). \tag{2}$$

Then we choose an x_0 and compute $x_1 = g(x_0)$, $x_2 = g(x_1)$, and in general

$$x_{n+1} = g(x_n) \qquad (n = 0, 1, \cdots). \tag{3}$$

A solution of (2) is called a **fixed point** of g, motivating the name of the method. This is a solution of (1), since from $x = g(x)$ we can return to the original form $f(x) = 0$. From (1) we may get several different forms of (2). The behavior of corresponding iterative sequences $x_0, x_1, \cdots$ may differ, in particular, with respect to their speed of convergence. Indeed, some of them may not converge at all. Let us illustrate these facts with a simple example.

EXAMPLE 1 **An Iteration Process (Fixed-Point Iteration)**

Set up an iteration process for the equation $f(x) = x^2 - 3x + 1 = 0$. Since we know the solutions

$$x = 1.5 \pm \sqrt{1.25}, \quad \text{thus} \quad 2.618\,034 \quad \text{and} \quad 0.381\,966,$$

we can watch the behavior of the error as the iteration proceeds.

Solution. The equation may be written

$$x = g_1(x) = \tfrac{1}{3}(x^2 + 1), \quad \text{thus} \quad x_{n+1} = \tfrac{1}{3}(x_n^2 + 1). \tag{4a}$$

If we choose $x_0 = 1$, we obtain the sequence (Fig. 423a; computed with 6S and then rounded)

$$x_0 = 1.000, \quad x_1 = 0.667, \quad x_2 = 0.481, \quad x_3 = 0.411, \quad x_4 = 0.390, \cdots$$

which seems to approach the smaller solution. If we choose $x_0 = 2$, the situation is similar. If we choose $x_0 = 3$, we obtain the sequence (Fig. 423a, upper part)

$$x_0 = 3.000, \quad x_1 = 3.333, \quad x_2 = 4.037, \quad x_3 = 5.766, \quad x_4 = 11.415, \cdots$$

which diverges.

Our equation may also be written (divide by x)

$$x = g_2(x) = 3 - \frac{1}{x}, \quad \text{thus} \quad x_{n+1} = 3 - \frac{1}{x_n}, \tag{4b}$$

and if we choose $x_0 = 1$, we obtain the sequence (Fig. 423b)

$$x_0 = 1.000, \quad x_1 = 2.000, \quad x_2 = 2.500, \quad x_3 = 2.600, \quad x_4 = 2.615, \cdots$$

which seems to approach the larger solution. Similarly, if we choose $x_0 = 3$, we obtain the sequence (Fig. 423*b*)

$$x_0 = 3.000, \quad x_1 = 2.667, \quad x_2 = 2.625, \quad x_3 = 2.619, \quad x_4 = 2.618, \cdots.$$

Our figures show the following. In the lower part of Fig. 423a the slope of $g_1(x)$ is less than the slope of $y = x$, which is 1, thus $|g_1'(x)| < 1$, and we seem to have convergence. In the upper part, $g_1(x)$ is steeper ($g_1'(x) > 1$) and we have divergence. In Fig. 423b the slope of $g_2(x)$ is less near the intersection point ($x = 2.618$, fixed point of g_2, solution of $f(x) = 0$), and both sequences seem to converge. From all this we conclude that convergence seems to depend on the fact that in a neighborhood of a solution the curve of $g(x)$ is less steep than the straight line $y = x$, and we shall now see that this condition $|g'(x)| < 1$ (= slope of $y = x$) is sufficient for convergence. ■

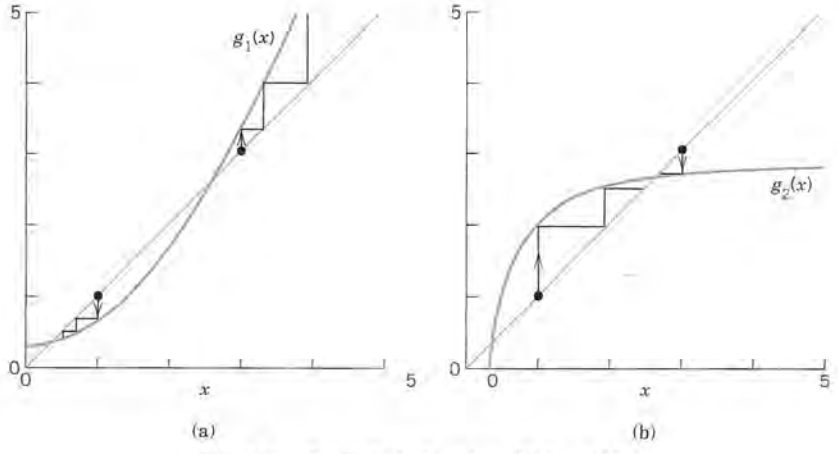

Fig. 423. Example 1, iterations (4a) and (4b)

An iteration process defined by (3) is called **convergent** for an x_0 if the corresponding sequence $x_0, x_1, \cdots$ is convergent.

A sufficient condition for convergence is given in the following theorem, which has various practical applications.

THEOREM 1

Convergence of Fixed-Point Iteration

Let $x = s$ be a solution of $x = g(x)$ and suppose that g has a continuous derivative in some interval J containing s. Then if $|g'(x)| \leqq K < 1$ in J, the iteration process defined by (3) converges for any x_0 in J, and the limit of the sequence $\{x_n\}$ is s.

PROOF By the mean value theorem of differential calculus there is a t between x and s such that

$$g(x) - g(s) = g'(t)\,(x - s) \qquad (x \text{ in } J).$$

Since $g(s) = s$ and $x_1 = g(x_0)$, $x_2 = g(x_1), \cdots$, we obtain from this and the condition on $|g'(x)|$ in the theorem

$$|x_n - s| = |g(x_{n-1}) - g(s)| = |g'(t)||x_{n-1} - s| \leqq K|x_{n-1} - s|.$$

Applying this inequality n times, for $n, n - 1, \cdots, 1$ gives

$$|x_n - s| \leqq K|x_{n-1} - s| \leqq K^2|x_{n-2} - s| \leqq \cdots \leqq K^n|x_0 - s|.$$

Since $K < 1$, we have $K^n \to 0$; hence $|x_n - s| \to 0$ as $n \to \infty$. ∎

We mention that a function g satisfying the condition in Theorem 1 is called a **contraction** because $|g(x) - g(v)| \leqq K|x - v|$, where $K < 1$. Furthermore, K gives information on the speed of convergence. For instance, if $K = 0.5$, then the accuracy increases by at least 2 digits in only 7 steps because $0.5^7 < 0.01$.

EXAMPLE 2 **An Iteration Process. Illustration of Theorem 1**

Find a solution of $f(x) = x^3 + x - 1 = 0$ by iteration.

Solution. A sketch shows that a solution lies near $x = 1$. We may write the equation as $(x^2 + 1)x = 1$ or

$$x = g_1(x) = \frac{1}{1 + x^2}, \qquad \text{so that} \qquad x_{n+1} = \frac{1}{1 + x_n^2}. \qquad \text{Also} \qquad |g_1'(x)| = \frac{2|x|}{(1 + x^2)^2} < 1$$

for any x because $4x^2/(1 + x^2)^4 = 4x^2/(1 + 4x^2 + \cdots) < 1$, so that by Theorem 1 we have convergence for any x_0. Choosing $x_0 = 1$, we obtain (Fig. 424 on p. 790)

$$x_1 = 0.500, \quad x_2 = 0.800, \quad x_3 = 0.610, \quad x_4 = 0.729, \quad x_5 = 0.653, \quad x_6 = 0.701, \cdots.$$

The solution exact to 6D is $s = 0.682\,328$.

The given equation may also be written

$$x = g_2(x) = 1 - x^3. \qquad \text{Then} \qquad |g_2'(x)| = 3x^2$$

and this is greater than 1 near the solution, so that we cannot apply Theorem 1 and assert convergence. Try $x_0 = 1$, $x_0 = 0.5$, $x_0 = 2$ and see what happens.

The example shows that the transformation of a given $f(x) = 0$ into the form $x = g(x)$ with g satisfying $|g'(x)| \leqq K < 1$ may need some experimentation. ∎

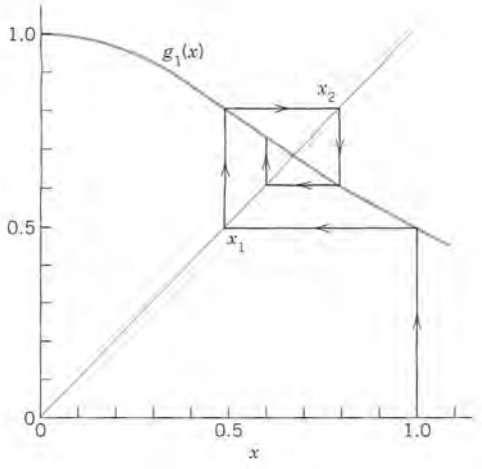

Fig. 424. Iteration in Example 2

Newton's Method for Solving Equations $f(x) = 0$

Newton's method, also known as **Newton–Raphson's method,**[1] is another iteration method for solving equations $f(x) = 0$, where f is assumed to have a continuous derivative f'. The method is commonly used because of its simplicity and great speed. The underlying idea is that we approximate the graph of f by suitable tangents. Using an approximate value x_0 obtained from the graph of f, we let x_1 be the point of intersection of the x-axis and the tangent to the curve of f at x_0 (see Fig. 425). Then

$$\tan \beta = f'(x_0) = \frac{f(x_0)}{x_0 - x_1}, \qquad \text{hence} \qquad x_1 = x_0 - \frac{f(x_0)}{f'(x_0)}.$$

In the second step we compute $x_2 = x_1 - f(x_1)/f'(x_1)$, in the third step x_3 from x_2 again by the same formula, and so on. We thus have the algorithm shown in Table 19.1. Formula (5) in this algorithm can also be obtained if we algebraically solve Taylor's formula

$$(5^*) \qquad f(x_{n+1}) \approx f(x_n) + (x_{n+1} - x_n) f'(x_n) = 0.$$

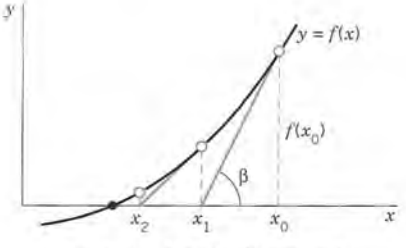

Fig. 425. Newton's method

[1]JOSEPH RAPHSON (1648–1715), English mathematician who published a method similar to Newton's method. For historical details, see Ref. [GR2], p. 203, listed in App. 1.

Table 19.1 Newton's Method for Solving Equations $f(x) = 0$

ALGORITHM NEWTON $(f, f', x_0, \epsilon, N)$

This algorithm computes a solution of $f(x) = 0$ given an initial approximation x_0 (starting value of the iteration). Here the function $f(x)$ is continuous and has a continuous derivative $f'(x)$.

INPUT: f, f', initial approximation x_0, tolerance $\epsilon > 0$, maximum number of iterations N.

OUTPUT: Approximate solution x_n $(n \leqq N)$ or message of failure.

For $n = 0, 1, 2, \cdots, N - 1$ do:

1 Compute $f'(x_n)$.

2 If $f'(x_n) = 0$ then OUTPUT "Failure". Stop.

[*Procedure completed unsuccessfully*]

3 Else compute

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}. \tag{5}$$

4 If $|x_{n+1} - x_n| \leqq \epsilon |x_n|$ then OUTPUT x_{n+1}. Stop.

[*Procedure completed successfully*]

End

5 OUTPUT "Failure". Stop.

[*Procedure completed unsuccessfully after N iterations*]

End NEWTON

If it happens that $f'(x_n) = 0$ for some n (see line 2 of the algorithm), then try another starting value x_0. Line 3 is the heart of Newton's method.

The inequality in line 4 is a **termination criterion.** If the sequence of the x_n converges and the criterion holds, we have reached the desired accuracy and stop. In this line the factor $|x_n|$ is needed in the case of zeros of very small (or very large) absolute value because of the high density (or of the scarcity) of machine numbers for those x.

WARNING! The criterion by itself does not imply convergence. *Example.* The harmonic series diverges, although its partial sums $x_n = \sum_{k=1}^{n} 1/k$ satisfy the criterion because $\lim (x_{n+1} - x_n) = \lim (1/(n + 1)) = 0$.

Line 5 gives another termination criterion and is needed because Newton's method may diverge or, due to a poor choice of x_0, may not reach the desired accuracy by a reasonable number of iterations. Then we may try another x_0. If $f(x) = 0$ has more than one solution, different choices of x_0 may produce different solutions. Also, an iterative sequence may sometimes converge to a solution different from the expected one.

EXAMPLE 3 Square Root

Set up a Newton iteration for computing the square root x of a given positive number c and apply it to $c = 2$.

Solution. We have $x = \sqrt{c}$, hence $f(x) = x^2 - c = 0$, $f'(x) = 2x$, and (5) takes the form

$$x_{n+1} = x_n - \frac{x_n^2 - c}{2x_n} = \frac{1}{2}\left(x_n + \frac{c}{x_n}\right).$$

For $c = 2$, choosing $x_0 = 1$, we obtain

$$x_1 = 1.500\,000, \quad x_2 = 1.416\,667, \quad x_3 = 1.414\,216, \quad x_4 = 1.414\,214, \cdots.$$

x_4 is exact to 6D. ■

EXAMPLE 4 Iteration for a Transcendental Equation

Find the positive solution of $2 \sin x = x$.

Solution. Setting $f(x) = x - 2 \sin x$, we have $f'(x) = 1 - 2 \cos x$, and (5) gives

$$x_{n+1} = x_n - \frac{x_n - 2 \sin x_n}{1 - 2 \cos x_n} = \frac{2(\sin x_n - x_n \cos x_n)}{1 - 2 \cos x_n} = \frac{N_n}{D_n}.$$

From the graph of f we conclude that the solution is near $x_0 = 2$. We compute:

n	x_n	N_n	D_n	x_{n+1}
0	2.00000	3.48318	1.83229	1.90100
1	1.90100	3.12470	1.64847	1.89552
2	1.89552	3.10500	1.63809	1.89550
3	1.89550	3.10493	1.63806	1.89549

$x_4 = 1.89549$ is exact to 5D since the solution to 6D is 1.895 494. ■

EXAMPLE 5 Newton's Method Applied to an Algebraic Equation

Apply Newton's method to the equation $f(x) = x^3 + x - 1 = 0$.

Solution. From (5) we have

$$x_{n+1} = x_n - \frac{x_n^3 + x_n - 1}{3x_n^2 + 1} = \frac{2x_n^3 + 1}{3x_n^2 + 1}.$$

Starting from $x_0 = 1$, we obtain

$$x_1 = 0.750\,000, \quad x_2 = 0.686\,047, \quad x_3 = 0.682\,340, \quad x_4 = 0.682\,328, \cdots$$

where x_4 has the error $-1 \cdot 10^{-6}$. A comparison with Example 2 shows that the present convergence is much more rapid. This may motivate the concept of the *order of an iteration process,* to be discussed next. ■

Order of an Iteration Method. Speed of Convergence

The quality of an iteration method may be characterized by the speed of convergence, as follows.

Let $x_{n+1} = g(x_n)$ define an iteration method, and let x_n approximate a solution s of $x = g(x)$. Then $x_n = s - \epsilon_n$, where ϵ_n is the error of x_n. Suppose that g is differentiable a number of times, so that the Taylor formula gives

$$(6) \qquad \begin{aligned} x_{n+1} = g(x_n) &= g(s) + g'(s)(x_n - s) + \tfrac{1}{2}g''(s)(x_n - s)^2 + \cdots \\ &= g(s) - g'(s)\epsilon_n + \tfrac{1}{2}g''(s)\epsilon_n^2 + \cdots, \end{aligned}$$

The exponent of ϵ_n in the first nonvanishing term after $g(s)$ is called the **order** of the iteration process defined by g. The order measures the speed of convergence.

To see this, subtract $g(s) = s$ on both sides of (6). Then on the left you get $x_{n+1} - s = -\epsilon_{n+1}$, where ϵ_{n+1} is the error of x_{n+1}. And on the right the remaining expression equals approximately its first nonzero term because $|\epsilon_n|$ is small in the case of convergence. Thus

$$\text{(7)} \qquad \begin{aligned} &\text{(a)} \quad \epsilon_{n+1} \approx +g'(s)\epsilon_n && \text{in the case of first order,} \\ &\text{(b)} \quad \epsilon_{n+1} \approx -\tfrac{1}{2}g''(s)\epsilon_n^{\,2} && \text{in the case of second order,} \qquad \text{etc.} \end{aligned}$$

Thus if $\epsilon_n = 10^{-k}$ in some step, then for second order, $\epsilon_{n+1} = c \cdot (10^{-k})^2 = c \cdot 10^{-2k}$, so that the number of significant digits is about doubled in each step.

Convergence of Newton's Method

In Newton's method, $g(x) = x - f(x)/f'(x)$. By differentiation,

$$\text{(8)} \qquad \begin{aligned} g'(x) &= 1 - \frac{f'(x)^2 - f(x)f''(x)}{f'(x)^2} \\ &= \frac{f(x)f''(x)}{f'(x)^2}. \end{aligned}$$

Since $f(s) = 0$, this shows that also $g'(s) = 0$. Hence Newton's method is at least of second order. If we differentiate again and set $x = s$, we find that

$$\text{(8*)} \qquad g''(s) = \frac{f''(s)}{f'(s)}$$

which will not be zero in general. This proves

THEOREM 2

Second-Order Convergence of Newton's Method

If $f(x)$ is three times differentiable and f' and f'' are not zero at a solution s of $f(x) = 0$, then for x_0 sufficiently close to s, Newton's method is of second order.

Comments. For Newton's method, (7b) becomes, by (8*),

$$\text{(9)} \qquad \epsilon_{n+1} \approx -\frac{f''(s)}{2f'(s)}\,\epsilon_n^{\,2}.$$

For the rapid convergence of the method indicated in Theorem 2 it is important that s be a *simple* zero of $f(x)$ (thus $f'(s) \neq 0$) and that x_0 be close to s, because in Taylor's formula we took only the linear term [see (5*)], assuming the quadratic term to be negligibly small. (With a bad x_0 the method may even diverge!)

EXAMPLE 6 Prior Error Estimate of the Number of Newton Iteration Steps

Use $x_0 = 2$ and $x_1 = 1.901$ in Example 4 for estimating how many iteration steps we need to produce the solution to 5D accuracy. This is an **a priori estimate** or **prior estimate** because we can compute it after only one iteration, prior to further iterations.

Solution. We have $f(x) = x - 2 \sin x = 0$. Differentiation gives

$$\frac{f''(s)}{2f'(s)} \approx \frac{f''(x_1)}{2f'(x_1)} = \frac{2 \sin x_1}{2(1 - 2 \cos x_1)} \approx 0.57.$$

Hence (9) gives

$$|\epsilon_{n+1}| \approx 0.57\epsilon_n^{\,2} \approx 0.57(0.57\epsilon_{n-1}^2)^2 = 0.57^3\epsilon_{n-1}^4 \approx \cdots \approx 0.57^M\epsilon_0^{M+1} \leqq 5 \cdot 10^{-6}$$

where $M = 2^n + 2^{n-1} + \cdots + 2 + 1 = 2^{n+1} - 1$. We show below that $\epsilon_0 \approx -0.11$. Consequently, our condition becomes

$$0.57^M 0.11^{M+1} \leqq 5 \cdot 10^{-6}.$$

Hence $n = 2$ is the smallest possible n, according to this crude estimate, in good agreement with Example 4.

$\epsilon_0 \approx -0.11$ is obtained from $\epsilon_1 - \epsilon_0 = (\epsilon_1 - s) - (\epsilon_0 - s) = -x_1 + x_0 \approx 0.10$, hence $\epsilon_1 = \epsilon_0 + 0.10 \approx -0.57\epsilon_0^{\,2}$ or $0.57\epsilon_0^{\,2} + \epsilon_0 + 0.10 \approx 0$, which gives $\epsilon_0 \approx -0.11$. ■

Difficulties in Newton's Method. Difficulties may arise if $|f'(x)|$ is very small near a solution s of $f(x) = 0$, for instance, if s is a zero of $f(x)$ of second (or higher) order (so that Newton's method converges only linearly, as an application of l'Hôpital's rule to (8) shows). Geometrically, small $|f'(x)|$ means that the tangent of $f(x)$ near s almost coincides with the x-axis (so that double precision may be needed to get $f(x)$ and $f'(x)$ accurately enough). Then for values $x = \tilde{s}$ far away from s we can still have small function values

$$R(\tilde{s}) = f(\tilde{s}).$$

In this case we call the equation $f(x) = 0$ **ill-conditioned.** $R(\tilde{s})$ is called the **residual** of $f(x) = 0$ at $\tilde{s}$. Thus a small residual guarantees a small error of $\tilde{s}$ only if the equation is ***not*** ill-conditioned.

EXAMPLE 7 An Ill-Conditioned Equation

$f(x) = x^5 + 10^{-4}x = 0$ is ill-conditioned. $x = 0$ is a solution. $f'(0) = 10^{-4}$ is small. At $\tilde{s} = 0.1$ the residual $f(0.1) = 2 \cdot 10^{-5}$ is small, but the error -0.1 is larger in absolute value by a factor 5000. Invent a more drastic example of your own. ■

Secant Method for Solving $f(x) = 0$

Newton's method is very powerful but has the disadvantage that the derivative f' may sometimes be a far more difficult expression than f itself and its evaluation therefore computationally expensive. This situation suggests the idea of replacing the derivative with the difference quotient

$$f'(x_n) \approx \frac{f(x_n) - f(x_{n-1})}{x_n - x_{n-1}}.$$

Then instead of (5) we have the formula of the popular secant method

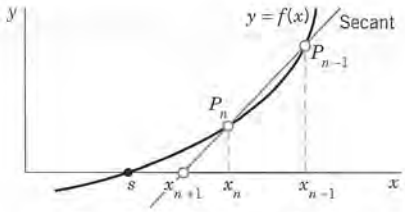

Fig. 426. Secant method

(10)
$$x_{n+1} = x_n - f(x_n)\,\frac{x_n - x_{n-1}}{f(x_n) - f(x_{n-1})}.$$

Geometrically, we intersect the x-axis at x_{n+1} with the secant of $f(x)$ passing through P_{n-1} and P_n in Fig. 426. We need two starting values x_0 and x_1. Evaluation of derivatives is now avoided. It can be shown that convergence is **superlinear** (that is, more rapid than linear, $|\epsilon_{n+1}| \approx const \cdot |\epsilon_n|^{1.62}$; see [E5] in App. 1), almost quadratic like Newton's method. The algorithm is similar to that of Newton's method, as the student may show.

CAUTION! It is ***not*** good to write (10) as

$$x_{n+1} = \frac{x_{n-1}f(x_n) - x_n f(x_{n-1})}{f(x_n) - f(x_{n-1})},$$

because this may lead to loss of significant digits if x_n and x_{n-1} are about equal. (Can you see this from the formula?)

EXAMPLE 8 **Secant Method**

Find the positive solution of $f(x) = x - 2\sin x = 0$ by the secant method, starting from $x_0 = 2$, $x_1 = 1.9$.

Solution. Here, (10) is

$$x_{n+1} = x_n - \frac{(x_n - 2\sin x_n)(x_n - x_{n-1})}{x_n - x_{n-1} + 2(\sin x_{n-1} - \sin x_n)} = x_n - \frac{N_n}{D_n}.$$

Numerical values are:

n	x_{n-1}	x_n	N_n	D_n	$x_{n+1} - x_n$
1	2.000 000	1.900 000	−0.000 740	−0.174 005	−0.004 253
2	1.900 000	1.895 747	−0.000 002	−0.006 986	−0.000 252
3	1.895 747	1.895 494	0		0

$x_3 = 1.895\,494$ is exact to 6D. See Example 4. ■

Summary of Methods. The methods for computing solutions s of $f(x) = 0$ with given continuous (or differentiable) $f(x)$ start with an initial approximation x_0 of s and generate a sequence $x_1, x_2, \cdots$ by **iteration. Fixed point methods** solve $f(x) = 0$ written as $x = g(x)$, so that s is a *fixed point* of g, that is, $s = g(s)$. For $g(x) = x - f(x)/f'(x)$ this is **Newton's method,** which for good x_0 and simple zeros converges quadratically (and for multiple zeros linearly). From Newton's method the **secant method** follows by replacing $f'(x)$ by a difference quotient. The **bisection method** and the **method of false position** in Problem Set 19.2 always converge, but often slowly.

PROBLEM SET 19.2

1–7 FIXED-POINT ITERATION

Apply fixed-point iteration and answer related questions where indicated. Show details of your work.

1. $x = 1.4 \sin x$, $x_0 = 1.4$
2. Do the iterations indicated at the end of Example 2. Sketch a figure similar to Fig. 424.
3. Why do we obtain a monotone sequence in Example 1, but not in Example 2?
4. $f = x^4 - x + 0.2 = 0$, the root near 1, $x_0 = 1$
5. f as in Prob. 4, the root near 0, $x_0 = 0$
6. Find the smallest positive solution of $\sin x = e^{-0.5x}$, $x_0 = 1$.
7. **(Bessel functions, drumhead)** A partial sum of the Maclaurin series of $J_0(x)$ (Sec. 5.5) is $f(x) = 1 - \frac{1}{4}x^2 + \frac{1}{64}x^4 - \frac{1}{2304}x^6$. Conclude from a sketch that $f(x) = 0$ near $x = 2$. Write $f(x) = 0$ as $x = g(x)$ (by dividing $f(x)$ by $\frac{1}{4}x$ and taking the resulting x-term to the other side). Find the zero. (See Sec. 12.9 for the importance of these zeros.)
8. **CAS PROJECT. Fixed-Point Iteration. (a) Existence.** Prove that if g is continuous in a closed interval I and its range lies in I, then the equation $x = g(x)$ has at least one solution in I. Illustrate that it may have more than one solution in I.

   (b) Convergence. Let $f(x) = x^3 + 2x^2 - 3x - 4 = 0$. Write this as $x = g(x)$, for g choosing (1) $(x^3 - f)^{1/3}$, (2) $(x^2 - \frac{1}{2}f)^{1/2}$, (3) $x + \frac{1}{3}f$, (4) $x(1 + \frac{1}{4}f)$, (5) $(x^3 - f)/x^2$, (6) $(2x^2 - f)/2x$, (7) $x - f/f'$ and in each case $x_0 = 1.5$. Find out about convergence and divergence and the number of steps to reach exact 6S-values of a root.

9–18 NEWTON'S METHOD

Apply Newton's method (6D accuracy). First sketch the function(s) to see what is going on.

9. $\sin x = \cot x$, $x_0 = 1$
10. $x = \cos x$, $x_0 = 1$
11. $x^3 - 5x + 3 = 0$, $x_0 = 2$
12. $x + \ln x = 2$, $x_0 = 2$
13. **(Vibrating beam)** Find the solution of $\cos x \cosh x = 1$ near $x = \frac{3}{2}\pi$. (This determines a frequency of a vibrating beam; see Problem Set 12.3.)
14. **(Heating, cooling)** At what time x (4S-accuracy only) will the processes governed by $f_1(x) = 100(1 - e^{-0.2x})$ and $f_2(x) = 40e^{-0.01x}$ reach the same temperature? Also find the latter.
15. **(Associated Legendre functions)** Find the smallest positive zero of $P_4^{\,2} = (1 - x^2)P_4'' = \frac{15}{2}(-7x^4 + 8x^2 - 1)$ (Sec. 5.3) (a) by Newton's method, (b) exactly, by solving a quadratic equation.
16. **(Legendre polynomials)** Find the largest root of the Legendre polynomial $P_5(x)$ given by $P_5(x) = \frac{1}{8}(63x^5 - 70x^3 + 15x)$ (Sec. 5.3) (to be needed in Gauss integration in Sec. 19.5) (a) by Newton's method, (b) from a quadratic equation.
17. Design a Newton iteration for cube roots and compute $\sqrt[3]{7}$ (6D, $x_0 = 2$).
18. Design a Newton iteration for $\sqrt[k]{c}$ $(c > 0)$. Use it to compute $\sqrt{2}$, $\sqrt[3]{2}$, $\sqrt[4]{2}$, $\sqrt[5]{2}$ (6D, $x_0 = 1$).
19. **TEAM PROJECT. Bisection Method.** This simple but slowly convergent method for finding a solution of $f(x) = 0$ with continuous f is based on the **intermediate value theorem,** which states that if a continuous function f has opposite signs at some $x = a$ and $x = b$ $(> a)$, that is, either $f(a) < 0$, $f(b) > 0$ or $f(a) > 0$, $f(b) < 0$, then f must be 0 somewhere on $[a, b]$. The solution is found by repeated bisection of the interval and in each iteration picking that half which also satisfies that sign condition.

   (a) Algorithm. Write an algorithm for the method.

   (b) Comparison. Solve $x = \cos x$ by Newton's method and by bisection. Compare.

   (c) Solve $e^{-x} = \ln x$ and $e^x + x^4 + x = 2$ by bisection.
20. **TEAM PROJECT. Method of False Position (Regula falsi).** Figure 427 shows the idea. We assume that f is continuous. We compute the x-intercept c_0 of the line through $(a_0, f(a_0))$, $(b_0, f(b_0))$. If $f(c_0) = 0$, we are done. If $f(a_0)f(c_0) < 0$ (as in Fig. 427), we set $a_1 = a_0$, $b_1 = c_0$ and repeat to get c_1, etc. If $f(a_0)f(c_0) > 0$, then $f(c_0)f(b_0) < 0$ and we set $a_1 = c_0$, $b_1 = b_0$, etc.

   (a) Algorithm. Show that

$$c_0 = \frac{a_0 f(b_0) - b_0 f(a_0)}{f(b_0) - f(a_0)}$$

   and write an algorithm for the method.

   (b) Comparison. Solve $x^3 = 5x + 6$ by Newton's method, the secant method, and the method of false position. Compare.

   (c) Solve $x^4 = 2$, $\cos x = \sqrt{x}$, and $x + \ln x = 2$ by the method of false position.

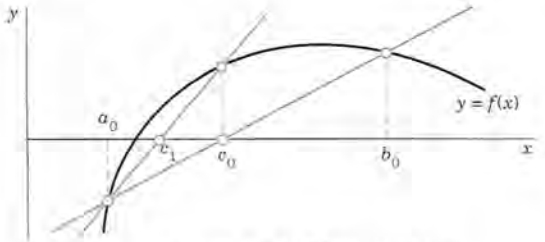

Fig. 427. Method of false position

21–24 SECANT METHOD

Solve, using x_0 and x_1 as indicated.

21. Prob. 11, $x_0 = 0.5$, $x_1 = 2.0$

22. $e^{-x} - \tan x = 0$, $x_0 = 1$, $x_1 = 0.7$

23. Prob. 9, $x_0 = 1$, $x_1 = 0.5$

24. Prob. 10, $x_0 = 0.5$, $x_1 = 1$

25. WRITING PROJECT. Solution of Equations. Compare the methods in this section and problem set, discussing advantages and disadvantages using examples of your own.

19.3 Interpolation

Interpolation means finding (approximate) values of a function $f(x)$ for an x between ***different*** x-values $x_0, x_1, \cdots, x_n$ at which the values of $f(x)$ are given. These values may come from a "mathematical" function, such as a logarithm or a Bessel function, or, perhaps more frequently, they may be measured or automatically recorded values of an "empirical" function, such as the air resistance of a car or an airplane at different speeds, or the yield of a chemical process at different temperatures, or the size of the U.S. population as it appears from censuses taken at 10-year intervals. We write these given values of a function f in the form

$$f_0 = f(x_0), \qquad f_1 = f(x_1), \qquad \cdots, \qquad f_n = f(x_n)$$

or as ordered pairs

$$(x_0, f_0), \qquad (x_1, f_1), \qquad \cdots, \qquad (x_n, f_n).$$

A standard idea in interpolation now is to find a polynomial $p_n(x)$ of degree n (or less) that assumes the given values; thus

$$\textbf{(1)} \qquad p_n(x_0) = f_0, \qquad p_n(x_1) = f_1, \qquad \cdots, \qquad p_n(x_n) = f_n.$$

We call this p_n an **interpolation polynomial** and $x_0, \cdots, x_n$ the **nodes.** And if $f(x)$ is a mathematical function, we call p_n an **approximation** of f (or a **polynomial approximation,** because there are other kinds of approximations, as we shall see later). We use p_n to get (approximate) values of f for x's between x_0 and x_n (**"interpolation"**) or sometimes outside this interval $x_0 \leqq x \leqq x_n$ (**"extrapolation"**).

Motivation. Polynomials are convenient to work with because we can readily differentiate and integrate them, again obtaining polynomials. Moreover, they approximate *continuous* functions with any desired accuracy. That is, for any continuous $f(x)$ on an interval J: $a \leqq x \leqq b$ and error bound $\beta > 0$, there is a polynomial $p_n(x)$ (of sufficiently high degree n) such that

$$|f(x) - p_n(x)| < \beta \quad \text{for all } x \text{ on } J.$$

This is the famous **Weierstrass approximation theorem** (for a proof see Ref. [GR7], p. 280; see App. 1).

Existence and Uniqueness. p_n satisfying (1) for given data exists—we give formulas for it below. p_n is unique. Indeed, if another polynomial q_n also satisfies $q_n(x_0) = f_0, \cdots, q_n(x_n) = f_n$, then $p_n(x) - q_n(x) = 0$ at $x_0, \cdots, x_n$, but a polynomial $p_n - q_n$ of degree n (or less) with $n + 1$ roots must be identically zero, as we know from algebra; thus $p_n(x) = q_n(x)$ for all x, which means uniqueness. ■

How to Find p_n? This is the important practical question. We answer it by explaining several standard methods. For given data, these methods give the same polynomial, by the uniqueness just proved (which is thus of practical interest!), but expressed in several forms suitable for different purposes.

Lagrange Interpolation

Given $(x_0, f_0), (x_1, f_1), \cdots, (x_n, f_n)$ with arbitrarily spaced x_j, Lagrange had the idea of multiplying each f_j by a polynomial that is 1 at x_j and 0 at the other n nodes and then taking the sum of these $n + 1$ polynomials. Clearly, this gives the unique interpolation polynomial of degree n or less. Beginning with the simplest case, let us see how this works.

Linear interpolation is interpolation by the straight line through $(x_0, f_0), (x_1, f_1)$; see Fig. 428. Thus the linear Lagrange polynomial p_1 is a sum $p_1 = L_0 f_0 + L_1 f_1$ with L_0 the linear polynomial that is 1 at x_0 and 0 at x_1; similarly, L_1 is 0 at x_0 and 1 at x_1. Obviously,

$$L_0(x) = \frac{x - x_1}{x_0 - x_1}, \qquad L_1(x) = \frac{x - x_0}{x_1 - x_0}.$$

This gives the linear Lagrange polynomial

$$\textbf{(2)} \qquad p_1(x) = L_0(x)f_0 + L_1(x)f_1 = \frac{x - x_1}{x_0 - x_1} \cdot f_0 + \frac{x - x_0}{x_1 - x_0} \cdot f_1.$$

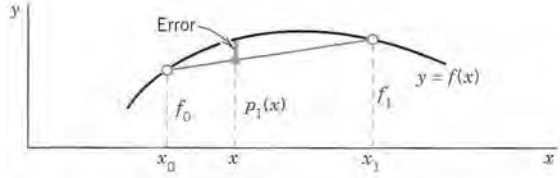

Fig. 428. Linear interpolation

EXAMPLE 1 Linear Lagrange Interpolation

Compute a 4D-value of ln 9.2 from ln 9.0 = 2.1972, ln 9.5 = 2.2513 by linear Lagrange interpolation and determine the error, using ln 9.2 = 2.2192 (4D).

Solution. $x_0 = 9.0$, $x_1 = 9.5$, $f_0 = \ln 9.0$, $f_1 = \ln 9.5$. In (2) we need

$$L_0(x) = \frac{x - 9.5}{-0.5} = -2.0(x - 9.5), \qquad L_0(9.2) = -2.0(-0.3) = 0.6$$

$$L_1(x) = \frac{x - 9.0}{0.5} = 2.0(x - 9.0), \qquad L_1(9.2) = 2 \cdot 0.2 = 0.4$$

(see Fig. 429) and obtain the answer

$$\ln 9.2 \approx p_1(9.2) = L_0(9.2)f_0 + L_1(9.2)f_1 = 0.6 \cdot 2.1972 + 0.4 \cdot 2.2513 = 2.2188.$$

The error is $\epsilon = a - \tilde{a} = 2.2192 - 2.2188 = 0.0004$. Hence linear interpolation is not sufficient here to get 4D-accuracy; it would suffice for 3D-accuracy. ■

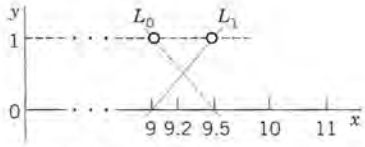

Fig. 429. L_0 and L_1 in Example 1

Quadratic interpolation is interpolation of given (x_0, f_0), (x_1, f_1), (x_2, f_2) by a second-degree polynomial $p_2(x)$, which by Lagrange's idea is

$$\textbf{(3a)} \qquad p_2(x) = L_0(x)f_0 + L_1(x)f_1 + L_2(x)f_2$$

with $L_0(x_0) = 1$, $L_1(x_1) = 1$, $L_2(x_2) = 1$, and $L_0(x_1) = L_0(x_2) = 0$, etc. We claim that

$$\textbf{(3b)} \qquad L_0(x) = \frac{l_0(x)}{l_0(x_0)} = \frac{(x - x_1)(x - x_2)}{(x_0 - x_1)(x_0 - x_2)}$$

$$L_1(x) = \frac{l_1(x)}{l_1(x_1)} = \frac{(x - x_0)(x - x_2)}{(x_1 - x_0)(x_1 - x_2)}$$

$$L_2(x) = \frac{l_2(x)}{l_2(x_2)} = \frac{(x - x_0)(x - x_1)}{(x_2 - x_0)(x_2 - x_1)}.$$

How did we get this? Well, the numerator makes $L_k(x_j) = 0$ if $j \neq k$. And the denominator makes $L_k(x_k) = 1$ because it equals the numerator at $x = x_k$.

EXAMPLE 2 **Quadratic Lagrange Interpolation**

Compute ln 9.2 by (3) from the data in Example 1 and the additional third value ln 11.0 = 2.3979.

Solution. In (3),

$$L_0(x) = \frac{(x - 9.5)(x - 11.0)}{(9.0 - 9.5)(9.0 - 11.0)} = x^2 - 20.5x + 104.5, \qquad L_0(9.2) = 0.5400,$$

$$L_1(x) = \frac{(x - 9.0)(x - 11.0)}{(9.5 - 9.0)(9.5 - 11.0)} = -\frac{1}{0.75}(x^2 - 20x + 99), \qquad L_1(9.2) = 0.4800,$$

$$L_2(x) = \frac{(x - 9.0)(x - 9.5)}{(11.0 - 9.0)(11.0 - 9.5)} = \frac{1}{3}(x^2 - 18.5x + 85.5), \qquad L_2(9.2) = -0.0200,$$

(see Fig. 430), so that (3a) gives, exact to 4D,

$$\ln 9.2 \approx p_2(9.2) = 0.5400 \cdot 2.1972 + 0.4800 \cdot 2.2513 - 0.0200 \cdot 2.3979 = 2.2192.$$ ■

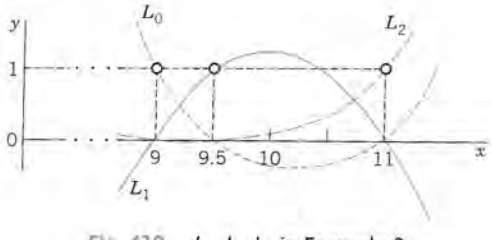

Fig. 430. L_0, L_1, L_2 in Example 2

General Lagrange Interpolation Polynomial. For general n we obtain

$$\textbf{(4a)} \qquad f(x) \approx p_n(x) = \sum_{k=0}^{n} L_k(x) f_k = \sum_{k=0}^{n} \frac{l_k(x)}{l_k(x_k)} f_k$$

where $L_k(x_k) = 1$ and L_k is 0 at the other nodes, and the L_k are independent of the function f to be interpolated. We get (4a) if we take

$$\textbf{(4b)} \qquad \begin{aligned} l_0(x) &= (x - x_1)(x - x_2) \cdots (x - x_n), \\ l_k(x) &= (x - x_0) \cdots (x - x_{k-1})(x - x_{k+1}) \cdots (x - x_n), \qquad 0 < k < n, \\ l_n(x) &= (x - x_0)(x - x_1) \cdots (x - x_{n-1}). \end{aligned}$$

We can easily see that $p_n(x_k) = f_k$. Indeed, inspection of (4b) shows that $l_k(x_j) = 0$ if $j \neq k$, so that for $x = x_k$, the sum in (4a) reduces to the single term $(l_k(x_k)/l_k(x_k))f_k = f_k$.

Error Estimate. If f is itself a polynomial of degree n (or less), it must coincide with p_n because the $n + 1$ data $(x_0, f_0), \cdots, (x_n, f_n)$ determine a polynomial uniquely, so the error is zero. Now the special f has its $(n + 1)$st derivative identically zero. This makes it plausible that for a *general* f its $(n + 1)$st derivative $f^{(n+1)}$ should measure the error

$$\epsilon_n(x) = f(x) - p_n(x).$$

It can be shown that this is true if $f^{(n+1)}$ exists and is continuous. Then, with a suitable t between x_0 and x_n (or between x_0, x_n, and x if we extrapolate),

$$\textbf{(5)} \qquad \epsilon_n(x) = f(x) - p_n(x) = (x - x_0)(x - x_1) \cdots (x - x_n) \frac{f^{(n+1)}(t)}{(n + 1)!}.$$

Thus $|\epsilon_n(x)|$ is 0 at the nodes and small near them, because of continuity. The product $(x - x_0) \cdots (x - x_n)$ is large for x away from the nodes. This makes extrapolation risky. And interpolation at an x will be best if we choose nodes on both sides of that x. Also, we get error bounds by taking the smallest and the largest value of $f^{(n+1)}(t)$ in (5) on the interval $x_0 \leqq t \leqq x_n$ (or on the interval also containing x if we *extra*polate).

Most importantly, since p_n is unique, as we have shown, we have

THEOREM 1

Error of Interpolation

Formula (5) *gives the error for* ***any*** *polynomial interpolation method if* $f(x)$ *has a continuous* $(n + 1)$*st derivative.*

Practical error estimate. If the derivative in (5) is difficult or impossible to obtain, apply the Error Principle (Sec. 19.1), that is, take another node and the Lagrange polynomial $p_{n+1}(x)$ and regard $p_{n+1}(x) - p_n(x)$ as a (crude) error estimate for $p_n(x)$.

EXAMPLE 3 Error Estimate (5) of Linear Interpolation. Damage by Roundoff. Error Principle

Estimate the error in Example 1 first by (5) directly and then by the Error Principle (Sec. 19.1).

Solution. **(A) *Estimation by* (5).** We have $n = 1$, $f(t) = \ln t$, $f'(t) = 1/t$, $f''(t) = -1/t^2$. Hence

$$\epsilon_1(x) = (x - 9.0)(x - 9.5)\frac{(-1)}{2t^2}, \qquad \text{thus} \qquad \epsilon_1(9.2) = \frac{0.03}{t^2}.$$

$t = 9.0$ gives the maximum $0.03/9^2 = 0.00037$ and $t = 9.5$ gives the minimum $0.03/9.5^2 = 0.00033$, so that we get $0.00033 \leqq \epsilon_1(9.2) \leqq 0.00037$, or better, 0.00038 because $0.3/81 = 0.003\,703\cdots$.

But the error 0.0004 in Example 1 disagrees, and we can learn something! Repetition of the computation there with 5D instead of 4D gives

$$\ln 9.2 \approx p_1(9.2) = 0.6 \cdot 2.19722 + 0.4 \cdot 2.25129 = 2.21885$$

with an actual error $\epsilon = 2.21920 - 2.21885 = 0.00035$, which lies nicely near the middle between our two error bounds.

This shows that the discrepancy (0.0004 vs. 0.00035) was caused by rounding, which is not taken into account in (5).

(B) *Estimation by the Error Principle.* We calculate $p_1(9.2) = 2.21885$ as before and then $p_2(9.2)$ as in Example 2 but with 5D, obtaining

$$p_2(9.2) = 0.54 \cdot 2.19722 + 0.48 \cdot 2.25129 - 0.02 \cdot 2.39790 = 2.21916.$$

The difference $p_2(9.2) - p_1(9.2) = 0.00031$ is the approximate error of $p_1(9.2)$ that we wanted to obtain; this is an approximation of the actual error 0.00035 given above. ■

Newton's Divided Difference Interpolation

For given data $(x_0, f_0), \cdots, (x_n, f_n)$ the interpolation polynomial $p_n(x)$ satisfying (1) is unique, as we have shown. But for different purposes we may use $p_n(x)$ in different forms. **Lagrange's form** just discussed is useful for deriving formulas in numeric differentiation (approximation formulas for derivatives) and integration (Sec. 19.5).

Practically more important are Newton's forms of $p_n(x)$, which we shall also use for solving ODEs (in Sec. 21.2). They involve fewer arithmetic operations than Lagrange's form. Moreover, it often happens that we have to increase the degree n to reach a required accuracy. Then in Newton's forms we can use all the previous work and just add another term, a possibility without counterpart for Lagrange's form. This also simplifies the application of the Error Principle (used in Example 3 for Lagrange). The details of these ideas are as follows.

Let $p_{n-1}(x)$ be the $(n-1)$st Newton polynomial (whose form we shall determine); thus $p_{n-1}(x_0) = f_0, p_{n-1}(x_1) = f_1, \cdots, p_{n-1}(x_{n-1}) = f_{n-1}$. Furthermore, let us write the nth Newton polynomial as

$$p_n(x) = p_{n-1}(x) + g_n(x); \tag{6}$$

hence

$$g_n(x) = p_n(x) - p_{n-1}(x). \tag{6'}$$

Here $g_n(x)$ is to be determined so that $p_n(x_0) = f_0, p_n(x_1) = f_1, \cdots, p_n(x_n) = f_n$.

Since p_n and p_{n-1} agree at $x_0, \cdots, x_{n-1}$, we see that g_n is zero there. Also, g_n will generally be a polynomial of nth degree because so is p_n, whereas p_{n-1} can be of degree $n-1$ at most. Hence g_n must be of the form

$$g_n(x) = a_n(x - x_0)(x - x_1)\cdots(x - x_{n-1}). \tag{6''}$$

We determine the constant a_n. For this we set $x = x_n$ and solve (6″) algebraically for a_n. Replacing $g_n(x_n)$ according to (6′) and using $p_n(x_n) = f_n$, we see that this gives

$$a_n = \frac{f_n - p_{n-1}(x_n)}{(x_n - x_0)(x_n - x_1) \cdots (x_n - x_{n-1})}. \tag{7}$$

We write a_k instead of a_n and show that a_k equals the **kth divided difference,** recursively denoted and defined as follows:

$$a_1 = f[x_0, x_1] = \frac{f_1 - f_0}{x_1 - x_0}$$

$$a_2 = f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$$

and in general

$$a_k = f[x_0, \cdots, x_k] = \frac{f[x_1, \cdots, x_k] - f[x_0, \cdots, x_{k-1}]}{x_k - x_0}. \tag{8}$$

PROOF If $n = 1$, then $p_{n-1}(x_n) = p_0(x_1) = f_0$ because $p_0(x)$ is constant and equal to f_0, the value of $f(x)$ at x_0. Hence (7) gives

$$a_1 = \frac{f_1 - p_0(x_1)}{x_1 - x_0} = \frac{f_1 - f_0}{x_1 - x_0} = f[x_0, x_1],$$

and (6) and (6″) give the Newton interpolation polynomial of the first degree

$$p_1(x) = f_0 + (x - x_0)f[x_0, x_1].$$

If $n = 2$, then this p_1 and (7) give

$$a_2 = \frac{f_2 - p_1(x_2)}{(x_2 - x_0)(x_2 - x_1)} = \frac{f_2 - f_0 - (x_2 - x_0)f[x_0, x_1]}{(x_2 - x_0)(x_2 - x_1)} = f[x_0, x_1, x_2]$$

where the last equality follows by straightforward calculation and comparison with the definition of the right side. (Verify it; be patient.) From (6) and (6″) we thus obtain the second Newton polynomial

$$p_2(x) = f_0 + (x - x_0)f[x_0, x_1] + (x - x_0)(x - x_1)f[x_0, x_1, x_2].$$

For $n = k$, formula (6) gives

$$p_k(x) = p_{k-1}(x) + (x - x_0)(x - x_1) \cdots (x - x_{k-1})f[x_0, \cdots, x_k]. \tag{9}$$

With $p_0(x) = f_0$ by repeated application with $k = 1, \cdots, n$ this finally gives **Newton's divided difference interpolation formula**

$$\begin{aligned} f(x) \approx\ & f_0 + (x - x_0)f[x_0, x_1] + (x - x_0)(x - x_1)f[x_0, x_1, x_2] \\ & + \cdots + (x - x_0)(x - x_1) \cdots (x - x_{n-1})f[x_0, \cdots, x_n]. \end{aligned} \tag{10}$$

An algorithm is shown in Table 19.2. The first do-loop computes the divided differences and the second the desired value $p_n(\hat{x})$.

Example 4 shows how to arrange differences near the values from which they are obtained; the latter always stand a half-line above and a half-line below in the preceding column. Such an arrangement is called a (divided) **difference table.** ■

Table 19.2 Newton's Divided Difference Interpolation

ALGORITHM INTERPOL $(x_0, \cdots, x_n; f_0, \cdots, f_n; \hat{x})$

This algorithm computes an approximation $p_n(\hat{x})$ of $f(\hat{x})$ at $\hat{x}$.

INPUT: Data $(x_0, f_0), (x_1, f_1), \cdots, (x_n, f_n)$; $\hat{x}$

OUTPUT: Approximation $p_n(\hat{x})$ of $f(\hat{x})$

Set $f[x_j] = f_j \quad (j = 0, \cdots, n)$.

For $m = 1, \cdots, n - 1$ do:

  For $j = 0, \cdots, n - m$ do:

$$f[x_j, \cdots, x_{j+m}] = \frac{f[x_{j+1}, \cdots, x_{j+m}] - f[x_j, \cdots, x_{j+m-1}]}{x_{j+m} - x_j}$$

  End

End

Set $p_0(x) = f_0$.

For $k = 1, \cdots, n$ do:

$$p_k(\hat{x}) = p_{k-1}(\hat{x}) + (\hat{x} - x_0) \cdots (\hat{x} - x_{k-1}) f[x_0, \cdots, x_k]$$

End

OUTPUT $p_n(\hat{x})$

End INTERPOL

EXAMPLE 4 Newton's Divided Difference Interpolation Formula

Compute $f(9.2)$ from the values shown in the first two columns of the following table.

x_j	$f_j = f(x_j)$	$f[x_j, x_{j+1}]$	$f[x_j, x_{j+1}, x_{j+2}]$	$f[x_j, \cdots, x_{j+3}]$
8.0	(2.079 442)			
		(0.117 783)		
9.0	2.197 225		(−0.006 433)	
		0.108 134		(0.000 411)
9.5	2.251 292		−0.005 200	
		0.097 735		
11.0	2.397 895			

Solution. We compute the divided differences as shown. Sample computation:

$$(0.097\,735 - 0.108\,134)/(11 - 9) = -0.005\,200.$$

The values we need in (10) are circled. We have

$$f(x) \approx p_3(x) = 2.079\,442 + 0.117\,783(x - 8.0) - 0.006\,433(x - 8.0)(x - 9.0) + 0.000\,411(x - 8.0)(x - 9.0)(x - 9.5).$$

At $x = 9.2$,

$$f(9.2) \approx 2.079\,442 + 0.141\,340 - 0.001\,544 - 0.000\,030 = 2.219\,208.$$

The value exact to 6D is $f(9.2) = \ln 9.2 = 2.219\,203$. Note that we can nicely see how the accuracy increases from term to term:

$$p_1(9.2) = 2.220\,782, \qquad p_2(9.2) = 2.219\,238, \qquad p_3(9.2) = 2.219\,208. \quad \blacksquare$$

Equal Spacing: Newton's Forward Difference Formula

Newton's formula (10) is valid for *arbitrarily spaced* nodes as they may occur in practice in experiments or observations. However, in many applications the x_j's are *regularly spaced*—for instance, in measurements taken at regular intervals of time. Then, denoting the distance by h, we can write

$$\textbf{(11)} \qquad x_0, \quad x_1 = x_0 + h, \quad x_2 = x_0 + 2h, \quad \cdots, \quad x_n = x_0 + nh.$$

We show how (8) and (10) now simplify considerably!

To get started, let us define the *first forward difference* of f at x_j by

$$\Delta f_j = f_{j+1} - f_j,$$

the *second forward difference* of f at x_j by

$$\Delta^2 f_j = \Delta f_{j+1} - \Delta f_j,$$

and, continuing in this way, the ***k*th forward difference** of f at x_j by

$$\textbf{(12)} \qquad \Delta^k f_j = \Delta^{k-1} f_{j+1} - \Delta^{k-1} f_j \qquad (k = 1, 2, \cdots).$$

Examples and an explanation of the name "forward" follow on p. 806. What is the point of this? We show that if we have regular spacing (11), then

$$\textbf{(13)} \qquad f[x_0, \cdots, x_k] = \frac{1}{k!\,h^k}\,\Delta^k f_0.$$

We prove (13) by induction. It is true for $k = 1$ because $x_1 = x_0 + h$, so that

$$f[x_0, x_1] = \frac{f_1 - f_0}{x_1 - x_0} = \frac{1}{h}\,(f_1 - f_0) = \frac{1}{1!\,h}\,\Delta f_0.$$

Assuming (13) to be true for all forward differences of order k, we show that (13) holds for $k + 1$. We use (8) with $k + 1$ instead of k; then we use $(k + 1)h = x_{k+1} - x_0$, resulting from (11), and finally (12) with $j = 0$, that is, $\Delta^{k+1} f_0 = \Delta^k f_1 - \Delta^k f_0$. This gives

$$\begin{aligned} f[x_0, \cdots, x_{k+1}] &= \frac{f[x_1, \cdots, x_{k+1}] - f[x_0, \cdots, x_k]}{(k+1)h} \\ &= \frac{1}{(k+1)h}\left[\frac{1}{k!\,h^k}\,\Delta^k f_1 - \frac{1}{k!\,h^k}\,\Delta^k f_0\right] \\ &= \frac{1}{(k+1)!\,h^{k+1}}\,\Delta^{k+1} f_0 \end{aligned}$$

which is (13) with $k + 1$ instead of k. Formula (13) is proved. ■

In (10) we finally set $x = x_0 + rh$. Then $x - x_0 = rh$, $x - x_1 = (r - 1)h$ since $x_1 - x_0 = h$, and so on. With this and (13), formula (10) becomes **Newton's** (or *Gregory*[2]*–Newton's*) **forward difference interpolation formula**

$$\begin{aligned} f(x) \approx p_n(x) &= \sum_{s=0}^{n} \binom{r}{s} \Delta^s f_0 \qquad (x = x_0 + rh, \quad r = (x - x_0)/h) \\ &= f_0 + r\Delta f_0 + \frac{r(r-1)}{2!}\,\Delta^2 f_0 + \cdots + \frac{r(r-1)\cdots(r-n+1)}{n!}\,\Delta^n f_0 \end{aligned} \tag{14}$$

where the **binomial coefficients** in the first line are defined by

$$\binom{r}{0} = 1, \quad \binom{r}{s} = \frac{r(r-1)(r-2)\cdots(r-s+1)}{s!} \qquad (s > 0, \text{ integer}) \tag{15}$$

and $s! = 1 \cdot 2 \cdots s$.

Error. From (5) we get, with $x - x_0 = rh$, $x - x_1 = (r - 1)h$, etc.,

$$\epsilon_n(x) = f(x) - p_n(x) = \frac{h^{n+1}}{(n+1)!}\, r(r-1)\cdots(r-n) f^{(n+1)}(t) \tag{16}$$

with t as characterized in (5).

Formula (16) is an exact formula for the error, but it involves the unknown t. In Example 5 (below) we show how to use (16) for obtaining an error estimate and an interval in which the true value of $f(x)$ must lie.

Comments on Accuracy. **(A)** The order of magnitude of the error $\epsilon_n(x)$ is about equal to that of the next difference not used in $p_n(x)$.

(B) One should choose $x_0, \cdots, x_n$ such that the x at which one interpolates is as well centered between $x_0, \cdots, x_n$ as possible.

---

[2]JAMES GREGORY (1638–1675), Scots mathematician, professor at St. Andrews and Edinburgh. Δ in (14) and ∇^2 (on p. 807) have nothing to do with the Laplacian.

The reason for (A) is that in (16),

$$f^{n+1}(t) \approx \frac{\Delta^{n+1} f(t)}{h^{n+1}}, \qquad \frac{|r(r-1)\cdots(r-n)|}{1\cdot 2\cdots(n+1)} \leqq 1 \quad \text{if} \quad |r| \leqq 1$$

(and actually for any r as long as we do not *extrapolate*). The reason for (B) is that $|r(r-1)\cdots(r-n)|$ becomes smallest for that choice.

EXAMPLE 5 **Newton's Forward Difference Formula. Error Estimation**

Compute cosh 0.56 from (14) and the four values in the following table and estimate the error.

j	x_j	$f_j = \cosh x_j$	Δf_j	$\Delta^2 f_j$	$\Delta^3 f_j$
0	0.5	(1.127 626)			
			(0.057 839)		
1	0.6	1.185 465		(0.011 865)	
			0.069 704		(0.000 697)
2	0.7	1.255 169		0.012 562	
			0.082 266		
3	0.8	1.337 435			

Solution. We compute the forward differences as shown in the table. The values we need are circled. In (14) we have $r = (0.56 - 0.50)/0.1 = 0.6$, so that (14) gives

$$\begin{aligned}\cosh 0.56 &\approx 1.127\,626 + 0.6 \cdot 0.057\,839 + \frac{0.6(-0.4)}{2} \cdot 0.011\,865 + \frac{0.6(-0.4)(-1.4)}{6} \cdot 0.000\,697 \\ &= 1.127\,626 + 0.034\,703 - 0.001\,424 + 0.000\,039 \\ &= 1.160\,944.\end{aligned}$$

Error estimate. From (16), since the fourth derivative is $\cosh^{(4)} t = \cosh t$,

$$\begin{aligned}\epsilon_3(0.56) &= \frac{0.1^4}{4!} \cdot 0.6(-0.4)(-1.4)(-2.4) \cosh t \\ &= A \cosh t,\end{aligned}$$

where $A = -0.000\,003\,36$ and $0.5 \leqq t \leqq 0.8$. We do not know t, but we get an inequality by taking the largest and smallest $\cosh t$ in that interval:

$$A \cosh 0.8 \leqq \epsilon_3(0.62) \leqq A \cosh 0.5.$$

Since

$$f(x) = p_3(x) + \epsilon_3(x),$$

this gives

$$p_3(0.56) + A \cosh 0.8 \leqq \cosh 0.56 \leqq p_3(0.56) + A \cosh 0.5.$$

Numeric values are

$$1.160\,939 \leqq \cosh 0.56 \leqq 1.160\,941.$$

The exact 6D-value is $\cosh 0.56 = 1.160\,941$. It lies within these bounds. Such bounds are not always so tight. Also, we did not consider roundoff errors, which will depend on the number of operations. ■

This example also explains the name "*forward* difference formula": we see that the differences in the formula slope forward in the difference table.

Equal Spacing: Newton's Backward Difference Formula

Instead of forward-sloping differences we may also employ backward-sloping differences. The difference table remains the same as before (same numbers, in the same positions), except for a very harmless change of the running subscript j (which we explain in Example 6, below). Nevertheless, purely for reasons of convenience it is standard to introduce a second name and notation for differences as follows. We define the *first backward difference* of f at x_j by

$$\nabla f_j = f_j - f_{j-1},$$

the *second backward difference* of f at x_j by

$$\nabla^2 f_j = \nabla f_j - \nabla f_{j-1},$$

and, continuing in this way, the ***k*th backward difference** of f at x_j by

$$\nabla^k f_j = \nabla^{k-1} f_j - \nabla^{k-1} f_{j-1} \qquad (k = 1, 2, \cdots). \tag{17}$$

A formula similar to (14) but involving backward differences is **Newton's** (or *Gregory–Newton's*) **backward difference interpolation formula**

$$\begin{aligned} f(x) \approx p_n(x) &= \sum_{s=0}^{n} \binom{r+s-1}{s} \nabla^s f_0 \qquad (x = x_0 + rh,\ r = (x - x_0)/h) \\ &= f_0 + r\nabla f_0 + \frac{r(r+1)}{2!}\nabla^2 f_0 + \cdots + \frac{r(r+1)\cdots(r+n-1)}{n!}\nabla^n f_0. \end{aligned} \tag{18}$$

EXAMPLE 6 **Newton's Forward and Backward Interpolations**

Compute a 7D-value of the Bessel function $J_0(x)$ for $x = 1.72$ from the four values in the following table, using (a) Newton's forward formula (14), (b) Newton's backward formula (18).

j_{for}	j_{back}	x_j	$J_0(x_j)$	1st Diff.	2nd Diff.	3rd Diff.
0	−3	1.7	0.397 9849			
				−0.057 9985		
1	−2	1.8	0.339 9864		−0.000 1693	
				−0.058 1678		0.000 4093
2	−1	1.9	0.281 8186		0.000 2400	
				−0.057 9278		
3	0	2.0	0.223 8908			

Solution. The computation of the differences is the same in both cases. Only their notation differs.

(a) Forward. In (14) we have $r = (1.72 - 1.70)/0.1 = 0.2$, and j goes from 0 to 3 (see first column). In each column we need the first given number, and (14) thus gives

$$J_0(1.72) \approx 0.397\,9849 + 0.2(-0.057\,9985) + \frac{0.2(-0.8)}{2}(-0.000\,1693) + \frac{0.2(-0.8)(-1.8)}{6} \cdot 0.000\,4093$$

$$= 0.397\,9849 - 0.011\,5997 + 0.000\,0135 + 0.000\,0196 = 0.386\,4183,$$

which is exact to 6D, the exact 7D-value being 0.386 4185.

(b) Backward. For (18) we use j shown in the second column, and in each column the last number. Since $r = (1.72 - 2.00)/0.1 = -2.8$, we thus get from (18)

$$J_0(1.72) \approx 0.223\,8908 - 2.8(-0.057\,9278) + \frac{-2.8(-1.8)}{2} \cdot 0.000\,2400 + \frac{-2.8(-1.8)(-0.8)}{6} \cdot 0.000\,4093$$

$$= 0.223\,8908 + 0.162\,1978 + 0.000\,6048 - 0.000\,2750$$

$$= 0.386\,4184. \quad \blacksquare$$

Central Difference Notation

This is a third notation for differences. The first central difference of $f(x)$ at x_j is defined by

$$\delta f_j = f_{j+1/2} - f_{j-1/2}$$

and the ***k*th central difference** of $f(x)$ at x_j by

$$\textbf{(19)} \qquad \delta^k f_j = \delta^{k-1} f_{j+1/2} - \delta^{k-1} f_{j-1/2} \qquad (j = 2, 3, \cdots).$$

Thus in this notation a difference table, for example, for f_{-1}, f_0, f_1, f_2, looks as follows:

x_{-1}	f_{-1}			
		$\delta f_{-1/2}$		
x_0	f_0		$\delta^2 f_0$	
		$\delta f_{1/2}$		$\delta^3 f_{1/2}$
x_1	f_1		$\delta^2 f_1$	
		$\delta f_{3/2}$		
x_2	f_2			

Central differences are used in numeric differentiation (Sec. 19.5), differential equations (Chap. 21), and centered interpolation formulas (e.g., Everett's formula in Team Project 22). These are formulas that use function values "symmetrically" located on both sides of the interpolation point x. Such values are available near the middle of a given table, where centered interpolation formulas tend to give better results than those of Newton's formulas, which do not have that "symmetry" property.

PROBLEM SET 19.3

1. **(Linear interpolation)** Calculate $p_1(x)$ in Example 1. Compute from it $\ln 9.4 \approx p_1(9.4)$.
2. Estimate the error in Prob. 1 by (5).
3. **(Quadratic interpolation)** Calculate the Lagrange polynomial $p_2(x)$ for the 4D-values of the Gamma function [(24), App. 3.1] $\Gamma(1.00) = 1.0000$, $\Gamma(1.02) = 0.9888$, $\Gamma(1.04) = 0.9784$, and from it approximations of $\Gamma(x)$ for $x = 1.005, 1.010, 1.015, 1.025, 1.030, 1.035$.
4. **(Error bounds)** Derive error bounds for $p_2(9.2)$ in Example 2 from (5).
5. **(Error function)** Calculate the Lagrange polynomial $p_2(x)$ for the 5D-values of the error function $f(x) = \operatorname{erf} x = (2/\sqrt{\pi}) \int_0^x e^{-w^2}\,dw$, namely, $f(0.25) = 0.27633$, $f(0.5) = 0.52050$, $f(1) = 0.84270$, and from p_2 an approximation of $f(0.75)$ (= 0.71116, 5D).
6. Derive an error bound in Prob. 5 from (5).
7. **(Sine integral)** Calculate the Lagrange polynomial $p_2(x)$ for the 4D-values of the sine integral $\mathrm{Si}(x)$ [(40) in App. 3.1], namely, $\mathrm{Si}(0) = 0$, $\mathrm{Si}(1) = 0.9461$, $\mathrm{Si}(2) = 1.6054$, and from p_2 approximations of $\mathrm{Si}(0.5)$ (= 0.4931, 4D) and $\mathrm{Si}(1.5)$ (= 1.3247, 4D).
8. **(Linear and quadratic interpolation)** Find $e^{-0.25}$ and $e^{-0.75}$ by linear interpolation with $x_0 = 0$, $x_1 = 0.5$ and $x_0 = 0.5$, $x_1 = 1$, respectively. Then find $p_2(x)$

interpolating e^{-x} with $x_0 = 0$, $x_1 = 0.5$, $x_2 = 1$ and from it $e^{-0.25}$ and $e^{-0.75}$. Compare the errors of these linear and quadratic interpolations. Use 4D-values of e^{-x}.

9. (Cubic Lagrange interpolation) Calculate and sketch or graph L_0, L_1, L_2, L_3 for $x = 0, 1, 2, 3$ on common axes. Find $p_3(x)$ for the data

(0, 1)

(1, 0.765198)

(2, 0.223891)

(3, −0.260052)

[values of the Bessel function $J_0(x)$]. Find p_3 for $x = 0.5, 1.5, 2.5$ by interpolation.

10. (Interpolation and extrapolation) Calculate $p_2(x)$ in Example 2. Compute from it approximations of ln 9.4, ln 10, ln 10.5, ln 11.5, ln 12, compute the errors by using exact 4D-values, and comment.

11. (Extrapolation) Does a sketch or graph of the product of the $(x - x_j)$ in (5) for the data in Prob. 10 indicate that extrapolation is likely to involve larger errors than interpolation does?

12. (Lower degree) Find the degree of the interpolation polynomial for the data

(−2, 33)

(0, 5)

(2, 9)

(4, 45)

(6, 113).

13. (Newton's forward difference formula) Set up (14) for the data in Prob. 7 and derive $p_2(x)$ from (14).

14. Set up Newton's forward difference formula for the data in Prob. 3 and compute $\Gamma(1.01)$, $\Gamma(1.03)$, $\Gamma(1.05)$.

15. (Newton's divided difference formula) Compute $f(0.8)$ and $f(0.9)$ from

$$f(0.5) = 0.479$$

$$f(1.0) = 0.841$$

$$f(2.0) = 0.909$$

by quadratic interpolation.

16. Compute $f(6.5)$ from

$$f(6.0) = 0.1506$$

$$f(7.0) = 0.3001$$

$$f(7.5) = 0.2663$$

$$f(7.7) = 0.2346$$

by cubic interpolation, using (10).

17. (Central differences) Write the difference in the table in Example 5 in central difference notation.

18. (Subtabulation) Compute the Bessel function $J_1(x)$ for $x = 0.1, 0.3, \cdots, 0.9$ from $J_1(0) = 0$, $J_1(0.2) = 0.09950$, $J_1(0.4) = 0.19603$, $J_1(0.6) = 0.28670$, $J_1(0.8) = 0.36884$, $J_1(1.0) = 0.44005$. Use (14) with $n = 5$.

19. (Notations) Compute a difference table of $f(x) = x^3$ for $x = 0, 1, 2, 3, 4, 5$. Choose $x_0 = 2$ and write all occurring numbers in terms of the notations (a) for central differences, (b) for forward differences, (c) for backward differences.

20. CAS EXPERIMENT. Adding Terms in Newton Formulas. Write a program for the forward formula (14). Experiment on the increase of accuracy by successively adding terms. As data use values of some function of your choice for which your CAS gives the values needed in determining errors.

21. WRITING PROJECT. Interpolation: Comparison of Methods. Make a list of 5–6 ideas that you feel are most basic in this section. Arrange them in the best logical order. Discuss them in a 2–3 page report.

22. TEAM PROJECT. Interpolation and Extrapolation. (a) Lagrange practical error estimate (after Theorem 1). Apply this to $p_1(9.2)$ and $p_2(9.2)$ for the data $x_0 = 9.0$, $x_1 = 9.5$, $x_2 = 11.0$, $f_0 = \ln x_0$, $f_1 = \ln x_1$, $f_2 = \ln x_2$ (6S-values).

(b) Extrapolation. Given $(x_j, f(x_j)) = (0.2, 0.9980)$, $(0.4, 0.9686)$, $(0.6, 0.8443)$, $(0.8, 0.5358)$, $(1.0, 0)$. Find $f(0.7)$ from the quadratic interpolation polynomials based on (α) 0.6, 0.8, 1.0, (β) 0.4, 0.6, 0.8, (γ) 0.2, 0.4, 0.6. Compare the errors and comment. [Exact $f(x) = \cos(\frac{1}{2}\pi x^2)$, $f(0.7) = 0.7181$ (4S).]

(c) Graph the product of factors $(x - x_j)$ in the error formula (5) for $n = 2, \cdots, 10$ separately. What do these graphs show regarding accuracy of interpolation and extrapolation?

(d) Central differences. Show that
$\delta^2 f_m = f_{m+1} - 2f_m + f_{m-1}$, and, furthermore
$\delta^3 f_{m+1/2} = f_{m+2} - 3f_{m+1} + 3f_m - f_{m-1}$,
$\delta^n f_m = \Delta^n f_{m-n/2} = \nabla^n f_{m+n/2}$.

(e) Everett's interpolation formula

$$f(x) \approx (1 - r)f_0 + rf_1 + \frac{(2 - r)(1 - r)(-r)}{3!}\delta^2 f_0 + \frac{(r + 1)r(r - 1)}{3!}\delta^2 f_1 \tag{20}$$

is an example of a formula involving only even-order differences. Use it to compute the Bessel function $J_0(x)$ for $x = 1.72$ from $J_0(1.60) = 0.455\,4022$ and $J_0(1.7)$, $J_0(1.8)$, $J_0(1.9)$ in Example 6.

19.4 Spline Interpolation

Given data (function values, points in the xy-plane) $(x_0, f_0), (x_1, f_1), \cdots, (x_n, f_n)$ can be interpolated by a polynomial $P_n(x)$ of degree n or less so that the curve of $P_n(x)$ passes through these $n + 1$ points (x_j, f_j); here $f_0 = f(x_0), \cdots, f_n = f(x_n)$. See Sec. 19.3.

Now if n is large, there may be trouble: $P_n(x)$ may tend to oscillate for x between the **nodes** $x_0, \cdots, x_n$. Hence we must be prepared for **numeric instability** (Sec. 19.1). Figure 431 shows a famous example by C. Runge[3] for which the maximum error even approaches ∞ as $n \to \infty$ (with the nodes kept equidistant and their number increased). Figure 432 illustrates the increase of the oscillation with n for some other function that is piecewise linear.

Those undesirable oscillations are avoided by the method of splines initiated by I. J. Schoenberg in 1946 (*Quarterly of Applied Mathematics* **4,** pp. 45–99, 112–141). This method is widely used in practice. It also laid the foundation for much of modern **CAD (computer-aided design).** Its name is borrowed from a *draftman's spline,* which is an elastic rod bent to pass through given points and held in place by weights. The mathematical idea of the method is as follows:

Instead of using a single high-degree polynomial P_n over the entire interval $a \leqq x \leqq b$ in which the nodes lie, that is,

$$a = x_0 < x_1 < \cdots < x_n = b, \tag{1}$$

we use n low-degree, e.g., cubic, polynomials

$$q_0(x), \qquad q_1(x), \qquad \cdots, \qquad q_{n-1}(x),$$

one over each subinterval between adjacent nodes, hence q_0 from x_0 to x_1, then q_1 from

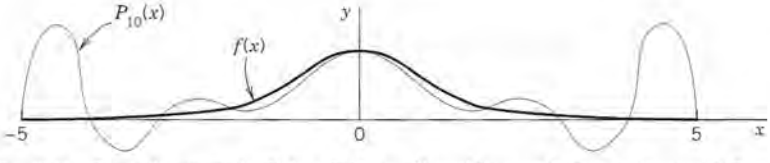

Fig. 431. Runge's example $f(x) = 1/(1 + x^2)$ and interpolating polynomial $P_{10}(x)$

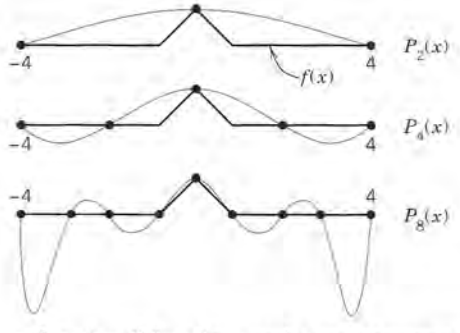

Fig. 432. Piecewise linear function $f(x)$ and interpolation polynomials of increasing degrees

[3]CARL RUNGE (1856–1927), German mathematician, also known for his work on ODEs (Sec. 21.1).

x_1 to x_2, and so on. From this we compose an interpolation function $g(x)$, called a **spline,** by fitting these polynomials together into a single continuous curve passing through the data points, that is,

$$(2)\quad g(x_0) = f(x_0) = f_0, \qquad g(x_1) = f(x_1) = f_1, \qquad \cdots, \qquad g(x_n) = f(x_n) = f_n.$$

Note that $g(x) = q_0(x)$ when $x_0 \leqq x \leqq x_1$, then $g(x) = q_1(x)$ when $x_1 \leqq x \leqq x_2$, and so on, according to our construction of g.

Thus **spline interpolation** *is piecewise polynomial interpolation.*

The simplest q_j's would be linear polynomials. However, the curve of a piecewise linear continuous function has corners and would be of little interest in general—think of designing the body of a car or a ship.

We shall consider cubic splines because these are the most important ones in applications. By definition, a **cubic spline** $g(x)$ interpolating given data $(x_0, f_0), \cdots, (x_n, f_n)$ is a continuous function on the interval $a = x_0 \leqq x \leqq x_n = b$ that has continuous first and second derivatives and satisfies the interpolation condition (2); furthermore, between adjacent nodes, $g(x)$ is given by a polynomial $q_j(x)$ of degree 3 or less.

We claim that there is such a cubic spline. And if in addition to (2) we also require that

$$(3)\qquad g'(x_0) = k_0, \qquad g'(x_n) = k_n$$

(given tangent directions of $g(x)$ at the two endpoints of the interval $a \leqq x \leqq b$), then we have a uniquely determined cubic spline. This is the content of the following existence and uniqueness theorem, whose proof will also suggest the actual determination of splines. (Condition (3) will be discussed after the proof.)

THEOREM 1

Existence and Uniqueness of Cubic Splines

Let $(x_0, f_0), (x_1, f_1), \cdots, (x_n, f_n)$ with arbitrarily spaced given x_j [see (1)] *and given $f_j = f(x_j)$, $j = 0, 1, \cdots, n$. Let k_0 and k_n be any given numbers. Then there is one and only one cubic spline $g(x)$ corresponding to* (1) *and satisfying* (2) *and* (3).

PROOF By definition, on every subinterval I_j given by $x_j \leqq x \leqq x_{j+1}$ the spline $g(x)$ must agree with a polynomial $q_j(x)$ of degree not exceeding 3 such that

$$(4)\qquad q_j(x_j) = f(x_j), \qquad q_j(x_{j+1}) = f(x_{j+1}) \qquad (j = 0, 1, \cdots, n-1).$$

For the derivatives we write

$$(5)\qquad q_j'(x_j) = k_j, \qquad q_j'(x_{j+1}) = k_{j+1} \qquad (j = 0, 1, \cdots, n-1)$$

with k_0 and k_n given and $k_1, \cdots, k_{n-1}$ to be determined later. Equations (4) and (5) are four conditions for each $q_j(x)$. By direct calculation, using the notation

$$(6^*)\qquad c_j = \frac{1}{h_j} = \frac{1}{x_{j+1} - x_j} \qquad (j = 0, 1, \cdots, n-1)$$

we can verify that the unique cubic polynomial $q_j(x)$ $(j = 0, 1, \cdots, n-1)$ satisfying

(4) and (5) is

$$
\begin{aligned}
q_j(x) = {} & f(x_j)c_j^2(x - x_{j+1})^2[1 + 2c_j(x - x_j)] \\
& + f(x_{j+1})c_j^2(x - x_j)^2[1 - 2c_j(x - x_{j+1})] \\
& + k_j c_j^2(x - x_j)(x - x_{j+1})^2 \\
& + k_{j+1}c_j^2(x - x_j)^2(x - x_{j+1}).
\end{aligned} \tag{6}
$$

Differentiating twice, we obtain

$$q_j''(x_j) = -6c_j^2 f(x_j) + 6c_j^2 f(x_{j+1}) - 4c_j k_j - 2c_j k_{j+1} \tag{7}$$

$$q_j''(x_{j+1}) = 6c_j^2 f(x_j) - 6c_j^2 f(x_{j+1}) + 2c_j k_j + 4c_j k_{j+1}. \tag{8}$$

By definition, $g(x)$ has continuous second derivatives. This gives the conditions

$$q_{j-1}''(x_j) = q_j''(x_j) \qquad (j = 1, \cdots, n - 1).$$

If we use (8) with j replaced by $j - 1$, and (7), these $n - 1$ equations become

$$c_{j-1}k_{j-1} + 2(c_{j-1} + c_j)k_j + c_j k_{j+1} = 3\left[c_{j-1}^2 \nabla f_j + c_j^2 \nabla f_{j+1}\right] \tag{9}$$

where $\nabla f_j = f(x_j) - f(x_{j-1})$ and $\nabla f_{j+1} = f(x_{j+1}) - f(x_j)$ and $j = 1, \cdots, n - 1$, as before. This linear system of $n - 1$ equations has a unique solution $k_1, \cdots, k_{n-1}$ since the coefficient matrix is strictly diagonally dominant (that is, in each row the (positive) diagonal entry is greater than the sum of the other (positive) entries). Hence the determinant of the matrix cannot be zero (as follows from Theorem 3 in Sec. 20.7), so that we may determine unique values $k_1, \cdots, k_{n-1}$ of the first derivative of $g(x)$ at the nodes. This proves the theorem. ■

Storage and Time Demands in solving (9) are modest, since the matrix of (9) is **sparse** (has few nonzero entries) and **tridiagonal** (may have nonzero entries only on the diagonal and on the two adjacent "parallels" above and below it). Pivoting (Sec. 7.3) is not necessary because of that dominance. This makes splines efficient in solving large problems with thousands of nodes or more. For some literature and some critical comments, see *American Mathematical Monthly* **105** (1998), 929–941.

Condition (3) includes the **clamped conditions**

$$g'(x_0) = f'(x_0), \qquad g'(x_n) = f'(x_n), \tag{10}$$

in which the tangent directions $f'(x_0)$ and $f'(x_n)$ at the ends are given. Other conditions of practical interest are the **free** or **natural conditions**

$$g''(x_0) = 0, \qquad g''(x_n) = 0 \tag{11}$$

(geometrically: zero curvature at the ends, as for the draftman's spline), giving a **natural spline.** These names are motivated by Fig. 290 in Problem Set 12.3.

Determination of Splines. Let k_0 and k_n be given. Obtain $k_1, \cdots, k_{n-1}$ by solving the linear system (9). Recall that the spline $g(x)$ to be found consists of n cubic polynomials $q_0, \cdots, q_{n-1}$. We write these polynomials in the form

$$\textbf{(12)} \qquad q_j(x) = a_{j0} + a_{j1}(x - x_j) + a_{j2}(x - x_j)^2 + a_{j3}(x - x_j)^3$$

where $j = 0, \cdots, n - 1$. Using Taylor's formula, we obtain

$$\begin{aligned} a_{j0} &= q_j(x_j) = f_j && \text{by (2),} \\ a_{j1} &= q_j'(x_j) = k_j && \text{by (5),} \\ \textbf{(13)} \qquad a_{j2} &= \frac{1}{2}\, q_j''(x_j) = \frac{3}{h^2}\,(f_{j+1} - f_j) - \frac{1}{h}\,(k_{j+1} + 2k_j) && \text{by (7),} \\ a_{j3} &= \frac{1}{6}\, q_j'''(x_j) = \frac{2}{h^3}\,(f_j - f_{j+1}) + \frac{1}{h^2}\,(k_{j+1} + k_j) \end{aligned}$$

with a_{j3} obtained by calculating $q_j''(x_{j+1})$ from (12) and equating the result to (8), that is,

$$q_j''(x_{j+1}) = 2a_{j2} + 6a_{j3}h = \frac{6}{h^2}\,(f_j - f_{j+1}) + \frac{2}{h}\,(k_j + 2k_{j+1}),$$

and now subtracting from this $2a_{j2}$ as given in (13) and simplifying.

Note that for ***equidistant nodes*** of distance $h_j = h$ we can write $c_j = c = 1/h$ in (6*) and have from (9) simply

$$\textbf{(14)} \qquad k_{j-1} + 4k_j + k_{j+1} = \frac{3}{h}\,(f_{j+1} - f_{j-1}) \qquad (j = 1, \cdots, n - 1).$$

EXAMPLE 1 **Spline Interpolation. Equidistant Nodes**

Interpolate $f(x) = x^4$ on the interval $-1 \leqq x \leqq 1$ by the cubic spline $g(x)$ corresponding to the nodes $x_0 = -1, x_1 = 0, x_2 = 1$ and satisfying the clamped conditions $g'(-1) = f'(-1), g'(1) = f'(1)$.

Solution. In our standard notation the given data are $f_0 = f(-1) = 1$, $f_1 = f(0) = 0$, $f_2 = f(1) = 1$. We have $h = 1$ and $n = 2$, so that our spline consists of $n = 2$ polynomials

$$\begin{aligned} q_0(x) &= a_{00} + a_{01}(x + 1) + a_{02}(x + 1)^2 + a_{03}(x + 1)^3 && (-1 \leqq x \leqq 0), \\ q_1(x) &= a_{10} + a_{11}x + a_{12}x^2 + a_{13}x^3 && (0 \leqq x \leqq 1). \end{aligned}$$

We determine the k_j from (14) (equidistance!) and then the coefficients of the spline from (13). Since $n = 2$, the system (14) is a single equation (with $j = 1$ and $h = 1$)

$$k_0 + 4k_1 + k_2 = 3(f_2 - f_0).$$

Here $f_0 = f_2 = 1$ (the value of x^4 at the ends) and $k_0 = -4$, $k_2 = 4$, the values of the derivative $4x^3$ at the ends -1 and 1. Hence

$$-4 + 4k_1 + 4 = 3(1 - 1) = 0, \qquad k_1 = 0.$$

From (13) we can now obtain the coefficients of q_0, namely, $a_{00} = f_0 = 1$, $a_{01} = k_0 = -4$, and

$$a_{02} = \frac{3}{1^2}(f_1 - f_0) - \frac{1}{1}(k_1 + 2k_0) = 3(0 - 1) - (0 - 8) = \quad 5$$

$$a_{03} = \frac{2}{1^3}(f_0 - f_1) + \frac{1}{1^2}(k_1 + k_0) = 2(1 - 0) + (0 - 4) = -2.$$

Similarly, for the coefficients of q_1 we obtain from (13) the values $a_{10} = f_1 = 0$, $a_{11} = k_1 = 0$, and

$$a_{12} = 3(f_2 - f_1) - (k_2 + 2k_1) = 3(1 - 0) - (4 + 0) = -1$$

$$a_{13} = 2(f_1 - f_2) + (k_2 + \ k_1) \ = 2(0 - 1) + (4 + 0) = 2.$$

This gives the polynomials of which the spline $g(x)$ consists, namely,

$$g(x) = \begin{cases} q_0(x) = 1 - 4(x + 1) + 5(x + 1)^2 - 2(x + 1)^3 = -x^2 - 2x^3 & \text{if} \quad -1 \leqq x \leqq 0 \\ q_1(x) = -x^2 + 2x^3 & \text{if} \quad 0 \leqq x \leqq 1. \end{cases}$$

Figure 433 shows $f(x)$ and this spline. Do you see that we could have saved over half of our work by using symmetry? ■

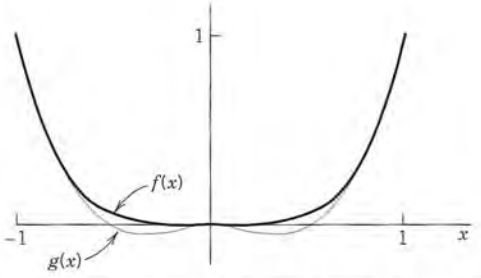

Fig. 433. Function $f(x) = x^4$ and cubic spline $g(x)$ in Example 1

EXAMPLE 2 **Natural Spline. Arbitrarily Spaced Nodes**

Find a spline approximation and a polynomial approximation for the curve of the cross section of the circular-shaped Shrine of the Book in Jerusalem shown in Fig. 434.

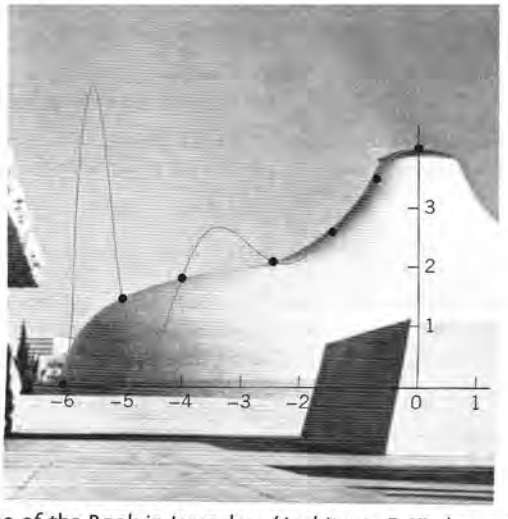

Fig. 434. Shrine of the Book in Jerusalem (Architects F. Kissler and A. M. Bartus)

Solution. Thirteen points, about equally distributed along the contour (not along the x-axis!), give these data:

x_j	−5.8	−5.0	−4.0	−2.5	−1.5	−0.8	0	0.8	1.5	2.5	4.0	5.0	5.8
f_j	0	1.5	1.8	2.2	2.7	3.5	3.9	3.5	2.7	2.2	1.8	1.5	0

The figure shows the corresponding interpolation polynomial of 12th degree, which is useless because of its oscillation. (Because of roundoff your software will also give you small error terms involving odd powers of x.) The polynomial is

$$P_{12}(x) = 3.9000 - 0.65083x^2 + 0.033858x^4 + 0.011041x^6 - 0.0014010x^8 + 0.000055595x^{10} - 0.00000071867x^{12}.$$

The spline follows practically the contour of the roof, with a small error near the nodes −0.8 and 0.8. The spline is symmetric. Its six polynomials corresponding to positive x have the following coefficients of their representations (12). (Note well that (12) is in terms of powers of $x - x_j$, not x!)

j	x-interval	a_{j0}	a_{j1}	a_{j2}	a_{j3}
0	0.0...0.8	3.9	0.00	−0.61	−0.015
1	0.8...1.5	3.5	−1.01	−0.65	0.66
2	1.5...2.5	2.7	−0.95	0.73	−0.27
3	2.5...4.0	2.2	−0.32	−0.091	0.084
4	4.0...5.0	1.8	−0.027	0.29	−0.56
5	5.0...5.8	1.5	−1.13	−1.39	0.58

PROBLEM SET 19.4

1. **WRITING PROJECT. Splines.** In your own words, and using as few formulas as possible, write a short report on spline interpolation, its motivation, a comparison with polynomial interpolation, and its applications.
2. **(Individual polynomial q_j)** Show that $q_j(x)$ in (6) satisfies the interpolation condition (4) as well as the derivative condition (5).
3. Verify the differentiations that give (7) and (8) from (6).
4. **(System for derivatives)** Derive the basic linear system (9) for $k_1, \cdots, k_{n-1}$ as indicated in the text.
5. **(Equidistant nodes)** Derive (14) from (9).
6. **(Coefficients)** Give the details of the derivation of a_{j2} and a_{j3} in (13).
7. Verify the computations in Example 1.
8. **(Comparison)** Compare the spline g in Example 1 with the quadratic interpolation polynomial over the whole interval. Find the maximum deviations of g and p_2 from f. Comment.
9. **(Natural spline condition)** Using the given coefficients, verify that the spline in Example 2 satisfies $g''(x) = 0$ at the ends.

10–16 DETERMINATION OF SPLINES

Find the cubic spline $g(x)$ for the given data with k_0 and k_n as given.

10. $f(-2) = f(-1) = f(1) = f(2) = 0$, $f(0) = 1$, $k_0 = k_4 = 0$
11. If we started from the piecewise linear function in Fig. 435, we would obtain $g(x)$ in Prob. 10 as the spline satisfying $g'(-2) = f'(-2) = 0$, $g'(2) = f'(2) = 0$. Find and sketch or graph the corresponding interpolation polynomial of 4th degree and compare it with the spline. Comment.

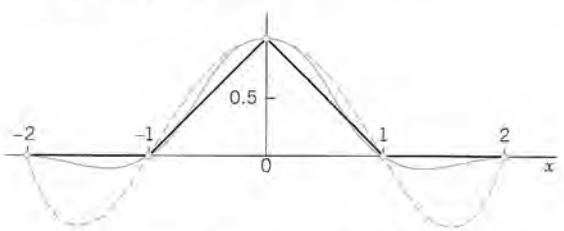

Fig. 435. Spline and interpolation polynomial in Problems 10 and 11

12. $f_0 = f(0) = 1$, $f_1 = f(2) = 9$, $f_2 = f(4) = 41$, $f_3 = f(6) = 41$, $k_0 = 0$, $k_3 = -12$

13. $f_0 = f(-1) = 0$, $f_1 = f(0) = 4$, $f_2 = f(1) = 0$, $k_0 = 0$, $k_2 = 0$. Is $g(x)$ even? (Give reason.)

14. $f_0 = f(0) = 0$, $f_1 = f(1) = 1$, $f_2 = f(2) = 6$, $f_3 = f(3) = 10$, $k_0 = 0$, $k_3 = 0$

15. $f_0 = f(0) = 1$, $f_1 = f(1) = 0$, $f_2 = f(2) = -1$, $f_3 = f(3) = 0$, $k_0 = 0$, $k_3 = -6$

16. It can happen that a spline is given by the same polynomial in two adjacent subintervals. To illustrate this, find the cubic spline $g(x)$ for $f(x) = \sin x$ corresponding to the partition $x_0 = -\pi/2$, $x_1 = 0$, $x_2 = \pi/2$ of the interval $-\pi/2 \leqq x \leqq \pi/2$ and satisfying $g'(-\pi/2) = f'(-\pi/2)$ and $g'(\pi/2) = f'(\pi/2)$.

17. (Natural conditions) Explain the remark after (11).

18. CAS EXPERIMENT. Spline versus Polynomial. If your CAS gives natural splines, find the natural splines when x is integer from $-m$ to m, and $y(0) = 1$ and all other y equal to 0. Graph each such spline along with the interpolation polynomial p_{2m}. Do this for $m = 2$ to 10 (or more). What happens with increasing m?

19. If a cubic spline is three times continuously differentiable (that is, it has continuous first, second, and third derivatives), show that it must be a single polynomial.

20. TEAM PROJECT. Hermite Interpolation and Bezier Curves. In **Hermite interpolation** we are looking for a polynomial $p(x)$ (of degree $2n + 1$ or less) such that $p(x)$ and its derivative $p'(x)$ have given values at $n + 1$ nodes. (More generally, $p(x)$, $p'(x)$, $p''(x)$, $\cdots$ may be required to have given values at the nodes.)

(a) Curves with given endpoints and tangents. Let C be a curve in the xy-plane parametrically represented by $\mathbf{r}(t) = [x(t), y(t)]$, $0 \leqq t \leqq 1$ (see Sec. 9.5). Show that for given initial and terminal points of a curve and given initial and terminal tangents, say,

$$\begin{aligned} A\text{:}\quad \mathbf{r}_0 &= [x(0), y(0)] \\ &= [x_0, y_0], \\ B\text{:}\quad \mathbf{r}_1 &= [x(1), y(1)] \\ &= [x_1, y_1] \\ \mathbf{v}_0 &= [x'(0), y'(0)] \\ &= [x_0', y_0'], \\ \mathbf{v}_1 &= [x'(1), y'(1)] \\ &= [x_1', y_1'] \end{aligned}$$

we can find a curve C, namely,

$$\begin{aligned} \mathbf{r}(t) &= \mathbf{r}_0 + \mathbf{v}_0 t \\ &\quad + (3(\mathbf{r}_1 - \mathbf{r}_0) - (2\mathbf{v}_0 + \mathbf{v}_1))t^2 \\ &\quad + (2(\mathbf{r}_0 - \mathbf{r}_1) + \mathbf{v}_0 + \mathbf{v}_1)t^3; \end{aligned} \tag{15}$$

in components,

$$\begin{aligned} x(t) &= x_0 + x_0' t + (3(x_1 - x_0) - (2x_0' + x_1'))t^2 \\ &\quad + (2(x_0 - x_1) + x_0' + x_1')t^3 \\ y(t) &= y_0 + y_0' t + (3(y_1 - y_0) - (2y_0' + y_1'))t^2 \\ &\quad + (2(y_0 - y_1) + y_0' + y_1')t^3. \end{aligned}$$

Note that this is a cubic Hermite interpolation polynomial, and $n = 1$ because we have two nodes (the endpoints of C). (This has nothing to do with the Hermite polynomials in Sec. 5.8.) The two points

$$\begin{aligned} G_A\text{:}\ \mathbf{g}_0 &= \mathbf{r}_0 + \mathbf{v}_0 \\ &= [x_0 + x_0',\ y_0 + y_0'] \end{aligned}$$

and

$$\begin{aligned} G_B\text{:}\ \mathbf{g}_1 &= \mathbf{r}_1 - \mathbf{v}_1 \\ &= [x_1 - x_1',\ y_1 - y_1'] \end{aligned}$$

are called **guidepoints** because the segments AG_A and BG_B specify the tangents graphically. A, B, G_A, G_B determine C, and C can be changed quickly by moving the points. A curve consisting of such Hermite interpolation polynomials is called a **Bezier curve,** after the French engineer P. Bezier of the Renault Automobile Company, who introduced them in the early 1960s in designing car bodies. Bezier curves (and surfaces) are used in computer-aided design (CAD) and computer-aided manufacturing (CAM). (For more details, see Ref. [E21] in App. 1.)

(b) Find and graph the Bezier curve and its guidepoints if A: [0, 0], B: [1, 0], $\mathbf{v}_0 = [\frac{1}{2}, \frac{1}{2}]$, $\mathbf{v}_1 = [-\frac{1}{2}, -\frac{1}{4}\sqrt{3}]$.

(c) Changing guidepoints changes C. Moving guidepoints farther away makes C "staying near the tangents for a longer time." Confirm this by changing $\mathbf{v}_0$ and $\mathbf{v}_1$ in (b) to $2\mathbf{v}_0$ and $2\mathbf{v}_1$ (see Fig. 436).

(d) Make experiments of your own. What happens if you change $\mathbf{v}_1$ in (b) to $-\mathbf{v}_1$. If you rotate the tangents? If you multiply $\mathbf{v}_0$ and $\mathbf{v}_1$ by positive factors less than 1?

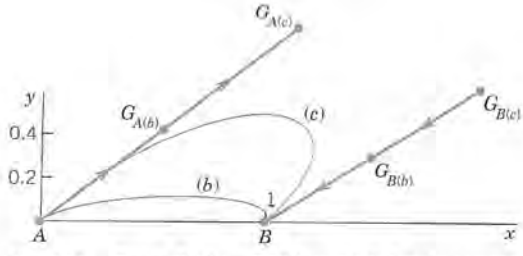

Fig. 436. Team Project 20(b) and (c): Bezier curves

19.5 Numeric Integration and Differentiation

Numeric integration means the numeric evaluation of integrals

$$J = \int_a^b f(x)\,dx$$

where a and b are given and f is a function given analytically by a formula or empirically by a table of values. Geometrically, J is the area under the curve of f between a and b (Fig. 437).

We know that if f is such that we can find a differentiable function F whose derivative is f, then we can evaluate J by applying the familiar formula

$$J = \int_a^b f(x)\,dx = F(b) - F(a) \qquad [F'(x) = f(x)].$$

Tables of integrals or a CAS (Mathematica, Maple, etc.) may be helpful for this purpose.

However, applications often lead to integrals whose analytic evaluation would be very difficult or even impossible, or whose integrand is an empirical function given by recorded numeric values. Then we may obtain approximate numeric values of the integral by a numeric integration method.

Rectangular Rule. Trapezoidal Rule

Numeric integration methods are obtained by approximating the integrand f by functions that can easily be integrated.

The simplest formula, the **rectangular rule,** is obtained if we subdivide the interval of integration $a \leqq x \leqq b$ into n subintervals of equal length $h = (b - a)/n$ and in each subinterval approximate f by the constant $f(x_j^*)$, the value of f at the midpoint x_j^* of the jth subinterval (Fig. 438). Then f is approximated by a **step function** (piecewise constant function), the n rectangles in Fig. 438 have the areas $f(x_1^*)h, \cdots, f(x_n^*)h$, and the **rectangular rule** is

$$\textbf{(1)} \qquad J = \int_a^b f(x)\,dx \approx h[f(x_1^*) + f(x_2^*) + \cdots + f(x_n^*)] \qquad \left(h = \frac{b-a}{n}\right).$$

The **trapezoidal rule** is generally more accurate. We obtain it if we take the same subdivision as before and approximate f by a broken line of segments (chords) with endpoints $[a, f(a)], [x_1, f(x_1)], \cdots, [b, f(b)]$ on the curve of f (Fig. 439). Then the area under the curve of f between a and b is approximated by n trapezoids of areas

$$\tfrac{1}{2}[f(a) + f(x_1)]h, \qquad \tfrac{1}{2}[f(x_1) + f(x_2)]h, \qquad \cdots, \qquad \tfrac{1}{2}[f(x_{n-1}) + f(b)]h.$$

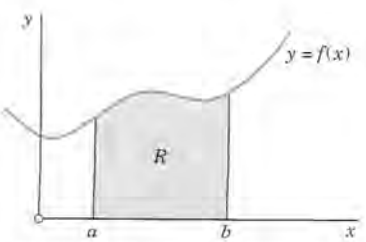

Fig. 437. Geometric interpretation of a definite integral

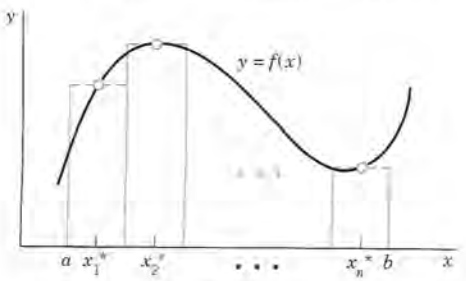

Fig. 438. Rectangular rule

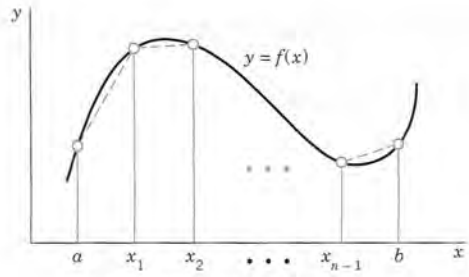

Fig. 439. Trapezoidal rule

By taking their sum we obtain the **trapezoidal rule**

$$\textbf{(2)} \qquad J = \int_a^b f(x)\,dx \approx h\left[\tfrac{1}{2}f(a) + f(x_1) + f(x_2) + \cdots + f(x_{n-1}) + \tfrac{1}{2}f(b)\right]$$

where $h = (b - a)/n$, as in (1). The x_j's and a and b are called **nodes.**

EXAMPLE 1 **Trapezoidal Rule**

Evaluate $J = \int_0^1 e^{-x^2}\,dx$ by means of (2) with $n = 10$.

Solution. $J \approx 0.1(0.5 \cdot 1.367\,879 + 6.778\,167) = 0.746\,211$ from Table 19.3. ■

Table 19.3 **Computations in Example 1**

10	1.0	1.00	0.367 879	
Sums			1.367 879	6.778 167

Error Bounds and Estimate for the Trapezoidal Rule

An error estimate for the trapezoidal rule can be derived from (5) in Sec. 19.3 with $n = 1$ by integration as follows. For a single subinterval we have

$$f(x) - p_1(x) = (x - x_0)(x - x_1)\,\frac{f''(t)}{2}$$

with a suitable t depending on x, between x_0 and x_1. Integration over x from $a = x_0$ to $x_1 = x_0 + h$ gives

$$\int_{x_0}^{x_0+h} f(x)\,dx - \frac{h}{2}\,[f(x_0) + f(x_1)] = \int_{x_0}^{x_0+h} (x - x_0)(x - x_0 - h)\,\frac{f''(t(x))}{2}\,dx.$$

Setting $x - x_0 = v$ and applying the mean value theorem of integral calculus, which we can use because $(x - x_0)(x - x_0 - h)$ does not change sign, we find that the right side equals

$$\textbf{(3*)} \qquad \int_0^h v(v - h)\,dv\,\frac{f''(\tilde{t})}{2} = \left(\frac{h^3}{3} - \frac{h^3}{2}\right)\frac{f''(\tilde{t})}{2} = -\frac{h^3}{12}\,f''(\tilde{t})$$

where $\tilde{t}$ is a (suitable, unknown) value between x_0 and x_1. This is the error for the trapezoidal rule with $n = 1$, often called the **local error.**

Hence the **error** ϵ of (2) with any n is the sum of such contributions from the n subintervals; since $h = (b - a)/n$, $nh^3 = n(b - a)^3/n^3$, and $(b - a)^2 = n^2h^2$, we obtain

$$\textbf{(3)} \qquad \epsilon = -\frac{(b - a)^3}{12n^2}\,f''(\hat{t}) = -\frac{(b - a)}{12}\,h^2 f''(\hat{t})$$

with (suitable, unknown) $\hat{t}$ between a and b.

Because of (3) the trapezoidal rule (2) is also written

$$\text{(2*)} \quad J = \int_a^b f(x)\,dx = h\left[\tfrac{1}{2}f(a) + f(x_1) + \cdots + f(x_{n-1}) + \tfrac{1}{2}f(b)\right] - \frac{b - a}{12}\,h^2 f''(\hat{t}).$$

Error Bounds are now obtained by taking the largest value for f'', say, M_2, and the smallest value, M_2^*, in the interval of integration. Then (3) gives (note that K is negative)

$$\textbf{(4)} \qquad KM_2 \leqq \epsilon \leqq KM_2^* \qquad \text{where} \qquad K = -\frac{(b - a)^3}{12n^2} = -\frac{b - a}{12}\,h^2.$$

Error Estimation by Halving h is advisable if h'' is very complicated or unknown, for instance, in the case of experimental data. Then we may apply the Error Principle of Sec. 19.1. That is, we calculate by (2), first with h, obtaining, say, $J = J_h + \epsilon_h$, and then with $\frac{1}{2}h$, obtaining $J = J_{h/2} + \epsilon_{h/2}$. Now if we replace h^2 in (3) with $(\frac{1}{2}h)^2$, the error is multiplied by 1/4. Hence $\epsilon_{h/2} \approx \frac{1}{4}\epsilon_h$ (not exactly because $\hat{t}$ may differ). Together, $J_{h/2} + \epsilon_{h/2} = J_h + \epsilon_h \approx J_h + 4\epsilon_{h/2}$. Thus $J_{h/2} - J_h = (4 - 1)\epsilon_{h/2}$. Division by 3 gives the error formula for $J_{h/2}$

$$\textbf{(5)} \qquad \epsilon_{h/2} \approx \frac{1}{3}\,(J_{h/2} - J_h).$$

EXAMPLE 2 **Error Estimation for the Trapezoidal Rule by (4) and (5)**

Estimate the error of the approximate value in Example 1 by (4) and (5).

Solution. **(A) *Error bounds by* (4).** By differentiation, $f''(x) = 2(2x^2 - 1)e^{-x^2}$. Also, $f'''(x) > 0$ if $0 < x < 1$, so that the minimum and maximum occur at the ends of the interval. We compute

$M_2 = f''(1) = 0.735\,759$ and $M_2^* = f''(0) = -2$. Furthermore, $K = -1/1200$, and (4) gives

$$-0.000\,614 \leqq \epsilon \leqq 0.001\,667.$$

Hence the exact value of J must lie between

$$0.746\,211 - 0.000\,614 = 0.745\,597 \quad \text{and} \quad 0.746\,211 + 0.001\,667 = 0.747\,878.$$

Actually, $J = 0.746\,824$, exact to 6D.

(B) *Error estimate by* (5). $J_h = 0.746211$ in Example 1. Also,

$$J_{h/2} = 0.05\left[\sum_{j=1}^{19} e^{-(j/20)^2} + \frac{1}{2}(1 + 0.367879)\right] = 0.746671.$$

Hence $\epsilon_{h/2} = \frac{1}{3}(J_{h/2} - J_h) = 0.000153$ and $J_{h/2} + \epsilon_{h/2} = 0.746824$, exact to 6D. ■

Simpson's Rule of Integration

Piecewise constant approximation of f led to the rectangular rule (1), piecewise linear approximation to the trapezoidal rule (2), and piecewise quadratic approximation will lead to Simpson's rule, which is of great practical importance because it is sufficiently accurate for most problems, but still sufficiently simple.

To derive Simpson's rule, we divide the interval of integration $a \leqq x \leqq b$ into an ***even number*** of equal subintervals, say, into $n = 2m$ subintervals of length $h = (b - a)/(2m)$, with endpoints $x_0\ (= a)$, $x_1, \cdots, x_{2m-1}, x_{2m}\ (= b)$; see Fig. 440. We now take the first two subintervals and approximate $f(x)$ in the interval $x_0 \leqq x \leqq x_2 = x_0 + 2h$ by the Lagrange polynomial $p_2(x)$ through (x_0, f_0), (x_1, f_1), (x_2, f_2), where $f_j = f(x_j)$. From (3) in Sec. 19.3 we obtain

$$(6)\quad p_2(x) = \frac{(x - x_1)(x - x_2)}{(x_0 - x_1)(x_0 - x_2)} f_0 + \frac{(x - x_0)(x - x_2)}{(x_1 - x_0)(x_1 - x_2)} f_1 + \frac{(x - x_0)(x - x_1)}{(x_2 - x_0)(x_2 - x_1)} f_2.$$

The denominators in (6) are $2h^2$, $-h^2$, and $2h^2$, respectively. Setting $s = (x - x_1)/h$, we have

$$x - x_1 = sh, \qquad x - x_0 = x - (x_1 - h) = (s + 1)h$$
$$x - x_2 = x - (x_1 + h) = (s - 1)h$$

and we obtain

$$p_2(x) = \tfrac{1}{2}s(s - 1)f_0 - (s + 1)(s - 1)f_1 + \tfrac{1}{2}(s + 1)sf_2.$$

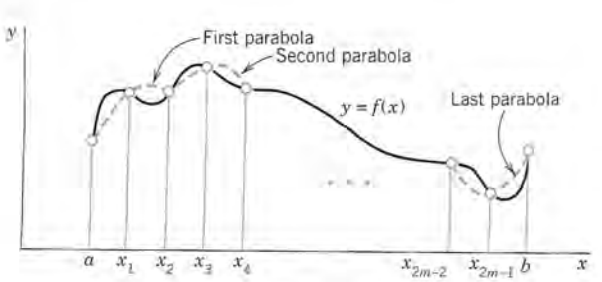

Fig. 440. Simpson's rule

We now integrate with respect to x from x_0 to x_2. This corresponds to integrating with respect to s from -1 to 1. Since $dx = h\,ds$, the result is

$$(7^*) \qquad \int_{x_0}^{x_2} f(x)\,dx \approx \int_{x_0}^{x_2} p_2(x)\,dx = h\left(\frac{1}{3}f_0 + \frac{4}{3}f_1 + \frac{1}{3}f_2\right).$$

A similar formula holds for the next two subintervals from x_2 to x_4, and so on. By summing all these m formulas we obtain **Simpson's rule**[4]

$$(7) \qquad \int_a^b f(x)\,dx \approx \frac{h}{3}\,(f_0 + 4f_1 + 2f_2 + 4f_3 + \cdots + 2f_{2m-2} + 4f_{2m-1} + f_{2m}),$$

where $h = (b - a)/(2m)$ and $f_j = f(x_j)$. Table 19.4 shows an algorithm for Simpson's rule.

Table 19.4 Simpson's Rule of Integration

ALGORITHM SIMPSON $(a, b, m, f_0, f_1, \cdots, f_{2m})$

This algorithm computes the integral $J = \int_a^b f(x)\,dx$ from given values $f_j = f(x_j)$ at equidistant $x_0 = a, x_1 = x_0 + h, \cdots, x_{2m} = x_0 + 2mh = b$ by Simpson's rule (7), where $h = (b - a)/(2m)$.

INPUT: $a, b, m, f_0, \cdots, f_{2m}$

OUTPUT: Approximate value $\tilde{J}$ of J

Compute $s_0 = f_0 + f_{2m}$

$$s_1 = f_1 + f_3 + \cdots + f_{2m-1}$$

$$s_2 = f_2 + f_4 + \cdots + f_{2m-2}$$

$$h = (b - a)/2m$$

$$\tilde{J} = \frac{h}{3}\,(s_0 + 4s_1 + 2s_2)$$

OUTPUT $\tilde{J}$. Stop.

End SIMPSON

Error of Simpson's Rule (7). If the fourth derivative $f^{(4)}$ exists and is continuous on $a \leqq x \leqq b$, the **error** of (7), call it ϵ_S, is

$$(8) \qquad \epsilon_S = -\frac{(b-a)^5}{180(2m)^4}\,f^{(4)}(\hat{t}) = -\frac{(b-a)}{180}\,h^4 f^{(4)}(\hat{t});$$

[4]THOMAS SIMPSON (1710–1761), self-taught English mathematician, author of several popular textbooks. Simpson's rule was used much earlier by Torricelli, Gregory (in 1668), and Newton (in 1676).

here $\hat{t}$ is a suitable unknown value between a and b. This is obtained similarly to (3). With this we may also write Simpson's rule (7) as

$$(7^{**}) \qquad \int_a^b f(x)\,dx = \frac{h}{3}\,(f_0 + 4f_1 + \cdots + f_{2m}) - \frac{(b-a)}{180}\,h^4 f^{(4)}(\hat{t}).$$

Error Bounds. By taking for $f^{(4)}$ in (8) the maximum M_4 and minimum M_4^* on the interval of integration we obtain from (8) the error bounds (note that C is negative)

$$(9) \qquad CM_4 \leqq \epsilon_S \leqq CM_4^* \qquad \text{where} \qquad C = -\frac{(b-a)^5}{180(2m)^4} = -\frac{(b-a)}{180}\,h^4.$$

Degree of Precision (DP) *of an integration formula.* This is the maximum degree of arbitrary polynomials for which the formula gives exact values of integrals over any intervals.

Hence for the trapezoidal rule,

$$\text{DP} = 1$$

because we approximate the curve of f by portions of straight lines (linear polynomials).

For Simpson's rule we might expect DP = 2 (why?). Actually,

$$\text{DP} = 3$$

by (9) because $f^{(4)}$ is identically zero for a cubic polynomial. This makes Simpson's rule sufficiently accurate for most practical problems and accounts for its popularity.

Numeric Stability *with respect to rounding* is another important property of Simpson's rule. Indeed, for the sum of the roundoff errors ϵ_j of the $2m + 1$ values f_j in (7) we obtain, since $h = (b - a)/2m$,

$$\frac{h}{3}\,|\epsilon_0 + 4\epsilon_1 + \cdots + \epsilon_{2m}| \leqq \frac{(b-a)}{3 \cdot 2m}\,6mu = (b-a)u$$

where u is the rounding unit ($u = \frac{1}{2} \cdot 10^{-6}$ if we round off to 6D; see Sec. 19.1). Also $6 = 1 + 4 + 1$ is the sum of the coefficients for a pair of intervals in (7); take $m = 1$ in (7) to see this. The bound $(b - a)u$ is independent of m, so that it cannot increase with increasing m, that is, with decreasing h. This proves stability. ∎

Newton–Cotes Formulas. We mention that the trapezoidal and Simpson rules are special *closed Newton–Cotes formulas,* that is, integration formulas in which $f(x)$ is interpolated at equally spaced nodes by a polynomial of degree n ($n = 1$ for trapezoidal, $n = 2$ for Simpson), and **closed** means that a and b are nodes ($a = x_0$, $b = x_n$). $n = 3$ (the three-eighths rule; Review Prob. 33) and a higher n are used occasionally. From $n = 8$ on, some of the coefficients become negative, so that a positive f_j could make a negative contribution to an integral, which is absurd. For more on this topic see Ref. [E25] in App. 1.

EXAMPLE 3 Simpson's Rule. Error Estimate

Evaluate $J = \int_0^1 e^{-x^2}\,dx$ by Simpson's rule with $2m = 10$ and estimate the error.

Solution. Since $h = 0.1$, Table 19.5 gives

$$J \approx \frac{0.1}{3}\,(1.367\,879 + 4 \cdot 3.740\,266 + 2 \cdot 3.037\,901) = 0.746\,825.$$

Estimate of error. Differentiation gives $f^{(4)}(x) = 4(4x^4 - 12x^2 + 3)e^{-x^2}$. By considering the derivative $f^{(5)}$ of $f^{(4)}$ we find that the largest value of $f^{(4)}$ in the interval of integration occurs at 0 and the smallest value at $x^* = (2.5 - 0.5\sqrt{10})^{1/2}$. Computation gives the values $M_4 = f^{(4)}(0) = 12$ and $M_4^* = f^{(4)}(x^*) = -7.419$. Since $2m = 10$ and $b - a = 1$, we obtain $C = -1/1\,800\,000 = -0.000\,000\,56$. Therefore, from (9),

$$-0.000\,007 \leqq \epsilon_S \leqq 0.000\,005.$$

Hence J must lie between $0.746\,825 - 0.000\,007 = 0.746\,818$ and $0.746\,825 + 0.000\,005 = 0.746\,830$, so that at least four digits of our approximate value are exact. Actually, the value 0.746 825 is exact to 5D because $J = 0.746\,824$ (exact to 6D).

Thus our result is much better than that in Example 1 obtained by the trapezoidal rule, whereas the number of operations is nearly the same in both cases. ■

Table 19.5 Computations in Example 3

j	x_j	x_j^2	$e^{-x_j^2}$		
0	0	0	1.000 000		
1	0.1	0.01		0.990 050	
2	0.2	0.04			0.960 789
3	0.3	0.09		0.913 931	
4	0.4	0.16			0.852 144
5	0.5	0.25		0.778 801	
6	0.6	0.36			0.697 676
7	0.7	0.49		0.612 626	
8	0.8	0.64			0.527 292
9	0.9	0.81		0.444 858	
10	1.0	1.00	0.367 879		
Sums			1.367 879	3.740 266	3.037 901

Instead of picking an $n = 2m$ and then estimating the error by (9), as in Example 3, it is better to require an accuracy (e.g., 6D) and then determine $n = 2m$ from (9).

EXAMPLE 4 Determination of $n = 2m$ in Simpson's Rule from the Required Accuracy

What n should we choose in Example 3 to get 6D-accuracy?

Solution. Using $M_4 = 12$ (which is bigger in absolute value than M_4^*), we get from (9), with $b - a = 1$ and the required accuracy,

$$|CM_4| = \frac{12}{180(2m)^4} = \frac{1}{2} \cdot 10^{-6}, \qquad \text{thus} \qquad m = \left[\frac{2 \cdot 10^6 \cdot 12}{180 \cdot 2^4}\right]^{1/4} = 9.55.$$

Hence we should choose $n = 2m = 20$. Do the computation, which parallels that in Example 3.

Note that the error bounds in (4) or (9) may sometimes be loose, so that in such a case a smaller $n = 2m$ may already suffice. ■

Error Estimation for Simpson's Rule by Halving h. The idea is the same as in (5) and gives

$$\epsilon_{h/2} \approx \frac{1}{15}(J_{h/2} - J_h). \tag{10}$$

J_h is obtained by using h and $J_{h/2}$ by using $\frac{1}{2}h$, and $\epsilon_{h/2}$ is the error of $J_{h/2}$.

Derivation. In (5) we had $\frac{1}{3}$ as the reciprocal of $3 = 4 - 1$ and $\frac{1}{4} = (\frac{1}{2})^2$ resulted from h^2 in (3) by replacing h with $\frac{1}{2}h$. In (10) we have $\frac{1}{15}$ as the reciprocal of $15 = 16 - 1$ and $\frac{1}{16} = (\frac{1}{2})^4$ results from h^4 in (8) by replacing h with $\frac{1}{2}h$.

EXAMPLE 5 **Error Estimation for Simpson's Rule by Halving**

Integrate $f(x) = \frac{1}{4}\pi x^4 \cos\frac{1}{4}\pi x$ from 0 to 2 with $h = 1$ and apply (10).

Solution. The exact 5D-value of the integral is $J = 1.25953$. Simpson's rule gives

$$J_h = \tfrac{1}{3}[f(0) + 4f(1) + f(2)] = \tfrac{1}{3}(0 + 4 \cdot 0.555360 + 0) = 0.740480,$$

$$J_{h/2} = \frac{1}{6}\left[f(0) + 4f\left(\frac{1}{2}\right) + 2f(1) + 4f\left(\frac{3}{2}\right) + f(2)\right]$$

$$= \frac{1}{6}[0 + 4 \cdot 0.045351 + 2 \cdot 0.555361 + 4 \cdot 1.521579 + 0] = 1.22974.$$

Hence (10) gives $\epsilon_{h/2} = \frac{1}{15}(1.22974 - 0.74048) = 0.032617$ and thus $J \approx J_{h/2} + \epsilon_{h/2} = 1.26236$, with an error -0.00283, which is less in absolute value than $\frac{1}{10}$ of the error 0.02979 of $J_{h/2}$. Hence the use of (10) was well worthwhile. ■

Adaptive Integration

The idea is to adapt step h to the variability of $f(x)$. That is, where f varies but little, we can proceed in large steps without causing a substantial error in the integral, but where f varies rapidly, we have to take small steps in order to stay everywhere close enough to the curve of f.

Changing h is done systematically, usually by halving h, and automatically (not "by hand") depending on the size of the (estimated) error over a subinterval. The subinterval is halved if the corresponding error is still too large, that is, larger than a given **tolerance** TOL (maximum admissible absolute error), or is not halved if the error is less than or equal to TOL.

Adapting is one of the techniques typical of modern software. In connection with integration it can be applied to various methods. We explain it here for Simpson's rule. In Table 19.6 a star means that for that subinterval, TOL has been reached.

EXAMPLE 6 **Adaptive Integration with Simpson's Rule**

Integrate $f(x) = \frac{1}{4}\pi x^4 \cos\frac{1}{4}\pi x$ from $x = 0$ to 2 by adaptive integration and with Simpson's rule and TOL[0, 2] = 0.0002.

Solution. Table 19.6 shows the calculations. Figure 441 shows the integrand $f(x)$ and the adapted intervals used. The first two intervals ([0, 0.5], [0.5, 1.0]) have length 0.5, hence $h = 0.25$ [because we use $2m = 2$ subintervals in Simpson's rule (7**)]. The next two intervals ([1.00, 1.25], [1.25, 1.50]) have length 0.25 (hence $h = 0.125$) and the last four intervals have length 0.125. *Sample computations.* For 0.740480 see Example 5. Formula (10) gives $(0.123716 - 0.122794)/15 = 0.000061$. Note that 0.123716 refers to [0, 0.5] and [0.5, 1], so that we must subtract the value corresponding to [0, 1] in the line before. Etc. TOL[0, 2] = 0.0002 gives

0.0001 for subintervals of length 1, 0.00005 for length 0.5, etc. The value of the integral obtained is the sum of the values marked by an asterisk (for which the error estimate has become less than TOL). This gives

$$J \approx 0.123716 + 0.528895 + 0.388263 + 0.218483 = 1.25936.$$

The exact 5D-value is $J = 1.25953$. Hence the error is 0.00017. This is about 1/200 of the absolute value of that in Example 5. Our more extensive computation has produced a much better result. ■

Gauss Integration Formulas Maximum Degree of Precision

Our integration formulas discussed so far use function values at *predetermined* (equidistant) x-values (nodes) and give exact results for polynomials not exceeding a certain degree [called the *degree of precision;* see after (9)]. But we can get much more accurate integration formulas as follows. We set

$$\textbf{(11)} \qquad \int_{-1}^{1} f(t)\,dt \approx \sum_{j=1}^{n} A_j f_j \qquad [f_j = f(t_j)]$$

with fixed n, and $t = \pm 1$ obtained from $x = a, b$ by setting $x = \frac{1}{2}[a(t-1) + b(t+1)]$. Then we determine the n coefficients $A_1, \cdots, A_n$ and n nodes $t_1, \cdots, t_n$ so that (11) gives exact results for polynomials of degree k as high as possible. Since $n + n = 2n$ is the number of coefficients of a polynomial of degree $2n - 1$, it follows that $k \leqq 2n - 1$.

Gauss has shown that exactness for polynomials of degree not exceeding $2n - 1$ (instead of $n - 1$ for predetermined nodes) can be attained, and he has given the location of the t_j (= the jth zero of the Legendre polynomial P_n in Sec. 5.3) and the coefficients A_j which depend on n but not on $f(t)$, and are obtained by using Lagrange's interpolation polynomial, as shown in Ref. [E5] listed in App. 1. With these t_j and A_j, formula (11) is called a **Gauss integration formula** or *Gauss quadrature formula.* Its degree of precision is $2n - 1$, as just explained. Table 19.7 gives the values needed for $n = 2, \cdots, 5$. (For larger n, see pp. 916–919 of Ref. [GR1] in App. 1.)

Table 19.7 Gauss Integration: Nodes t_j and Coefficients A_j

n	Nodes t_j	Coefficients A_j	Degree of Precision
2	−0.57735 02692	1	3
	0.57735 02692	1	
3	−0.77459 66692	0.55555 55556	5
	0	0.88888 88889

EXAMPLE 7 Gauss Integration Formula with $n = 3$

Evaluate the integral in Example 3 by the Gauss integration formula (11) with $n = 3$.

Solution. We have to convert our integral from 0 to 1 into an integral from −1 to 1. We set $x = \frac{1}{2}(t + 1)$. Then $dx = \frac{1}{2}\,dt$, and (11) with $n = 3$ and the above values of the nodes and the coefficients yields

$$\int_0^1 \exp(-x^2)\,dx = \frac{1}{2}\int_{-1}^{1} \exp\left(-\frac{1}{4}(t+1)^2\right) dt$$

$$\approx \frac{1}{2}\left[\frac{5}{9}\exp\left(-\frac{1}{4}\left(1-\sqrt{\frac{3}{5}}\right)^2\right) + \frac{8}{9}\exp\left(-\frac{1}{4}\right) + \frac{5}{9}\exp\left(-\frac{1}{4}\left(1+\sqrt{\frac{3}{5}}\right)^2\right)\right] = 0.746\,815$$

(exact to 6D: 0.746 825), which is almost as accurate as the Simpson result obtained in Example 3 with a much larger number of arithmetic operations. With 3 function values (as in this example) and Simpson's rule we would get $\frac{1}{6}(1 + 4e^{-0.25} + e^{-1}) = 0.747\,180$, with an error over 30 times that of the Gauss integration. ■

EXAMPLE 8 Gauss Integration Formula with $n = 4$ and 5

Integrate $f(x) = \frac{1}{4}\pi x^4 \cos\frac{1}{4}\pi x$ from $x = 0$ to 2 by Gauss. Compare with the adaptive integration in Example 6 and comment.

Solution. $x = t + 1$ gives $f(t) = \frac{1}{4}\pi(t+1)^4 \cos(\frac{1}{4}\pi(t+1))$, as needed in (11). For $n = 4$ we calculate (6S)

$$J \approx A_1 f_1 + \cdots + A_4 f_4 = A_1(f_1 + f_4) + A_2(f_2 + f_3)$$

$$= 0.347855(0.000290309 + 1.02570) + 0.652145(0.129464 + 1.25459) = 1.25950.$$

The error is 0.00003 because $J = 1.25953$ (6S). Calculating with 10S and $n = 4$ gives the same result; so the error is due to the formula, not rounding. For $n = 5$ and 10S we get $J \approx 1.25952\,6185$, too large by the amount 0.00000 0250 because $J = 1.25952\,5935$ (10S). The accuracy is impressive, particularly if we compare the amount of work with that in Example 6. ■

Gauss integration is of considerable practical importance. Whenever the integrand f is given by a formula (not just by a table of numbers) or when experimental measurements can be set at times t_j (or whatever t represents) shown in Table 19.7 or in Ref. [GR1], then the great accuracy of Gauss integration outweighs the disadvantage of the complicated t_j and A_j (which may have to be stored). Also, Gauss coefficients A_j are positive for all n, in contrast with some of the Newton–Cotes coefficients for larger n.

Of course, there are frequent applications with equally spaced nodes, so that Gauss integration does not apply (or has no great advantage if one first has to get the t_j in (11) by interpolation).

Since the endpoints -1 and 1 of the interval of integration in (11) are not zeros of P_n, they do not occur among $t_0, \cdots, t_n$, and the Gauss formula (11) is called, therefore, an **open formula,** in contrast with a **closed formula,** in which the endpoints of the interval of integration are t_0 and t_n. [For example, (2) and (7) are closed formulas.]

Numeric Differentiation

Numeric differentiation is the computation of values of the derivative of a function f from given values of f. Numeric differentiation should be avoided whenever possible, because, whereas *integration* is a *smoothing* process and is not affected much by small inaccuracies in function values, *differentiation* tends to make matters *rough* and generally gives values of f' much less accurate than those of f—remember that the derivative is the limit of the difference quotient, and in the latter you usually have a small difference of large quantities that you then divide by a small quantity. However, the formulas to be obtained will be basic in the numeric solution of differential equations.

We use the notations $f_j' = f'(x_j)$, $f_j'' = f''(x_j)$, etc., and may obtain rough approximation formulas for derivatives by remembering that

$$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}.$$

This suggests

$$f'_{1/2} \approx \frac{\delta f_{1/2}}{h} = \frac{f_1 - f_0}{h}. \tag{12}$$

Similarly, for the second derivative we obtain

$$f''_1 \approx \frac{\delta^2 f_1}{h^2} = \frac{f_2 - 2f_1 + f_0}{h^2}, \quad \text{etc.} \tag{13}$$

More accurate approximations are obtained by differentiating suitable Lagrange polynomials. Differentiating (6) and remembering that the denominators in (6) are $2h^2$, $-h^2$, $2h^2$, we have

$$f'(x) \approx p'_2(x) = \frac{2x - x_1 - x_2}{2h^2} f_0 - \frac{2x - x_0 - x_2}{h^2} f_1 + \frac{2x - x_0 - x_1}{2h^2} f_2.$$

Evaluating this at x_0, x_1, x_2, we obtain the "three-point formulas"

$$\text{(a)} \quad f'_0 \approx \frac{1}{2h}(-3f_0 + 4f_1 - f_2),$$

$$\text{(b)} \quad f'_1 \approx \frac{1}{2h}(-f_0 + f_2), \tag{14}$$

$$\text{(c)} \quad f'_2 \approx \frac{1}{2h}(f_0 - 4f_1 + 3f_2).$$

Applying the same idea to the Lagrange polynomial $p_4(x)$, we obtain similar formulas, in particular,

$$f'_2 \approx \frac{1}{12h}(f_0 - 8f_1 + 8f_3 - f_4). \tag{15}$$

Some examples and further formulas are included in the problem set as well as in Ref. [E5] listed in App. 1.

PROBLEM SET 19.5

1. **(Rectangular rule)** Evaluate the integral in Example 1 by the rectangular rule (1) with a subinterval of length 0.1.
2. Derive a formula for lower and upper bounds for the rectangular rule and apply it to Prob. 1.

3–8 TRAPEZOIDAL AND SIMPSON'S RULES

Evaluate the integrals numerically as indicated and determine the error by using an integration formula known from calculus.

$$F(x) = \int_1^x \frac{dx^*}{x^*}, \qquad G(x) \int_0^x \frac{dx^*}{\cos^2 x^*},$$

$$H(x) = \int_0^x x^* e^{-x^*}\, dx^*$$

3. $F(2)$ by (2), $n = 10$
4. $F(2)$ by (7), $n = 10$
5. $G(1)$ by (2), $n = 10$
6. $G(1)$ by (7), $n = 10$
7. $H(4)$ by (2), $n = 10$
8. $H(4)$ by (7), $n = 10$

9–12 HALVING

Estimate the error by halving.

9. In Prob. 5
10. In Prob. 6
11. In Prob. 7
12. In Prob. 8

13–19 NONELEMENTARY INTEGRALS

The following integrals cannot be evaluated by the usual methods of calculus. Evaluate them as indicated.

$$\mathrm{Si}(x) = \int_0^x \frac{\sin x^*}{x^*}\, dx^*,$$

$$\mathrm{S}(x) = \int_0^x \sin\,(x^{*2})\, dx^*, \quad \mathrm{C}(x) = \int_0^x \cos\,(x^{*2})\, dx^*$$

$\mathrm{Si}(x)$ is the **sine integral.** $\mathrm{S}(x)$ and $\mathrm{C}(x)$ are the **Fresnel integrals.** (See App. 3.1.)

13. Si(1) by (2), $n = 5$, $n = 10$

14. Using the values in Prob. 13, obtain a better value for Si(1). *Hint.* Use (5).

15. Si(1) by (7), $2m = 2$, $2m = 4$

16. Obtain a better value in Prob. 15. *Hint.* Use (10).

17. Si(1) by (7), $2m = 10$

18. S(1.25) by (7), $2m = 10$

19. C(1.25) by (7), $2m = 10$

20. (Stability) Prove that the trapezoidal rule is stable with respect to rounding.

21–24 GAUSS INTEGRATION

Integrate by (11) with $n = 5$:

21. $1/x$ from 1 to 3

22. $\cos x$ from 0 to $\frac{1}{2}\pi$

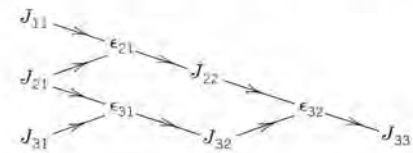
23. e^{-x^2} from 0 to 1

24. $\sin(x^2)$ from 0 to 1.25

25. (Given TOL) Find the smallest n in computing the integral of $1/x$ from 1 to 2 for which 5D-accuracy is guaranteed (a) by (4) in the use of (2), (b) by (9) in the use of (7). Compare and comment.

26. TEAM PROJECT. Romberg Integration (W. Romberg, *Norske Videnskab. Trondheim. Førh.* 28, Nr. 7, 1955). This method uses the trapezoidal rule and gains precision stepwise by halving h and adding an error estimate. Do this for the integral of $f(x) = e^{-x}$ from $x = 0$ to $x = 2$ with TOL $= 10^{-3}$, as follows.

Step 1. Apply the trapezoidal rule (2) with $h = 2$ (hence $n = 1$) to get an approximation J_{11}. Halve h and use (2) to get J_{21} and an error estimate



$$\epsilon_{21} = \frac{1}{2^2 - 1}\,(J_{21} - J_{11}).$$

If $|\epsilon_{21}| \leqq$ TOL, stop. The result is $J_{22} = J_{21} + \epsilon_{21}$.

Step 2. Show that $\epsilon_{21} = -0.066596$, hence $|\epsilon_{21}| >$ TOL and go on. Use (2) with $h/4$ to get J_{31} and add to it the error estimate $\epsilon_{31} = \frac{1}{3}(J_{31} - J_{21})$ to get the better $J_{32} = J_{31} + \epsilon_{31}$. Calculate

$$\epsilon_{32} = \frac{1}{2^4 - 1}\,(J_{32} - J_{22}) = \frac{1}{15}\,(J_{32} - J_{22}).$$

If $|\epsilon_{32}| \leqq$ TOL, stop. The result is $J_{33} = J_{32} + \epsilon_{32}$. (Why does $2^4 = 16$ come in?) Show that we obtain $\epsilon_{32} = -0.000266$, so that we can stop. Arrange your J- and ϵ-values in a kind of "difference table."

If $|\epsilon_{32}|$ were greater than TOL, you would have to go on and calculate in the next step J_{41} from (2) with $h = \frac{1}{4}$; then

$$J_{42} = J_{41} + \epsilon_{41} \quad \text{with} \quad \epsilon_{41} = \frac{1}{3}\,(J_{41} - J_{31})$$

$$J_{43} = J_{42} + \epsilon_{42} \quad \text{with} \quad \epsilon_{42} = \frac{1}{15}\,(J_{42} - J_{32})$$

$$J_{44} = J_{43} + \epsilon_{43} \quad \text{with} \quad \epsilon_{43} = \frac{1}{63}\,(J_{43} - J_{33})$$

where $63 = 2^6 - 1$. (How does this come in?)

Apply the Romberg method to the integral of $f(x) = \frac{1}{4}\pi x^4 \cos\frac{1}{4}\pi x$ from $x = 0$ to 2 with TOL $= 10^{-4}$.

DIFFERENTIATION

27. Consider $f(x) = x^4$ for $x_0 = 0$, $x_1 = 0.2$, $x_2 = 0.4$, $x_3 = 0.6$, $x_4 = 0.8$. Calculate f_2' from (14a), (14b), (14c), (15). Determine the errors. Compare and comment.

28. A **"four-point formula"** for the derivative is

$$f_2' \approx \frac{1}{6h}\,(-2f_1 - 3f_2 + 6f_3 - f_4).$$

Apply it to $f(x) = x^4$ with $x_1, \cdots, x_4$ as in Prob. 27, determine the error, and compare it with that in the case of (15).

29. The derivative $f'(x)$ can also be approximated in terms of first-order and higher order differences (see Sec. 19.3):

$$f'(x_0) \approx \frac{1}{h}\left(\Delta f_0 - \frac{1}{2}\,\Delta^2 f_0 + \frac{1}{3}\,\Delta^3 f_0 - \frac{1}{4}\,\Delta^4 f_0 + - \cdots\right).$$

Compute $f'(0.4)$ in Prob. 27 from this formula, using differences up to and including first order, second order, third order, fourth order.

30. Derive the formula in Prob. 29 from (14) in Sec. 19.3.

CHAPTER 19 REVIEW QUESTIONS AND PROBLEMS

1. What is a numeric method? How has the computer influenced numeric methods?
2. What is floating-point representation of numbers? Overflow and underflow?
3. How do error and relative error behave under addition? Under multiplication?
4. Why are roundoff errors important? State the rounding rules.
5. What is an algorithm? Which of its properties are important in software implementation?
6. Why is the selection of a *good* method at least as important on a large computer as it is on a small one?
7. Explain methods for solving equations, in particular fixed-point iteration and its convergence.
8. Can the Newton (–Raphson) method diverge? Is it fast? Same questions for the bisection method.
9. What is the advantage of Newton's interpolation formulas over Lagrange's?
10. What do you remember about errors in polynomial interpolation?
11. What is spline interpolation? Its advantage over polynomial interpolation?
12. List and compare numeric integration methods. When would you apply them?
13. In what sense is Gauss integration optimal? Explain details.
14. What does adaptive integration mean? Why is it useful?
15. Why is numeric differentiation generally more delicate than numeric integration?
16. Write -0.35287, 1274.799, -0.00614, 24.9482, $1/3$, $85/7$ in floating-point form with 5S (5 significant digits, properly rounded).
17. Compute $(5.346 - 3.644)/(3.454 - 3.055)$ as given and then rounded stepwise to 3S, 2S, 1S. ("Stepwise" means rounding the four rounded numbers, not the given ones.) Comment on your results.
18. Compute $0.29731/(4.1232 - 4.0872)$ with the numbers as given and then rounded stepwise (that is, rounding the rounded numbers) to 4S, 3S, 2S. Comment.
19. Solve $x^2 - 50x + 1 = 0$ by (6) and by (7) in Sec. 19.1, using 5S in the computation. Compare and comment.
20. Solve $x^2 - 200x + 4 = 0$ by (6) and by (7) in Sec. 19.1, using 5S in the computation. Compare and comment.
21. Let 4.81 and 12.752 be correctly rounded to the number of digits shown. Determine the smallest interval in which the sum (using the true instead of the rounded values) must lie.
22. Answer the question in Prob. 21 for the difference $4.81 - 12.752$.
23. What is the relative error of $n\bar{a}$ in terms of that of $\bar{a}$?
24. Show that the relative error of $\bar{a}^2$ is about twice that of $\bar{a}$.
25. Compute the solution of $x^5 = x + 0.2$ near $x = 0$ by transforming the equation into the form $x = g(x)$ and starting from $x_0 = 0$. (Use 6S.)
26. Solve $\cos x = x$ by iteration (6S, $x_0 = 1$), writing it as $x = (0.74x + \cos x)/1.74$, obtaining $x_4 = 0.739\,085$ (exact to 6S!). Why does this converge so rapidly?
27. Solve $x^4 - x^3 - 2x - 34 = 0$ by Newton's method with $x_0 = 3$ and 6S accuracy.
28. Solve $\cos x - x = 0$ by the method of false position.
29. Compute $f(1.28)$ from

$$\begin{aligned} f(1.0) &= 3.00000 \\ f(1.2) &= 2.98007 \\ f(1.4) &= 2.92106 \\ f(1.6) &= 2.82534 \\ f(1.8) &= 2.69671 \\ f(2.0) &= 2.54030 \end{aligned}$$

by linear interpolation. By quadratic interpolation, using $f(1.2)$, $f(1.4)$, $f(1.6)$.

30. Find the cubic spline for the data

$$\begin{aligned} f(-1) &= 3 \\ f(1) &= 1 \\ f(3) &= 23 \\ f(5) &= 45 \\ k_0 &= k_3 = 3. \end{aligned}$$

31. Compute the integral of x^3 from 0 to 1 by the trapezoidal rule with $n = 5$. What error bounds are obtained from (4) in Sec. 19.5? What is the actual error of the result? Why is this result larger than the exact value?
32. Compute the integral of $\cos(x^2)$ from 0 to 1 by Simpson's rule with $2m = 2$ and $2m = 4$ and estimate the error by (10) in Sec. 19.5. (This is the Fresnel integral (38) in App. 3.1 with $x = 1$.)
33. Compute the integral of $\cos x$ from 0 to $\frac{1}{2}\pi$ by the **three-eights rule**

$$\int_a^b f(x)\,dx = \frac{3}{8}\,h(f_0 + 3f_1 + 3f_2 + f_3) - \frac{1}{80}\,(b-a)h^4 f^{(\mathrm{iv})}(\hat{t})$$

and give error bounds; here $a \leqq \hat{t} \leqq b$ and $x_j = a + (b-a)j/3$, $j = 0, \cdots, 3$.

SUMMARY OF CHAPTER 19
Numerics in General

In this chapter we discussed concepts that are relevant throughout numeric work as a whole and methods of a general nature, as opposed to methods for linear algebra (Chap. 20) or differential equations (Chap. 21).

In scientific computations we use the **floating-point** representation of numbers (Sec. 19.1); fixed-point representation is less suitable in most cases.

Numeric methods give approximate values $\tilde{a}$ of quantities. The **error** ϵ of $\tilde{a}$ is

$$\epsilon = a - \tilde{a} \tag{1}$$

(Sec. 19.1)

where a is the exact value. The *relative error* of $\tilde{a}$ is ϵ/a. Errors arise from rounding, inaccuracy of measured values, truncation (that is, replacement of integrals by sums, series by partial sums), and so on.

An algorithm is called **numerically stable** if small changes in the initial data give only correspondingly small changes in the final results. Unstable algorithms are generally useless because errors may become so large that results will be very inaccurate. Numeric instability of algorithms must not be confused with mathematical instability of problems (*"ill-conditioned problems,"* Sec. 19.2).

Fixed-point iteration is a method for solving equations $f(x) = 0$ in which the equation is first transformed algebraically to $x = g(x)$, an initial guess x_0 for the solution is made, and then approximations $x_1, x_2, \cdots$, are successively computed by iteration from (see Sec. 19.2)

$$x_{n+1} = g(x_n) \qquad (n = 0, 1, \cdots). \tag{2}$$

Newton's method for solving equations $f(x) = 0$ is an iteration

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} \tag{3}$$

(Sec. 19.2).

Here x_{n+1} is the x-intercept of the tangent of the curve $y = f(x)$ at the point x_n. This method is of second order (Theorem 2, Sec. 19.2). If we replace f' in (3) by a difference quotient (geometrically: we replace the tangent by a secant), we obtain the **secant method;** see (10) in Sec. 19.2. For the *bisection method* (which converges slowly) and the *method of false position,* see Problem Set 19.2.

Polynomial interpolation means the determination of a polynomial $p_n(x)$ such that $p_n(x_j) = f_j$, where $j = 0, \cdots, n$ and $(x_0, f_0), \cdots, (x_n, f_n)$ are measured or observed values, values of a function, etc. $p_n(x)$ is called an *interpolation polynomial.* For given data, $p_n(x)$ of degree n (or less) is unique. However, it can be written in different forms, notably in **Lagrange's form** (4), Sec. 19.3, or in **Newton's divided difference form** (10), Sec. 19.3, which requires fewer operations. For regularly spaced $x_0, x_1 = x_0 + h, \cdots, x_n = x_0 + nh$ the latter becomes **Newton's forward difference formula** (formula (14) in Sec. 19.3)

(4) $$f(x) \approx p_n(x) = f_0 + r\Delta f_0 + \cdots + \frac{r(r-1)\cdots(r-n+1)}{n!}\,\Delta^n f_0$$

where $r = (x - x_0)/h$ and the forward differences are $\Delta f_j = f_{j+1} - f_j$ and

$$\Delta^k f_j = \Delta^{k-1} f_{j+1} - \Delta^{k-1} f_j \qquad (k = 2, 3, \cdots).$$

A similar formula is *Newton's backward difference interpolation formula* (formula (18) in Sec. 19.3).

Interpolation polynomials may become numerically unstable as n increases, and instead of interpolating and approximating by a single high-degree polynomial it is preferable to use a cubic **spline** $g(x)$, that is, a twice continuously differentiable interpolation function [thus, $g(x_j) = f_j$], which in each subinterval $x_j \leqq x \leqq x_{j+1}$ consists of a cubic polynomial $q_j(x)$; see Sec. 19.4.

Simpson's rule of numeric integration is [see (7), Sec. 19.5]

(5) $$\int_a^b f(x)\,dx \approx \frac{h}{3}\,(f_0 + 4f_1 + 2f_2 + 4f_3 + \cdots + 2f_{2m-2} + 4f_{2m-1} + f_{2m})$$

with equally spaced nodes $x_j = x_0 + jh$, $j = 1, \cdots, 2m$, $h = (b - a)/(2m)$, and $f_j = f(x_j)$. It is simple but accurate enough for many applications. Its degree of precision is DP = 3 because the error (8), Sec. 19.5, involves h^4. A more practical error estimate is (10), Sec. 19.5,

$$\epsilon_{h/2} = \frac{1}{15}\,(J_{h/2} - J_h),$$

obtained by first computing with step h, then with step $h/2$, and then taking 1/15 of the difference of the results.

Simpson's rule is the most important of the **Newton–Cotes formulas,** which are obtained by integrating Lagrange interpolation polynomials, linear ones for the **trapezoidal rule** (2), Sec. 19.5, quadratic for Simpson's rule, cubic for the *three-eights rule* (see the Chap. 19 Review Problems), etc.

Adaptive integration (Sec. 19.5, Example 6) is integration that adjusts (*"adapts"*) the step (automatically) to the variability of $f(x)$.

Romberg integration (Team Project 26, Problem Set 19.5) starts from the trapezoidal rule (2), Sec. 19.5, with h, $h/2$, $h/4$, etc. and improves results by systematically adding error estimates.

Gauss integration (11), Sec. 19.5, is important because of its great accuracy (DP = $2n - 1$, compared to Newton–Cotes's DP = $n - 1$ or n). This is achieved by an optimal choice of the nodes, which are not equally spaced; see Table 19.7, Sec. 19.5.

Numeric differentiation is discussed at the end of Sec. 19.5. (Its main application (to differential equations) follows in Chap. 21.)

CHAPTER 20

Numeric Linear Algebra

In this chapter we explain some of the most important numeric methods for solving linear systems of equations (Secs. 20.1–20.4), for fitting straight lines or parabolas (Sec. 20.5), and for matrix eigenvalue problems (Secs. 20.6–20.9). These methods are of considerable practical importance because many problems in engineering, statistics, and elsewhere lead to mathematical models whose solution requires methods of numeric linear algebra.

COMMENT. ***This chapter is independent of Chap. 19 and can be studied immediately after Chap. 7 or 8.***

Prerequisite: Secs. 7.1, 7.2, 8.1.
Sections that may be omitted in a shorter course: 20.4, 20.5, 20.9
References and Answers to Problems: App. 1 Part E, App. 2

20.1 Linear Systems: Gauss Elimination

A **linear system of *n* equations** in n *unknowns* $x_1 \cdots, x_n$ is a set of equations $E_1, \cdots, E_n$ of the form

$$\begin{aligned} E_1: &\quad a_{11}x_1 + \cdots + a_{1n}x_n = b_1 \\ E_2: &\quad a_{21}x_1 + \cdots + a_{2n}x_n = b_2 \\ &\quad \cdots\cdots\cdots\cdots\cdots\cdots \\ E_n: &\quad a_{n1}x_1 + \cdots + a_{nn}x_n = b_n \end{aligned} \tag{1}$$

where the **coefficients** a_{jk} and the b_j are given numbers. The system is called **homogeneous** if all the b_j are zero; otherwise it is called **nonhomogeneous.** Using matrix multiplication (Sec. 7.2), we can write (1) as a single vector equation

$$\mathbf{Ax} = \mathbf{b} \tag{2}$$

where the **coefficient matrix** $\mathbf{A} = [a_{jk}]$ is the $n \times n$ matrix

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}, \quad \text{and} \quad \mathbf{x} = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} \quad \text{and} \quad \text{and } \mathbf{b} = \begin{bmatrix} b_1 \\ \vdots \\ b_n \end{bmatrix}$$

are column vectors. The following matrix $\widetilde{\mathbf{A}}$ is called the **augmented matrix** of the system (1):

$$\widetilde{\mathbf{A}} = [\mathbf{A} \quad \mathbf{b}] = \begin{bmatrix} a_{11} & \cdots & a_{1n} & b_1 \\ a_{21} & \cdots & a_{2n} & b_2 \\ \cdot & \cdots & \cdot & \cdot \\ a_{n1} & \cdots & a_{nn} & b_n \end{bmatrix}.$$

A **solution** of (1) is a set of numbers $x_1, \cdots, x_n$ that satisfy all the n equations, and a **solution vector** of (1) is a vector $\mathbf{x}$ whose components constitute a solution of (1).

The method of solving such a system by determinants (Cramer's rule in Sec. 7.7) is not practical, even with efficient methods for evaluating the determinants.

A practical method for the solution of a linear system is the so-called *Gauss elimination*, which we shall now discuss ***(proceeding independently of Sec. 7.3).***

Gauss Elimination

This standard method for solving linear systems (1) is a systematic process of elimination that reduces (1) to **"triangular form"** because the system can then be easily solved by **"back substitution."** For instance, a triangular system is

$$\begin{aligned} 3x_1 + 5x_2 + 2x_3 &= 8 \\ 8x_2 + 2x_3 &= -7 \\ 6x_3 &= 3 \end{aligned}$$

and back substitution gives $x_3 = 3/6 = 1/2$ from the third equation, then

$$x_2 = \tfrac{1}{8}(-7 - 2x_3) = -1$$

from the second equation, and finally from the first equation

$$x_1 = \tfrac{1}{3}(8 - 5x_2 - 2x_3) = 4.$$

How do we reduce a given system (1) to triangular form? In the first step we ***eliminate*** $\boldsymbol{x_1}$ from equation E_2 to E_n in (1). We do this by adding (or subtracting) suitable multiples of E_1 from equations $\mathrm{E}_2, \cdots, \mathrm{E}_n$ and taking the resulting equations, call them $\mathrm{E}_2^*, \cdots, \mathrm{E}_n^*$ as the new equations. The first equation, E_1, is called the **pivot equation** in this step, and a_{11} is called the **pivot.** This equation is left unaltered. In the second step we take the new second equation E_2^* (which no longer contains x_1) as the pivot equation and use it to ***eliminate*** $\boldsymbol{x_2}$ from E_3^* to E_n^*. And so on. After $n - 1$ steps this gives a triangular system that can be solved by back substitution as just shown. In this way we obtain precisely all solutions of the *given* system (as proved in Sec. 7.3).

The pivot a_{kk} (in step k) ***must be*** different from zero and ***should be*** large in absolute value, to avoid roundoff magnification by the multiplication in the elimination. For this we choose as our pivot equation one that has the absolutely largest a_{jk} in column k on or below the main diagonal (actually, the uppermost if there are several such equations). This popular method is called **partial pivoting.** It is used in CASs (e.g., in Maple).

Partial pivoting distinguishes it from **total pivoting,** which involves both row and column interchanges but is hardly used in practice.

Let us illustrate this method with a simple example.

EXAMPLE 1 Gauss Elimination. Partial Pivoting

Solve the system

$$\begin{aligned} \mathrm{E}_1: \quad & 8x_2 + 2x_3 = -7 \\ \mathrm{E}_2: \quad 3x_1 + 5x_2 + 2x_3 &= 8 \\ \mathrm{E}_3: \quad 6x_1 + 2x_2 + 8x_3 &= 26. \end{aligned}$$

Solution. We must pivot since E_1 has no x_1-term. In Column 1, equation E_3 has the largest coefficient. Hence we interchange E_1 and E_3,

$$\begin{aligned} 6x_1 + 2x_2 + 8x_3 &= 26 \\ 3x_1 + 5x_2 + 2x_3 &= 8 \\ 8x_2 + 2x_3 &= -7. \end{aligned}$$

Step 1. Elimination of x_1

It would suffice to show the augmented matrix and operate on it. We show both the equations and the augmented matrix. In the first step, the first equation is the pivot equation. Thus

$$\begin{aligned} &\text{Pivot } 6 \longrightarrow \boxed{6x_1} + 2x_2 + 8x_3 = 26 \\ &\text{Eliminate} \longrightarrow \boxed{3x_1} + 5x_2 + 2x_3 = 8 \\ &\qquad\qquad 8x_2 + 2x_3 = -7 \end{aligned} \qquad \left[\begin{array}{ccc|c} 6 & 2 & 8 & 26 \\ 3 & 5 & 2 & 8 \\ 0 & 8 & 2 & -7 \end{array}\right]$$

To eliminate x_1 from the other equations (here, from the second equation), do:

Subtract 3/6 = 1/2 times the pivot equation from the second equation.

The result is

$$\begin{aligned} 6x_1 + 2x_2 + 8x_3 &= 26 \\ 4x_2 - 2x_3 &= -5 \\ 8x_2 + 2x_3 &= -7 \end{aligned} \qquad \left[\begin{array}{ccc|c} 6 & 2 & 8 & 26 \\ 0 & 4 & -2 & -5 \\ 0 & 8 & 2 & -7 \end{array}\right]$$

Step 2. Elimination of x_2

The largest coefficient in Column 2 is 8. Hence we take the *new* third equation as the pivot equation, interchanging equations 2 and 3,

$$\begin{aligned} 6x_1 + 2x_2 + 8x_3 &= 26 \\ &\text{Pivot } 8 \longrightarrow \boxed{8x_2} + 2x_3 = -7 \\ &\text{Eliminate} \longrightarrow \boxed{4x_2} - 2x_3 = -5 \end{aligned} \qquad \left[\begin{array}{ccc|c} 6 & 2 & 8 & 26 \\ 0 & 8 & 2 & -7 \\ 0 & 4 & -2 & -5 \end{array}\right]$$

To eliminate x_2 from the third equation, do:

Subtract 1/2 times the pivot equation from the third equation.

The resulting triangular system is shown below. This is the end of the forward elimination. Now comes the back substitution.

Back substitution. ***Determination of x_3, x_2, x_1***

The triangular system obtained in Step 2 is

$$\begin{aligned} 6x_1 + 2x_2 + 8x_3 &= 26 \\ 8x_2 + 2x_3 &= -7 \\ -3x_3 &= -\tfrac{3}{2} \end{aligned} \qquad \left[\begin{array}{ccc|c} 6 & 2 & 8 & 26 \\ 0 & 8 & 2 & -7 \\ 0 & 0 & -3 & -\frac{3}{2} \end{array}\right]$$

From this system, taking the last equation, then the second equation, and finally the first equation, we compute the solution

$$x_3 = \tfrac{1}{2}$$

$$x_2 = \tfrac{1}{8}(-7 - 2x_3) = -1$$

$$x_1 = \tfrac{1}{6}(26 - 2x_2 - 8x_3) = 4.$$

This agrees with the values given above, before the beginning of the example. ■

The general algorithm for the Gauss elimination is shown in Table 20.1. To help explain the algorithm, we have numbered some of its lines. b_j is denoted by $a_{j,n+1}$, for uniformity. In lines 1 and 2 we look for a possible pivot. [For $k = 1$ we can always find one; otherwise x_1 would not occur in (1).] In line 2 we do pivoting if necessary, picking an a_{jk} of greatest absolute value (the one with the smallest j if there are several) and interchange the corresponding rows. If $|a_{kk}|$ is greatest, we do no pivoting. m_{jk} in line 3 suggests *multiplier*, since these are the factors by which we have to multiply the pivot equation E_k^* in Step k before subtracting it from an equation E_j^* below E_k^* from which we want to eliminate x_k. Here we have written E_k^* and E_j^* to indicate that after Step 1 these are no longer the given equations in (1), but these underwent a change in each step, as indicated in line 4. Accordingly, a_{jk} etc. in lines 1–4 refer to the most recent equations, and $j \geqq k$ in line 1 indicates that we leave untouched all the equations that have served as pivot equations in previous steps. For $p = k$ in line 4 we get 0 on the right, as it should be in the elimination,

$$a_{jk} - m_{jk}a_{kk} = a_{jk} - \frac{a_{jk}}{a_{kk}}\, a_{kk} = 0.$$

In line 5, if the last equation in the *triangular* system is $0 = b_n^* \neq 0$, we have no solution. If it is $0 = b_n^* = 0$, we have no unique solution because we then have fewer equations than unknowns.

EXAMPLE 2 **Gauss Elimination in Table 20.1, Sample Computation**

In Example 1 we had $a_{11} = 0$, so that pivoting was necessary. The greatest coefficient in Column 1 was a_{31}. Thus $\tilde{j} = 3$ in line 2, and we interchanged E_1 and E_3. Then in lines 3 and 4 we computed $m_{21} = 3/6 = \frac{1}{2}$ and

$$a_{22} = 5 - \tfrac{1}{2} \cdot 2 = 4, \qquad a_{23} = 2 - \tfrac{1}{2} \cdot 8 = -2, \qquad a_{24} = 8 - \tfrac{1}{2} \cdot 26 = -5,$$

and then $m_{31} = 0/6 = 0$, so that the third equation $8x_2 + 2x_3 = -7$ did not change in Step 1. In Step 2 ($k = 2$) we had 8 as the greatest coefficient in Column 2, hence $\tilde{j} = 3$. We interchanged equations 2 and 3, computed $m_{32} = -4/8 = -\frac{1}{2}$ in line 4, and the $a_{33} = -2 - \frac{1}{2} \cdot 2 = -3$, $a_{34} = -5 - \frac{1}{2}(-7) = -\frac{3}{2}$. This produced the triangular form used in the back substitution. ■

If $a_{kk} = 0$ in Step k, ***we must pivot.*** If $|a_{kk}|$ is small, ***we should pivot*** because of roundoff error magnification that may seriously affect accuracy or even produce nonsensical results.

EXAMPLE 3 **Difficulty with Small Pivots**

The solution of the system

$$0.0004x_1 + 1.402x_2 = 1.406$$

$$0.4003x_1 - 1.502x_2 = 2.501$$

is $x_1 = 10$, $x_2 = 1$. We solve this system by the Gauss elimination, using four-digit floating-point arithmetic. (4D is for simplicity. Make an 8D-arithmetic example that shows the same.)

(a) Picking the first of the given equations as the pivot equation, we have to multiply this equation by $m = 0.4003/0.0004 = 1001$ and subtract the result from the second equation, obtaining

Table 20.1 Gauss Elimination

ALGORITHM GAUSS ($\widetilde{\mathbf{A}} = [a_{jk}] = [\mathbf{A} \quad \mathbf{b}]$)

This algorithm computes a unique solution $\mathbf{x} = [x_j]$ of the system (1) or indicates that (1) has no unique solution.

INPUT: Augmented $n \times (n + 1)$ matrix $\widetilde{\mathbf{A}} = [a_{jk}]$, where $a_{j,n+1} = b_j$

OUTPUT: Solution $\mathbf{x} = [x_j]$ of (1) or message that the system (1) has no unique solution

For $k = 1, \cdots, n - 1$, do:

1 If $a_{jk} = 0$ for all $j \geqq k$ then OUTPUT "No unique solution exists." Stop

[*Procedure completed unsuccessfully;* $\mathbf{A}$ *is singular*]

2 Else exchange the contents of rows $\widetilde{j}$ and k of $\widetilde{\mathbf{A}}$ with $\widetilde{j}$ the smallest $j \geqq k$ such that $|a_{jk}|$ is maximum in column k.

3 For $j = k + 1, \cdots, n$, do:

$$m_{jk} := \frac{a_{jk}}{a_{kk}}$$

4 For $p = k + 1, \cdots, n + 1$, do:

$$a_{jp} := a_{jp} - m_{jk}a_{kp}$$

End

End

5 If $a_{nn} = 0$ then OUTPUT "No unique solution exists." Stop

Else

6 $$x_n = \frac{a_{n,n+1}}{a_{nn}} \qquad [\textit{Start back substitution}]$$

For $i = n - 1, \cdots, 1$, do:

7 $$x_i = \frac{1}{a_{ii}} \left(a_{i,n+1} - \sum_{j=i+1}^{n} a_{ij}x_j \right)$$

End

OUTPUT $\mathbf{x} = [x_j]$. Stop

End GAUSS

$$-1405x_2 = -1404.$$

Hence $x_2 = -1404/(-1405) = 0.9993$, and from the first equation, instead of $x_1 = 10$, we get

$$x_1 = \frac{1}{0.0004} (1.406 - 1.402 \cdot 0.9993) = \frac{0.005}{0.0004} = 12.5.$$

This failure occurs because $|a_{11}|$ is small compared with $|a_{12}|$, so that a small roundoff error in x_2 leads to a large error in x_1.

(b) Picking the second of the given equations as the pivot equation, we have to multiply this equation by 0.0004/0.4003 = 0.000 9993 and subtract the result from the first equation, obtaining

$$1.404x_2 = 1.404.$$

Hence $x_2 = 1$, and from the pivot equation $x_1 = 10$. This success occurs because $|a_{21}|$ is not very small compared to $|a_{22}|$, so that a small roundoff error in x_2 would not lead to a large error in x_1. Indeed, for instance, if we had the value $x_2 = 1.002$, we would still have from the pivot equation the good value $x_1 = (2.501 + 1.505)/0.4003 = 10.01$. ■

Error estimates for the Gauss elimination are discussed in Ref. [E5] listed in App. 1.

Row scaling means the multiplication of each Row j by a suitable scaling factor s_j. It is done in connection with partial pivoting to get more accurate solutions. Despite much research (see Refs. [E9], [E24] in App. 1) and the proposition of several principles, scaling is still not well understood. As a possibility, one can scale for pivot choice only (not in the calculation, to avoid additional roundoff) and take as first pivot the entry a_{j1} for which $|a_{j1}|/|A_j|$ is largest; here A_j is an entry of largest absolute value in Row j. Similarly in the further steps of the Gauss elimination.

For instance, for the system

$$4.0000x_1 + 14020x_2 = 14060$$

$$0.4003x_1 - 1.502x_2 = 2.501$$

we might pick 4 as pivot, but dividing the first equation by 10^4 gives the system in Example 3, for which the second equation is a better pivot equation.

Operation Count

Quite generally, important factors in judging the quality of a numeric method are

Amount of storage

Amount of time (≡ number of operations)

Effect of roundoff error.

For the Gauss elimination, the operation count for a full matrix (a matrix with relatively many nonzero entries) is as follows. In Step k we eliminate x_k from $n - k$ equations. This needs $n - k$ divisions in computing the m_{jk} (line 3) and $(n - k)(n - k + 1)$ multiplications and as many subtractions (both in line 4). Since we do $n - 1$ steps, k goes from 1 to $n - 1$ and thus the total number of operations in this forward elimination is

$$f(n) = \sum_{k=1}^{n-1} (n - k) + 2\sum_{k=1}^{n-1} (n - k)(n - k + 1) \qquad \text{(write } n - k = s\text{)}$$

$$= \sum_{s=1}^{n-1} s + 2\sum_{s=1}^{n-1} s(s + 1) = \tfrac{1}{2}(n - 1)n + \tfrac{2}{3}(n^2 - 1)n \approx \tfrac{2}{3}n^3$$

where $2n^3/3$ is obtained by dropping lower powers of n. We see that $f(n)$ grows about proportional to n^3. We say that $f(n)$ is of *order* n^3 and write

$$f(n) = O(n^3)$$

where O suggests **order.** The general definition of O is as follows. We write

$$f(n) = O(h(n))$$

if the quotient $|f(n)/h(n)|$ remains bounded (does not trail off to infinity) as $n \to \infty$. In our present case, $h(n) = n^3$ and, indeed, $f(n)/n^3 \to 2/3$ because the omitted terms divided by n^3 go to zero as $n \to \infty$.

In the back substitution of x_i we make $n - i$ multiplications and as many subtractions, as well as 1 division. Hence the number of operations in the back substitution is

$$b(n) = 2\sum_{i=1}^{n}(n - i) + n = 2\sum_{s=1}^{n} s + n = n(n + 1) + n = n^2 + 2n = O(n^2).$$

We see that it grows more slowly than the number of operations in the forward elimination of the Gauss algorithm, so that it is negligible for large systems because it is smaller by a factor n, approximately. For instance, if an operation takes 10^{-9} sec, then the times needed are:

Algorithm	$n = 1000$	$n = 10\,000$
Elimination	0.7 sec	11 min
Back substitution	0.001 sec	0.1 sec

PROBLEM SET 20.1

For ***applications*** of linear systems see Secs. 7.1 and 8.2.

1–3 GEOMETRIC INTERPRETATION

Solve graphically and explain geometrically.

1. $4x_1 + x_2 = -4.3$

$3x_1 - 5x_2 = -33.7$

2. $1.820x_1 - 1.183x_2 = 0$

$-12.74x_1 + 8.281x_2 = 0$

3. $7.2x_1 - 3.5x_2 = 16.0$

$-21.6x_1 + 10.5x_2 = -48.5$

4–14 GAUSS ELIMINATION

Solve the following linear systems by Gauss elimination, with partial pivoting if necessary (but without scaling). Show the intermediate steps. Check the result by substitution. If no solution or more than one solution exists, give a reason.

4. $6x_1 + x_2 = -3$

$4x_1 - 2x_2 = 6$

5. $2x_1 - 8x_2 = -4$

$6x_1 + 2x_2 = 14$

6. $25.38x_1 - 15.48x_2 = 30.60$

$-7.05x_1 + 4.30x_2 = -8.50$

7. $6x_2 + 13x_3 = 137.86$

$6x_1 - 8x_3 = -85.88$

$13x_1 - 8x_2 = 178.54$

8. $5x_1 + 3x_2 + x_3 = 2$

$-4x_2 + 8x_3 = -3$

$10x_1 - 6x_2 + 26x_3 = 0$

9. $4x_1 + 10x_2 - 2x_3 = -20$

$-x_1 - 15x_2 + 3x_3 = 30$

$25x_2 - 5x_3 = -50$

10.
$$\begin{aligned} x_1 + 2x_2 - 3x_3 &= -11 \\ 10x_1 + x_2 + x_3 &= 8 \\ 10x_2 + 2x_3 &= 2 \end{aligned}$$

11.
$$\begin{aligned} 3.4x_1 - 6.12x_2 - 2.72x_3 &= 0 \\ -x_1 + 1.80x_2 + 0.80x_3 &= 0 \\ 2.7x_1 - 4.86x_2 - 2.16x_3 &= 0 \end{aligned}$$

12.
$$\begin{aligned} 3x_2 + 5x_3 &= 1.20736 \\ 3x_1 - 4x_2 &= -2.34066 \\ 5x_1 + 6x_3 &= -0.329193 \end{aligned}$$

13.
$$\begin{aligned} 6.4x_1 + 3.2x_2 &= -1.6 \\ 3.2x_1 - 1.6x_2 + 4.8x_3 &= 32.0 \\ 4.8x_2 - 9.6x_3 + 7.2x_4 &= -78.0 \\ 7.2x_3 + 4.8x_4 &= 20.4 \end{aligned}$$

14.
$$\begin{aligned} 4.4x_2 + 3.0x_3 - 6.6x_4 &= -4.65 \\ 0.4x_1 + 3.6x_2 + 8.4x_4 &= 4.62 \\ -2.0x_1 - 6.2x_2 + 5.0x_3 &= -4.35 \\ x_1 - 7.6x_3 + 3.0x_4 &= 5.97 \end{aligned}$$

15. CAS EXPERIMENT. Gauss Elimination. Write a program for the Gauss elimination with pivoting. Apply it to Probs. 11–14. Experiment with systems whose coefficient determinant is small in absolute value. Also investigate the performance of your program for larger systems of your choice, including sparse systems.

16. TEAM PROJECT. Linear Systems and Gauss Elimination. (a) Existence and uniqueness. Find a and b such that $ax_1 + x_2 = b$, $x_1 + x_2 = 3$ has (i) a unique solution, (ii) infinitely many solutions, (iii) no solutions.

(b) Gauss elimination and nonexistence. Apply the Gauss elimination to the following two systems and compare the calculations step by step. Explain why the elimination fails if no solution exists.

$$\begin{aligned} x_1 + x_2 + x_3 &= 3 \\ 4x_1 + 2x_2 - x_3 &= 5 \\ 9x_1 + 5x_2 - x_3 &= 13 \end{aligned}$$

$$\begin{aligned} x_1 + x_2 + x_3 &= 3 \\ 4x_1 + 2x_2 - x_3 &= 5 \\ 9x_1 + 5x_2 - x_3 &= 12. \end{aligned}$$

(c) Zero determinant. Why may a computer program give you the result that a homogeneous linear system has only the trivial solution although you know its coefficient determinant to be zero?

(d) Pivoting. Solve System (A) (below) by the Gauss elimination first without pivoting. Show that for any fixed machine word length and sufficiently small $\epsilon > 0$ the computer gives $x_2 = 1$ and then $x_1 = 0$. What is the exact solution? Its limit as $\epsilon \to 0$? Then solve the system by the Gauss elimination with pivoting. Compare and comment.

(e) Pivoting. Solve System (B) by the Gauss elimination and three-digit rounding arithmetic, choosing (i) the first equation, (ii) the second equation as pivot equation. (Remember to round to 3S after each operation before doing the next, just as would be done on a computer!) Then use four-digit rounding arithmetic in those two calculations. Compare and comment.

(A)
$$\begin{aligned} \epsilon x_1 + x_2 &= 1 \\ x_1 + x_2 &= 2 \end{aligned}$$

(B)
$$\begin{aligned} 4.03x_1 + 2.16x_2 &= -4.61 \\ 6.21x_1 + 3.35x_2 &= -7.19 \end{aligned}$$

20.2 Linear Systems: LU-Factorization, Matrix Inversion

We continue our discussion of numeric methods for solving linear systems of n equations in n unknowns $x_1, \cdots, x_n$.

$$\mathbf{Ax} = \mathbf{b} \tag{1}$$

where $\mathbf{A} = [a_{jk}]$ is the $n \times n$ coefficient matrix and $\mathbf{x}^T = [x_1 \cdots x_n]$ and $\mathbf{b}^T = [b_1 \cdots b_n]$. We present three related methods that are modifications of the Gauss elimination, which

require fewer arithmetic operations. They are named after Doolittle, Crout, and Cholesky and use the idea of the LU-factorization of **A,** which we explain first.

An **LU-factorization** of a given square matrix **A** is of the form

$$\mathbf{A} = \mathbf{LU} \tag{2}$$

where **L** is ***lower triangular*** and **U** is ***upper triangular.*** For example,

$$\mathbf{A} = \begin{bmatrix} 2 & 3 \\ 8 & 5 \end{bmatrix} = \mathbf{LU} = \begin{bmatrix} 1 & 0 \\ 4 & 1 \end{bmatrix} \begin{bmatrix} 2 & 3 \\ 0 & -7 \end{bmatrix}.$$

It can be proved that for any nonsingular matrix (see Sec. 7.8) the rows can be reordered so that the resulting matrix **A** has an LU-factorization (2) in which **L** turns out to be the matrix of the ***multipliers*** m_{jk} of the Gauss elimination, with main diagonal $1, \cdots, 1$, and **U** is the matrix of the triangular system at the end of the Gauss elimination. (See Ref. [E5], pp. 155–156, listed in App. 1.)

The ***crucial idea*** now is that **L** and **U** in (2) can be computed directly, without solving simultaneous equations (thus, without using the Gauss elimination). As a count shows, this needs about $n^3/3$ operations, about half as many as the Gauss elimination, which needs about $2n^3/3$ (see Sec. 20.1). And once we have (2), we can use it for solving $\mathbf{Ax} = \mathbf{b}$ in two steps, involving only about n^2 operations, simply by noting that $\mathbf{Ax} = \mathbf{LUx} = \mathbf{b}$ may be written

$$\text{(3)} \qquad \text{(a)} \quad \mathbf{Ly} = \mathbf{b} \qquad \text{where} \qquad \text{(b)} \quad \mathbf{Ux} = \mathbf{y}$$

and solving first (3a) for **y** and then (3b) for **x.** Here we can require that **L** have main diagonal $1, \cdots, 1$ as stated before; then this is called **Doolittle's method.** Both systems (3a) and (3b) are triangular, so we can solve them as in the back substitution for the Gauss elimination.

A similar method, **Crout's method,** is obtained from (2) if **U** (instead of **L**) is required to have main diagonal $1, \cdots, 1$. In either case the factorization (2) is unique.

EXAMPLE 1 **Doolittle's Method**

Solve the system in Example 1 of Sec. 20.1 by Doolittle's method.

Solution. The decomposition (2) is obtained from

$$\mathbf{A} = [a_{jk}] = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} = \begin{bmatrix} 3 & 5 & 2 \\ 0 & 8 & 2 \\ 6 & 2 & 8 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ m_{21} & 1 & 0 \\ m_{31} & m_{32} & 1 \end{bmatrix} \begin{bmatrix} u_{11} & u_{12} & u_{13} \\ 0 & u_{22} & u_{23} \\ 0 & 0 & u_{33} \end{bmatrix}$$

by determining the m_{jk} and u_{jk}, using matrix multiplication. By going through **A** row by row we get successively

$a_{11} = 3 = 1 \cdot u_{11} = u_{11}$	$a_{12} = 5 = 1 \cdot u_{12} = u_{12}$	$a_{13} = 2 = 1 \cdot u_{13} = u_{13}$
$a_{21} = 0 = m_{21}u_{11}$	$a_{22} = 8 = m_{21}u_{12} + u_{22}$	$a_{23} = 2 = m_{21}u_{13} + u_{23}$
$m_{21} = 0$	$u_{22} = 8$	$u_{23} = 2$
$a_{31} = 6 = m_{31}u_{11}$	$a_{32} = 2 = m_{31}u_{12} + m_{32}u_{22}$	$a_{33} = 8 = m_{31}u_{13} + m_{32}u_{23} + u_{33}$
$= m_{31} \cdot 3$	$= 2 \cdot 5 + m_{32} \cdot 8$	$= 2 \cdot 2 - 1 \cdot 2 + u_{33}$
$m_{31} = 2$	$m_{32} = -1$	$u_{33} = 6$

Thus the factorization (2) is

$$\begin{bmatrix} 3 & 5 & 2 \\ 0 & 8 & 2 \\ 6 & 2 & 8 \end{bmatrix} = \mathbf{LU} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 2 & -1 & 1 \end{bmatrix} \begin{bmatrix} 3 & 5 & 2 \\ 0 & 8 & 2 \\ 0 & 0 & 6 \end{bmatrix}.$$

We first solve $\mathbf{Ly} = \mathbf{b}$, determining $y_1 = 8$, then $y_2 = -7$, then y_3 from $2y_1 - y_2 + y_3 = 16 + 7 + y_3 = 26$; thus (note the interchange in $\mathbf{b}$ because of the interchange in $\mathbf{A}$!)

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 2 & -1 & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} 8 \\ -7 \\ 26 \end{bmatrix}. \qquad \text{Solution} \qquad \mathbf{y} = \begin{bmatrix} 8 \\ -7 \\ 3 \end{bmatrix}.$$

Then we solve $\mathbf{Ux} = \mathbf{y}$, determining $x_3 = 3/6$, then x_2, then x_1, that is,

$$\begin{bmatrix} 3 & 5 & 2 \\ 0 & 8 & 2 \\ 0 & 0 & 6 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 8 \\ -7 \\ 3 \end{bmatrix}. \qquad \text{Solution} \qquad \mathbf{x} = \begin{bmatrix} 4 \\ -1 \\ 1/2 \end{bmatrix}.$$

This agrees with the solution in Example 1 of Sec. 20.1. ■

Our formulas in Example 1 suggest that for general n the entries of the matrices $\mathbf{L} = [m_{jk}]$ (with main diagonal $1, \cdots, 1$ and m_{jk} suggesting "multiplier") and $\mathbf{U} = [u_{jk}]$ in the **Doolittle method** are computed from

$$\begin{aligned} u_{1k} &= a_{1k} && k = 1, \cdots, n \\ m_{j1} &= \frac{a_{j1}}{u_{11}} && j = 2, \cdots, n \\ \textbf{(4)} \qquad u_{jk} &= a_{jk} - \sum_{s=1}^{j-1} m_{js}u_{sk} && k = j, \cdots, n; \quad j \geqq 2 \\ m_{jk} &= \frac{1}{u_{kk}} \left(a_{jk} - \sum_{s=1}^{k-1} m_{js}u_{sk} \right) && j = k+1, \cdots, n; \quad k \geqq 2. \end{aligned}$$

Row Interchanges. Matrices, such as

$$\begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix} \qquad \text{or} \qquad \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

have no LU-factorization (try!). This indicates that for obtaining an LU-factorization, row interchanges of $\mathbf{A}$ (and corresponding interchanges in $\mathbf{b}$) may be necessary.

Cholesky's Method

For a ***symmetric, positive definite*** matrix $\mathbf{A}$ (thus $\mathbf{A} = \mathbf{A}^\mathsf{T}$, $\mathbf{x}^\mathsf{T}\mathbf{Ax} > 0$ for all $\mathbf{x} \neq \mathbf{0}$) we can in (2) even choose $\mathbf{U} = \mathbf{L}^\mathsf{T}$, thus $u_{jk} = m_{kj}$ (but cannot impose conditions on the main diagonal entries). For example,

$$\textbf{(5)} \qquad \mathbf{A} = \begin{bmatrix} 4 & 2 & 14 \\ 2 & 17 & -5 \\ 14 & -5 & 83 \end{bmatrix} = \mathbf{LL}^\mathsf{T} = \begin{bmatrix} 2 & 0 & 0 \\ 1 & 4 & 0 \\ 7 & -3 & 5 \end{bmatrix} \begin{bmatrix} 2 & 1 & 7 \\ 0 & 4 & -3 \\ 0 & 0 & 5 \end{bmatrix}.$$

The popular method of solving $\mathbf{Ax} = \mathbf{b}$ based on this factorization $\mathbf{A} = \mathbf{LL}^T$ is called **Cholesky's method.** In terms of the entries of $\mathbf{L} = [l_{jk}]$ the formulas for the factorization are

$$
\begin{aligned}
l_{11} &= \sqrt{a_{11}} \\
l_{j1} &= \frac{a_{j1}}{l_{11}} && j = 2, \cdots, n \\
l_{jj} &= \sqrt{a_{jj} - \sum_{s=1}^{j-1} l_{js}^2} && j = 2, \cdots, n \qquad (6) \\
l_{pj} &= \frac{1}{l_{jj}} \left(a_{pj} - \sum_{s=1}^{j-1} l_{js} l_{ps} \right) && p = j+1, \cdots, n; \quad j \geqq 2.
\end{aligned}
$$

If $\mathbf{A}$ is symmetric but not positive definite, this method could still be applied, but then leads to a *complex* matrix $\mathbf{L}$, so that the method becomes impractical.

EXAMPLE 2 Cholesky's Method

Solve by Cholesky's method:

$$
\begin{aligned}
4x_1 + 2x_2 + 14x_3 &= 14 \\
2x_1 + 17x_2 - 5x_3 &= -101 \\
14x_1 - 5x_2 + 83x_3 &= 155.
\end{aligned}
$$

Solution. From (6) or from the form of the factorization

$$
\begin{bmatrix} 4 & 2 & 14 \\ 2 & 17 & -5 \\ 14 & -5 & 83 \end{bmatrix} = \begin{bmatrix} l_{11} & 0 & 0 \\ l_{21} & l_{22} & 0 \\ l_{31} & l_{32} & l_{33} \end{bmatrix} \begin{bmatrix} l_{11} & l_{21} & l_{31} \\ 0 & l_{22} & l_{32} \\ 0 & 0 & l_{33} \end{bmatrix}
$$

we compute, in the given order,

$$
l_{11} = \sqrt{a_{11}} = 2 \qquad l_{21} = \frac{a_{21}}{l_{11}} = \frac{2}{2} = 1 \qquad l_{31} = \frac{a_{31}}{l_{11}} = \frac{14}{2} = 7
$$

$$
l_{22} = \sqrt{a_{22} - l_{21}^2} = \sqrt{17 - 1} = 4
$$

$$
l_{32} = \frac{1}{l_{22}} (a_{32} - l_{31} l_{21}) = \frac{1}{4} (-5 - 7 \cdot 1) = -3
$$

$$
l_{33} = \sqrt{a_{33} - l_{31}^2 - l_{32}^2} = \sqrt{83 - 7^2 - (-3)^2} = 5.
$$

This agrees with (5). We now have to solve $\mathbf{Ly} = \mathbf{b}$, that is,

$$
\begin{bmatrix} 2 & 0 & 0 \\ 1 & 4 & 0 \\ 7 & -3 & 5 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} 14 \\ -101 \\ 155 \end{bmatrix}. \qquad \text{Solution} \qquad \mathbf{y} = \begin{bmatrix} 7 \\ -27 \\ 5 \end{bmatrix}.
$$

As the second step, we have to solve $\mathbf{Ux} = \mathbf{L}^T\mathbf{x} = \mathbf{y}$, that is,

$$
\begin{bmatrix} 2 & 1 & 7 \\ 0 & 4 & -3 \\ 0 & 0 & 5 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 7 \\ -27 \\ 5 \end{bmatrix}. \qquad \text{Solution} \qquad \mathbf{x} = \begin{bmatrix} 3 \\ -6 \\ 1 \end{bmatrix}. \qquad \blacksquare
$$

THEOREM 1

Stability of the Cholesky Factorization

The Cholesky LL^T-factorization is numerically stable (as defined in Sec. 19.1).

PROOF We have $a_{jj} = l_{j1}^2 + l_{j2}^2 + \cdots + l_{jj}^2$ by squaring the third formula in (6) and solving it for a_{jj}. Hence for all l_{jk} (note that $l_{jk} = 0$ for $k > j$) we obtain (the inequality being trivial)

$$l_{jk}^2 \leqq l_{j1}^2 + l_{j2}^2 + \cdots + l_{jj}^2 = a_{jj}.$$

That is, l_{jk}^2 is bounded by an entry of **A,** which means stability against rounding. ■

Gauss–Jordan Elimination. Matrix Inversion

Another variant of the Gauss elimination is the **Gauss–Jordan elimination,** introduced by W. Jordan in 1920, in which back substitution is avoided by additional computations that reduce the matrix to diagonal form, instead of the triangular form in the Gauss elimination. But this reduction from the Gauss triangular to the diagonal form requires more operations than back substitution does, so that the method is *disadvantageous* for solving systems $\mathbf{Ax} = \mathbf{b}$. But it may be used for matrix inversion, where the situation is as follows.

The **inverse** of a nonsingular square matrix **A** may be determined in principle by solving the n systems

$$\mathbf{Ax} = \mathbf{b}_j \qquad (j = 1, \cdots, n) \tag{7}$$

where $\mathbf{b}_j$ is the jth column of the $n \times n$ unit matrix.

However, it is preferable to produce $\mathbf{A}^{-1}$ by operating on the unit matrix **I** in the same way as the Gauss–Jordan algorithm, reducing **A** to **I.** A typical illustrative example of this method is given in Sec. 7.8.

PROBLEM SET 20.2

1–7 DOOLITTLE'S METHOD

Show the factorization and solve by Doolittle's method.

1.
$$3x_1 + 2x_2 = 15.2$$
$$15x_1 + 11x_2 = 77.3$$

2.
$$2x_1 + 9x_2 = 41$$
$$3x_1 - 5x_2 = -31$$

3.
$$4x_1 - 6x_2 = -34$$
$$8x_1 - 7x_2 = -53$$

4.
$$2x_1 + x_2 + 2x_3 = 0$$
$$-2x_1 + 2x_2 + x_3 = 0$$
$$x_1 + 2x_2 - 2x_3 = 36$$

5.
$$6x_1 + 4x_2 + 3x_3 = 2.0$$
$$4x_1 + 3x_2 + 2x_3 = 0.5$$
$$3x_1 + 4x_2 + 2x_3 = -2.5$$

6.
$$x_1 - x_2 + 2.6x_3 = -9.88$$
$$0.5x_1 - 3.0x_2 + 3.3x_3 = -16.54$$
$$-1.5x_1 - 3.5x_2 - 10.4x_3 = 21.02$$

7.
$$3x_1 + 9x_2 + 6x_3 = 2.3$$
$$18x_1 + 48x_2 + 39x_3 = 13.6$$
$$9x_1 - 27x_2 + 42x_3 = 4.5$$

8. TEAM PROJECT. Crout's method factorizes $\mathbf{A} = \mathbf{LU}$, where **L** is lower triangular and **U** is upper

triangular with diagonal entries $u_{jj} = 1, j = 1, \cdots, n$,

(a) Formulas. Obtain formulas for Crout's method similar to (4).

(b) Examples. Solve Probs. 1 and 7 by Crout's method.

(c) Factor the following matrix by the Doolittle, Crout, and Cholesky methods.

$$\begin{bmatrix} 1 & -4 & 2 \\ -4 & 25 & 4 \\ 2 & 4 & 24 \end{bmatrix}$$

(d) Give the formulas for factoring a tridiagonal matrix by Crout's method.

(e) When can you obtain Crout's factorization from Doolittle's by transposition?

9–13 CHOLESKY'S METHOD

Show the factorization and solve.

9.
$$\begin{aligned} 9x_1 + 6x_2 + 12x_3 &= 87 \\ 6x_1 + 13x_2 + 11x_3 &= 118 \\ 12x_1 + 11x_2 + 26x_3 &= 154 \end{aligned}$$

10.
$$\begin{aligned} 0.04x_1 + 0.12x_3 &= 1.4 \\ 0.64x_2 + 0.32x_3 &= 1.6 \\ 0.12x_1 + 0.32x_2 + 0.56x_3 &= 5.4 \end{aligned}$$

11.
$$\begin{aligned} 4x_1 + 6x_2 + 8x_3 &= 0 \\ 6x_1 + 34x_2 + 52x_3 &= -80 \\ 8x_1 + 52x_2 + 129x_3 &= -226 \end{aligned}$$

12.
$$\begin{aligned} x_1 - x_2 + 3x_3 + 2x_4 &= 30 \\ -x_1 + 5x_2 - 5x_3 - 2x_4 &= -70 \\ 3x_1 - 5x_2 + 19x_3 + 3x_4 &= 188 \\ 2x_1 - 2x_2 + 3x_3 + 21x_4 &= 2 \end{aligned}$$

13.
$$\begin{aligned} 4x_1 + 2x_2 + 4x_3 &= 20 \\ 2x_1 + 2x_2 + 3x_3 + 2x_4 &= 36 \\ 4x_1 + 3x_2 + 6x_3 + 3x_4 &= 60 \\ 2x_2 + 3x_3 + 9x_4 &= 122 \end{aligned}$$

14. CAS PROJECT. Cholesky's Method. (a) Write a program for solving linear systems by Cholesky's method and apply it to Example 2 in the text, to Probs. 9–11, and to systems of your choice.

(b) Splines. Apply the factorization part of the program to the following matrices (as they occur in (9), Sec. 19.4 (with $c_j = 1$), in connection with splines).

$$\begin{bmatrix} 2 & 1 & 0 \\ 1 & 4 & 1 \\ 0 & 1 & 2 \end{bmatrix}, \qquad \begin{bmatrix} 2 & 1 & 0 & 0 \\ 1 & 4 & 1 & 0 \\ 0 & 1 & 4 & 1 \\ 0 & 0 & 1 & 2 \end{bmatrix}.$$

15. (Definiteness) Let $\mathbf{A}$ and $\mathbf{B}$ be positive definite $n \times n$ matrices. Are $-\mathbf{A}, \mathbf{A}^{\mathrm{T}}, \mathbf{A} + \mathbf{B}, \mathbf{A} - \mathbf{B}$ positive definite?

16–19 INVERSE

Find the inverse by the Gauss–Jordan method, showing the details.

16. In Prob 4.

17. In Prob. 5.

18. In Prob. 6.

19. In Prob. 7.

20. (Rounding) For the following matrix $\mathbf{A}$ find $\det \mathbf{A}$. What happens if you round off the given entries to (a) 5S, (b) 4S, (c) 3S, (d) 2S, (e) 1S? What is the practical implication of your work?

$$\mathbf{A} = \begin{bmatrix} 1/3 & 1/4 & 2 \\ -1/9 & 1 & 1/7 \\ 4/63 & -3/28 & 13/49 \end{bmatrix}$$

20.3 Linear Systems: Solution by Iteration

The Gauss elimination and its variants in the last two sections belong to the **direct methods** for solving linear systems of equations; these are methods that give solutions after an amount of computation that can be specified in advance. In contrast, in an **indirect** or **iterative method** we start from an approximation to the true solution and, if successful, obtain better and better approximations from a computational cycle repeated as often as may be necessary for achieving a required accuracy, so that the amount of arithmetic depends upon the accuracy required and varies from case to case.

We apply iterative methods if the convergence is rapid (if matrices have large main diagonal entries, as we shall see), so that we save operations compared to a direct method. We also use iterative methods if a large system is **sparse,** that is, has very many zero coefficients, so that one would waste space in storing zeros, for instance, 9995 zeros per equation in a potential problem of 10^4 equations in 10^4 unknowns with typically only 5 nonzero terms per equation (more on this in Sec. 21.4).

Gauss–Seidel Iteration Method[1]

This is an iterative method of great practical importance, which we can simply explain in terms of an example.

EXAMPLE 1 Gauss–Seidel Iteration

We consider the linear system

$$
\begin{aligned}
x_1 - 0.25x_2 - 0.25x_3 &= 50 \\
-0.25x_1 + x_2 - 0.25x_4 &= 50 \\
-0.25x_1 + x_3 - 0.25x_4 &= 25 \\
-0.25x_2 - 0.25x_3 + x_4 &= 25.
\end{aligned} \tag{1}
$$

(Equations of this form arise in the numeric solution of PDEs and in spline interpolation.) We write the system in the form

$$
\begin{aligned}
x_1 &= 0.25x_2 + 0.25x_3 + 50 \\
x_2 &= 0.25x_1 + 0.25x_4 + 50 \\
x_3 &= 0.25x_1 + 0.25x_4 + 25 \\
x_4 &= 0.25x_2 + 0.25x_3 + 25.
\end{aligned} \tag{2}
$$

These equations are now used for iteration; that is, we start from a (possibly poor) approximation to the solution, say $x_1^{(0)} = 100$, $x_2^{(0)} = 100$, $x_3^{(0)} = 100$, $x_4^{(0)} = 100$, and compute from (2) a perhaps better approximation

Use "old" values
("New" values here not yet available)

$$
\begin{aligned}
x_1^{(1)} &= 0.25x_2^{(0)} + 0.25x_3^{(0)} + 50.00 = 100.00 \\
x_2^{(1)} &= 0.25x_1^{(1)} + 0.25x_4^{(0)} + 50.00 = 100.00 \\
x_3^{(1)} &= 0.25x_1^{(1)} + 0.25x_4^{(0)} + 25.00 = 75.00 \\
x_4^{(1)} &= 0.25x_2^{(1)} + 0.25x_3^{(1)} + 25.00 = 68.75
\end{aligned} \tag{3}
$$

Use "new" values

These equations (3) are obtained from (2) by substituting on the right the ***most recent*** approximation for each unknown. In fact, corresponding values replace previous ones as soon as they have been computed, so that in

[1]PHILIPP LUDWIG VON SEIDEL (1821–1896), German mathematician. For Gauss see footnote 5 in Sec. 5.4.

the second and third equations we use $x_1^{(1)}$ (not $x_1^{(0)}$), and in the last equation of (3) we use $x_2^{(1)}$ and $x_3^{(1)}$ (not $x_2^{(0)}$ and $x_3^{(0)}$). Using the same principle, we obtain in the next step

$$\begin{aligned}
x_1^{(2)} &= 0.25x_2^{(1)} + 0.25x_3^{(1)} + 50.00 = 93.750 \\
x_2^{(2)} &= 0.25x_1^{(2)} + 0.25x_4^{(1)} + 50.00 = 90.625 \\
x_3^{(2)} &= 0.25x_1^{(2)} + 0.25x_4^{(1)} + 25.00 = 65.625 \\
x_4^{(2)} &= 0.25x_2^{(2)} + 0.25x_3^{(2)} + 25.00 = 64.062
\end{aligned}$$

Further steps give the values

x_1	x_2	x_3	x_4
89.062	88.281	63.281	62.891
87.891	87.695	62.695	62.598
87.598	87.549	62.549	62.524
87.524	87.512	62.512	62.506
87.506	87.503	62.503	62.502

Hence convergence to the exact solution $x_1 = x_2 = 87.5$, $x_3 = x_4 = 62.5$ (verify!) seems rather fast.

An algorithm for the Gauss–Seidel iteration is shown on the next page. To obtain the algorithm, let us derive the general formulas for this iteration.

We assume that $a_{jj} = 1$ for $j = 1, \cdots, n$. (Note that this can be achieved if we can rearrange the equations so that no diagonal coefficient is zero; then we may divide each equation by the corresponding diagonal coefficient.) We now write

$$\mathbf{A} = \mathbf{I} + \mathbf{L} + \mathbf{U} \qquad (a_{jj} = 1) \tag{4}$$

where $\mathbf{I}$ is the $n \times n$ unit matrix and $\mathbf{L}$ and $\mathbf{U}$ are respectively lower and upper triangular matrices with zero main diagonals. If we substitute (4) into $\mathbf{Ax} = \mathbf{b}$, we have

$$\mathbf{Ax} = (\mathbf{I} + \mathbf{L} + \mathbf{U})\mathbf{x} = \mathbf{b}.$$

Taking $\mathbf{Lx}$ and $\mathbf{Ux}$ to the right, we obtain, since $\mathbf{Ix} = \mathbf{x}$,

$$\mathbf{x} = \mathbf{b} - \mathbf{Lx} - \mathbf{Ux}. \tag{5}$$

Remembering from (3) in Example 1 that below the main diagonal we took "new" approximations and above the main diagonal "old" ones, we obtain from (5) the desired iteration formulas

$$\mathbf{x}^{(m+1)} = \mathbf{b} - \mathbf{L}\mathbf{x}^{(m+1)} - \mathbf{U}\mathbf{x}^{(m)} \qquad (a_{jj} = 1) \tag{6}$$

("New" $\mathbf{x}^{(m+1)}$, "Old" $\mathbf{x}^{(m)}$)

where $\mathbf{x}^{(m)} = \left[x_j^{(m)}\right]$ is the mth approximation and $\mathbf{x}^{(m+1)} = \left[x_j^{(m+1)}\right]$ is the $(m + 1)$st approximation. In components this gives the formula in line 1 in Table 20.2. The matrix $\mathbf{A}$ must satisfy $a_{jj} \neq 0$ for all j. In Table 20.2 our assumption $a_{jj} = 1$ is no longer required, but is automatically taken care of by the factor $1/a_{jj}$ in line 1.

Table 20.2 Gauss–Seidel Iteration

ALGORITHM GAUSS–SEIDEL ($\mathbf{A}$, $\mathbf{b}$, $\mathbf{x}^{(0)}$, ϵ, N)

This algorithm computes a solution $\mathbf{x}$ of the system $\mathbf{Ax} = \mathbf{b}$ given an initial approximation $\mathbf{x}^{(0)}$, where $\mathbf{A} = [a_{jk}]$ is an $n \times n$ matrix with $a_{jj} \neq 0, j = 1, \cdots, n$.

INPUT: $\mathbf{A}$, $\mathbf{b}$, initial approximation $\mathbf{x}^{(0)}$, tolerance $\epsilon > 0$, maximum number of iterations N

OUTPUT: Approximate solution $\mathbf{x}^{(m)} = [x_j^{(m)}]$ or failure message that $\mathbf{x}^{(N)}$ does not satisfy the tolerance condition

For $m = 0, \cdots, N - 1$, do:

  For $j = 1, \cdots, n$, do:

1 $$x_j^{(m+1)} = \frac{1}{a_{jj}} \left(b_j - \sum_{k=1}^{j-1} a_{jk} x_k^{(m+1)} - \sum_{k=j+1}^{n} a_{jk} x_k^{(m)} \right)$$

  End

2 If $\max_j |x_j^{(m+1)} - x_j^{(m)}| < \epsilon$ then OUTPUT $\mathbf{x}^{(m+1)}$. Stop

  [*Procedure completed successfully*]

End

OUTPUT: "No solution satisfying the tolerance condition obtained after N iteration steps." Stop

[*Procedure completed unsuccessfully*]

End GAUSS–SEIDEL

Convergence and Matrix Norms

An iteration method for solving $\mathbf{Ax} = \mathbf{b}$ is said to **converge** for an initial $\mathbf{x}^{(0)}$ if the corresponding iterative sequence $\mathbf{x}^{(0)}, \mathbf{x}^{(1)}, \mathbf{x}^{(2)}, \cdots$ converges to a solution of the given system. Convergence depends on the relation between $\mathbf{x}^{(m)}$ and $\mathbf{x}^{(m+1)}$. To get this relation for the Gauss–Seidel method, we use (6). We first have

$$(\mathbf{I} + \mathbf{L})\mathbf{x}^{(m+1)} = \mathbf{b} - \mathbf{U}\mathbf{x}^{(m)}$$

and by multiplying by $(\mathbf{I} + \mathbf{L})^{-1}$ from the left,

$$\textbf{(7)} \qquad \mathbf{x}^{(m+1)} = \mathbf{C}\mathbf{x}^{(m)} + (\mathbf{I} + \mathbf{L})^{-1}\mathbf{b} \qquad \text{where} \qquad \mathbf{C} = -(\mathbf{I} + \mathbf{L})^{-1}\mathbf{U}.$$

The Gauss–Seidel iteration converges for every $\mathbf{x}^{(0)}$ if and only if all the eigenvalues (Sec. 8.1) of the "iteration matrix" $\mathbf{C} = [c_{jk}]$ have absolute value less than 1. (Proof in Ref. [E5], p. 191, listed in App. 1.)

CAUTION! If you want to get $\mathbf{C}$, first divide the rows of $\mathbf{A}$ by a_{jj} to have main diagonal $1, \cdots, 1$. If the **spectral radius** of $\mathbf{C}$ (= maximum of those absolute values) is small, then the convergence is rapid.

Sufficient Convergence Condition. A sufficient condition for convergence is

$$\textbf{(8)} \qquad \|\mathbf{C}\| < 1.$$

Here $\|\mathbf{C}\|$ is some **matrix norm,** such as

(9) $$\|\mathbf{C}\| = \sqrt{\sum_{j=1}^{n}\sum_{k=1}^{n} c_{jk}^2} \qquad \textbf{(Frobenius norm)}$$

or the greatest of the sums of the $|c_{jk}|$ in a *column* of $\mathbf{C}$

(10) $$\|\mathbf{C}\| = \max_k \sum_{j=1}^{n} |c_{jk}| \qquad \textbf{(Column "sum" norm)}$$

or the greatest of the sums of the $|c_{jk}|$ in a *row* of $\mathbf{C}$

(11) $$\|\mathbf{C}\| = \max_j \sum_{k=1}^{n} |c_{jk}| \qquad \textbf{(Row "sum" norm).}$$

These are the most frequently used matrix norms in numerics.

In most cases the choice of one of these norms is a matter of computational convenience. However, the following example shows that sometimes one of these norms is preferable to the others.

EXAMPLE 2 **Test of Convergence of the Gauss–Seidel Iteration**

Test whether the Gauss–Seidel iteration converges for the system

$$\begin{aligned} 2x + y + z &= 4 \\ x + 2y + z &= 4 \\ x + y + 2z &= 4 \end{aligned} \qquad \text{written} \qquad \begin{aligned} x &= 2 - \tfrac{1}{2}y - \tfrac{1}{2}z \\ y &= 2 - \tfrac{1}{2}x - \tfrac{1}{2}z \\ z &= 2 - \tfrac{1}{2}x - \tfrac{1}{2}y. \end{aligned}$$

Solution. The decomposition (multiply the matrix by 1/2 − why?) is

$$\begin{bmatrix} 1 & 1/2 & 1/2 \\ 1/2 & 1 & 1/2 \\ 1/2 & 1/2 & 1 \end{bmatrix} = \mathbf{I} + \mathbf{L} + \mathbf{U} = \mathbf{I} + \begin{bmatrix} 0 & 0 & 0 \\ 1/2 & 0 & 0 \\ 1/2 & 1/2 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 1/2 & 1/2 \\ 0 & 0 & 1/2 \\ 0 & 0 & 0 \end{bmatrix}.$$

It shows that

$$\mathbf{C} = -(\mathbf{I} + \mathbf{L})^{-1}\mathbf{U} = -\begin{bmatrix} 1 & 0 & 0 \\ -1/2 & 1 & 0 \\ -1/4 & -1/2 & 1 \end{bmatrix}\begin{bmatrix} 0 & 1/2 & 1/2 \\ 0 & 0 & 1/2 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 0 & -1/2 & -1/2 \\ 0 & 1/4 & -1/4 \\ 0 & 1/8 & 3/8 \end{bmatrix}.$$

We compute the Frobenius norm of $\mathbf{C}$

$$\|\mathbf{C}\| = \left(\frac{1}{4} + \frac{1}{4} + \frac{1}{16} + \frac{1}{16} + \frac{1}{64} + \frac{9}{64}\right)^{1/2} = \left(\frac{50}{64}\right)^{1/2} = 0.884 < 1$$

and conclude from (8) that this Gauss–Seidel iteration converges. It is interesting that the other two norms would permit no conclusion, as you should verify. Of course, this points to the fact that (8) is sufficient for convergence rather than necessary. ■

Residual. Given a system $\mathbf{Ax} = \mathbf{b}$, the **residual** $\mathbf{r}$ of $\mathbf{x}$ with respect to this system is defined by

(12) $$\mathbf{r} = \mathbf{b} - \mathbf{Ax}.$$

Clearly, $\mathbf{r} = \mathbf{0}$ if and only if $\mathbf{x}$ is a solution. Hence $\mathbf{r} \neq \mathbf{0}$ for an approximate solution. In the Gauss–Seidel iteration, at each stage we modify or *relax* a component of an approximate solution in order to reduce a component of $\mathbf{r}$ to zero. Hence the Gauss–Seidel iteration belongs to a class of methods often called **relaxation methods.** More about the residual follows in the next section.

Jacobi Iteration

The Gauss–Seidel iteration is a method of **successive corrections** because for each component we successively replace an approximation of a component by a corresponding new approximation as soon as the latter has been computed. An iteration method is called a method of **simultaneous corrections** if no component of an approximation $\mathbf{x}^{(m)}$ is used until ***all*** the components of $\mathbf{x}^{(m)}$ have been computed. A method of this type is the **Jacobi iteration,** which is similar to the Gauss–Seidel iteration but involves *not* using improved values until a step has been completed and then replacing $\mathbf{x}^{(m)}$ by $\mathbf{x}^{(m+1)}$ at once, directly before the beginning of the next step. Hence if we write $\mathbf{Ax} = \mathbf{b}$ (***with*** $a_{jj} = 1$ ***as before!***) in the form $\mathbf{x} = \mathbf{b} + (\mathbf{I} - \mathbf{A})\mathbf{x}$, the Jacobi iteration in matrix notation is

$$\mathbf{x}^{(m+1)} = \mathbf{b} + (\mathbf{I} - \mathbf{A})\mathbf{x}^{(m)} \qquad (a_{jj} = 1). \tag{13}$$

This method converges for every choice of $\mathbf{x}^{(0)}$ if and only if the spectral radius of $\mathbf{I} - \mathbf{A}$ is less than 1. It has recently gained greater practical interest since on parallel processors all n equations can be solved simultaneously at each iteration step.

For Jacobi, see Sec. 10.3. For exercises, see the problem set.

PROBLEM SET 20.3

1. Verify the claim at the end of Example 2.
2. Show that for the system in Example 2 the Jacobi iteration diverges. *Hint.* Use eigenvalues.

3–8 GAUSS–SEIDEL ITERATION

Do 5 steps, starting from $\mathbf{x}_0 = [1 \quad 1 \quad 1]^T$ and using 6S in the computation. *Hint.* Make sure that you solve each equation for the variable that has the largest coefficient (why?). Show the details.

3. $x_1 + x_2 + 6x_3 = -61.3$
   $x_1 + 9x_2 - 2x_3 = 49.1$
   $8x_1 + 2x_2 - x_3 = 185.8$

4. $x_2 + 7x_3 = 25.5$
   $5x_1 + x_2 = 0$
   $x_1 + 6x_2 + x_3 = -10.5$

5. $5x_1 + x_2 + 2x_3 = 19$
   $x_1 + 4x_2 - 2x_3 = -2$
   $2x_1 + 3x_2 + 8x_3 = 39$

6. $4x_1 - x_2 = 21$
   $-x_1 + 4x_2 - x_3 = -45$
   $- x_2 + 4x_3 = 33$

7. $10x_1 + x_2 + x_3 = 6$
   $x_1 + 10x_2 + x_3 = 6$
   $x_1 + x_2 + 10x_3 = 6$

8. $4x_1 + 5x_3 = 12.5$
   $x_1 + 6x_2 + 2x_3 = 18.5$
   $8x_1 + 2x_2 + x_3 = -11.5$

9. Apply the Gauss–Seidel iteration (3 steps) to the system in Prob. 7, starting from (a) 0, 0, 0, (b) 10, 10, 10. Compare and comment.
10. In Prob. 7, compute $\mathbf{C}$ (a) if you solve the first equation for x_1, the second for x_2, the third for x_3, proving convergence; (b) if you nonsensically solve the third equation for x_1, the first for x_2, the second for x_3, proving divergence.

11. CAS PROJECT. Gauss–Seidel Iteration. (a) Write a program for Gauss–Seidel iteration.

(b) Apply the program to $\mathbf{A}(t)\mathbf{x} = \mathbf{b}$, starting from $[0 \quad 0 \quad 0]^T$, where

$$\mathbf{A}(t) = \begin{bmatrix} 1 & t & t \\ t & 1 & t \\ t & t & 1 \end{bmatrix}, \qquad \mathbf{b} = \begin{bmatrix} 2 \\ 2 \\ 2 \end{bmatrix}.$$

For $t = 0.2, 0.5, 0.8, 0.9$ determine the number of steps to obtain the exact solution to 6S and the corresponding spectral radius of $\mathbf{C}$. Graph the number of steps and the spectral radius as functions of t and comment.

(c) Successive overrelaxation (SOR). Show that by adding and subtracting $\mathbf{x}^{(m)}$ on the right, formula (6) can be written

$$\mathbf{x}^{(m+1)} = \mathbf{x}^{(m)} + \mathbf{b} - \mathbf{L}\mathbf{x}^{(m+1)} - (\mathbf{U} + \mathbf{I})\mathbf{x}^{(m)} \qquad (a_{jj} = 1).$$

Anticipation of further corrections motivates the introduction of an **overrelaxation factor** $\omega > 1$ to get the **SOR formula for Gauss–Seidel**

$$\mathbf{x}^{(m+1)} = \mathbf{x}^{(m)} + \omega(\mathbf{b} - \mathbf{L}\mathbf{x}^{(m+1)} - (\mathbf{U} + \mathbf{I})\mathbf{x}^{(m)}) \qquad (a_{jj} = 1) \tag{14}$$

intended to give more rapid convergence. A recommended value is $\omega = 2/(1 + \sqrt{1 - \rho})$, where ρ is the spectral radius of $\mathbf{C}$ in (7). Apply SOR to the matrix in (b) for $t = 0.5$ and 0.8 and notice the improvement of convergence. (Spectacular gains are made with larger systems.)

12–15 JACOBI ITERATION

Do 5 steps, starting from $\mathbf{x}_0 = [1 \quad 1 \quad 1]^T$. Compare with the Gauss–Seidel iteration. Which of the two seems to converge faster? (Show the details of your work.)

12. The system in Prob. 6

13. The system in Prob. 5

14. The system in Prob. 8

15. Show convergence in Prob. 14 by verifying that $\mathbf{I} - \mathbf{A}$, where $\mathbf{A}$ is the matrix in Prob. 14 with the rows divided by the corresponding main diagonal entries, has the eigenvalues -0.519589 and $0.259795 \pm 0.246603i$.

16–20 NORMS

Compute the norms (9), (10), (11) for the following (square) matrices. Comment on the reasons for greater or smaller differences among the three numbers.

16. The matrix in Prob. 3

17. The matrix in Prob. 7

18. The matrix in Prob. 8

19. $\begin{bmatrix} 2k & -k & -k \\ k & -2k & k \\ -k & -k & 2k \end{bmatrix}$

20. $\begin{bmatrix} 4 & -3 & 5 \\ -7 & 1 & 0 \\ 17 & -12 & -2 \end{bmatrix}$

20.4 Linear Systems: Ill-Conditioning, Norms

One does not need much experience to observe that some systems $\mathbf{A}\mathbf{x} = \mathbf{b}$ are good, giving accurate solutions even under roundoff or coefficient inaccuracies, whereas others are bad, so that these inaccuracies affect the solution strongly. We want to see what is going on and whether or not we can "trust" a linear system. Let us first formulate the two relevant concepts (ill- and well-conditioned) for general numeric work and then turn to linear systems and matrices.

A computational problem is called **ill-conditioned** (or *ill-posed*) if "small" changes in the data (the input) cause "large" changes in the solution (the output). On the other hand, a problem is called **well-conditioned** (or *well-posed*) if "small" changes in the data cause only "small" changes in the solution.

These concepts are qualitative. We would certainly regard a magnification of inaccuracies by a factor 100 as "large," but could debate where to draw the line between "large" and "small," depending on the kind of problem and on our viewpoint. Double precision may sometimes help, but if data are measured inaccurately, one should attempt ***changing the mathematical setting*** of the problem to a well-conditioned one.

Let us now turn to linear systems. Figure 442 explains that ill-conditioning occurs if and only if the two equations give two nearly parallel lines, so that their intersection point (the solution of the system) moves substantially if we raise or lower a line just a little. For larger systems the situation is similar in principle, although geometry no longer helps. We shall see that we may regard ill-conditioning as an approach to singularity of the matrix.

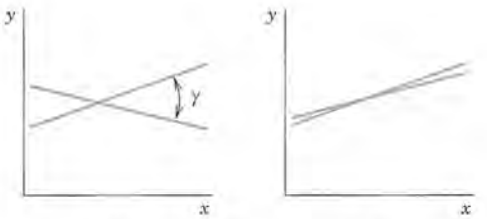


Fig. 442. (a) Well-conditioned and (b) ill-conditioned linear system of two equations in two unknowns

EXAMPLE 1 **An Ill-Conditioned System**

You may verify that the system

$$\begin{aligned} 0.9999x - 1.0001y &= 1 \\ x - \quad y &= 1 \end{aligned}$$

has the solution $x = 0.5$, $y = -0.5$, whereas the system

$$\begin{aligned} 0.9999x - 1.0001y &= 1 \\ x - \quad y &= 1 + \epsilon \end{aligned}$$

has the solution $x = 0.5 + 5000.5\,\epsilon$, $y = -0.5 + 4999.5\,\epsilon$. This shows that the system is ill-conditioned because a change on the right of magnitude ϵ produces a change in the solution of magnitude 5000ϵ, approximately. We see that the lines given by the equations have nearly the same slope. ■

Well-conditioning can be asserted if the main diagonal entries of $\mathbf{A}$ have large absolute values compared to those of the other entries. Similarly if $\mathbf{A}^{-1}$ and $\mathbf{A}$ have maximum entries of about the same absolute value.

Ill-conditioning is indicated if $\mathbf{A}^{-1}$ has entries of large absolute value compared to those of the solution (about 5000 in Example 1) and if poor approximate solutions may still produce small residuals.

Residual. The *residual* $\mathbf{r}$ of an approximate solution $\tilde{\mathbf{x}}$ of $\mathbf{Ax} = \mathbf{b}$ is defined as

$$\mathbf{r} = \mathbf{b} - \mathbf{A}\tilde{\mathbf{x}}. \tag{1}$$

Now $\mathbf{b} = \mathbf{Ax}$, so that

$$\mathbf{r} = \mathbf{A}(\mathbf{x} - \tilde{\mathbf{x}}). \tag{2}$$

Hence $\mathbf{r}$ is small if $\tilde{\mathbf{x}}$ has high accuracy, but the converse may be false:

EXAMPLE 2 Inaccurate Approximate Solution with a Small Residual

The system

$$1.0001x_1 + x_2 = 2.0001$$
$$x_1 + 1.0001x_2 = 2.0001$$

has the exact solution $x_1 = 1$, $x_2 = 1$. Can you see this by inspection? The very inaccurate approximation $\tilde{x}_1 = 2.0000$, $\tilde{x}_2 = 0.0001$ has the very small residual (to 4D)

$$\mathbf{r} = \begin{bmatrix} 2.0001 \\ 2.0001 \end{bmatrix} - \begin{bmatrix} 1.0001 & 1.0000 \\ 1.0000 & 1.0001 \end{bmatrix} \begin{bmatrix} 2.0000 \\ 0.0001 \end{bmatrix} = \begin{bmatrix} 2.0001 \\ 2.0001 \end{bmatrix} - \begin{bmatrix} 2.0003 \\ 2.0001 \end{bmatrix} = \begin{bmatrix} -0.0002 \\ 0.0000 \end{bmatrix}.$$

From this, a naive person might draw the false conclusion that the approximation should be accurate to 3 or 4 decimals.

Our result is probably unexpected, but we shall see that it has to do with the fact that the system is ill-conditioned. ■

Our goal is to show that ill-conditioning of a linear system and of its coefficient matrix **A** can be measured by a number, the *"condition number"* $\kappa(\mathbf{A})$. Other measures for ill-conditioning have also been proposed, but $\kappa(\mathbf{A})$ is probably the most widely used one. $\kappa(\mathbf{A})$ is defined in terms of norm, a concept of great general interest throughout numerics (and in modern mathematics in general!). We shall reach our goal in three steps, discussing

1. **Vector norms**
2. **Matrix norms**
3. **Condition number** κ of a square matrix.

Vector Norms

A **vector norm** for column vectors $\mathbf{x} = [x_j]$ with n components (n fixed) is a generalized length or distance. It is denoted by $\|\mathbf{x}\|$ and is defined by four properties of the usual length of vectors in three-dimensional space, namely,

(3)

(a) $\|\mathbf{x}\|$ is a nonnegative real number.

(b) $\|\mathbf{x}\| = 0$ if and only if $\mathbf{x} = \mathbf{0}$.

(c) $\|k\,\mathbf{x}\| = |k|\,\|\mathbf{x}\|$ for all k.

(d) $\|\mathbf{x} + \mathbf{y}\| \leqq \|\mathbf{x}\| + \|\mathbf{y}\|$ (Triangle inequality).

If we use several norms, we label them by a subscript. Most important in connection with computations is the ***p-norm*** defined by

$$\|\mathbf{x}\|_p = (|x_1|^p + |x_2|^p + \cdots + |x_n|^p)^{1/p} \tag{4}$$

where p is a fixed number and $p \geqq 1$. In practice, one usually takes $p = 1$ or 2 and, as a third norm, $\|\mathbf{x}\|_\infty$ (the latter as defined below), that is,

$$\|\mathbf{x}\|_1 = |x_1| + \cdots + |x_n| \qquad (\text{"}l_1\text{-norm"}) \tag{5}$$

$$\|\mathbf{x}\|_2 = \sqrt{x_1^2 + \cdots + x_n^2} \qquad (\text{"Euclidean" or "}l_2\text{-norm"}) \tag{6}$$

$$\|\mathbf{x}\|_\infty = \max_j |x_j| \qquad (\text{"}l_\infty\text{-norm"}). \tag{7}$$

For $n = 3$ the l_2-norm is the usual length of a vector in three-dimensional space. The l_1-norm and l_∞-norm are generally more convenient in computation. But all three norms are in common use.

EXAMPLE 3 **Vector Norms**

If $\mathbf{x}^T = [2 \quad -3 \quad 0 \quad 1 \quad -4]$, then $\|\mathbf{x}\|_1 = 10$, $\|\mathbf{x}\|_2 = \sqrt{30}$, $\|\mathbf{x}\|_\infty = 4$. ■

In three-dimensional space, two points with position vectors $\mathbf{x}$ and $\tilde{\mathbf{x}}$ have distance $|\mathbf{x} - \tilde{\mathbf{x}}|$ from each other. For a linear system $\mathbf{Ax} = \mathbf{b}$, this suggests that we take $\|\mathbf{x} - \tilde{\mathbf{x}}\|$ as a measure of inaccuraty and call it the **distance** between an exact and an approximate solution, or the **error** of $\tilde{\mathbf{x}}$.

Matrix Norm

If $\mathbf{A}$ is an $n \times n$ matrix and $\mathbf{x}$ any vector with n components, then $\mathbf{Ax}$ is a vector with n components. We now take a vector norm and consider $\|\mathbf{x}\|$ and $\|\mathbf{Ax}\|$. One can prove (see Ref. [E17], p. 77, 92–93, listed in App. 1) that there is a number c (depending on $\mathbf{A}$) such that

$$\|\mathbf{Ax}\| \leqq c\|\mathbf{x}\| \qquad \text{for all } \mathbf{x}. \tag{8}$$

Let $\mathbf{x} \neq \mathbf{0}$. Then $\|\mathbf{x}\| > 0$ by (3b) and division gives $\|\mathbf{Ax}\|/\|\mathbf{x}\| \leqq c$. We obtain the smallest possible c valid for *all* $\mathbf{x}$ ($\neq \mathbf{0}$) by taking the maximum on the left. This smallest c is called the **matrix norm of A** *corresponding to the vector norm we picked* and is denoted by $\|\mathbf{A}\|$. Thus

$$\|\mathbf{A}\| = \max \frac{\|\mathbf{Ax}\|}{\|\mathbf{x}\|} \qquad (\mathbf{x} \neq \mathbf{0}), \tag{9}$$

the maximum being taken over all $\mathbf{x} \neq \mathbf{0}$. Alternatively [see (c) in Team Project 24],

$$\|\mathbf{A}\| = \max_{\|\mathbf{x}\| = 1} \|\mathbf{Ax}\|. \tag{10}$$

The maximum in (10) and thus also in (9) exists. And the name "matrix ***norm***" is justified because $\|\mathbf{A}\|$ satisfies (3) with $\mathbf{x}$ and $\mathbf{y}$ replaced by $\mathbf{A}$ and $\mathbf{B}$. (Proofs in Ref. [E17] pp. 77, 92–93.)

Note carefully that $\|\mathbf{A}\|$ depends on the vector norm that we selected. In particular, one can show that

for the l_1-norm (5) one gets the column "sum" norm (10), Sec. 20.3,

for the l_∞-norm (7) one gets the row "sum" norm (11), Sec. 20.3.

By taking our best possible (our smallest) $c = \|\mathbf{A}\|$ we have from (8)

$$\|\mathbf{Ax}\| \leqq \|\mathbf{A}\|\,\|\mathbf{x}\|. \tag{11}$$

This is the formula we shall need. Formula (9) also implies for two $n \times n$ matrices (see Ref. [E17], p. 98)

$$\|\mathbf{AB}\| \leqq \|\mathbf{A}\|\,\|\mathbf{B}\|, \qquad \text{thus} \qquad \|\mathbf{A}^n\| \leqq \|\mathbf{A}\|^n. \tag{12}$$

See Refs. [E9] and [E17] for other useful formulas on norms.

Before we go on, let us do a simple illustrative computation.

EXAMPLE 4 **Matrix Norms**

Compute the matrix norms of the coefficient matrix $\mathbf{A}$ in Example 1 and of its inverse $\mathbf{A}^{-1}$, assuming that we use (a) the l_1-vector norm, (b) the l_∞-vector norm.

Solution. We use (4*), Sec. 7.8, for the inverse and then (10) and (11) in Sec. 20.3. Thus

$$\mathbf{A} = \begin{bmatrix} 0.9999 & -1.0001 \\ 1.0000 & -1.0000 \end{bmatrix}, \qquad \mathbf{A}^{-1} = \begin{bmatrix} -5000.0 & 5000.5 \\ -5000.0 & 4999.5 \end{bmatrix}.$$

(a) The l_1-vector norm gives the column "sum" norm (10), Sec. 20.3; from Column 2 we thus obtain $\|\mathbf{A}\| = |-1.0001| + |-1.0000| = 2.0001$. Similarly, $\|\mathbf{A}^{-1}\| = 10000$.

(b) The l_∞-vector norm gives the row "sum" norm (11), Sec. 20.3; thus $\|\mathbf{A}\| = 2$, $\|\mathbf{A}^{-1}\| = 10000.5$ from Row 1. We notice that $\|\mathbf{A}^{-1}\|$ is surprisingly large, which makes the product $\|\mathbf{A}\|\ \|\mathbf{A}^{-1}\|$ large (20001). We shall see below that this is typical of an ill-conditioned system. ■

Condition Number of a Matrix

We are now ready to introduce the key concept in our discussion of ill-conditioning, the **condition number** $\kappa(\mathbf{A})$ of a (nonsingular) square matrix $\mathbf{A}$, defined by

$$\kappa(\mathbf{A}) = \|\mathbf{A}\|\,\|\mathbf{A}^{-1}\|. \tag{13}$$

The role of the condition number is seen from the following theorem.

THEOREM 1 **Condition Number**

A linear system of equations $\mathbf{Ax} = \mathbf{b}$ *and its matrix* $\mathbf{A}$ *whose condition number* (13) *is small are well-conditioned. A large condition number indicates ill-conditioning.*

PROOF $\mathbf{b} = \mathbf{Ax}$ and (11) give $\|\mathbf{b}\| \leqq \|\mathbf{A}\|\|\mathbf{x}\|$. Let $\mathbf{b} \neq \mathbf{0}$ and $\mathbf{x} \neq \mathbf{0}$. Then division by $\|\mathbf{b}\|\,\|\mathbf{x}\|$ gives

$$\frac{1}{\|\mathbf{x}\|} \leqq \frac{\|\mathbf{A}\|}{\|\mathbf{b}\|}. \tag{14}$$

Multiplying (2) $\mathbf{r} = \mathbf{A}(\mathbf{x} - \tilde{\mathbf{x}})$ by $\mathbf{A}^{-1}$ from the left and interchanging sides, we have $\mathbf{x} - \tilde{\mathbf{x}} = \mathbf{A}^{-1}\mathbf{r}$. Now (11) with $\mathbf{A}^{-1}$ and $\mathbf{r}$ instead of $\mathbf{A}$ and $\mathbf{x}$ yields

$$\|\mathbf{x} - \tilde{\mathbf{x}}\| = \|\mathbf{A}^{-1}\mathbf{r}\| \leqq \|\mathbf{A}^{-1}\|\,\|\mathbf{r}\|.$$

Division by $\|\mathbf{x}\|$ [note that $\|\mathbf{x}\| \neq 0$ by (3b)] and use of (14) finally gives

$$\frac{\|\mathbf{x} - \tilde{\mathbf{x}}\|}{\|\mathbf{x}\|} \leqq \frac{1}{\|\mathbf{x}\|}\,\|\mathbf{A}^{-1}\|\,\|\mathbf{r}\| \leqq \frac{\|\mathbf{A}\|}{\|\mathbf{b}\|}\,\|\mathbf{A}^{-1}\|\,\|\mathbf{r}\| = \kappa(\mathbf{A})\,\frac{\|\mathbf{r}\|}{\|\mathbf{b}\|}. \tag{15}$$

Hence if $\kappa(\mathbf{A})$ is small, a small $\|\mathbf{r}\|/\|\mathbf{b}\|$ implies a small relative error $\|\mathbf{x} - \tilde{\mathbf{x}}\|/\|\mathbf{x}\|$, so that the system is well-conditioned. However, this does not hold if $\kappa(\mathbf{A})$ is large; then a small $\|\mathbf{r}\|/\|\mathbf{b}\|$ does not necessarily imply a small relative error $\|\mathbf{x} - \tilde{\mathbf{x}}\|/\|\mathbf{x}\|$. ■

EXAMPLE 5 Condition Numbers. Gauss–Seidel Iteration

$$\mathbf{A} = \begin{bmatrix} 5 & 1 & 1 \\ 1 & 4 & 2 \\ 1 & 2 & 4 \end{bmatrix} \quad \text{has the inverse} \quad \mathbf{A}^{-1} = \frac{1}{56}\begin{bmatrix} 12 & -2 & -2 \\ -2 & 19 & -9 \\ -2 & -9 & 19 \end{bmatrix}.$$

Since $\mathbf{A}$ is symmetric, (10) and (11) in Sec. 20.3 give the same condition number

$$\kappa(\mathbf{A}) = \|\mathbf{A}\|\,\|\mathbf{A}^{-1}\| = 7 \cdot \tfrac{1}{56} \cdot 30 = 3.75.$$

We see that a linear system $\mathbf{Ax} = \mathbf{b}$ with this $\mathbf{A}$ is well-conditioned.

For instance, if $\mathbf{b} = [14 \quad 0 \quad 28]^T$, the Gauss algorithm gives the solution $\mathbf{x} = [2 \quad -5 \quad 9]^T$ (confirm this). Since the main diagonal entries of $\mathbf{A}$ are relatively large, we can expect reasonably good convergence of the Gauss–Seidel iteration. Indeed, starting from, say, $\mathbf{x}_0 = [1 \quad 1 \quad 1]^T$, we obtain the first 8 steps (3D values)

x_1	x_2	x_3
1.000	1.000	1.000
2.400	−1.100	6.950
1.630	−3.882	8.534
1.870	−4.734	8.900
1.967	−4.942	8.979
1.993	−4.988	8.996
1.998	−4.997	8.999
2.000	−5.000	9.000
2.000	−5.000	9.000

■

EXAMPLE 6 Ill-Conditioned Linear System

Example 4 gives by (10) or (11), Sec. 20.3, for the matrix in Example 1 the very large condition number $\kappa(\mathbf{A}) = 2.0001 \cdot 10\,000 = 2 \cdot 10\,000.5 = 20\,0001$. This confirms that the system is very ill-conditioned.

Similarly in Example 2, where by (4*), Sec. 7.8 and 6D-computation,

$$\mathbf{A}^{-1} = \frac{1}{0.0002}\begin{bmatrix} 1.0001 & -1.0000 \\ -1.0000 & 1.0001 \end{bmatrix} = \begin{bmatrix} 5000.5 & -5.000.0 \\ -5000.0 & 5000.5 \end{bmatrix}$$

so that (10), Sec. 20.3, gives a very large $\kappa(\mathbf{A})$, explaining the surprising result in Example 2,

$$\kappa(\mathbf{A}) = (1.0001 + 1.0000)(5000.5 + 5000.0) = 20\,002.$$

■

In practice, $\mathbf{A}^{-1}$ will not be known, so that in computing the condition number $\kappa(\mathbf{A})$, one must estimate $\|\mathbf{A}^{-1}\|$. A method for this (proposed in 1979) is explained in Ref. [E9] listed in App. 1.

Inaccurate Matrix Entries. $\kappa(\mathbf{A})$ can be used for estimating the effect $\delta\mathbf{x}$ of an inaccuracy $\delta\mathbf{A}$ of $\mathbf{A}$ (errors of measurements of the a_{jk}, for instance). Instead of $\mathbf{Ax} = \mathbf{b}$ we then have

$$(\mathbf{A} + \delta\mathbf{A})(\mathbf{x} + \delta\mathbf{x}) = \mathbf{b}.$$

Multiplying out and subtracting $\mathbf{Ax} = \mathbf{b}$ on both sides, we obtain

$$\mathbf{A}\delta\mathbf{x} + \delta\mathbf{A}(\mathbf{x} + \delta\mathbf{x}) = \mathbf{0}.$$

Multiplication by $\mathbf{A}^{-1}$ from the left and taking the second term to the right gives

$$\delta\mathbf{x} = -\mathbf{A}^{-1}\delta\mathbf{A}(\mathbf{x} + \delta\mathbf{x}).$$

Applying (11) with $\mathbf{A}^{-1}$ and vector $\delta\mathbf{A}(\mathbf{x} + \delta\mathbf{x})$ instead of $\mathbf{A}$ and $\mathbf{x}$, we get

$$\|\delta\mathbf{x}\| = \|\mathbf{A}^{-1}\delta\mathbf{A}(\mathbf{x} + \delta\mathbf{x})\| \leqq \|\mathbf{A}^{-1}\| \, \|\delta\mathbf{A}(\mathbf{x} + \delta\mathbf{x})\| .$$

Applying (11) on the right, with $\delta\mathbf{A}$ and $\mathbf{x} - \delta\mathbf{x}$ instead of $\mathbf{A}$ and $\mathbf{x}$, we obtain

$$\|\delta\mathbf{x}\| \leqq \|\mathbf{A}^{-1}\| \, \|\delta\mathbf{A}\| \, \|\mathbf{x} + \delta\mathbf{x}\| .$$

Now $\|\mathbf{A}^{-1}\| = \kappa(\mathbf{A})/\|\mathbf{A}\|$ by the definition of $\kappa(\mathbf{A})$, so that division by $\|\mathbf{x} + \delta\mathbf{x}\|$ shows that the relative inaccuracy of $\mathbf{x}$ is related to that of $\mathbf{A}$ via the condition number by the inequality

$$\text{(16)} \qquad \frac{\|\delta\mathbf{x}\|}{\|\mathbf{x}\|} \approx \frac{\|\delta\mathbf{x}\|}{\|\mathbf{x} + \delta\mathbf{x}\|} \leqq \|\mathbf{A}^{-1}\| \, \|\delta\mathbf{A}\| = \kappa(\mathbf{A}) \frac{\|\delta\mathbf{A}\|}{\|\mathbf{A}\|} .$$

Conclusion. If the system is well-conditioned, small inaccuracies $\|\delta\mathbf{A}\|/\|\mathbf{A}\|$ can have only a small effect on the solution. However, in the case of ill-conditioning, if $\|\delta\mathbf{A}\|/\|\mathbf{A}\|$ is small, $\|\delta\mathbf{x}\|/\|\mathbf{x}\|$ ***may*** be large.

Inaccurate Right Side. You may show that, similarly, when $\mathbf{A}$ is accurate, an inaccuracy $\delta\mathbf{b}$ of $\mathbf{b}$ causes an inaccuracy $\delta\mathbf{x}$ satisfying

$$\text{(17)} \qquad \frac{\|\delta\mathbf{x}\|}{\|\mathbf{x}\|} \leqq \kappa(\mathbf{A}) \frac{\|\delta\mathbf{b}\|}{\|\mathbf{b}\|} .$$

Hence $\|\delta\mathbf{x}\|/\|\mathbf{x}\|$ must remain relatively small whenever $\kappa(\mathbf{A})$ is small.

EXAMPLE 7 **Inaccuracies. Bounds (16) and (17)**

If each of the nine entries of $\mathbf{A}$ in Example 5 is measured with an inaccuracy of 0.1, then $\|\delta\mathbf{A}\| = 9 \cdot 0.1$ and (16) gives

$$\frac{\|\delta\mathbf{x}\|}{\|\mathbf{x}\|} \leqq 7.5 \cdot \frac{3 \cdot 0.1}{7} = 0.321 \qquad \text{thus} \qquad \|\delta\mathbf{x}\| \leqq 0.321 \, \|\mathbf{x}\| = 0.321 \cdot 16 = 5.14.$$

By experimentation you will find that the actual inaccuracy $\|\delta\mathbf{x}\|$ is only about 30% of the bound 5.14. This is typical.

Similarly, if $\delta\mathbf{b} = [0.1 \quad 0.1 \quad 0.1]^T$, then $\|\delta\mathbf{b}\| = 0.3$ and $\|\mathbf{b}\| = 42$ in Example 5, so that (17) gives

$$\frac{\|\delta\mathbf{x}\|}{\|\mathbf{x}\|} \leqq 7.5 \cdot \frac{0.3}{42} = 0.0536, \qquad \text{hence} \qquad \|\delta\mathbf{x}\| \leqq 0.0536 \cdot 16 = 0.857$$

but this bound is again much greater than the actual inaccuracy, which is about 0.15. ■

Further Comments on Condition Numbers. The following additional explainations may be helpful.

1. There is no sharp dividing line between "well-conditioned" and "ill-conditioned," but generally the situation will get worse as we go from systems with small $\kappa(\mathbf{A})$ to systems with larger $\kappa(\mathbf{A})$. Now always $\kappa(\mathbf{A}) \geqq 1$, so that values of 10 or 20 or so give no reason for concern, whereas $\kappa(\mathbf{A}) = 100$, say, calls for caution, and systems such as those in Examples 1 and 2 are extremely ill-conditioned.

2. If $\kappa(\mathbf{A})$ is large (or small) in one norm, it will be large (or small, respectively) in any other norm. See Example 5.

3. The literature on ill-conditioning is extensive. For an introduction to it, see [E9].

This is the end of our discussion of numerics for solving linear systems. In the next section we consider curve fitting, an important area in which solutions are obtained from linear systems.

PROBLEM SET 20.4

1–8 VECTOR NORMS

Compute (5), (6), (7). Compute a corresponding **unit vector** (vector of norm 1) with respect to the l_∞-norm.

1. [1 −6 5]

2. [0.4 −1.2 0 8.0]

3. [−4 4 3 −3]

4. [0 0 1 0 0]

5. [0.3 −0.1 0.5 1.0]

6. [16 21 54 −119]

7. [1 1 1 1 1 1]

8. [3 0 0 −3 0]

9. Show that $\|\mathbf{x}\|_\infty \leqq \|\mathbf{x}\|_2 \leqq \|\mathbf{x}\|_1$.

10–15 MATRIX NORMS, CONDITION NUMBERS

Compute the matrix norm and the condition number corresponding to the l_1-vector norm.

10. $\begin{bmatrix} -3 & 4 \\ 1 & 2 \end{bmatrix}$

11. $\begin{bmatrix} 5 & 7 \\ 7 & 10 \end{bmatrix}$

12. $\begin{bmatrix} \sqrt{3} & 3 \\ 0 & -\sqrt{3} \end{bmatrix}$

13. $\begin{bmatrix} 0 & 0 & 100 \\ 0 & 100 & 0 \\ 0.01 & 0 & 0 \end{bmatrix}$

14. $\begin{bmatrix} 21 & 10.5 & 7 & 5.25 \\ 10.5 & 7 & 5.25 & 4.2 \\ 7 & 5.25 & 4.2 & 3.5 \\ 5.25 & 4.2 & 3.5 & 3 \end{bmatrix}$

15. $\begin{bmatrix} 1 & 0.1 & 0 \\ 0.1 & 1 & 0.1 \\ 0 & 0.1 & 1 \end{bmatrix}$

16. Verify (11) for $\mathbf{x} = [4 \quad -5 \quad 2]^T$ taken with the l_∞-norm and the matrix in Prob. 15.

17. Verify (12) for the matrices in Probs. 10 and 11.

18. Verify the calculations in Examples 5 and 6 of the text.

19–20 ILL-CONDITIONED SYSTEMS

Solve $\mathbf{Ax} = \mathbf{b}_1$, $\mathbf{Ax} = \mathbf{b}_2$, compare the solutions, and comment. Compute the condition number of $\mathbf{A}$.

19. $\mathbf{A} = \begin{bmatrix} 2 & 1.4 \\ 1.4 & 1 \end{bmatrix}$, $\mathbf{b}_1 = \begin{bmatrix} 1.4 \\ 1 \end{bmatrix}$, $\mathbf{b}_2 = \begin{bmatrix} 1.44 \\ 1 \end{bmatrix}$

20. $\mathbf{A} = \begin{bmatrix} 5 & -7 \\ -7 & 10 \end{bmatrix}$, $\mathbf{b}_1 = \begin{bmatrix} -2 \\ 3 \end{bmatrix}$, $\mathbf{b}_2 = \begin{bmatrix} -2 \\ 3.1 \end{bmatrix}$

21. (Residual) For $\mathbf{Ax} = \mathbf{b}_1$ in Prob. 19 guess what the residual of $\tilde{\mathbf{x}} = [113 \quad -160]^T$ might be (the solution being $\mathbf{x} = [0 \quad 1]^T$). Then calculate and comment.

22. Show that $\kappa(\mathbf{A}) \geqq 1$ for the matrix norms (10), (11), Sec. 20.3, and $\kappa(\mathbf{A}) \geqq \sqrt{n}$ for the Frobenius norm (9), Sec. 20.3.

23. CAS EXPERIMENT. Hilbert Matrices. The 3×3 Hilbert matrix is

$$\mathbf{H}_3 = \begin{bmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \end{bmatrix}.$$

The $n \times n$ Hilbert matrix is $\mathbf{H}_n = [h_{jk}]$, where $h_{jk} = 1/(j + k - 1)$. (Similar matrices occur in curve fitting by least squares.) Compute the condition number $\kappa(\mathbf{H}_n)$ for the matrix norm corresponding to the l_∞- (or l_1-) vector norm, for $n = 2, 3, \cdots, 6$ (or further if you wish). Try to find a formula that gives reasonable approximate values of these rapidly growing numbers. Solve a few linear systems involving an $\mathbf{H}_n$ of your choice.

24. TEAM PROJECT. Norms. (a) Vector norms in our text are **equivalent,** that is, they are related by double inequalities; for instance,

$$(18)\quad \text{(a)}\quad \|\mathbf{x}\|_\infty \leqq \|\mathbf{x}\|_1 \leqq n\|\mathbf{x}\|_\infty$$

$$\text{(b)}\quad \frac{1}{n}\|\mathbf{x}\|_1 \leqq \|\mathbf{x}\|_\infty \leqq \|\mathbf{x}\|_1.$$

Hence if for some $\mathbf{x}$, one norm is large (or small), the other norm must also be large (or small). Thus in many investigations the particular choice of a norm is not essential. Prove (18).

(b) The **Cauchy–Schwarz inequality** is

$$|\mathbf{x}^T\mathbf{y}| \leqq \|\mathbf{x}\|_2\,\|\mathbf{y}\|_2.$$

It is very important. (Proof in Ref. [GR7] listed in App. 1.) Use it to prove

$$(19a)\qquad \|\mathbf{x}\|_2 \leqq \|\mathbf{x}\|_1 \leqq \sqrt{n}\,\|\mathbf{x}\|_2$$

$$(19b)\qquad \frac{1}{\sqrt{n}}\,\|\mathbf{x}\|_1 \leqq \|\mathbf{x}\|_2 \leqq \|\mathbf{x}\|_1.$$

(c) Formula (10) is often more practical than (9). Derive (10) from (9).

(d) Matrix norms. Illustrate (11) with examples. Give examples of (12) with equality as well as with strict inequality. Prove that the matrix norms (10), (11) in Sec. 20.3 satisfy the *axioms of a norm*

$$\|\mathbf{A}\| \geqq 0.$$

$$\|\mathbf{A}\| = 0 \text{ if and only if } \mathbf{A} = \mathbf{0},$$

$$\|k\mathbf{A}\| = |k|\,\|\mathbf{A}\|,$$

$$\|\mathbf{A} + \mathbf{B}\| \leqq \|\mathbf{A}\| + \|\mathbf{B}\|.$$

25. WRITING PROJECT. Norms and Their Use in This Section. Make a list of the most important of the many ideas covered in this section and write a two-page report on them.

20.5 Least Squares Method

Having discussed numerics for linear systems, we now turn to an important application, curve fitting, in which the solutions are obtained from linear systems.

In **curve fitting** we are given n points (pairs of numbers) $(x_1, y_1), \cdots, (x_n, y_n)$ and we want to determine a function $f(x)$ such that

$$f(x_1) \approx y_1, \cdots, f(x_n) \approx y_n,$$

approximately. The type of function (for example, polynomials, exponential functions, sine and cosine functions) may be suggested by the nature of the problem (the underlying physical law, for instance), and in many cases a polynomial of a certain degree will be appropriate.

Let us begin with a motivation.

If we require strict equality $f(x_1) = y_1, \cdots, f(x_n) = y_n$ and use polynomials of sufficiently high degree, we may apply one of the methods discussed in Sec. 19.3 in connection with interpolation. However, in certain situations this would not be the appropriate solution of the actual problem. For instance, to the four points

$$(1)\quad (-1.3,\ 0.103),\qquad (-0.1,\ 1.099),\qquad (0.2,\ 0.808),\qquad (1.3,\ 1.897)$$

there corresponds the interpolation polynomial $f(x) = x^3 - x + 1$ (Fig. 443), but if we

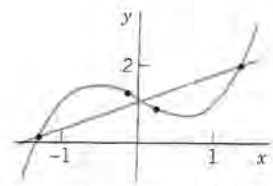

Fig. 443. Approximate fitting of a straight line

graph the points, we see that they lie nearly on a straight line. Hence if these values are obtained in an experiment and thus involve an experimental error, and if the nature of the experiment suggests a linear relation, we better fit a straight line through the points (Fig. 443). Such a line may be useful for predicting values to be expected for other values of x. A widely used principle for fitting straight lines is the **method of least squares** by Gauss and Legendre. In the present situation it may be formulated as follows.

Method of Least Squares. *The straight line*

$$y = a + bx \tag{2}$$

should be fitted through the given points $(x_1, y_1), \cdots, (x_n, y_n)$ *so that the sum of the squares of the distances of those points from the straight line is minimum, where the distance is measured in the vertical direction (the y-direction).*

The point on the line with abscissa x_j has the ordinate $a + bx_j$. Hence its distance from (x_j, y_j) is $|y_j - a - bx_j|$ (Fig. 444) and that sum of squares is

$$q = \sum_{j=1}^{n} (y_j - a - bx_j)^2.$$

q depends on a and b. A necessary condition for q to be minimum is

$$\begin{aligned} \frac{\partial q}{\partial a} &= -2 \sum (y_j - a - bx_j) = 0 \\ \frac{\partial q}{\partial b} &= -2 \sum x_j (y_j - a - bx_j) = 0 \end{aligned} \tag{3}$$

(where we sum over j from 1 to n). Dividing by 2, writing each sum as three sums, and taking one of them to the right, we obtain the result

$$\begin{aligned} an \quad &+ b \sum x_j = \sum y_j \\ a \sum x_j &+ b \sum x_j^2 = \sum x_j y_j. \end{aligned} \tag{4}$$

These equations are called the **normal equations** of our problem.

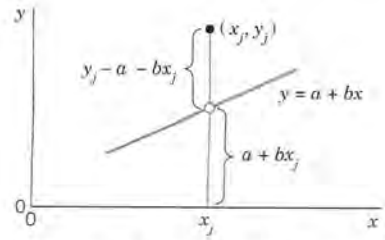

Fig. 444. Vertical distance of a point (x_j, y_j) from a straight line $y = a + bx$

EXAMPLE 1 Straight Line

Using the method of least squares, fit a straight line to the four points given in formula (1).

Solution. We obtain

$$n = 4, \qquad \sum x_j = 0.1, \qquad \sum x_j^2 = 3.43, \qquad \sum y_j = 3.907, \qquad \sum x_j y_j = 2.3839.$$

Hence the normal equations are

$$4a + 0.10b = 3.9070$$
$$0.1a + 3.43b = 2.3839.$$

The solution (rounded to 4D) is $a = 0.9601$, $b = 0.6670$, and we obtain the straight line (Fig. 443)

$$y = 0.9601 + 0.6670x.$$

■

Curve Fitting by Polynomials of Degree m

Our method of curve fitting can be generalized from a polynomial $y = a + bx$ to a polynomial of degree m

$$p(x) = b_0 + b_1 x + \cdots + b_m x^m \tag{5}$$

where $m \leqq n - 1$. Then q takes the form

$$q = \sum_{j=1}^{n} (y_j - p(x_j))^2$$

and depends on $m + 1$ parameters $b_0, \cdots, b_m$. Instead of (3) we then have $m + 1$ conditions

$$\frac{\partial q}{\partial b_0} = 0, \qquad \cdots, \qquad \frac{\partial q}{\partial b_m} = 0 \tag{6}$$

which give a system of $m + 1$ normal equations.

In the case of a quadratic polynomial

$$p(x) = b_0 + b_1 x + b_2 x^2 \tag{7}$$

the normal equations are (summation from 1 to n)

$$\begin{aligned} b_0 n \quad &+ b_1 \sum x_j \quad + b_2 \sum x_j^2 = \sum y_j \\ b_0 \sum x_j \quad &+ b_1 \sum x_j^2 + b_2 \sum x_j^3 = \sum x_j y_j \\ b_0 \sum x_j^2 \; &+ b_1 \sum x_j^3 + b_2 \sum x_j^4 = \sum x_j^2 y_j. \end{aligned} \tag{8}$$

The derivation of (8) is left to the reader.

EXAMPLE 2 **Quadratic Parabola by Least Squares**

Fit a parabola through the data (0, 5), (2, 4), (4, 1), (6, 6), (8, 7).

Solution. For the normal equations we need $n = 5$, $\Sigma x_j = 20$, $\Sigma x_j^2 = 120$, $\Sigma x_j^3 = 800$, $\Sigma x_j^4 = 5664$, $\Sigma y_j = 23$, $\Sigma x_j y_j = 104$, $\Sigma x_j^2 y_j = 696$. Hence these equations are

$$\begin{aligned} 5b_0 + 20b_1 + 120b_2 &= 23 \\ 20b_0 + 120b_1 + 800b_2 &= 104 \\ 120b_0 + 800b_1 + 5664b_2 &= 696. \end{aligned}$$

Solving them we obtain the quadratic least squares parabola (Fig. 445)

$$y = 5.11429 - 1.41429x + 0.21429x^2.$$

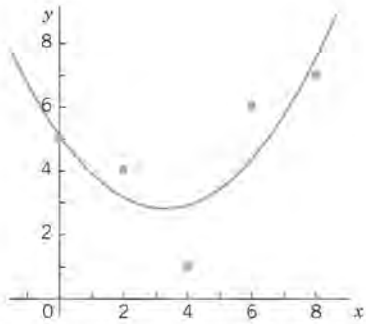

Fig. 445. Least squares parabola in Example 2

For a general polynomial (5) the normal equations form a linear system of equations in the unknowns $b_0, \cdots, b_m$. When its matrix $\mathbf{M}$ is nonsingular, we can solve the system by Cholesky's method (Sec. 20.2) because then $\mathbf{M}$ is positive definite (and symmetric). When the equations are nearly linearly dependent, the normal equations may become ill-conditioned and should be replaced by other methods; see [E5], Sec. 5.7, listed in App. 1.

The least squares method also plays a role in statistics (see Sec. 25.9).

PROBLEM SET 20.5

1–6 FITTING A STRAIGHT LINE

Fit a straight line to the given points (x, y) by least squares. Show the details. Check your result by sketching the points and the line. Judge the goodness of fit.

1. (2, 0), (3, 4), (4, 10), (5, 16)
2. How does the line in Prob. 1 change if you add a point far above it, say, (3, 20)?
3. (2.5, 8.0), (5.0, 6.9), (7.5, 6.2), (10.0, 5.0)
4. **(Ohm's law $U = Ri$)** Estimate the resistance R from the least squares line that fits $(i, U) = (2.0, 104)$, (4.0, 206), (6.0, 314), (10.0, 530).
5. **(Average speed)** Estimate the average speed v_{av} of a car traveling according to $s = v \cdot t$ [km] (s = distance traveled, t [h] = time) from $(t, s) = (9, 140)$, (10, 220), (11, 310), (12, 410).
6. **(Hooke's law $F = ks$)** Estimate the spring modulus k from the force F [lb] and extension s [cm], where $(F, s) = (1, 0.50)$, (2, 1.02), (4, 1.99), (6, 3.01), (10, 4.98), (20, 10.03).
7. Derive the normal equations (8).

8–10 FITTING A QUADRATIC PARABOLA

Fit a parabola (7) to the given points (x, y) by least squares. Check by sketching.

8. $(-1, 3)$, (0, 0), (1, 2), (2, 8)
9. (0, 4), (2, 2), (4, -1), (6, -5)

10.

Worker's time on duty x [h]	1	2	3	4	5
Worker's reaction time [sec]	1.50	1.28	1.40	1.85	2.20

11. Fit (2) and (7) by least squares to $(-1.0, 5.4)$, $(-0.5, 4.1)$, $(0, 3.9)$, $(0.5, 4.8)$, $(1.0, 6.3)$, $(1.5, 9.3)$. Graph the data and the curves on common axes and comment.

12. (Cubic parabola) Derive the formula for the normal equations of a cubic least squares parabola.

13. Fit curves (2) and (7) and a cubic parabola by least squares to $(-2, -35)$, $(-1, -9)$, $(0, -1)$, $(1, -1)$, $(2, 17)$, $(3, 63)$. Graph the three curves and the points on common axes. Comment on the goodness of fit.

14. CAS PROJECT. Least Squares. Write programs for calculating and solving the normal equations (4) and (8). Apply the programs to Probs. 3, 5, 9, 11. If your CAS has a command for fitting (Maple and Mathematica do), compare your results with those by your CAS commands.

15. CAS EXPERIMENT. Least Squares versus Interpolation. For the given data and for data of your choice find the interpolation polynomial and the least squares approximations (linear, quadratic, etc.). Compare and comment.

(a) $(-2, 0)$, $(-1, 0)$, $(0, 1)$, $(1, 0)$, $(2, 0)$

(b) $(-4, 0)$, $(-3, 0)$, $(-2, 0)$, $(-1, 0)$, $(0, 1)$, $(1, 0)$, $(2, 0)$, $(3, 0)$, $(4, 0)$

(c) Choose five points on a straight line, e.g., $(0, 0)$, $(1, 1)$, $\cdots$, $(4, 4)$. Move one point 1 unit upward and find the quadratic least squares polynomial. Do this for each point. Graph the five polynomials on common axes. Which of the five motions has the greatest effect?

16. TEAM PROJECT. The least squares approximation of a function $f(x)$ on an interval $a \leqq x \leqq b$ by a function

$$F_m(x) = a_0 y_0(x) + a_1 y_1(x) + \cdots + a_m y_m(x)$$

where $y_0(x), \cdots, y_m(x)$ are given functions, requires the determination of the coefficients $a_0, \cdots, a_m$ such that

$$(9) \qquad \int_a^b [f(x) - F_m(x)]^2 \, dx$$

becomes minimum. This integral is denoted by $\|f - F_m\|^2$, and $\|f - F_m\|$ is called the L_2**-norm** of $f - F_m$ (L suggesting Lebesgue[2]). A necessary condition for that minimum is given by $\partial \|f - F_m\|^2 / \partial a_j = 0$, $j = 0, \cdots, m$ [the analog of (6)]. **(a)** Show that this leads to $m + 1$ normal equations ($j = 0, \cdots, m$)

$$\sum_{k=0}^{m} h_{jk} a_k = b_j \qquad \text{where}$$

$$(10) \qquad h_{jk} = \int_a^b y_j(x) y_k(x) \, dx,$$

$$b_j = \int_a^b f(x) y_j(x) \, dx.$$

(b) Polynomial. What form does (10) take if $F_m(x) = a_0 + a_1 x + \cdots + a_m x^m$? What is the coefficient matrix of (10) in this case when the interval is $0 \leqq x \leqq 1$?

(c) Orthogonal functions. What are the solutions of (10) if $y_0(x), \cdots, y_m(x)$ are orthogonal on the interval $a \leqq x \leqq b$? (For the definition, see Sec. 5.7. See also Sec. 5.8.)

20.6 Matrix Eigenvalue Problems: Introduction

In the remaining sections of this chapter we discuss some of the most important ideas and numeric methods for matrix eigenvalue problems. This very extensive part of numeric linear algebra is of great practical importance, with much research going on, and hundreds, if not thousands of papers published in various mathematical journals (see the references in [E8], [E9], [E11], [E29]). We begin with the concepts and general results we shall need in explaining and applying numeric methods for eigenvalue problems. (For typical models of eigenvalue problems see Chap. 8.)

[2]HENRI LEBESGUE (1875–1941), great French mathematician, creator of a modern theory of measure and integration in his famous doctoral thesis of 1902.

An **eigenvalue** or **characteristic value** (or *latent root*) of a given $n \times n$ matrix $\mathbf{A} = [a_{jk}]$ is a real or complex number λ such that the vector equation

$$\mathbf{Ax} = \lambda \mathbf{x} \tag{1}$$

has a nontrivial solution, that is, a solution $\mathbf{x} \neq \mathbf{0}$, which is then called an **eigenvector** or **characteristic vector** of $\mathbf{A}$ corresponding to that eigenvalue λ. The set of all eigenvalues of $\mathbf{A}$ is called the **spectrum** of $\mathbf{A}$. Equation (1) can be written

$$(\mathbf{A} - \lambda \mathbf{I})\mathbf{x} = \mathbf{0} \tag{2}$$

where $\mathbf{I}$ is the $n \times n$ unit matrix. This homogeneous system has a nontrivial solution if and only if the **characteristic determinant** $\det(\mathbf{A} - \lambda \mathbf{I})$ is 0 (see Theorem 2 in Sec. 7.5). This gives (see Sec. 8.1)

THEOREM 1

Eigenvalues

The eigenvalues of $\mathbf{A}$ *are the solutions* λ *of the* **characteristic equation**

$$\det(\mathbf{A} - \lambda \mathbf{I}) = \begin{vmatrix} a_{11} - \lambda & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} - \lambda & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ a_{n1} & a_{n2} & \cdots & a_{nn} - \lambda \end{vmatrix} = 0. \tag{3}$$

Developing the characteristic determinant, we obtain the **characteristic polynomial** of $\mathbf{A}$, which is of degree n in λ. Hence $\mathbf{A}$ has at least one and at most n numerically different eigenvalues. If $\mathbf{A}$ is real, so are the coefficients of the characteristic polynomial. By familiar algebra it follows that then the roots (the eigenvalues of $\mathbf{A}$) are ***real or complex conjugates*** in pairs.

We shall usually denote the eigenvalues of $\mathbf{A}$ by

$$\lambda_1, \lambda_2, \cdots, \lambda_n$$

with the understanding that some (or all) of them may be equal.

The sum of these n eigenvalues equals the sum of the entries on the main diagonal of $\mathbf{A}$, called the **trace** of $\mathbf{A}$; thus

$$\text{trace } \mathbf{A} = \sum_{j=1}^{n} a_{jj} = \sum_{k=1}^{n} \lambda_k. \tag{4}$$

Also, the product of the eigenvalues equals the determinant of $\mathbf{A}$,

$$\det \mathbf{A} = \lambda_1 \lambda_2 \cdots \lambda_n. \tag{5}$$

Both formulas follow from the product representation of the characteristic polynomial, which we denote by $f(\lambda)$,

$$f(\lambda) = (-1)^n(\lambda - \lambda_1)(\lambda - \lambda_2) \cdots (\lambda - \lambda_n).$$

If we take equal factors together and denote the *numerically distinct* eigenvalues of $\mathbf{A}$ by $\lambda_1, \cdots, \lambda_r$ $(r \leqq n)$, then the product becomes

$$f(\lambda) = (-1)^n(\lambda - \lambda_1)^{m_1}(\lambda - \lambda_2)^{m_2} \cdots (\lambda - \lambda_r)^{m_r}. \tag{6}$$

The exponent m_j is called the **algebraic multiplicity** of λ_j. The maximum number of linearly independent eigenvectors corresponding to λ_j is called the **geometric multiplicity** of λ_j. It is equal to or smaller than m_j.

A subspace S of R^n or C^n (if $\mathbf{A}$ is complex) is called an **invariant subspace** of $\mathbf{A}$ if for every $\mathbf{v}$ in S the vector $\mathbf{Av}$ is also in S. **Eigenspaces** of $\mathbf{A}$ (spaces of eigenvectors; Sec. 8.1) are important invariant subspaces of $\mathbf{A}$.

An $n \times n$ matrix $\mathbf{B}$ is called **similar** to $\mathbf{A}$ if there is a nonsingular $n \times n$ matrix $\mathbf{T}$ such that

$$\mathbf{B} = \mathbf{T}^{-1}\mathbf{AT}. \tag{7}$$

Similarity is important for the following reason.

THEOREM 2

Similar Matrices

Similar matrices have the same eigenvalues. If $\mathbf{x}$ *is an eigenvector of* $\mathbf{A}$*, then* $\mathbf{y} = \mathbf{T}^{-1}\mathbf{x}$ *is an eigenvector of* $\mathbf{B}$ *in* (7) *corresponding to the same eigenvalue.* (Proof in Sec. 8.4.)

Another theorem that has various applications in numerics is as follows.

THEOREM 3

Spectral Shift

If $\mathbf{A}$ *has the eigenvalues* $\lambda_1, \cdots, \lambda_n$*, then* $\mathbf{A} - k\mathbf{I}$ *with arbitrary* k *has the eigenvalues* $\lambda_1 - k, \cdots, \lambda_n - k$.

This theorem is a special case of the following **spectral mapping theorem.**

THEOREM 4

Polynomial Matrices

If λ *is an eigenvalue of* $\mathbf{A}$*, then*

$$q(\lambda) = \alpha_s\lambda^s + \alpha_{s-1}\lambda^{s-1} + \cdots + \alpha_1\lambda + \alpha_0$$

is an eigenvalue of the **polynomial matrix**

$$q(\mathbf{A}) = \alpha_s\mathbf{A}^s + \alpha_{s-1}\mathbf{A}^{s-1} + \cdots + \alpha_1\mathbf{A} + \alpha_0\mathbf{I}.$$

PROOF $\mathbf{Ax} = \lambda\mathbf{x}$ implies $\mathbf{A}^2\mathbf{x} = \mathbf{A}\lambda\mathbf{x} = \lambda\mathbf{Ax} = \lambda^2\mathbf{x}$, $\mathbf{A}^3\mathbf{x} = \lambda^3\mathbf{x}$, etc. Thus

$$\begin{aligned} q(\mathbf{A})\mathbf{x} &= (\alpha_s\mathbf{A}^s + \alpha_{s-1}\mathbf{A}^{s-1} + \cdots)\,\mathbf{x} \\ &= \alpha_s\mathbf{A}^s\mathbf{x} + \alpha_{s-1}\mathbf{A}^{s-1}\mathbf{x} + \cdots \\ &= \alpha_s\lambda^s\mathbf{x} + \alpha_{s-1}\lambda^{s-1}\mathbf{x} + \cdots = q(\lambda)\,\mathbf{x}. \end{aligned}$$

■

The eigenvalues of important special matrices can be characterized as follows.

THEOREM 5

Special Matrices

The eigenvalues of Hermitian matrices (i.e., $\overline{\mathbf{A}}^\mathsf{T} = \mathbf{A}$), *hence of real symmetric matrices* (i.e., $\mathbf{A}^\mathsf{T} = \mathbf{A}$), *are real. The eigenvalues of skew-Hermitian matrices* (i.e., $\overline{\mathbf{A}}^\mathsf{T} = -\mathbf{A}$), *hence of real skew-symmetric matrices* (i.e., $\mathbf{A}^\mathsf{T} = -\mathbf{A}$) *are pure imaginary or* 0. *The eigenvalues of unitary matrices* (i.e., $\overline{\mathbf{A}}^\mathsf{T} = \mathbf{A}^{-1}$), *hence of orthogonal matrices* (i.e., $\mathbf{A}^\mathsf{T} = \mathbf{A}^{-1}$), *have absolute value* 1. (Proofs in Secs. 8.3 and 8.5.)

The **choice of a numeric method** for matrix eigenvalue problems depends essentially on two circumstances, on the kind of matrix (real symmetric, real general, complex, sparse, or full) and on the kind of information to be obtained, that is, whether one wants to know all eigenvalues or merely specific ones, for instance, the largest eigenvalue, whether eigenvalues *and* eigenvectors are wanted, and so on. It is clear that we cannot enter into a systematic discussion of all these and further possibilities that arise in practice, but we shall concentrate on some basic aspects and methods that will give us a general understanding of this fascinating field.

20.7 Inclusion of Matrix Eigenvalues

The whole numerics for matrix eigenvalues is motivated by the fact that except for a few trivial cases we cannot determine eigenvalues *exactly* by a finite process because these values are the roots of a polynomial of nth degree. Hence we must mainly use iteration.

In this section we state a few general theorems that give approximations and error bounds for eigenvalues. Our matrices will continue to be real (except in formula (5) below), but since (nonsymmetric) matrices may have complex eigenvalues, complex numbers will play a (very modest) role in this section.

The important theorem by Gerschgorin gives a region consisting of closed circular disks in the complex plane and including all the eigenvalues of a given matrix. Indeed, for each $j = 1, \cdots, n$ the inequality (1) in the theorem determines a closed circular disk in the complex λ-plane with center a_{jj} and radius given by the right side of (1); and Theorem 1 states that each of the eigenvalues of $\mathbf{A}$ lies in one of these n disks.

THEOREM 1

Gerschgorin's Theorem

Let λ be an eigenvalue of an arbitrary $n \times n$ matrix $\mathbf{A} = [a_{jk}]$. Then for some integer j $(1 \leqq j \leqq n)$ we have

(1) $$|a_{jj} - \lambda| \leqq |a_{j1}| + |a_{j2}| + \cdots + |a_{j,j-1}| + |a_{j,j+1}| + \cdots + |a_{jn}|.$$

PROOF Let $\mathbf{x}$ be an eigenvector corresponding to an eigenvalue λ of $\mathbf{A}$. Then

(2) $$\mathbf{Ax} = \lambda\mathbf{x} \qquad \text{or} \qquad (\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}.$$

Let x_j be a component of $\mathbf{x}$ that is largest in absolute value. Then we have $|x_m/x_j| \leqq 1$ for $m = 1, \cdots, n$. The vector equation (2) is equivalent to a system of n equations for the

n components of the vectors on both sides. The jth of these n equations with j as just indicated is

$$a_{j1}x_1 + \cdots + a_{j,j-1}x_{j-1} + (a_{jj} - \lambda)x_j + a_{j,j+1}x_{j+1} + \cdots + a_{jn}x_n = 0.$$

Division by x_j (which cannot be zero; why?) and reshuffling terms gives

$$a_{jj} - \lambda = -a_{j1}\frac{x_1}{x_j} - \cdots - a_{j,j-1}\frac{x_{j-1}}{x_j} - a_{j,j+1}\frac{x_{j+1}}{x_j} - \cdots - a_{jn}\frac{x_n}{x_j}.$$

By taking absolute values on both sides of this equation, applying the triangle inequality $|a + b| \leqq |a| + |b|$ (where a and b are any complex numbers), and observing that because of the choice of j (which is crucial!), $|x_1/x_j| \leqq 1, \cdots, |x_n/x_j| \leqq 1$, we obtain (1), and the theorem is proved. ■

EXAMPLE 1 **Gerschgorin's Theorem**

For the eigenvalues of the matrix

$$\mathbf{A} = \begin{bmatrix} 0 & 1/2 & 1/2 \\ 1/2 & 5 & 1 \\ 1/2 & 1 & 1 \end{bmatrix}$$

we get the Gerschgorin disks (Fig. 446)

D_1: Center 0, radius 1, D_2: Center 5, radius 1.5, D_3: Center 1, radius 1.5.

The centers are the main diagonal entries of **A**. These would be the eigenvalues of **A** if **A** were diagonal. We can take these values as crude approximations of the unknown eigenvalues (3D values) $\lambda_1 = -0.209$, $\lambda_2 = 5.305$, $\lambda_3 = 0.904$ (verify this); then the radii of the disks are corresponding error bounds.

Since **A** is symmetric, it follows from Theorem 5, Sec. 20.6, that the spectrum of **A** must actually lie in the intervals $[-1, 2.5]$ and $[3.5, 6.5]$.

It is interesting that here the Gerschgorin disks form two disjoint sets, namely, $D_1 \cup D_3$, which contains two eigenvalues, and D_2, which contains one eigenvalue. This is typical, as the following theorem shows. ■

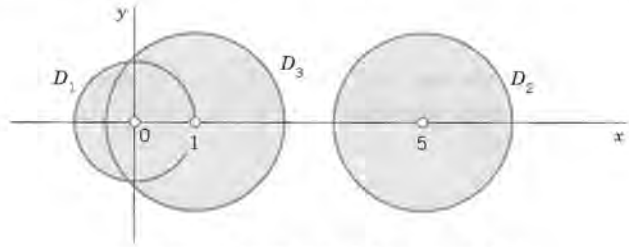

Fig. 446. Gerschgorin disks in Example 1

THEOREM 2 **Extension of Gerschgorin's Theorem**

If p Gerschgorin disks form a set S that is disjoint from the $n - p$ other disks of a given matrix **A**, *then S contains precisely p eigenvalues of* **A** *(each counted with its algebraic multiplicity, as defined in Sec.* 20.6*).*

Idea of Proof. Set $\mathbf{A} = \mathbf{B} + \mathbf{C}$, where **B** is the diagonal matrix with entries a_{jj}, and apply Theorem 1 to $\mathbf{A}_t = \mathbf{B} + t\mathbf{C}$ with real t growing from 0 to 1. ■

EXAMPLE 2 **Another Application of Gerschgorin's Theorem. Similarity**

Suppose that we have diagonalized a matrix by some numeric method that left us with some off-diagonal entries of size 10^{-5}, say,

$$\mathbf{A} = \begin{bmatrix} 2 & 10^{-5} & 10^{-5} \\ 10^{-5} & 2 & 10^{-5} \\ 10^{-5} & 10^{-5} & 4 \end{bmatrix}.$$

What can we conclude about deviations of the eigenvalues from the main diagonal entries?

Solution. By Theorem 2, one eigenvalue must lie in the disk of radius $2 \cdot 10^{-5}$ centered at 4 and two eigenvalues (or an eigenvalue of algebraic multiplicity 2) in the disk of radius $2 \cdot 10^{-5}$ centered at 2. Actually, since the matrix is symmetric, these eigenvalues must lie in the intersections of these disks and the real axis, by Theorem 5 in Sec. 20.6.

We show how an isolated disk can always be reduced in size by a similarity transformation. The matrix

$$\mathbf{B} = \mathbf{T}^{-1}\mathbf{A}\mathbf{T} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 10^{-5} \end{bmatrix} \begin{bmatrix} 2 & 10^{-5} & 10^{-5} \\ 10^{-5} & 2 & 10^{-5} \\ 10^{-5} & 10^{-5} & 4 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 10^{5} \end{bmatrix}$$

$$= \begin{bmatrix} 2 & 10^{-5} & 1 \\ 10^{-5} & 2 & 1 \\ 10^{-10} & 10^{-10} & 4 \end{bmatrix}$$

is similar to **A**. Hence by Theorem 2, Sec. 20.6, it has the same eigenvalues as **A**. From Row 3 we get the smaller disk of radius $2 \cdot 10^{-10}$. Note that the other disks got bigger, approximately by a factor of 10^5. And in choosing **T** we have to watch that the new disks do not overlap with the disk whose size we want to decrease.

For further interesting facts, see the new book [E28]. ■

By definition, a **diagonally dominant** matrix $\mathbf{A} = [a_{jk}]$ is an $n \times n$ matrix such that

$$|a_{jj}| \geqq \sum_{k \neq j} |a_{jk}| \qquad j = 1, \cdots, n \tag{3}$$

where we sum over all off-diagonal entries in Row j. The matrix is said to be **strictly diagonally dominant** if $>$ in (3) for all j. Use Theorem 1 to prove the following basic property.

THEOREM 3 **Strict Diagonal Dominance**

Strictly diagonally dominant matrices are nonsingular.

Further Inclusion Theorems

An **inclusion theorem** is a theorem that specifies a set which contains at least one eigenvalue of a given matrix. Thus, Theorems 1 and 2 are inclusion theorems; they even include the whole spectrum. We now discuss some famous theorems that yield further inclusions of eigenvalues. We state the first two of them without proofs (which would exceed the level of this book).

THEOREM 4

Schur's Theorem[3]

Let $\mathbf{A} = [a_{jk}]$ *be an* $n \times n$ *matrix. Then for each of its eigenvalues* $\lambda_1, \cdots, \lambda_n$,

$$|\lambda_m|^2 \leqq \sum_{i=1}^{n} |\lambda_i|^2 \leqq \sum_{j=1}^{n} \sum_{k=1}^{n} |a_{jk}|^2 \quad \textbf{(Schur's inequality).} \tag{4}$$

In (4) *the second equality sign holds if and only if* $\mathbf{A}$ *is such that*

$$\bar{\mathbf{A}}^{\mathsf{T}}\mathbf{A} = \mathbf{A}\bar{\mathbf{A}}^{\mathsf{T}}. \tag{5}$$

Matrices that satisfy (5) are called **normal matrices.** It is not difficult to see that Hermitian, skew-Hermitian, and unitary matrices are normal, and so are real symmetric, skew-symmetric, and orthogonal matrices.

EXAMPLE 3 **Bounds for Eigenvalues Obtained from Schur's Inequality**

For the matrix

$$\mathbf{A} = \begin{bmatrix} 26 & -2 & 2 \\ 2 & 21 & 4 \\ 4 & 2 & 28 \end{bmatrix}$$

we obtain from Schur's inequality $|\lambda| \leqq \sqrt{1949} = 44.1475$. You may verify that the eigenvalues are 30, 25, and 20. Thus $30^2 + 25^2 + 20^2 = 1925 < 1949$; in fact, $\mathbf{A}$ is not normal. ■

The preceding theorems are valid for every real or complex square matrix. Other theorems hold for special classes of matrices only. Famous is the following.

THEOREM 5

Perron's Theorem[4]

Let $\mathbf{A}$ *be a real* $n \times n$ *matrix whose entries are all positive. Then* $\mathbf{A}$ *has a positive real eigenvalue* $\lambda = \rho$ *of multiplicity* 1. *The corresponding eigenvector can be chosen with all components positive. (The other eigenvalues are less than* ρ *in absolute value.)*

For a proof see Ref. [B3], vol. II, pp. 53–62. The theorem also holds for matrices with *nonnegative* real entries (**"Perron–Frobenius Theorem"**[4]) provided $\mathbf{A}$ is **irreducible,** that is, it cannot be brought to the following form by interchanging rows and columns; here $\mathbf{B}$ and $\mathbf{F}$ are square and $\mathbf{0}$ is a zero matrix.

$$\begin{bmatrix} \mathbf{B} & \mathbf{C} \\ \mathbf{0} & \mathbf{F} \end{bmatrix}$$

[3]ISSAI SCHUR (1875–1941), German mathematician, also known by his important work in group theory.

[4]OSKAR PERRON (1880–1975), GEORG FROBENIUS (1849–1917), LOTHAR COLLATZ (1910–1990), German mathematicians, known for their work in potential theory, ODEs (Sec. 5.4) and group theory, and numerics, respectively.

Perron's theorem has various applications, for instance, in economics. It is interesting that one can obtain from it a theorem that gives a numeric algorithm:

THEOREM 6

Collatz Inclusion Theorem[4]

Let $\mathbf{A} = [a_{jk}]$ *be a real* $n \times n$ *matrix whose elements are all positive. Let* $\mathbf{x}$ *be any real vector whose components* $x_1, \cdots, x_n$ *are positive, and let* $y_1, \cdots, y_n$ *be the components of the vector* $\mathbf{y} = \mathbf{Ax}$. *Then the closed interval on the real axis bounded by the smallest and the largest of the* n *quotients* $q_j = y_j/x_j$ *contains at least one eigenvalue of* $\mathbf{A}$.

PROOF We have $\mathbf{Ax} = \mathbf{y}$ or

$$\mathbf{y} - \mathbf{Ax} = \mathbf{0}. \tag{6}$$

The transpose $\mathbf{A}^T$ satisfies the conditions of Theorem 5. Hence $\mathbf{A}^T$ has a positive eigenvalue λ and, corresponding to this eigenvalue, an eigenvector $\mathbf{u}$ whose components u_j are all positive. Thus $\mathbf{A}^T\mathbf{u} = \lambda\mathbf{u}$, and by taking the transpose we obtain $\mathbf{u}^T\mathbf{A} = \lambda\mathbf{u}^T$. From this and (6) we have

$$\mathbf{u}^T(\mathbf{y} - \mathbf{Ax}) = \mathbf{u}^T\mathbf{y} - \mathbf{u}^T\mathbf{Ax} = \mathbf{u}^T\mathbf{y} - \lambda\mathbf{u}^T\mathbf{x} = \mathbf{u}^T(\mathbf{y} - \lambda\mathbf{x}) = 0$$

or written out

$$\sum_{j=1}^{n} u_j(y_j - \lambda x_j) = 0.$$

Since all the components u_j are positive, it follows that

$$\begin{array}{llll} y_j - \lambda x_j \geqq 0, & \text{that is,} & q_j \geqq \lambda & \text{for at least one } j, \\ y_j - \lambda x_j \leqq 0, & \text{that is,} & q_j \leqq \lambda & \text{for at least one } j. \end{array} \quad \text{and} \tag{7}$$

Since $\mathbf{A}$ and $\mathbf{A}^T$ have the same eigenvalues, λ is an eigenvalue of $\mathbf{A}$, and from (7) the statement of the theorem follows. ∎

EXAMPLE 4 **Bounds for Eigenvalues from Collatz's Theorem. Iteration**

For a given matrix $\mathbf{A}$ with positive entries we choose an $\mathbf{x} = \mathbf{x}_0$ and **iterate**, that is, we compute $\mathbf{x}_1 = \mathbf{Ax}_0$, $\mathbf{x}_2 = \mathbf{Ax}_1, \cdots, \mathbf{x}_{20} = \mathbf{Ax}_{19}$. In each step, taking $\mathbf{x} = \mathbf{x}_j$ and $\mathbf{y} = \mathbf{Ax}_j = \mathbf{x}_{j+1}$ we compute an inclusion interval by Collatz's theorem. This gives (6S)

$$\mathbf{A} = \begin{bmatrix} 0.49 & 0.02 & 0.22 \\ 0.02 & 0.28 & 0.20 \\ 0.22 & 0.20 & 0.40 \end{bmatrix}, \quad \mathbf{x}_0 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \quad \mathbf{x}_1 = \begin{bmatrix} 0.73 \\ 0.50 \\ 0.82 \end{bmatrix}, \quad \mathbf{x}_2 = \begin{bmatrix} 0.5481 \\ 0.3186 \\ 0.5886 \end{bmatrix},$$

$$\cdots, \quad \mathbf{x}_{19} = \begin{bmatrix} 0.00216309 \\ 0.00108155 \\ 0.00216309 \end{bmatrix}, \quad \mathbf{x}_{20} = \begin{bmatrix} 0.00155743 \\ 0.000778713 \\ 0.00155743 \end{bmatrix}$$

and the intervals $0.5 \leqq \lambda \leqq 0.82$, $0.3186/0.50 = 0.6372 \leqq \lambda \leqq 0.5481/0.73 = 0.750822$, etc. These intervals have length

j	1	2	3	10	15	20
Length	0.32	0.113622	0.0539835	0.0004217	0.0000132	0.0000004

Using the characteristic polynomial, you may verify that the eigenvalues of $\mathbf{A}$ are 0.72, 0.36, 0.09, so that those intervals include the largest eigenvalue, 0.72. Their lengths decreased with j, so that the iteration was worthwhile. The reason will appear in the next section, where we discuss an iteration method for eigenvalues. ■

PROBLEM SET 20.7

1–6 GERSCHGORIN DISKS

Find and sketch disks or intervals that contain the eigenvalues. If you have a CAS, find the spectrum and compare.

1. $\begin{bmatrix} 6 & -1 & 0 \\ -1 & 7 & 1 \\ 0 & 1 & 8 \end{bmatrix}$

2. $\begin{bmatrix} 5 & 10^{-2} & 10^{-2} \\ 10^{-2} & 8 & 10^{-2} \\ 10^{-2} & 10^{-2} & 9 \end{bmatrix}$

3. $\begin{bmatrix} 5 & -2 & 2 \\ 2 & 0 & 4 \\ 4 & 2 & 7 \end{bmatrix}$

4. $\begin{bmatrix} 1+i & 0.3 & 0.5i \\ 0.3i & -3+2i & 0.1 \\ 0.1i & 0.2 & 4-i \end{bmatrix}$

5. $\begin{bmatrix} 4i & 0.1i & 1+i \\ 0.1i & 0 & 0 \\ -1+i & 0 & 9i \end{bmatrix}$

6. $\begin{bmatrix} 10 & 0.1 & -0.2 \\ 0.1 & 6 & 0 \\ -0.2 & 0 & 3 \end{bmatrix}$

7. (Similarity) Find $\mathbf{T}^{-\mathrm{T}}\mathbf{A}\mathbf{T}$ such that in Prob. 2 the radius of the Gerschgorin circle with center 5 is reduced by a factor 1/100.

8. By what integer factor can you at most reduce the Gerschgorin circle with center 3 in Prob. 6?

9. If a symmetric $n \times n$ matrix $\mathbf{A} = [a_{jk}]$ has been diagonalized except for small off-diagonal entries of size 10^{-6}, what can you say about the eigenvalues?

10. (Extended Gerschgorin theorem) Prove Theorem 2.

11. Prove Theorem 3.

12. (Normal matrices) Show that Hermitian, skew-Hermitian, and unitary matrices (hence real symmetric, skew-symmetric, and orthogonal matrices) are normal. Why is this of practical interest?

13. (Spectral radius $\rho(\mathbf{A})$) Show that $\rho(\mathbf{A})$ cannot be greater than the row sum norm of $\mathbf{A}$.

14. (Eigenvalues on the circle) Illustrate with a 2×2 matrix that an eigenvalue may very well lie on a Gerschgorin circle (so that Gerschgorin disks can generally not be replaced with smaller disks without losing the inclusion property).

15–17 SCHUR'S INEQUALITY

Use (4) to obtain an upper bound for the spectral radius:

15. In Prob. 1

16. In Prob. 6

17. In Prob. 3

18–19 COLLATZ'S THEOREM

Apply Theorem 6, choosing the given vectors as vectors $\mathbf{x}$.

18. $\begin{bmatrix} 10 & 1 & 1 \\ 1 & 9 & 3 \\ 1 & 3 & 11 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 2 \\ 3 \\ 2 \end{bmatrix}$

19. $\begin{bmatrix} 4 & 2 & 2 \\ 2 & 4 & 2 \\ 2 & 2 & 4 \end{bmatrix}, \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$

20. CAS EXPERIMENT. Collatz Iteration. **(a)** Write a program for the iteration in Example 4 (with any $\mathbf{A}$ and $\mathbf{x}_0$) that at each step prints the midpoint (why?), the endpoints, and the length of the inclusion interval.

(b) Apply the program to symmetric matrices of your choice. Explore how convergence depends on the choice of initial vectors. Can you construct cases in which the lengths of the inclusion intervals are not monotone decreasing? Can you explain the reason? Can you experiment on the effect of rounding?

20.8 Power Method for Eigenvalues

A simple standard procedure for computing approximate values of the eigenvalues of an $n \times n$ matrix $\mathbf{A} = [a_{jk}]$ is the **power method.** In this method we start from any vector $\mathbf{x}_0$ ($\neq \mathbf{0}$) with n components and compute successively

$$\mathbf{x}_1 = \mathbf{A}\mathbf{x}_0, \qquad \mathbf{x}_2 = \mathbf{A}\mathbf{x}_1, \qquad \cdots, \qquad \mathbf{x}_s = \mathbf{A}\mathbf{x}_{s-1}.$$

For simplifying notation, we denote $\mathbf{x}_{s-1}$ by $\mathbf{x}$ and $\mathbf{x}_s$ by $\mathbf{y}$, so that $\mathbf{y} = \mathbf{A}\mathbf{x}$.

The method applies to any $n \times n$ matrix $\mathbf{A}$ that has a **dominant eigenvalue** (a λ such that $|\lambda|$ is greater than the absolute values of the other eigenvalues). If $\mathbf{A}$ is *symmetric,* it also gives the error bound (2), in addition to the approximation (1).

THEOREM 1

Power Method, Error Bounds

Let $\mathbf{A}$ be an $n \times n$ real symmetric matrix. Let $\mathbf{x}$ ($\neq \mathbf{0}$) be any real vector with n components. Furthermore, let

$$\mathbf{y} = \mathbf{A}\mathbf{x}, \qquad m_0 = \mathbf{x}^\mathsf{T}\mathbf{x}, \qquad m_1 = \mathbf{x}^\mathsf{T}\mathbf{y}, \qquad m_2 = \mathbf{y}^\mathsf{T}\mathbf{y}.$$

Then the quotient

(1) $$q = \frac{m_1}{m_0}$$ **(Rayleigh[5] quotient)**

is an approximation for an eigenvalue λ of $\mathbf{A}$ (usually that which is greatest in absolute value, but no general statements are possible).

Furthermore, if we set $q = \lambda - \epsilon$, so that ϵ is the error of q, then

(2) $$|\epsilon| \leqq \delta = \sqrt{\frac{m_2}{m_0} - q^2}.$$

[5]LORD RAYLEIGH (JOHN WILLIAM STRUTT) (1842–1919), great English physicist and mathematician, professor at Cambridge and London, known for his important contributions to various branches of applied mathematics and theoretical physics, in particular, the theory of waves, elasticity, and hydrodynamics. In 1904 he received a Nobel Prize in physics.

PROOF δ^2 denotes the radicand in (2). Since $m_1 = qm_0$ by (1), we have

$$(3) \qquad (\mathbf{y} - q\mathbf{x})^\mathsf{T}(\mathbf{y} - q\mathbf{x}) = m_2 - 2qm_1 + q^2m_0 = m_2 - q^2m_0 = \delta^2 m_0.$$

Since $\mathbf{A}$ is real symmetric, it has an orthogonal set of n real unit eigenvectors $\mathbf{z}_1, \cdots, \mathbf{z}_n$ corresponding to the eigenvalues $\lambda_1, \cdots, \lambda_n$, respectively (some of which may be equal). (Proof in Ref. [B3], vol. 1, pp. 270–272, listed in App. 1.) Then $\mathbf{x}$ has a representation of the form

$$\mathbf{x} = a_1\mathbf{z}_1 + \cdots + a_n\mathbf{z}_n.$$

Now $\mathbf{A}\mathbf{z}_1 = \lambda_1\mathbf{z}_1$, etc., and we obtain

$$\mathbf{y} = \mathbf{A}\mathbf{x} = a_1\lambda_1\mathbf{z}_1 + \cdots + a_n\lambda_n\mathbf{z}_n$$

and, since the $\mathbf{z}_j$ are orthogonal unit vectors,

$$(4) \qquad m_0 = \mathbf{x}^\mathsf{T}\mathbf{x} = {a_1}^2 + \cdots + {a_n}^2.$$

It follows that in (3),

$$\mathbf{y} - q\mathbf{x} = a_1(\lambda_1 - q)\mathbf{z}_1 + \cdots + a_n(\lambda_n - q)\mathbf{z}_n.$$

Since the $\mathbf{z}_j$ are orthogonal unit vectors, we thus obtain from (3)

$$(5) \qquad \delta^2 m_0 = (\mathbf{y} - q\mathbf{x})^\mathsf{T}(\mathbf{y} - q\mathbf{x}) = {a_1}^2(\lambda_1 - q)^2 + \cdots + {a_n}^2(\lambda_n - q)^2.$$

Now let λ_c be an eigenvalue of $\mathbf{A}$ to which q is closest, where c suggests "closest". Then $(\lambda_c - q)^2 \leqq (\lambda_j - q)^2$ for $j = 1, \cdots, n$. From this and (5) we obtain the inequality

$$\delta^2 m_0 \geqq (\lambda_c - q)^2({a_1}^2 + \cdots + {a_n}^2) = (\lambda_c - q)^2 m_0.$$

Dividing by m_0, taking square roots, and recalling the meaning of δ^2 gives

$$\delta = \sqrt{\frac{m_2}{m_0} - q^2} \geqq |\lambda_c - q|.$$

This shows that δ is a bound for the error ϵ of the approximation q of an eigenvalue of $\mathbf{A}$ and completes the proof. ∎

The main advantage of the method is its simplicity. And it can handle *sparse matrices* too large to store as a full square array. Its disadvantage is its possibly slow convergence. From the proof of Theorem 1 we see that the speed of convergence depends on the ratio of the dominant eigenvalue to the next in absolute value (2:1 in Example 1, below).

If we want a convergent sequence of **eigenvectors,** then at the beginning of each step we **scale** the vector, say, by dividing its components by an absolutely largest one, as in Example 1, as follows.

EXAMPLE 1 Application of Theorem 1. Scaling

For the symmetric matrix $\mathbf{A}$ in Example 4, Sec. 20.7, and $\mathbf{x}_0 = [1 \quad 1 \quad 1]^T$ we obtain from (1) and (2) and the indicated scaling

$$\mathbf{A} = \begin{bmatrix} 0.49 & 0.02 & 0.22 \\ 0.02 & 0.28 & 0.20 \\ 0.22 & 0.20 & 0.40 \end{bmatrix}, \quad \mathbf{x}_0 = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \quad \mathbf{x}_1 = \begin{bmatrix} 0.890244 \\ 0.609756 \\ 1 \end{bmatrix}, \quad \mathbf{x}_2 = \begin{bmatrix} 0.931193 \\ 0.541284 \\ 1 \end{bmatrix}$$

$$\mathbf{x}_5 = \begin{bmatrix} 0.990663 \\ 0.504682 \\ 1 \end{bmatrix}, \qquad \mathbf{x}_{10} = \begin{bmatrix} 0.999707 \\ 0.500146 \\ 1 \end{bmatrix}, \qquad \mathbf{x}_{15} = \begin{bmatrix} 0.999991 \\ 0.500005 \\ 1 \end{bmatrix}.$$

Here $\mathbf{A}\mathbf{x}_0 = [0.73 \quad 0.5 \quad 0.82]^T$, scaled to $\mathbf{x}_1 = [0.73/0.82 \quad 0.5/0.82 \quad 1]^T$, etc. The dominant eigenvalue is 0.72, an eigenvector $[1 \quad 0.5 \quad 1]^T$. The corresponding q and δ are computed each time before the next scaling. Thus in the first step,

$$q = \frac{m_1}{m_0} = \frac{\mathbf{x}_0^T \mathbf{A}\mathbf{x}_0}{\mathbf{x}_0^T \mathbf{x}_0} = \frac{2.05}{3} = 0.683333$$

$$\delta = \left(\frac{m_2}{m_0} - q^2 \right)^{1/2} = \left(\frac{(\mathbf{A}\mathbf{x}_0)^T \mathbf{A}\mathbf{x}_0}{\mathbf{x}_0^T \mathbf{x}_0} - q^2 \right)^{1/2} = \left(\frac{1.4553}{3} - q^2 \right)^{1/2} = 0.134743.$$

This gives the following values of q, δ, and the error $\epsilon = 0.72 - q$ (calculations with 10D, rounded to 6D):

j	1	2	5	10
q	0.683333	0.716048	0.719944	0.720000
δ	0.134743	0.038887	0.004499	0.000141
ϵ	0.036667	0.003952	0.000056	$5 \cdot 10^{-8}$

The error bounds are much larger than the actual errors. This is typical, although the bounds cannot be improved; that is, for special symmetric matrices they agree with the errors.

Our present results are somewhat better than those of Collatz's method in Example 4 of Sec. 20.7, at the expense of more operations. ■

Spectral shift, the transition from $\mathbf{A}$ to $\mathbf{A} - k\mathbf{I}$, shifts every eigenvalue by $-k$. Although finding a good k can hardly be made automatic, it may be helped by some other method or small preliminary computational experiments. In Example 1, Gerschgorin's theorem gives $-0.02 \leqq \lambda \leqq 0.82$ for the whole spectrum (verify!). Shifting by -0.4 might be too much (then $-0.42 \leqq \lambda \leqq 0.42$), so let us try -0.2.

EXAMPLE 2 Power Method with Spectral Shift

For $\mathbf{A} - 0.2\mathbf{I}$ with $\mathbf{A}$ as in Example 1 we obtain the following substantial improvements (where the index 1 refers to Example 1 and the index 2 to the present example).

j	1	2	5	10
δ_1	0.134743	0.038887	0.004499	0.000141
δ_2	0.134743	0.034474	0.000693	$1.8 \cdot 10^{-6}$
ϵ_1	0.036667	0.003952	0.000056	$5 \cdot 10^{-8}$
ϵ_2	0.036667	0.002477	$1.3 \cdot 10^{-6}$	$9 \cdot 10^{-12}$

■

PROBLEM SET 20.8

1–7 POWER METHOD WITH SCALING

Apply the power method (3 steps) with scaling, using $\mathbf{x}_0 = [1 \quad 1]^T$ or $[1 \quad 1 \quad 1]^T$ or $[1 \quad 1 \quad 1 \quad 1]^T$, as applicable. Give Rayleigh quotients and error bounds. Show the details of your work.

1. $\begin{bmatrix} 3.5 & 2.0 \\ 2.0 & 0.5 \end{bmatrix}$ **2.** $\begin{bmatrix} 0.6 & 0.8 \\ 0.8 & -0.6 \end{bmatrix}$

3. $\begin{bmatrix} 5 & 2 \\ 2 & 7 \end{bmatrix}$

4. $\begin{bmatrix} -2 & 2 & 3 \\ 2 & 1 & 6 \\ 3 & 6 & -2 \end{bmatrix}$ **5.** $\begin{bmatrix} 2 & -1 & 1 \\ -1 & 3 & 2 \\ 1 & 2 & 3 \end{bmatrix}$

6. $\begin{bmatrix} 0 & 4 & 0 & 1 \\ 4 & -1 & 2 & 8 \\ 0 & 2 & 3 & 2 \\ 1 & 8 & 2 & -2 \end{bmatrix}$ **7.** $\begin{bmatrix} 5 & 1 & 0 & 0 \\ 1 & 3 & 1 & 0 \\ 0 & 1 & 3 & 1 \\ 0 & 0 & 1 & 5 \end{bmatrix}$

8. (Optimality of δ) In Prob. 2 choose $\mathbf{x}_0 = [3 \quad -1]^T$ and show that $q = 0$ and $\delta = 1$ for all steps and that the eigenvalues are ± 1, so that the interval $[q - \delta, q + \delta]$ cannot be shortened in general! Experiment with other $\mathbf{x}_0$.

9. Prove that if $\mathbf{x}$ is an eigenvector, then $\delta = 0$ in (2). Give two examples.

10. (Rayleigh quotient) Why does q generally approximate the eigenvalue of greatest absolute value? When will q be a good approximation?

11. (Spectral shift, smallest eigenvalue) In Prob. 5 set $\mathbf{B} = \mathbf{A} - 3\mathbf{I}$ (as perhaps suggested by the diagonal entries) and try whether you may get a sequence of q's converging to an eigenvalue of $\mathbf{A}$ that *is smallest* (not largest) in absolute value. Use $\mathbf{x}_0 = [1 \quad 1 \quad 1]^T$. Do 8 steps. Verify that $\mathbf{A}$ has the spectrum $\{0, 3, 5\}$.

12. CAS EXPERIMENT. Power Method with Scaling. Shifting. (a) Write a program for $n \times n$ matrices that prints every step. Apply it to the (nonsymmetric!) matrix (20 steps), starting from $[1 \quad 1 \quad 1]^T$.

$$\mathbf{A} = \begin{bmatrix} 15 & 12 & 3 \\ 18 & 44 & 18 \\ -19 & -36 & -7 \end{bmatrix}.$$

(b) Experiment in (a) with shifting. Which shift do you find optimal?

(c) Write a program as in (a) but for symmetric matrices that prints vectors, scaled vectors, q, and δ. Apply it to the matrix in Prob. 6.

(d) Find a (nonsymmetric) matrix for which δ in (2) is no longer an error bound.

(e) Experiment systematically with speed of convergence by choosing matrices with the second greatest eigenvalue (i) almost equal to the greatest, (ii) somewhat different, (iii) much different.

20.9 Tridiagonalization and QR-Factorization

We consider the problem of computing *all* the eigenvalues of a ***real symmetric*** matrix $\mathbf{A} = [a_{jk}]$, discussing a method widely used in practice. In the ***first stage*** we reduce the given matrix stepwise to a **tridiagonal matrix,** that is, a matrix having all its nonzero entries on the main diagonal and in the positions immediately adjacent to the main diagonal (such as $\mathbf{A}_3$ in Fig. 447, Third Step). This reduction was invented by A. S. Householder (*J. Assn. Comput. Machinery* **5** (1958), 335–342). See also Ref. [E29] in App. 1.

This Householder tridiagonalization will simplify the matrix without changing its eigenvalues. The latter will then be determined (approximately) by factoring the tridiagonalized matrix, as discussed later in this section.

Householder's Tridiagonalization Method

An $n \times n$ real symmetric matrix $\mathbf{A} = [a_{jk}]$ being given, we reduce it by $n - 2$ successive similarity transformations (see Sec. 20.6) involving matrices $\mathbf{P}_1, \cdots, \mathbf{P}_{n-2}$ to tridiagonal form. These matrices are orthogonal and symmetric. Thus $\mathbf{P}_1^{-1} = \mathbf{P}_1^{\mathsf{T}} = \mathbf{P}_1$ and similarly for the others. These transformations produce from the given $\mathbf{A}_0 = \mathbf{A} = [a_{jk}]$ the matrices $\mathbf{A}_1 = \left[a_{jk}^{(1)}\right]$, $\mathbf{A}_2 = \left[a_{jk}^{(2)}\right]$, $\cdots$, $\mathrm{A}_{n-2} = \left[a_{jk}^{(n-2)}\right]$ in the form

$$\begin{aligned} \mathbf{A}_1 &= \mathbf{P}_1\mathbf{A}_0\mathbf{P}_1 \\ \mathbf{A}_2 &= \mathbf{P}_2\mathbf{A}_1\mathbf{P}_2 \\ &\cdots\cdots\cdots\cdots \\ \mathbf{B} = \mathbf{A}_{n-2} &= \mathbf{P}_{n-2}\mathbf{A}_{n-3}\mathbf{P}_{n-2}. \end{aligned} \tag{1}$$

The transformations (1) create the necessary zeros, in the first step in Row 1 and Column 1, in the second step in Row 2 and Column 2, etc., as Fig. 447 illustrates for a 5×5 matrix. $\mathbf{B}$ is tridiagonal.

How do we determine $\mathbf{P}_1, \mathbf{P}_2, \cdots \mathbf{P}_{n-2}$? Now, all these $\mathbf{P}_r$ are of the form

$$\mathbf{P}_r = \mathbf{I} - 2\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}} \qquad (r = 1, \cdots, n-2) \tag{2}$$

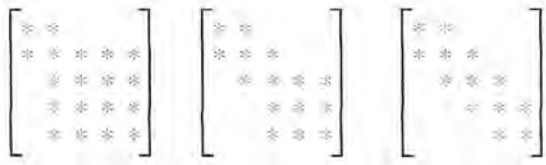
where $\mathbf{I}$ is the $n \times n$ unit matrix and $\mathbf{v}_r = [v_{jr}]$ is a unit vector with its first r components 0; thus

$$\mathbf{v}_1 = \begin{bmatrix} 0 \\ * \\ * \\ \vdots \\ * \end{bmatrix}, \qquad \mathbf{v}_2 = \begin{bmatrix} 0 \\ 0 \\ * \\ \vdots \\ * \end{bmatrix}, \qquad \cdots, \qquad \mathbf{v}_{n-2} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ * \\ * \end{bmatrix} \tag{3}$$

where the asterisks denote the other components (which will be nonzero in general).

Step 1. $\mathbf{v}_1$ has the components

$$v_{11} = 0$$



$$\text{(a)} \qquad v_{21} = \sqrt{\frac{1}{2}\left(1 + \frac{|a_{21}|}{S_1}\right)}$$

$$\text{(b)} \qquad v_{j1} = \frac{a_{j1} \operatorname{sgn} a_{21}}{2v_{21}S_1} \qquad j = 3, 4, \cdots, n \tag{4}$$

where

$$\text{(c)} \qquad S_1 = \sqrt{a_{21}^2 + a_{31}^2 + \cdots + a_{n1}^2}$$

where $S_1 > 0$, and $\operatorname{sgn} a_{21} = +1$ if $a_{21} \geqq 0$ and $\operatorname{sgn} a_{21} = -1$ if $a_{21} < 0$. With this we compute $\mathbf{P}_1$ by (2) and then $\mathbf{A}_1$ by (1). This was the first step.

First Step $\mathbf{A}_1 = \mathbf{P}_1\mathbf{A}\mathbf{P}_1$ Second Step $\mathbf{A}_2 = \mathbf{P}_2\mathbf{A}_1\mathbf{P}_2$ Third Step $\mathbf{A}_3 = \mathbf{P}_3\mathbf{A}_2\mathbf{P}_3$

Fig. 447. Householder's method for a 5×5 matrix. Positions left blank are zeros created by the method.

Step 2. We compute $\mathbf{v}_2$ by (4) with all subscripts increased by 1 and the a_{jk} replaced by $a_{jk}^{(1)}$, the entries of $\mathbf{A}_1$ just computed. Thus [see also (3)]

$$v_{12} = v_{22} = 0$$

$$\text{(4*)} \qquad v_{32} = \sqrt{\frac{1}{2}\left(1 + \frac{|a_{32}^{(1)}|}{S_2}\right)}$$

$$v_{j2} = \frac{a_{j2}^{(1)} \operatorname{sgn} a_{32}^{(1)}}{2v_{32}S_2} \qquad j = 4, 5, \cdots, n$$

where

$$S_2 = \sqrt{a_{32}^{(1)2} + a_{42}^{(1)2} + \cdots + a_{n2}^{(1)2}}.$$

With this we compute $\mathbf{P}_2$ by (2) and then $\mathbf{A}_2$ by (1).

Step 3. We compute $\mathbf{v}_3$ by (4*) with all subscripts increased by 1 and the $a_{jk}^{(1)}$ replaced by the entries $a_{jk}^{(2)}$ of $\mathbf{A}_2$, and so on.

EXAMPLE 1 **Householder Tridiagonalization**

Tridiagonalize the real symmetric matrix

$$\mathbf{A} = \mathbf{A}_0 = \begin{bmatrix} 6 & 4 & 1 & 1 \\ 4 & 6 & 1 & 1 \\ 1 & 1 & 5 & 2 \\ 1 & 1 & 2 & 5 \end{bmatrix}.$$

Solution. ***Step 1.*** We compute $S_1^2 = 4^2 + 1^2 + 1^2 = 18$ from (4c). Since $a_{21} = 4 > 0$, we have $\operatorname{sgn} a_{21} = +1$ in (4b) and get from (4) by straightforward computation

$$\mathbf{v}_1 = \begin{bmatrix} 0 \\ v_{21} \\ v_{31} \\ v_{41} \end{bmatrix} = \begin{bmatrix} 0 \\ 0.985\,598\,56 \\ 0.119\,573\,16 \\ 0.119\,573\,16 \end{bmatrix}.$$

From this and (2),

$$\mathbf{P}_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -0.942\,809\,04 & -0.235\,702\,27 & -0.235\,702\,27 \\ 0 & -0.235\,702\,27 & 0.971\,404\,52 & -0.028\,595\,48 \\ 0 & -0.235\,702\,27 & -0.028\,595\,48 & 0.971\,404\,52 \end{bmatrix}.$$

From the first line in (1) we now get

$$\mathbf{A}_1 = \mathbf{P}_1\mathbf{A}_0\mathbf{P}_1 = \begin{bmatrix} 6 & -\sqrt{18} & 0 & 0 \\ -\sqrt{18} & 7 & -1 & -1 \\ 0 & -1 & 9/2 & 3/2 \\ 0 & -1 & 3/2 & 9/2 \end{bmatrix}.$$

Step 2. From (4*) we compute $s_2^2 = 2$ and

$$\mathbf{v}_2 = \begin{bmatrix} 0 \\ 0 \\ v_{32} \\ v_{42} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0.923\,879\,53 \\ 0.382\,683\,43 \end{bmatrix}.$$

From this and (2),

$$\mathbf{P}_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1/\sqrt{2} & -1/\sqrt{2} \\ 0 & 0 & -1\sqrt{2} & 1/\sqrt{2} \end{bmatrix}.$$

The second line in (1) now gives

$$\mathbf{B} = \mathbf{A}_2 = \mathbf{P}_2\mathbf{A}_1\mathbf{P}_2 = \begin{bmatrix} 6 & -\sqrt{18} & 0 & 0 \\ -\sqrt{18} & 7 & \sqrt{2} & 0 \\ 0 & \sqrt{2} & 6 & 0 \\ 0 & 0 & 0 & 3 \end{bmatrix}.$$

This matrix $\mathbf{B}$ is tridiagonal. Since our given matrix has order $n = 4$, we needed $n - 2 = 2$ steps to accomplish this reduction, as claimed. (Do you see that we got more zeros than we can expect in general?)

$\mathbf{B}$ is similar to $\mathbf{A}$, as we now show in general. This is essential because $\mathbf{B}$ thus has the same spectrum as $\mathbf{A}$, by Theorem 2 in Sec. 20.6. ■

B *Similar to* A. We assert that $\mathbf{B}$ in (1) is similar to $\mathbf{A} = \mathbf{A}_0$. The matrix $\mathbf{P}_r$ is symmetric; indeed,

$$\mathbf{P}_r^{\mathsf{T}} = (\mathbf{I} - 2\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}})^{\mathsf{T}} = \mathbf{I}^{\mathsf{T}} - 2(\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}})^{\mathsf{T}} = \mathbf{I} - 2\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}} = \mathbf{P}_r.$$

Also, $\mathbf{P}_r$ is orthogonal because $\mathbf{v}_r$ is a unit vector, so that $\mathbf{v}_r^{\mathsf{T}}\mathbf{v}_r = 1$ and thus

$$\begin{aligned} \mathbf{P}_r\mathbf{P}_r^{\mathsf{T}} = \mathbf{P}_r^2 = (\mathbf{I} - 2\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}})^2 &= \mathbf{I} - 4\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}} + 4\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}}\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}} \\ &= \mathbf{I} - 4\mathbf{v}_r\mathbf{v}_r^{\mathsf{T}} + 4\mathbf{v}_r(\mathbf{v}_r^{\mathsf{T}}\mathbf{v}_r)\mathbf{v}_r^{\mathsf{T}} = \mathbf{I}. \end{aligned}$$

Hence $\mathbf{P}_r^{-1} = \mathbf{P}_r^{\mathsf{T}} = \mathbf{P}_r$ and from (1) we now obtain

$$\begin{aligned} \mathbf{B} &= \mathbf{P}_{n-2}\mathbf{A}_{n-3}\mathbf{P}_{n-2} = \cdots \\ \cdots &= \mathbf{P}_{n-2}\mathbf{P}_{n-3}\cdots\mathbf{P}_1\mathbf{A}\mathbf{P}_1\cdots\mathbf{P}_{n-3}\mathbf{P}_{n-2} \\ &= \mathbf{P}_{n-2}^{-1}\mathbf{P}_{n-3}^{-1}\cdots\mathbf{P}_1^{-1}\mathbf{A}\mathbf{P}_1\cdots\mathbf{P}_{n-3}\mathbf{P}_{n-2} \\ &= \mathbf{P}^{-1}\mathbf{A}\mathbf{P} \end{aligned}$$

where $\mathbf{P} = \mathbf{P}_1\mathbf{P}_2\cdots\mathbf{P}_{n-2}$. This proves our assertion. ■

QR-Factorization Method

In 1958 H. Rutishauser of Switzerland proposed the idea of using the LU-factorization (Sec. 20.2; he called it LR-factorization) in solving eigenvalue problems. An improved version of Rutishauser's method (avoiding breakdown if certain submatrices become singular, etc.; see Ref. [E29]) is the QR-method, independently proposed by the American J. G. F. Francis (*Computer J.* **4** (1961–62), 265–271, 332–345) and the Russian V. N. Kublanovskaya (*Zhurnal Vych. Mat. i Mat. Fiz.* **1** (1961), 555–570). The QR-method uses the factorization **QR** with orthogonal **Q** and upper triangular **R.** We discuss the QR-method for a real ***symmetric*** matrix. (For extensions to general matrices see Ref. [E29] in App. 1.)

In this method we first transform a given real symmetric $n \times n$ matrix $\mathbf{A}$ into a tridiagonal matrix $\mathbf{B}_0 = \mathbf{B}$ by Householder's method. This creates many zeros and thus reduces the amount of further work. Then we compute $\mathbf{B}_1, \mathbf{B}_2, \cdots$ stepwise according to the following iteration method.

Step 1. Factor $\mathbf{B}_0 = \mathbf{Q}_0\mathbf{R}_0$ with orthogonal $\mathbf{R}_0$ and upper triangular $\mathbf{R}_0$. Then compute $\mathbf{B}_1 = \mathbf{R}_0\mathbf{Q}_0$.

Step 2. Factor $\mathbf{B}_1 = \mathbf{Q}_1\mathbf{R}_1$. Then compute $\mathbf{B}_2 = \mathbf{R}_1\mathbf{Q}_1$.

General Step s + 1.

$$\textbf{(5)} \qquad \begin{aligned} &\textbf{(a)} \qquad \text{Factor } \mathbf{B}_s = \mathbf{Q}_s\mathbf{R}_s. \\ &\textbf{(b)} \qquad \text{Compute } \mathbf{B}_{s+1} = \mathbf{R}_s\mathbf{Q}_s. \end{aligned}$$

Here $\mathbf{Q}_s$ is orthogonal and $\mathbf{R}_s$ upper triangular. The factorization (5a) will be explained below.

$\mathbf{B}_{s+1}$ Similar to B. Convergence to a Diagonal Matrix. From (5a) we have $\mathbf{R}_s = \mathbf{Q}_s^{-1}\mathbf{B}_s$. Substitution into (5b) gives

$$\mathbf{B}_{s+1} = \mathbf{R}_s\mathbf{Q}_s = \mathbf{Q}_s^{-1}\mathbf{B}_s\mathbf{Q}_s. \tag{6}$$

Thus $\mathbf{B}_{s+1}$ is similar to $\mathbf{B}_s$. Hence $\mathbf{B}_{s+1}$ is similar to $\mathbf{B}_0 = \mathbf{B}$ for all s. By Theorem 2, Sec. 20.6, this implies that $\mathbf{B}_{s+1}$ has the same eigenvalues as $\mathbf{B}$.

Also, $\mathbf{B}_{s+1}$ is symmetric. This follows by induction. Indeed, $\mathbf{B}_0 = \mathbf{B}$ is symmetric. Assuming $\mathbf{B}_s$ to be symmetric, that is, $\mathbf{B}_s^{\mathsf{T}} = \mathbf{B}_s$, and using $\mathbf{Q}_s^{-1} = \mathbf{Q}_s^{\mathsf{T}}$ (since $\mathbf{Q}_s$ is orthogonal), we get from (6) the symmetry,

$$\mathbf{B}_{s+1}^{\mathsf{T}} = (\mathbf{Q}_s^{\mathsf{T}}\mathbf{B}_s\mathbf{Q}_s)^{\mathsf{T}} = \mathbf{Q}_s^{\mathsf{T}}\mathbf{B}_s^{\mathsf{T}}\mathbf{Q}_s = \mathbf{Q}_s^{\mathsf{T}}\mathbf{B}_s\mathbf{Q}_s = \mathbf{B}_{s+1}.$$

If the eigenvalues of $\mathbf{B}$ are different in absolute value, say, $|\lambda_1| > |\lambda_2| > \cdots > |\lambda_n|$, then

$$\lim_{s\to\infty} \mathbf{B}_s = \mathbf{D}$$

where $\mathbf{D}$ is diagonal, with main diagonal entries $\lambda_1, \lambda_2, \cdots, \lambda_n$. (Proof in Ref. [E29] listed in App. 1.)

How to Get the QR-Factorization, say, $\mathbf{B} = \mathbf{B}_0 = [b_{jk}] = \mathbf{Q}_0\mathbf{R}_0$. The tridiagonal matrix $\mathbf{B}$ has $n - 1$ generally nonzero entries below the main diagonal. These are $b_{21}, b_{32}, \cdots, b_{n,n-1}$. We multiply $\mathbf{B}$ from the left by a matrix $\mathbf{C}_2$ such that $\mathbf{C}_2\mathbf{B} = [b_{jk}^{(2)}]$ has $b_{21}^{(2)} = 0$. We multiply this by a matrix $\mathbf{C}_3$ such that $\mathbf{C}_3\mathbf{C}_2\mathbf{B} = [b_{jk}^{(3)}]$ has $b_{32}^{(3)} = 0$, etc. After $n - 1$ such multiplications we are left with an upper triangular matrix $\mathbf{R}_0$, namely,

$$\mathbf{C}_n\mathbf{C}_{n-1} \cdots \mathbf{C}_3\mathbf{C}_2\mathbf{B}_0 = \mathbf{R}_0. \tag{7}$$

These $n \times n$ matrices $\mathbf{C}_j$ are very simple, $\mathbf{C}_j$ has the 2×2 submatrix

$$\begin{bmatrix} \cos\theta_j & \sin\theta_j \\ -\sin\theta_j & \cos\theta_j \end{bmatrix} \qquad (\theta_j \text{ suitable})$$

in Rows $j - 1$ and j and Columns $j - 1$ and j; everywhere else on the main diagonal the matrix $\mathbf{C}_j$ has entries 1; and all its other entries are 0. (This submatrix is the matrix of a plane rotation through the angle θ_j; see Team Project 28, Sec. 7.2.) For instance, if $n = 4$, writing $c_j = \cos\theta_j$, $s_j = \sin\theta_j$, we have

$$\mathbf{C}_2 = \begin{bmatrix} c_2 & s_2 & 0 & 0 \\ -s_2 & c_2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{C}_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & c_3 & s_3 & 0 \\ 0 & -s_3 & c_3 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{C}_4 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & c_4 & s_4 \\ 0 & 0 & -s_4 & c_4 \end{bmatrix}.$$

These $\mathbf{C}_j$ are orthogonal. Hence their product in (7) is orthogonal, and so is the inverse of this product. We call this inverse $\mathbf{Q}_0$. Then from (7),

$$\mathbf{B}_0 = \mathbf{Q}_0\mathbf{R}_0 \tag{8}$$

where, with $\mathbf{C}_j^{-1} = \mathbf{C}_j^{\mathsf{T}}$,

$$\mathbf{Q}_0 = (\mathbf{C}_n\mathbf{C}_{n-1} \cdots \mathbf{C}_3\mathbf{C}_2)^{-1} = \mathbf{C}_2^{\mathsf{T}}\mathbf{C}_3^{\mathsf{T}} \cdots \mathbf{C}_{n-1}^{\mathsf{T}}\mathbf{C}_n^{\mathsf{T}}. \tag{9}$$

This is our QR-factorization of $\mathbf{B}_0$. From it we have by (5b) with $s = 0$

$$\mathbf{B}_1 = \mathbf{R}_0\mathbf{Q}_0 = \mathbf{R}_0\mathbf{C}_2^{\mathsf{T}}\mathbf{C}_3^{\mathsf{T}} \cdots \mathbf{C}_{n-1}^{\mathsf{T}}\mathbf{C}_n^{\mathsf{T}}. \tag{10}$$

We do not need $\mathbf{Q}_0$ explicitly, but to get $\mathbf{B}_1$ from (10), we first compute $\mathbf{R}_0\mathbf{C}_2^{\mathsf{T}}$, then $(\mathbf{R}_0\mathbf{C}_2^{\mathsf{T}})\mathbf{C}_3^{\mathsf{T}}$, etc. Similarly in the further steps that produce $\mathbf{B}_2, \mathbf{B}_3, \cdots$.

Determination of $\cos\theta_j$ and $\sin\theta_j$. We finally show how to find the angles of rotation. $\cos\theta_2$ and $\sin\theta_2$ in $\mathbf{C}_2$ must be such that $b_{21}^{(2)} = 0$ in the product

$$\mathbf{C}_2\mathbf{B} = \begin{bmatrix} c_2 & s_2 & 0 & \cdots \\ -s_2 & c_2 & 0 & \cdots \\ \cdot & \cdot & \cdot & \cdots \\ \cdot & \cdot & \cdot & \cdots \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} & b_{13} & \cdots \\ b_{21} & b_{22} & b_{23} & \cdots \\ \cdot & \cdot & \cdot & \cdots \\ \cdot & \cdot & \cdot & \cdots \end{bmatrix}.$$

Now $b_{21}^{(2)}$ is obtained by multiplying the second row of $\mathbf{C}_2$ by the first column of $\mathbf{B}$,

$$b_{21}^{(2)} = -s_2 b_{11} + c_2 b_{21} = -(\sin\theta_2) b_{11} + (\cos\theta_2) b_{21} = 0.$$

Hence $\tan\theta_2 = s_2/c_2 = b_{21}/b_{11}$, and

$$\cos\theta_2 = \frac{1}{\sqrt{1+\tan^2\theta_2}} = \frac{1}{\sqrt{1+(b_{21}/b_{11})^2}}$$

(11)

$$\sin\theta_2 = \frac{\tan\theta_2}{\sqrt{1+\tan^2\theta_2}} = \frac{b_{21}/b_{11}}{\sqrt{1+(b_{21}/b_{11})^2}}.$$

Similarly for $\theta_3, \theta_4, \cdots$. The next example illustrates all this.

EXAMPLE 2 **QR-Factorization Method**

Compute all the eigenvalues of the matrix

$$\mathbf{A} = \begin{bmatrix} 6 & 4 & 1 & 1 \\ 4 & 6 & 1 & 1 \\ 1 & 1 & 5 & 2 \\ 1 & 1 & 2 & 5 \end{bmatrix}.$$

Solution. We first reduce $\mathbf{A}$ to tridiagonal form. Applying Householder's method, we obtain (see Example 1)

$$\mathbf{A}_2 = \begin{bmatrix} 6 & -\sqrt{18} & 0 & 0 \\ -\sqrt{18} & 7 & \sqrt{2} & 0 \\ 0 & \sqrt{2} & 6 & 0 \\ 0 & 0 & 0 & 3 \end{bmatrix}.$$

From the characteristic determinant we see that $\mathbf{A}_2$, hence $\mathbf{A}$, has the eigenvalue 3. (Can you see this directly from $\mathbf{A}_2$?) Hence it suffices to apply the QR-method to the tridiagonal 3×3 matrix

$$\mathbf{B}_0 = \mathbf{B} = \begin{bmatrix} 6 & -\sqrt{18} & 0 \\ -\sqrt{18} & 7 & \sqrt{2} \\ 0 & \sqrt{2} & 6 \end{bmatrix}.$$

Step 1. We multiply $\mathbf{B}$ from the left by

$$\mathbf{C}_2 = \begin{bmatrix} \cos\theta_2 & \sin\theta_2 & 0 \\ -\sin\theta_2 & \cos\theta_2 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{and then } \mathbf{C}_2\mathbf{B} \text{ by} \quad \mathbf{C}_3 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\theta_3 & \sin\theta_3 \\ 0 & -\sin\theta_3 & \cos\theta_3 \end{bmatrix}.$$

Here $(-\sin\theta_2)\cdot 6 + (\cos\theta_2)(-\sqrt{18}) = 0$ gives (11) $\cos\theta_2 = 0.816\,496\,58$ and $\sin\theta_2 = -0.577\,350\,27$. With these values we compute

$$\mathbf{C}_2\mathbf{B} = \begin{bmatrix} 7.348\,469\,23 & -7.505\,553\,50 & -0.816\,496\,58 \\ 0 & 3.265\,986\,32 & 1.154\,700\,54 \\ 0 & 1.414\,213\,56 & 6.000\,000\,00 \end{bmatrix}.$$

In $\mathbf{C}_3$ we get from $(-\sin\theta_3)\cdot 3.265\,986\,32 + (\cos\theta_3)\cdot 1.414\,213\,56 = 0$ the values $\cos\theta_3 = 0.917\,662\,94$ and $\sin\theta_3 = 0.397\,359\,71$. This gives

$$\mathbf{R}_0 = \mathbf{C}_3\mathbf{C}_2\mathbf{B} = \begin{bmatrix} 7.348\,469\,23 & -7.505\,553\,50 & -0.816\,496\,58 \\ 0 & 3.559\,026\,08 & 3.443\,784\,13 \\ 0 & 0 & 5.047\,146\,15 \end{bmatrix}.$$

From this we compute

$$\mathbf{B}_1 = \mathbf{R}_0\mathbf{C}_2^{\mathsf{T}}\mathbf{C}_3^{\mathsf{T}} = \begin{bmatrix} 10.333\,333\,33 & -2.054\,804\,67 & 0 \\ -2.054\,804\,67 & 4.035\,087\,72 & 2.005\,532\,51 \\ 0 & 2.005\,532\,51 & 4.631\,578\,95 \end{bmatrix}$$

which is symmetric and tridiagonal. The off-diagonal entries in $\mathbf{B}_1$ are still large in absolute value. Hence we have to go on.

Step 2. We do the same computations as in the first step, with $\mathbf{B}_0 = \mathbf{B}$ replaced by $\mathbf{B}_1$ and $\mathbf{C}_2$ and $\mathbf{C}_3$ changed accordingly, the new angles being $\theta_2 = -0.196\,291\,533$ and $\theta_3 = 0.513\,415\,589$. We obtain

$$\mathbf{R}_1 = \begin{bmatrix} 10.535\,653\,75 & -2.802\,322\,41 & -0.391\,145\,88 \\ 0 & 4.083\,295\,84 & 3.988\,240\,28 \\ 0 & 0 & 3.068\,326\,68 \end{bmatrix}$$

and from this

$$\mathbf{B}_2 = \begin{bmatrix} 10.879\,879\,88 & -0.796\,379\,18 & 0 \\ -0.796\,379\,18 & 5.447\,386\,64 & 1.507\,025\,00 \\ 0 & 1.507\,025\,00 & 2.672\,733\,48 \end{bmatrix}.$$

We see that the off-diagonal entries are somewhat smaller in absolute value than those of $\mathbf{B}_1$, but still much too large for the diagonal entries to be good approximations of the eigenvalues of $\mathbf{B}$.

Further Steps. We list the main diagonal entries and the absolutely largest off-diagonal entry, which is $|b_{12}^{(j)}| = |b_{21}^{(j)}|$ in all steps. You may show that the given matrix $\mathbf{A}$ has the spectrum 11, 6, 3, 2.

Step j	$b_{11}^{(j)}$	$b_{22}^{(j)}$	$b_{33}^{(j)}$	$\max_{j \neq k} \lvert b_{jk}^{(j)} \rvert$
3	10.966 892 9	5.945 898 56	2.087 208 51	0.585 235 82
5	10.997 087 2	6.001 815 41	2.001 097 38	0.120 653 34
7	10.999 742 1	6.000 244 39	2.000 013 55	0.035 911 07
9	10.999 977 2	6.000 022 67	2.000 000 17	0.010 684 77

Looking back at our discussion, we recognize that the purpose of applying Householder's tridiagonalization before the QR-factorization method is a substantial reduction of cost in each QR-factorization, in particular if $\mathbf{A}$ is large.

Convergence acceleration and thus further reduction of cost can be achieved by a **spectral shift,** that is, by taking $\mathbf{B}_s - k_s\mathbf{I}$ instead of $\mathbf{B}_s$ with a suitable k_s. Possible choices of k_s are discussed in Ref. [E29], p. 510.

PROBLEM SET 20.9

1–4 HOUSEHOLDER TRIDIAGONALIZATION

Tridiagonalize, showing the details:

1. $\begin{bmatrix} 3.5 & 1.0 & 1.5 \\ 1.0 & 5.0 & 3.0 \\ 1.5 & 3.0 & 3.5 \end{bmatrix}$ **2.** $\begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}$

3. $\begin{bmatrix} 0.98 & 0.04 & 0.44 \\ 0.04 & 0.56 & 0.40 \\ 0.44 & 0.40 & 0.80 \end{bmatrix}$

4. $\begin{bmatrix} 8 & 8 & 2 & 2 \\ 8 & 8 & 2 & 2 \\ 2 & 2 & 6 & 4 \\ 2 & 2 & 4 & 6 \end{bmatrix}$

5–9 QR-FACTORIZATION

Do three QR-steps to find approximations of the eigenvalues of:

5. The matrix in the answer to Prob. 1

6. The matrix in the answer to Prob. 3

7. $\begin{bmatrix} 18 & 2 & 0 \\ 2 & 8 & 2 \\ 0 & 2 & 2 \end{bmatrix}$

8. $\begin{bmatrix} 16.2 & -0.1 & 0 \\ -0.1 & -4.3 & 0.2 \\ 0 & 0.2 & 4.1 \end{bmatrix}$

9. $\begin{bmatrix} 7.0 & 0.1 & 0 \\ 0.1 & 4.0 & 0.1 \\ 0 & 0.1 & 1.0 \end{bmatrix}$

10. CAS EXPERIMENT. QR-Method. Try to find out experimentally on what properties of a matrix the speed of decrease of off-diagonal entries in the QR-method depends. For this purpose write a program that first tridiagonalizes and then does QR-steps. Try the program out on the matrices in Probs. 1, 3, and 4. Summarize your findings in a short report.

CHAPTER 20 REVIEW QUESTIONS AND PROBLEMS

1. What are the main problem areas in numeric linear algebra?
2. What is pivoting? When and how would you apply it?
3. What happens if you apply Gauss elimination to a system that has no solutions?
4. What is Doolittle's method? Its connection to Gauss elimination?
5. What is Cholesky's method? When would you apply it?
6. What do you know about the convergence of the Gauss–Seidel method?
7. What is ill-conditioning? What is the condition number and its significance?
8. What is least squares approximation? What are the normal equations?
9. What is an eigenvalue of a matrix? Why are eigenvalue problems important? Give typical examples.
10. Why are similarity transformations of matrices important in designing numeric methods? Give examples.
11. What is the power method for eigenvalues? What are its advantages and disadvantages?
12. State Gerschgorin's theorem from memory. Can you remember its proof?
13. State Schur's inequality and give some applications of it.
14. What is tridiagonalization? When would you apply it?
15. What is the idea of the QR-method? When would you apply the method?

16–19 GAUSS ELIMINATION

Solve:

16.
$$\begin{aligned} 4x_2 - 3x_3 &= 11.8 \\ 5x_1 + 3x_2 + x_3 &= 34.2 \\ 6x_1 - 7x_2 + 2x_3 &= -3.1 \end{aligned}$$

17.
$$\begin{aligned} x_1 + x_2 + x_3 &= 5 \\ x_1 + 2x_2 + 2x_3 &= 6 \\ x_1 + 2x_2 + 3x_3 &= 8 \end{aligned}$$

18.
$$\begin{aligned} 5x_1 + x_2 - 3x_3 &= 17 \\ -5x_2 + 15x_3 &= -10 \\ 2x_1 - 3x_2 + 9x_3 &= 0 \end{aligned}$$

19.
$$\begin{aligned} 2x_1 + 3x_3 &= 15 \\ 4x_2 - x_3 &= -13 \\ 3x_1 - x_2 + 5x_3 &= 26 \end{aligned}$$

20. Solve Prob. 17 by Doolittle's method.

21. Solve Prob. 17 by Cholesky's method.

22–24 INVERSE MATRIX

Compute the inverse of:

22. $\begin{bmatrix} 1.0 & 2.0 & 0.5 \\ 0.5 & 1.0 & 0.5 \\ 1.5 & 2.0 & 1.0 \end{bmatrix}$

23. $\begin{bmatrix} 1.5 & 2.0 & 1.0 \\ 2.0 & 3.5 & 1.5 \\ 1.0 & 1.5 & 9.0 \end{bmatrix}$

24. $\begin{bmatrix} 5 & 1 & 1 \\ 1 & 6 & 0 \\ 1 & 0 & 8 \end{bmatrix}$

25–26 GAUSS–SEIDEL METHOD

Do 3 steps without scaling, starting from $[1 \quad 1 \quad 1]^T$:

25.
$$\begin{aligned} x_1 + 15x_2 - x_3 &= 11 \\ 10x_1 + 3x_2 &= -17 \\ 2x_1 - x_2 + 5x_3 &= 5 \end{aligned}$$

26.
$$\begin{aligned} 4x_1 - x_2 &= 5.5 \\ 4x_2 - x_3 &= 0.4 \\ -x_1 + 4x_3 &= 11.2 \end{aligned}$$

27–32 VECTOR NORMS

Compute the ℓ_1-, ℓ_2-, and ℓ_∞-norms of the vectors

27. $[0 \quad 4 \quad -8 \quad 3]^T$

28. $[3 \quad 8 \quad -11]^T$

29. $[-4 \quad 1 \quad 0 \quad 2]^T$

30. $[0 \quad 0 \quad 1 \quad 0]^T$

31. $[-5 \quad -2 \quad 7 \quad 0 \quad 0]^T$

32. $[0.3 \quad 1.4 \quad 0.2 \quad -0.6]^T$

33–35 MATRIX NORM

Compute the matrix norm corresponding to the ℓ_∞-vector norm for the coefficient matrix:

33. In Prob. 17

34. In Prob. 18

35. In Prob. 19

36–38 CONDITION NUMBER

Compute the condition number (corresponding to the ℓ_∞-vector norm) of the coefficient matrix:

36. In Prob. 22

37. In Prob. 23

38. In Prob. 24

39–40 FITTING BY LEAST SQUARES

Fit:

39. A straight line to (−2, 0.1), (0, 1.9), (2, 3.8), (4, 6.1), (6, 7.8)

40. A quadratic parabola to (1, 9), (2, 5), (3, 4), (4, 5), (5, 7)

41–43 EIGENVALUES

Find three circular disks that must contain all the eigenvalues of the matrix:

41. In Prob. 22

42. In Prob. 23

43. In Prob. 24

44. (Power method) Do 4 steps of the power method for the matrix in Prob. 24, starting from $[1 \quad 1 \quad 1]^T$ and computing the Rayleigh quotients and error bounds.

45. (Householder and QR) Tridiagonalize the matrix in Prob. 23. Then apply 3 QR steps. (Spectrum (6S): 9.65971, 4.07684, 0.263451)

SUMMARY OF CHAPTER 20
Numeric Linear Algebra

Main tasks are the numeric solution of linear systems (Secs. 20.1–20.4), curve fitting (Sec. 20.5), and eigenvalue problems (Secs. 20.6–20.9).

Linear systems Ax = b with $\mathbf{A} = [a_{jk}]$, written out

$$(1) \qquad \begin{aligned} &\mathrm{E}_1: \quad a_{11}x_1 + \cdots + a_{1n}x_n = b_1 \\ &\mathrm{E}_2: \quad a_{21}x_1 + \cdots + a_{2n}x_n = b_2 \\ &\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ &\mathrm{E}_n: \quad a_{n1}x_1 + \cdots + a_{nn}x_n = b_n \end{aligned}$$

can be solved by a **direct method** (one in which the number of numeric operations can be specified in advance, e.g., Gauss's elimination) or by an **indirect** or **iterative method** (in which an initial approximation is improved stepwise).

The **Gauss elimination** (Sec. 20.1) is direct, namely, a systematic elimination process that reduces (1) stepwise to triangular form. In Step 1 we eliminate x_1 from equations E_2 to E_n by subtracting $(a_{21}/a_{11})\ E_1$ from E_2, then $(a_{31}/a_{11})\ E_1$ from E_3, etc. Equation E_1 is called the **pivot equation** in this step and a_{11} the **pivot.** In Step 2 we take the new second equation as pivot equation and eliminate x_2, etc. If the triangular form is reached, we get x_n from the last equation, then x_{n-1} from the second last, etc. **Partial pivoting** (= interchange of equations) is *necessary* if candidates for pivots are zero, and *advisable* if they are small in absolute value.

Doolittle's, Crout's, and **Cholesky's methods** in Sec. 20.2 are variants of the Gauss elimination. They factor $\mathbf{A} = \mathbf{LU}$ ($\mathbf{L}$ lower triangular, $\mathbf{U}$ upper triangular) and solve $\mathbf{Ax} = \mathbf{LUx} = \mathbf{b}$ by solving $\mathbf{Ly} = \mathbf{b}$ for $\mathbf{y}$ and then $\mathbf{Ux} = \mathbf{y}$ for $\mathbf{x}$.

In the **Gauss–Seidel iteration** (Sec. 20.3) we make $a_{11} = a_{22} = \cdots = a_{nn} = 1$ (by division) and write $\mathbf{Ax} = (\mathbf{I} + \mathbf{L} + \mathbf{U})\mathbf{x} = \mathbf{b}$; thus $\mathbf{x} = \mathbf{b} - (\mathbf{L} + \mathbf{U})\mathbf{x}$, which suggests the iteration formula

$$\mathbf{x}^{(m+1)} = \mathbf{b} - \mathbf{L}\mathbf{x}^{(m+1)} - \mathbf{U}\mathbf{x}^{(m)} \tag{2}$$

in which we always take the most recent approximate x_j's on the right. If $\|\mathbf{C}\| < 1$, where $\mathbf{C} = -(\mathbf{I} + \mathbf{L})^{-1}\mathbf{U}$, then this process converges. Here, $\|\mathbf{C}\|$ denotes any matrix norm (Sec. 20.3).

If the **condition number** $\kappa(\mathbf{A}) = \|\mathbf{A}\|\ \|\mathbf{A}^{-1}\|$ of $\mathbf{A}$ is large, then the system $\mathbf{Ax} = \mathbf{b}$ is **ill-conditioned** (Sec. 20.4), and a small **residual** $\mathbf{r} = \mathbf{b} - \mathbf{A}\tilde{\mathbf{x}}$ does *not* imply that $\tilde{\mathbf{x}}$ is close to the exact solution.

The fitting of a polynomial $p(x) = b_0 + b_1 x + \cdots + b_m x^m$ through given data (points in the xy-plane) $(x_1, y_1), \cdots, (x_n, y_n)$ by the method of **least squares** is discussed in Sec. 20.5 (and in statistics in Sec. 25.9).

Eigenvalues λ (values λ for which $\mathbf{Ax} = \lambda\mathbf{x}$ has a solution $\mathbf{x} \neq \mathbf{0}$, called an **eigenvector**) can be characterized by inequalities (Sec. 20.7), e.g. in **Gerschgorin's theorem,** which gives n circular disks which contain the whole spectrum (all eigenvalues) of $\mathbf{A}$, of centers a_{jj} and radii $\Sigma|a_{jk}|$ (sum over k from 1 to n, $k \neq j$).

Approximations of eigenvalues can be obtained by iteration, starting from an $\mathbf{x}_0 \neq \mathbf{0}$ and computing $\mathbf{x}_1 = \mathbf{Ax}_0$, $\mathbf{x}_2 = \mathbf{Ax}_1$, $\cdots$, $\mathbf{x}_n = \mathbf{Ax}_{n-1}$. In this **power method** (Sec. 20.8) the **Rayleigh quotient**

$$q = \frac{(\mathbf{Ax})^{\mathsf{T}}\mathbf{x}}{\mathbf{x}^{\mathsf{T}}\mathbf{x}} \qquad (\mathbf{x} = \mathbf{x}_n) \tag{3}$$

gives an approximation of an eigenvalue (usually that of the greatest absolute value) and, if $\mathbf{A}$ is symmetric, an error bound is

$$|\epsilon| \leqq \sqrt{\frac{(\mathbf{Ax})^{\mathsf{T}}\mathbf{Ax}}{\mathbf{x}^{\mathsf{T}}\mathbf{x}} - q^2}\,. \tag{4}$$

Convergence may be slow but can be improved by a *spectral shift.*

For determining all the eigenvalues of a symmetric matrix $\mathbf{A}$ it is best to first tridiagonalize $\mathbf{A}$ and then to apply the QR-method (Sec. 20.9), which is based on a factorization $\mathbf{A} = \mathbf{QR}$ with orthogonal $\mathbf{Q}$ and upper triangular $\mathbf{R}$ and uses similarity transformations.

CHAPTER 21

Numerics for ODEs and PDEs

Numeric methods for differential equations are of great practical importance to the engineer and physicist because practical problems often lead to differential equations that cannot be solved by one of the methods in Chaps. 1–6 or 12 or by similar methods. Also, sometimes an ODE does have a solution formula (as the ODEs in Secs. 1.3–1.5 do), which, however, in some specific cases may become so complicated that one prefers to apply a numeric method instead.

This chapter explains and applies basic methods for the numeric solution of ODEs (Secs. 21.1–21.3) and PDEs (Secs. 21.4–21.7).

***Sections* 21.1 *and* 21.2 *may be studied immediately after Chap.* 1 *and Sec.* 21.3 *immediately after Chap.* 2,** because these sections are independent of Chaps. 19 and 20.

***Sections* 21.4–21.7 *on PDEs may be studied immediately after Chap.* 12** if students have some knowledge of linear systems of algebraic equations.

Prerequisite: Secs. 1.1–1.5 for ODEs, Secs. 12.1–12.3, 12.5, 12.10 for PDEs.
References and Answers to Problems App. 1 Part E (see also Parts A and C), App. 2.

21.1 Methods for First-Order ODEs

From Chap. 1 we know that an ODE of the first order is of the form $F(x, y, y') = 0$ and can often be written in the explicit form $y' = f(x, y)$. An **initial value problem** for this equation is of the form

$$y' = f(x, y), \qquad y(x_0) = y_0 \tag{1}$$

where x_0 and y_0 are given and we assume that the problem has a unique solution on some open interval $a < x < b$ containing x_0.

In this section we shall discuss methods of computing approximate numeric values of the solution $y(x)$ of (1) at the equidistant points on the x-axis

$$x_1 = x_0 + h, \qquad x_2 = x_0 + 2h, \qquad x_3 = x_0 + 3h, \qquad \cdots$$

where the **step size** h is a fixed number, for instance, 0.2 or 0.1 or 0.01, whose choice we discuss later in this section. Those methods are **step-by-step methods,** using the same formula in each step. Such formulas are suggested by the Taylor series

$$y(x + h) = y(x) + hy'(x) + \frac{h^2}{2}y''(x) + \cdots. \tag{2}$$

For a small h the higher powers h^2, h^3, $\cdots$ are very small. This suggests the crude approximation

$$\begin{aligned} y(x + h) &\approx y(x) + hy'(x) \\ &= y(x) + hf(x, y) \end{aligned}$$

(with the second line obtained from the given ODE) and the following iteration process. In the first step we compute

$$y_1 = y_0 + hf(x_0, y_0)$$

which approximates $y(x_1) = y(x_0 + h)$. In the second step we compute

$$y_2 = y_1 + hf(x_1, y_1)$$

which approximates $y(x_2) = y(x_0 + 2h)$, etc., and in general

$$y_{n+1} = y_n + hf(x_n, y_n) \qquad (n = 0, 1, \cdots). \tag{3}$$

This is called the **Euler method** or the **Euler–Cauchy method.** Geometrically it is an approximation of the curve of $y(x)$ by a polygon whose first side is tangent to this curve at x_0 (see Fig. 448).

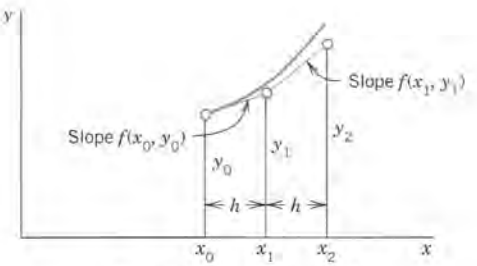


Fig. 448. Euler method

This crude method is hardly ever used in practice, but since it is simple, it nicely explains the principle of methods based on the Taylor series.

Taylor's formula with remainder has the form

$$y(x + h) = y(x) + hy'(x) + \tfrac{1}{2}h^2y''(\xi)$$

(where $x \leqq \xi \leqq x + h$). It shows that in the Euler method the *truncation error in each step* or **local truncation error** is proportional to h^2, written $O(h^2)$, where O suggests *order* (see also Sec. 20.1). Now over a fixed x-interval in which we want to solve an ODE the number of steps is proportional to $1/h$. Hence the *total error* or **global error** is proportional to $h^2(1/h) = h^1$. For this reason, the Euler method is called a **first-order method.** In addition, there are **roundoff errors** in this and other methods, which may affect the accuracy of the values y_1, y_2, $\cdots$ more and more as n increases, as we shall see.

Table 21.1 Euler Method Applied to (4) in Example 1 and Error

n	x_n	y_n	$0.2(x_n + y_n)$	Exact Values	Error ϵ_n
0	0.0	0.000	0.000	0.000	0.000
1	0.2	0.000	0.040	0.021	0.021
2	0.4	0.040	0.088	0.092	0.052
3	0.6	0.128	0.146	0.222	0.094
4	0.8	0.274	0.215	0.426	0.152
5	1.0	0.489		0.718	0.229

EXAMPLE 1 Euler Method

Apply the Euler method to the following initial value problem, choosing $h = 0.2$ and computing $y_1, \cdots, y_5$:

$$y' = x + y, \qquad y(0) = 0. \tag{4}$$

Solution. Here $f(x, y) = x + y$; hence $f(x_n, y_n) = x_n + y_n$, and we see that (3) becomes

$$y_{n+1} = y_n + 0.2(x_n + y_n).$$

Table 21.1 shows the computations, the values of the exact solution

$$y(x) = e^x - x - 1$$

obtained from (4) in Sec. 1.5, and the error. In practice the exact solution is unknown, but an indication of the accuracy of the values can be obtained by applying the Euler method once more with step $2h = 0.4$, letting y_n^* denote the approximation now obtained, and comparing corresponding approximations. This computation is:

x_n	y_n^*	$0.4(x_n + y_n)$	y_n in Table 21.1	Difference $y_n - y_n^*$
0.0	0.000	0.000	0.000	0.000
0.4	0.000	0.160	0.040	0.040
0.8	0.160		0.274	0.114

Let ϵ_n and ϵ_n^* be the errors of the computations with h and $2h$, respectively. Since the error is of order h^2, in a switch from h to $2h$ it is multiplied by $2^2 = 4$, but since we need only half as many steps as before, it will be multiplied only by $4/2 = 2$. Hence $\epsilon_n^* \approx 2\epsilon_n$ so that the difference is $\epsilon_n^* - \epsilon_n \approx 2\epsilon_n - \epsilon_n = \epsilon_n$. Now $y = y_n + \epsilon_n = y_n^* + \epsilon_n^*$ by the definition of error; hence $\epsilon_n^* - \epsilon_n = y_n - y_n^*$ indicates ϵ_n qualitatively. In our computations, $y_2 - y_2^* = 0.04 - 0 = 0.04$ (actual error 0.052, see Table 21.1) and $y_4 - y_4^* = 0.274 - 0.160 = 0.114$ (actually 0.152). ■

EXAMPLE 2 Euler Method for a Nonlinear ODE

Figure 449 concerns the initial value problem

$$y' = (y - 0.01x^2)^2 \sin(x^2) + 0.02x, \qquad y(0) = 0.4 \tag{5}$$

and shows the curve of the solution $y = 1/[2.5 - S(x)] + 0.01x^2$ where $S(x)$ is the Fresnel integral (38) in App. 3.1. It also shows 80 approximate values for $0 \leqq x \leqq 4$ obtained by the Euler method from (3),

$$y_{n+1} = y_n + 0.05\left[(y_n - 0.01x_n^2)^2 \sin(x_n^2) + 0.02x_n\right].$$

Although $h = 0.05$ is smaller than h in Example 1, the accuracy is still not good. It is interesting that the error is not monotone increasing, obviously since the solution is not monotone. We shall return to this ODE in the problem set. ■

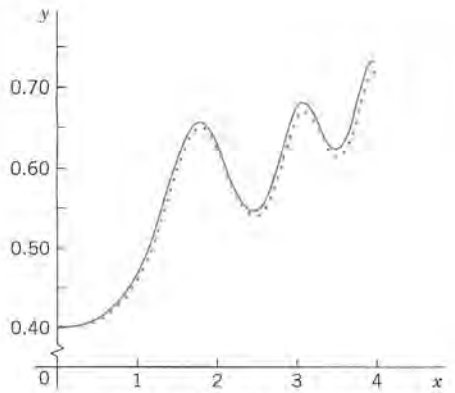

Fig. 449. Solution curve and Euler approximation in Example 2

Automatic Variable Step Size Selection in Modern Numeric Software

The idea of adaptive integration as motivated and explained in Sec. 19.5 applies equally well to the numeric solution of ODEs. It now concerns automatically changing the step size h depending on the variability of $y' = f$ determined by

$$y'' = f' = f_x + f_y y' = f_x + f_y f. \tag{6*}$$

Accordingly, modern software automatically selects variable step sizes h_n so that the error of the solution will not exceed a given maximum size TOL (suggesting *tolerance*). Now for the Euler method, when the step size is $h = h_n$, the local error at x_n is about $\frac{1}{2}h_n^2\,|y''(x_n)|$. We require that this be equal to a given tolerance TOL,

$$\text{(6)} \qquad \text{(a)} \quad \tfrac{1}{2}h_n^2|y''(x_n)| = \text{TOL}, \qquad \text{thus} \qquad \text{(b)} \quad h_n = \sqrt{\frac{2\ \text{TOL}}{|y''(x_n)|}}\ .$$

$y''(x)$ must not be zero on the interval J: $x_0 \leqq x = x_N$ on which the solution is wanted. Let K be the minimum of $|y''(x)|$ on J and assume that $K > 0$. Minimum $|y''(x)|$ corresponds to maximum $h = H = \sqrt{2\ \text{TOL}/K}$ by (6). Thus, $\sqrt{2\ \text{TOL}} = H\sqrt{K}$. We can insert this into (6b), obtaining by straightforward algebra

$$\text{(7)} \qquad h_n = \varphi(x_n)H \qquad \text{where} \qquad \varphi(x_n) = \sqrt{\frac{K}{|y''(x_n)|}}\ .$$

For other methods, automatic step size selection is based on the same principle.

Improved Euler Method

By taking more terms in (2) into account we obtain numeric methods of higher order and precision. But there is a practical problem. If we substitute $y' = f(x, y(x))$ into (2), we have

$$y(x + h) = y(x) + hf + \tfrac{1}{2}h^2 f' + \tfrac{1}{6}h^3 f'' + \cdots, \tag{2*}$$

Now y in f depends on x, so that we have f' as shown in (6*) and f'', f''' even much more cumbersome. The ***general strategy*** now is to avoid the computation of these derivatives and to replace it by computing f for one or several suitably chosen auxiliary values of (x, y). "Suitably" means that these values are chosen to make the order of the method as high as possible (to have high accuracy). Let us discuss two such methods that are of practical importance, namely, the improved Euler method and the (classical) Runge-Kutta method.

In the **improved Euler method** or **improved Euler–Cauchy method** (sometimes also called **Heun method**), in each step we compute first the auxiliary value

$$\textbf{(8a)} \qquad y_{n+1}^* = y_n + hf(x_n, y_n)$$

and then the new value

$$\textbf{(8b)} \qquad y_{n+1} = y_n + \tfrac{1}{2}h[f(x_n, y_n) + f(x_{n+1}, y_{n+1}^*)].$$

This method has a simple geometric interpretation. In fact, we may say that in the interval from x_n to $x_n + \frac{1}{2}h$ we approximate the solution y by the straight line through (x_n, y_n) with slope $f(x_n, y_n)$, and then we continue along the straight line with slope $f(x_{n+1}, y_{n+1}^*)$ until x reaches x_{n+1}.

The improved Euler–Cauchy method is a **predictor–corrector method,** because in each step we first ***predict*** a value by (8a) and then ***correct*** it by (8b).

In algorithmic form, using the notations $k_1 = hf(x_n, y_n)$ in (8a) and $k_2 = hf(x_{n+1}, y_{n+1}^*)$ in (8b), we can write this method as shown in Table 21.2.

Table 21.2 Improved Euler Method (Heun's Method)

ALGORITHM EULER (f, x_0, y_0, h, N)

This algorithm computes the solution of the initial value problem $y' = f(x, y)$, $y(x_0) = y_0$ at equidistant points $x_1 = x_0 + h$, $x_2 = x_0 + 2h, \cdots, x_N = x_0 + Nh$; here f is such that this problem has a unique solution on the interval $[x_0, x_N]$ (see Sec. 1.7).

INPUT: Initial values x_0, y_0, step size h, number of steps N

OUTPUT: Approximation y_{n+1} to the solution $y(x_{n+1})$ at $x_{n+1} = x_0 + (n + 1)h$, where $n = 0, \cdots, N - 1$

For $n = 0, 1, \cdots, N - 1$ do:

$x_{n+1} = x_n + h$

$k_1 = hf(x_n, y_n)$

$k_2 = hf(x_{n+1}, y_n + k_1)$

$y_{n+1} = y_n + \frac{1}{2}(k_1 + k_2)$

OUTPUT x_{n+1}, y_{n+1}

End

Stop

End EULER

EXAMPLE 3 **Improved Euler Method**

Apply the improved Euler method to the initial value problem (4), choosing $h = 0.2$, as before.

Solution. For the present problem we have in Table 21.2

$$k_1 = 0.2(x_n + y_n)$$

$$k_2 = 0.2(x_n + 0.2 + y_n + 0.2(x_n + y_n))$$

$$y_{n+1} = y_n + \frac{0.2}{2}(2.2x_n + 2.2y_n + 0.2) = y_n + 0.22(x_n + y_n) + 0.02.$$

Table 21.3 shows that our present results are more accurate than those in Example 1; see also Table 21.6. ■

Table 21.3 **Improved Euler Method Applied to (4) and Error**

n	x_n	y_n	$0.22(x_n + y_n) + 0.02$	Exact Values (4D)	Error
0	0.0	0.0000	0.0200	0.0000	0.0000
1	0.2	0.0200	0.0684	0.0214	0.0014
2	0.4	0.0884	0.1274	0.0918	0.0034
3	0.6	0.2158	0.1995	0.2221	0.0063
4	0.8	0.4153	0.2874	0.4255	0.0102
5	1.0	0.7027		0.7183	0.0156

Error of the Improved Euler Method. *The local error is of order h^3 and the global error of order h^2, so that the method is a* **second-order method.**

PROOF Setting $\tilde{f}_n = f(x_n, y(x_n))$ and using (2*), we have

$$y(x_n + h) - y(x_n) = h\tilde{f}_n + \tfrac{1}{2}h^2\tilde{f}_n' + \tfrac{1}{6}h^3\tilde{f}_n'' + \cdots. \tag{9a}$$

Approximating the expression in the brackets in (8b) by $\tilde{f}_n + \tilde{f}_{n+1}$ and again using the Taylor expansion, we obtain from (8b)

$$\begin{aligned} y_{n+1} - y_n &\approx \tfrac{1}{2}h\left[\tilde{f}_n + \tilde{f}_{n+1}\right] \\ &= \tfrac{1}{2}h\left[\tilde{f}_n + (\tilde{f}_n + h\tilde{f}_n' + \tfrac{1}{2}h^2\tilde{f}_n'' + \cdots)\right] \\ &= h\tilde{f}_n + \tfrac{1}{2}h^2\tilde{f}_n' + \tfrac{1}{4}h^3\tilde{f}_n'' + \cdots \end{aligned} \tag{9b}$$

(where $' = d/dx_n$, etc.). Subtraction of (9b) from (9a) gives the local error

$$\frac{h^3}{6}\tilde{f}_n'' - \frac{h^3}{4}\tilde{f}_n'' + \cdots = -\frac{h^3}{12}\tilde{f}_n'' + \cdots.$$

Since the number of steps over a fixed x-interval is proportional to $1/h$, the global error is of order $h^3/h = h^2$, so that the method is of second order. ■

Runge–Kutta Methods (RK Methods)

A method of great practical importance and much greater accuracy than that of the improved Euler method is the *classical Runge–Kutta method of fourth order*, which we call briefly the **Runge–Kutta method.**[1] It is shown in Table 21.4. We see that in each step we first compute four auxiliary quantities k_1, k_2, k_3, k_4 and then the new value y_{n+1}. The method is well suited to the computer because it needs no special starting procedure, makes light demand on storage, and repeatedly uses the same straightforward computational procedure. It is numerically stable.

Note that if f depends only on x, this method reduces to Simpson's rule of integration (Sec. 19.5). Note further that $k_1, \cdots, k_4$ depend on n and generally change from step to step.

Table 21.4 Classical Runge–Kutta Method of Fourth Order

ALGORITHM RUNGE–KUTTA (f, x_0, y_0, h, N).

This algorithm computes the solution of the initial value problem $y' = f(x, y)$, $y(x_0) = y_0$ at equidistant points

$$x_1 = x_0 + h,\ x_2 = x_0 + 2h, \cdots, x_N = x_0 + Nh;$$

here f is such that this problem has a unique solution on the interval $[x_0, x_N]$ (see Sec. 1.7).

INPUT: Function f, initial values x_0, y_0, step size h, number of steps N

OUTPUT: Approximation y_{n+1} to the solution $y(x_{n+1})$ at $x_{n+1} = x_0 + (n + 1)h$, where $n = 0, 1, \cdots, N - 1$

For $n = 0, 1, \cdots, N - 1$ do:

$$k_1 = hf(x_n, y_n)$$
$$k_2 = hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_1)$$
$$k_3 = hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_2)$$
$$k_4 = hf(x_n + h, y_n + k_3)$$
$$x_{n+1} = x_n + h$$
$$y_{n+1} = y_n + \tfrac{1}{6}(k_1 + 2k_2 + 2k_3 + k_4)$$
OUTPUT x_{n+1}, y_{n+1}

End

Stop

End RUNGE–KUTTA

[1] Named after the German mathematicians KARL RUNGE (Sec. 19.4) and WILHELM KUTTA (1867–1944). Runge [*Math. Annalen* **46** (1895), 167–178], KARL HEUN [*Zeitschr. Math. Phys.* **45** (1900), 23–38], and Kutta [*Zeitschr. Math. Phys.* **46** 1901), 435–453] developed various such methods. Theoretically, there are infinitely many fourth-order methods using four function values per step. The method in Table 21.4 is most popular from a practical viewpoint because of its "symmetrical" form and its simple coefficients. It was given by Kutta.

EXAMPLE 4 **Classical Runge–Kutta Method**

Apply the Runge–Kutta method to the initial value problem (4) in Example 1, choosing $h = 0.2$, as before, and computing five steps.

Solution. For the present problem we have $f(x, y) = x + y$. Hence

$$k_1 = 0.2(x_n + y_n), \qquad k_2 = 0.2(x_n + 0.1 + y_n + 0.5k_1),$$
$$k_3 = 0.2(x_n + 0.1 + y_n + 0.5k_2), \qquad k_4 = 0.2(x_n + 0.2 + y_n + k_3).$$

Table 21.5 shows the results and their errors, which are smaller by factors 10^3 and 10^4 than those for the two Euler methods. See also Table 21.6. We mention in passing that since the present $k_1, \cdots, k_4$ are simple, operations were saved by substituting k_1 into k_2, then k_2 into k_3, etc.; the resulting formula is shown in Column 4 of Table 21.5. ■

Table 21.5 Runge–Kutta Method Applied to (4)

n	x_n	y_n	$0.2214(x_n + y_n) + 0.0214$	Exact Values (6D) $y = e^x - x - 1$	$10^6 \times$ Error of y_n

Error and Step Size Control. RKF (Runge–Kutta–Fehlberg)

The idea of adaptive integration (Sec. 19.5) has analogs for Runge–Kutta (and other) methods. In Table 21.4 for RK (Runge–Kutta), if we compute in each step approximations $\tilde{y}$ and $\tilde{\tilde{y}}$ with step sizes h and $2h$, respectively, the latter has error per step equal to $2^5 = 32$ times that of the former; however, since we have only half as many steps for $2h$, the actual factor is $2^5/2 = 16$, so that, say,

$$\epsilon^{(2h)} \approx 16\epsilon^{(h)} \qquad \text{and thus} \qquad y^{(h)} - y^{(2h)} = \epsilon^{(2h)} - \epsilon^{(h)} \approx (16 - 1)\epsilon^{(h)}.$$

Hence the error $\epsilon = \epsilon^{(h)}$ for step size h is about

(10) $$\epsilon = \tfrac{1}{15}(\tilde{y} - \tilde{\tilde{y}})$$

where $\tilde{y} - \tilde{\tilde{y}} = y^{(h)} - y^{(2h)}$, as said before. Table 21.7 illustrates (10) for the initial value problem

(11) $$y' = (y - x - 1)^2 + 2, \qquad y(0) = 1,$$

the step size $h = 0.1$ and $0 \leqq x \leqq 0.4$. We see that the estimate is close to the actual error. This method of error estimation is simple but may be unstable.

Table 21.7 Runge–Kutta Method Applied to the Initial Value Problem (11) and Error Estimate (10). Exact Solution $y = \tan x + x + 1$

x	$\tilde{y}$ (Step size h)	$\tilde{\tilde{y}}$ (Step size $2h$)	Error Estimate (10)	Actual Error	Exact Solution (9D)
0.0	1.000 000 000	1.000 000 000	0.000 000 000	0.000 000 000	1.000 000 000
0.1	1.200 334 589			0.000 000 083	1.200 334 672
0.2	1.402 709 878	1.402 707 408	0.000 000 165	0.000 000 157	1.402 710 036
0.3	1.609 336 039			0.000 000 210	1.609 336 250
0.4	1.822 792 993	1.822 788 993	0.000 000 267	0.000 000 226	1.822 793 219

RKF. E. Fehlberg [*Computing* **6** (1970), 61–71] proposed and developed error control by using two RK methods of different orders to go from (x_n, y_n) to (x_{n+1}, y_{n+1}). The difference of the computed y-values at x_{n+1} gives an error estimate to be used for step size control. Fehlberg discovered two RK formulas that together need only 6 function evaluations per step. We present these formulas here because RKF has become quite popular. For instance, Maple uses it (also for systems of ODEs).

Fehlberg's fifth-order RK method is

(12a) $$y_{n+1} = y_n + \gamma_1 k_1 + \cdots + \gamma_6 k_6$$

with coefficient vector $\gamma = [\gamma_1 \cdots \gamma_6]$,

(12b) $$\gamma = \left[\tfrac{16}{135} \quad 0 \quad \tfrac{6656}{12825} \quad \tfrac{28561}{56430} \quad -\tfrac{9}{50} \quad \tfrac{2}{55}\right].$$

His **fourth-order RK method** is

(13a) $$y^*_{n+1} = y_n + \gamma^*_1 k_1 + \cdots + \gamma^*_5 k_5$$

with coefficient vector

(13b) $$\gamma^* = \left[\tfrac{25}{216} \quad 0 \quad \tfrac{1408}{2565} \quad \tfrac{2197}{4104} \quad -\tfrac{1}{5}\right].$$

In both formulas we use only 6 different function evaluations altogether, namely,

$$
\begin{aligned}
k_1 &= hf(x_n, y_n) \\
k_2 &= hf(x_n + \tfrac{1}{4}h, \quad y_n + \tfrac{1}{4}k_1) \\
k_3 &= hf(x_n + \tfrac{3}{8}h, \quad y_n + \tfrac{3}{32}k_1 + \tfrac{9}{32}k_2) \\
k_4 &= hf(x_n + \tfrac{12}{13}h, \quad y_n + \tfrac{1932}{2197}k_1 - \tfrac{7200}{2197}k_2 + \tfrac{7296}{2197}k_3) \\
k_5 &= hf(x_n + h, \quad y_n + \tfrac{439}{216}k_1 - 8k_2 + \tfrac{3680}{513}k_3 - \tfrac{845}{4104}k_4) \\
k_6 &= hf(x_n + \tfrac{1}{2}h, \quad y_n - \tfrac{8}{27}k_1 + 2k_2 - \tfrac{3544}{2565}k_3 + \tfrac{1859}{4104}k_4 - \tfrac{11}{40}k_5).
\end{aligned} \tag{14}
$$

The difference of (12) and (13) gives the **error estimate**

$$
\epsilon_{n+1} \approx y_{n+1} - y_{n+1}^* = \tfrac{1}{360}k_1 - \tfrac{128}{4275}k_3 - \tfrac{2197}{75240}k_4 + \tfrac{1}{50}k_5 + \tfrac{2}{55}k_6. \tag{15}
$$

EXAMPLE 5 **Runge–Kutta–Fehlberg**

For the initial value problem (11) we obtain from (12)–(14) with $h = 0.1$ in the first step the 12S-values

$$
\begin{aligned}
k_1 &= 0.200000\,000000 & k_2 &= 0.200062\,500000 \\
k_3 &= 0.200140\,756867 & k_4 &= 0.200856\,926154 \\
k_5 &= 0.201006\,676700 & k_6 &= 0.200250\,418651
\end{aligned}
$$

$$
y_1^* = 1.200334\,66949
$$

$$
y_1 = 1.200334\,67253
$$

and the error estimate

$$
\epsilon_1 \approx y_1 - y_1^* = 0.000000\,00304.
$$

The exact 12S-value is $y(0.1) = 1.200334\,67209$. Hence the actual error of y_1 is $-4.4 \cdot 10^{-10}$, smaller than that in Table 21.7 by a factor 200. ■

Table 21.8 summarizes essential features of the methods in this section. It can be shown that these methods are *numerically stable* (definition in Sec. 19.1). They are **one-step methods** because in each step we use the data of just *one* preceding step, in contrast to **multistep methods** where in each step we use data from *several* preceding steps, as we shall see in the next section.

Table 21.8 **Methods Considered and Their Order (= Their Global Error)**

Method	Function Evaluation per Step	Global Error	Local Error
Euler	1	$O(h)$	$O(h^2)$
Improved Euler	2	$O(h^2)$	$O(h^3)$
RK (fourth order)	4	$O(h^4)$	$O(h^5)$
RKF	6	$O(h^5)$	$O(h^6)$

Backward Euler Method. Stiff ODEs

The **backward Euler formula** for numerically solving (1) is

$$y_{n+1} = y_n + hf(x_{n+1}, y_{n+1}) \qquad (n = 0, 1, \cdots). \tag{16}$$

This formula is obtained by evaluating the right side at the *new* location (x_{n+1}, y_{n+1}); this is called the **backward Euler scheme.** For known y_n it gives y_{n+1} *implicitly,* so it defines an **implicit method,** in contrast to the Euler method (3), which gives y_{n+1} explicitly. Hence (16) must be solved for y_{n+1}. How difficult this is depends on f in (1). For a linear ODE this provides no problem, as Example 6 (below) illustrates. The method is particularly useful for "stiff" ODEs, as they occur quite frequently in the study of vibrations, electric circuits, chemical reactions, etc. The situation of stiffness is roughly as follows; for details, see, for example, [E5], [E25], [E26] in App. 1.

Error terms of the methods considered so far involve a higher derivative. And we ask what happens if we let h *increase.* Now if the error (the derivative) grows fast but the desired solution also grows fast, nothing will happen. However, if that solution does not grow fast, then with growing h the error term can take over to an extent that the numeric result becomes completely nonsensical, as in Fig. 450. Such an ODE for which h must thus be restricted to small values, and the physical system the ODE models, are called **stiff.** This term is suggested by a mass–spring system with a stiff spring (spring with a large k; see Sec. 2.4). Example 6 illustrates that implicit methods remove the difficulty of increasing h in the case of stiffness: it can be shown that in the application of an implicit method the solution remains stable under any increase of h, although the accuracy decreases with increasing h.

EXAMPLE 6 **Backward Euler Method. Stiff ODE**

The initial value problem

$$y' = f(x, y) = -20y + 20x^2 + 2x, \qquad y(0) = 1$$

has the solution (verify!)

$$y = e^{-20x} + x^2.$$

The backward Euler formula (16) is

$$y_{n+1} = y_n + hf(x_{n+1}, y_{n+1}) = y_n + h(-20y_{n+1} + 20x_{n+1}^2 + 2x_{n+1}).$$

Noting that $x_{n+1} = x_n + h$, taking the term $-20hy_{n+1}$ to the left, and dividing, we obtain

$$y_{n+1} = \frac{y_n + h[20(x_n + h)^2 + 2(x_n + h)]}{1 + 20h}. \tag{16*}$$

The numeric results in Table 21.9 show the following.

Stability of the backward Euler method for $h = 0.05$ and also for $h = 0.2$ with an error increase by about a factor 4 for $h = 0.2$,

Stability of the Euler method for $h = 0.05$ but instability for $h = 0.1$ (Fig. 450),

Stability of RK for $h = 0.1$ but instability for $h = 0.2$.

This illustrates that the ODE is stiff. Note that even in the case of stability the approximation of the solution near $x = 0$ is poor. ■

Stiffness will be considered further in Sec. 21.3 in connection with systems of ODEs.

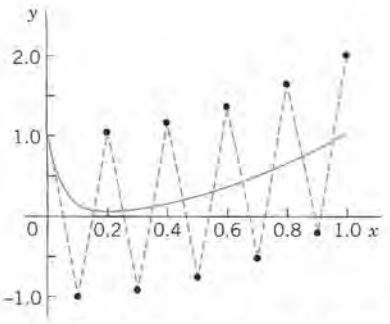

Fig. 450. Euler method with $h = 0.1$ for the stiff ODE in Example 6 and exact solution

PROBLEM SET 21.1

1–4 EULER METHOD

Do 10 steps. Solve the problem exactly. Compute the error. (Show the details.)

1. $y' = y$, $y(0) = 1$, $h = 0.1$
2. $y' = y$, $y(0) = 1$, $h = 0.01$
3. $y' = (y - x)^2$, $y(0) = 0$, $h = 0.1$
4. $y' = (y + x)^2$, $y(0) = 0$, $h = 0.1$

5–10 IMPROVED EULER METHOD

Do 10 steps. Solve exactly. Compute the error. (Show the details.)

5. $y' = y$, $y(0) = 1$, $h = 0.1$. Compare with Prob. 1 and comment.
6. **(Logistic population)** $y' = y - y^2$, $y(0) = 0.2$, $h = 0.1$
7. $y' - xy^2 = 0$, $y(0) = 1$, $h = 0.1$
8. $y' + y \tan x = \sin 2x$, $y(0) = 1$, $h = 0.1$
9. Do Prob. 7 using the Euler method with $h = 0.1$ and compare the accuracy.
10. $y' = 1 - \frac{1}{4}y^2$, $y(0) = 0$, $h = 0.1$

11–17 CLASSICAL RUNGE–KUTTA METHOD OF FOURTH ORDER

Do 10 steps. Compare as indicated. Comment. (Show the details.)

11. $y' - xy^2 = 0$, $y(0) = 1$, $h = 0.1$. Compare with Prob. 7. Apply (10) to y_{10}.
12. $y' = y - y^2$, $y(0) = 0.2$, $h = 0.1$. Compare with Prob. 6. Apply (10) to y_{10}.

13. $y' = (1 + x^{-1})y$, $y(1) = e$, $h = 0.2$

14. $y' = \frac{1}{2}(y/x - x/y)$, $y(2) = 2$, $h = 0.2$

15. $y' + y \tan x = \sin 2x$, $y(0) = 1$, $h = 0.1$

16. In Prob. 15 use $h = 0.2$ (5 steps) and compare the error.

17. $y' + 5x^4y^2 = 0$, $y(0) = 1$, $h = 0.2$

18. Kutta's third-order method is defined by $y_{n+1} = y_n + \frac{1}{6}(k_1 + 4k_2 + k_3^*)$ with k_1 and k_2 as in RK (Table 21.4) and $k_3^* = hf(x_{n+1}, y_n - k_1 + 2k_2)$. Apply this method to (4) in Example 1. Choose $h = 0.2$ and do 5 steps. Compare with Table 21.6.

19. CAS EXPERIMENT. Euler–Cauchy vs. RK. **(a)** Solve (5) in Example 2 by Euler, Improved Euler, and RK for $0 \leqq x \leqq 5$ with step $h = 0.2$. Compare the errors for $x = 1, 3, 5$ and comment.

(b) Graph solution curves of the ODE in (5) for various positive and negative initial values.

(c) Do a similar experiment as in (a) for an initial value problem that has a monotone increasing or monotone decreasing solution. Compare the behavior of the error with that in (a). Comment.

20. CAS EXPERIMENT. RKF. **(a)** Write a program for RKF that gives x_n, y_n, the estimate (10), and if the solution is known, the actual error ϵ_n.

(b) Apply the program to Example 5 in the text (10 steps, $h = 0.1$).

(c) ϵ_n in (b) gives a relatively good idea of the size of the actual error. Is this typical or accidental? Find out by experimentation with other problems on what properties of the ODE or solution this might depend.

21.2 Multistep Methods

In a **one-step method** we compute y_{n+1} using only a single step, namely, the previous value y_n. *One-step methods are* **"self-starting,"** they need no help to get going because they obtain y_1 from the initial value y_0, etc. All methods in Sec. 21.1 are one-step.

In contrast, a **multistep method** uses in each step values from two or more previous steps. These methods are motivated by the expectation that the additional information will increase accuracy and stability. But to get started, one needs values, say, y_0, y_1, y_2, y_3 in a 4-step method, obtained by Runge–Kutta or another accurate method. Thus, multistep methods are not self-starting. Such methods are obtained as follows.

Adams–Bashforth Methods

We consider an initial value problem

$$\textbf{(1)} \qquad y' = f(x, y), \qquad y(x_0) = y_0$$

as before, with f such that the problem has a unique solution on some open interval containing x_0. We integrate $y' = f(x, y)$ from x_n to $x_{n+1} = x_n + h$. This gives

$$\int_{x_n}^{x_{n+1}} y'(x)\,dx = y(x_{n+1}) - y(x_n) = \int_{x_n}^{x_{n+1}} f(x, y(x))\,dx.$$

Now comes the main idea. We replace $f(x, y(x))$ by an interpolation polynomial $p(x)$ (see Sec. 19.3), so that we can later integrate. This gives approximations y_{n+1} of $y(x_{n+1})$ and y_n of $y(x_n)$,

$$(2) \qquad y_{n+1} = y_n + \int_{x_n}^{x_{n+1}} p(x)\,dx.$$

Different choices of $p(x)$ will now produce different methods. We explain the principle by taking a cubic polynomial, namely, the polynomial $p_3(x)$ that at (equidistant)

$$x_n, \qquad x_{n-1}, \qquad x_{n-2}, \qquad x_{n-3}$$

has the respective values

$$\begin{aligned} f_n &= f(x_n, y_n) \\ f_{n-1} &= f(x_{n-1}, y_{n-1}) \\ f_{n-2} &= f(x_{n-2}, y_{n-2}) \\ f_{n-3} &= f(x_{n-3}, y_{n-3}). \end{aligned} \tag{3}$$

This will lead to a practically useful formula. We can obtain $p_3(x)$ from Newton's backward difference formula (18), Sec. 19.3:

$$p_3(x) = f_n + r\nabla f_n + \tfrac{1}{2}r(r+1)\nabla^2 f_n + \tfrac{1}{6}r(r+1)(r+2)\nabla^3 f_n$$

where

$$r = \frac{x - x_n}{h}.$$

We integrate $p_3(x)$ over x from x_n to $x_{n+1} = x_n + h$, thus over r from 0 to 1. Since

$$x = x_n + hr, \qquad \text{we have} \qquad dx = h\,dr.$$

The integral of $\frac{1}{2}r(r+1)$ is 5/12 and that of $\frac{1}{6}r(r+1)(r+2)$ is 3/8. We thus obtain

$$\int_{x_n}^{x_{n+1}} p_3\,dx = h\int_0^1 p_3\,dr = h\left(f_n + \frac{1}{2}\nabla f_n + \frac{5}{12}\nabla^2 f_n + \frac{3}{8}\nabla^3 f_n\right). \tag{4}$$

It is practical to replace these differences by their expressions in terms of f:

$$\begin{aligned} \nabla f_n &= f_n - f_{n-1} \\ \nabla^2 f_n &= f_n - 2f_{n-1} + f_{n-2} \\ \nabla^3 f_n &= f_n - 3f_{n-1} + 3f_{n-2} - f_{n-3}. \end{aligned}$$

We substitute this into (4) and collect terms. This gives the multistep formula of the **Adams–Bashforth method** *of fourth order*

$$y_{n+1} = y_n + \frac{h}{24}(55f_n - 59f_{n-1} + 37f_{n-2} - 9f_{n-3}). \tag{5}$$

It expresses the new value y_{n+1} [approximation of the solution y of (1) at x_{n+1}] in terms of 4 values of f computed from the y-values obtained in the preceding 4 steps. The local truncation error is of order h^5, as can be shown, so that the global error is of order h^4; hence (5) does define a fourth-order method.

Adams–Moulton Methods

Adams–Moulton methods are obtained if for $p(x)$ in (2) we choose a polynomial that interpolates $f(x, y(x))$ at $x_{n+1}, x_n, x_{n-1}, \cdots$ (as opposed to $x_n, x_{n-1}, \cdots$ used before; this is the main point). We explain the principle for the cubic polynomial $\tilde{p}_3(x)$ that interpolates at $x_{n+1}, x_n, x_{n-1}, x_{n-2}$. (Before we had $x_n, x_{n-1}, x_{n-2}, x_{n-3}$.) Again using (18) in Sec. 19.3 but now setting $r = (x - x_{n+1})/h$, we have

$$\tilde{p}_3(x) = f_{n+1} + r\nabla f_{n+1} + \tfrac{1}{2}r(r+1)\nabla^2 f_{n+1} + \tfrac{1}{6}r(r+1)(r+2)\nabla^3 f_{n+1}.$$

We now integrate over x from x_n to x_{n+1} as before. This corresponds to integrating over r from -1 to 0. We obtain

$$\int_{x_n}^{x_{n+1}} \tilde{p}_3(x)\,dx = h\left(f_{n+1} - \frac{1}{2}\nabla f_{n+1} - \frac{1}{12}\nabla^2 f_{n+1} - \frac{1}{24}\nabla^3 f_{n+1}\right).$$

Replacing the differences as before gives

$$(6) \qquad y_{n+1} = y_n + \int_{x_n}^{x_{n+1}} \tilde{p}_3(x)\,dx = y_n + \frac{h}{24}(9f_{n+1} + 19f_n - 5f_{n-1} + f_{n-2}).$$

This is usually called an **Adams–Moulton formula.** It is an **implicit formula** because $f_{n+1} = f(x_{n+1}, y_{n+1})$ appears on the right, so that it defines y_{n+1} only *implicitly,* in contrast to (5), which is an **explicit formula,** not involving y_{n+1} on the right. To use (6) we must ***predict*** a value y_{n+1}^*, for instance, by using (5), that is,

$$\textbf{(7a)} \qquad y_{n+1}^* = y_n + \frac{h}{24}(55f_n - 59f_{n-1} + 37f_{n-2} - 9f_{n-3}).$$

The ***corrected*** new value y_{n+1} is then obtained from (6) with f_{n+1} replaced by $f_{n+1}^* = f(x_{n+1}, y_{n+1}^*)$ and the other f's as in (6); thus,

$$\textbf{(7b)} \qquad y_{n+1} = y_n + \frac{h}{24}(9f_{n+1}^* + 19f_n - 5f_{n-1} + f_{n-2}).$$

This **predictor–corrector method** (7a), (7b) is usually called the **Adams–Moulton method** *of fourth order.* It has the advantage over RK that (7) gives the error estimate

$$\epsilon_{n+1} \approx \tfrac{1}{15}(y_{n+1} - y_{n+1}^*),$$

as can be shown. This is the analog of (10) in Sec. 21.1.

Sometimes the name 'Adams–Moulton method' is reserved for the method with *several* corrections per step by (7b) until a specific accuracy is reached. Popular codes exist for both versions of the method.

Getting Started. In (5) we need f_0, f_1, f_2, f_3. Hence from (3) we see that we must first compute y_1, y_2, y_3 by some other method of comparable accuracy, for instance, by RK or by RKF. For other choices see Ref. [E26] listed in App. 1.

EXAMPLE 1 Adams–Bashforth Prediction (7a), Adams–Moulton Correction (7b)

Solve the initial value problem

$$y' = x + y, \qquad y(0) = 0 \tag{8}$$

by (7a), (7b) on the interval $0 \leqq x \leqq 2$, choosing $h = 0.2$.

Solution. The problem is the same as in Examples 1–3, Sec. 21.1, so that we can compare the results. We compute starting values y_1, y_2, y_3 by the classical Runge–Kutta method. Then in each step we predict by (7a) and make one correction by (7b) before we execute the next step. The results are shown and compared with the exact values in Table 21.10. We see that the corrections improve the accuracy considerably. This is typical. ■

Table 21.10 Adams–Moulton Method Applied to the Initial Value Problem (8); Predicted Values Computed by (7a) and Corrected Values by (7b)

n	x_n	Starting y_n	Predicted y_n^*	Corrected y_n	Exact Values	$10^6 \cdot$ Error of y_n
0	0.0	0.000 000			0.000 000	0
1	0.2	0.021 400			0.021 403	3
2	0.4	0.091 818			0.091 825	7
3	0.6	0.222 107			0.222 119	12
4	0.8		0.425 361	0.425 529	0.425 541	12
5	1.0		0.718 066	0.718 270	0.718 282	12
6	1.2		1.119 855	1.120 106	1.120 117	11
7	1.4		1.654 885	1.655 191	1.655 200	9
8	1.6		2.352 653	2.353 026	2.353 032	6
9	1.8		3.249 190	3.249 646	3.249 647	1
10	2.0		4.388 505	4.389 062	4.389 056	−6

Comments on Comparison of Methods. An Adams–Moulton formula is generally much more accurate than an Adams–Bashforth formula of the same order. This justifies the greater complication and expense in using the former. The method (7a), (7b) is ***numerically stable,*** whereas the exclusive use of (7a) might cause instability. Step size control is relatively simple. If |Corrector − Predictor| > TOL, use interpolation to generate "old" results at half the current step size and then try $h/2$ as the new step.

Whereas the Adams–Moulton formula (7a), (7b) needs only 2 evaluations per step, Runge–Kutta needs 4; however, with Runge–Kutta one may be able to take a step size more than twice as large, so that a comparison of this kind (widespread in the literature) is meaningless.

For more details, see Refs. [E25], [E26] listed in App. 1.

PROBLEM SET 21.2

1. Carry out and show the details of the calculations leading to (4)–(7) in the text.

2–11 ADAMS–MOULTON METHOD (7a), (7b)

Solve the initial value problems by Adams–Moulton, 10 steps with 1 correction per step. Solve exactly and compute the error. (Use RK where no starting values are given.)

2. $y' = y$, $y(0) = 1$, $h = 0.1$ (1.105171, 1.221403, 1.349859)

3. $y' = -0.2xy$, $y(0) = 1$, $h = 0.2$

4. $y' = 2xy$, $y(0) = 1$, $h = 0.1$

5. $y' = 1 + y^2$, $y(0) = 0$, $h = 0.1$

6. Do Prob. 4 by RK, 5 steps, $h = 0.2$. Compare the errors.

7. Do Prob. 5 by RK, 5 steps, $h = 0.2$. Compare the errors.

8. $y' = x/y$, $y(1) = 3$, $h = 0.2$

9. $y' = (x + y - 4)^2$, $y(0) = 4$, $h = 0.2$, only 7 steps (why?)

10. $y' = 1 - 4y^2$, $y(0) = 0$, $h = 0.1$

11. $y' = x + y$, $y(0) = 0$, $h = 0.1$ (0.00517083, 0.0214026, 0.0498585)

12. Show that by applying the method in the text to a polynomial of second degree we obtain the predictor and corrector formulas

$$y_{n+1}^* = y_n + \frac{h}{12}(23f_n - 16f_{n-1} + 5f_{n-2}),$$

$$y_{n+1} = y_n + \frac{h}{12}(5f_{n+1} + 8f_n - f_{n-1}).$$

13. Use Prob. 12 to solve $y' = 2xy$, $y(0) = 1$ (10 steps, $h = 0.1$, RK starting values). Compare with the exact solution and comment.

14. How much can you reduce the error in Prob. 13 by halving h (20 steps, $h = 0.05$)? First guess, then compute.

15. **CAS PROJECT. Adams–Moulton. (a) Accurate starting** is important in (7a), (7b). Illustrate this in Example 1 of the text by using starting values from the improved Euler–Cauchy method and compare the results with those in Table 21.9.

(b) How much does the error in Prob. 11 decrease if you use exact starting values (instead of RK-values)?

(c) Experiment to find out for what ODEs poor starting is very damaging and for what ODEs it is not.

(d) The classical **RK method** often gives the same accuracy with step $2h$ as Adams–Moulton with step h, so that the total number of function evaluations is the same in both cases. Illustrate this with Prob. 8. (Hence corresponding comparisons in the literature in favor of Adams–Moulton are not valid. See also Probs. 6 and 7.)

21.3 Methods for Systems and Higher Order ODEs

Initial value problems for first-order systems of ODEs are of the form

$$\mathbf{y}' = \mathbf{f}(x, \mathbf{y}), \qquad \mathbf{y}(x_0) = \mathbf{y}_0, \tag{1}$$

in components

$$\begin{aligned} y_1' &= f_1(x, y_1, \cdots, y_m), & y_1(x_0) &= y_{10} \\ y_2' &= f_2(x, y_1, \cdots, y_m), & y_2(x_0) &= y_{20} \\ &\cdots\cdots\cdots\cdots\cdots & &\cdots\cdots\cdots \\ y_m' &= f_m(x, y_1, \cdots, y_m). & y_m(x_0) &= y_{m0}. \end{aligned}$$

$\mathbf{f}$ is assumed to be such that the problem has a unique solution $\mathbf{y}(x)$ on some open x-interval containing x_0. Our discussion will be independent of Chap. 4 on systems.

Before explaining solution methods it is important to note that (1) includes initial value problems for single mth-order ODEs,

$$y^{(m)} = f(x, y, y', y'', \cdots, y^{(m-1)}) \tag{2}$$

and initial conditions $y(x_0) = K_1$, $y'(x_0) = K_2, \cdots, y^{(m-1)}(x_0) = K_m$ as special cases.

Indeed, the connection is achieved by setting

$$(3) \qquad y_1 = y, \quad y_2 = y', \quad y_3 = y'', \quad \cdots, \quad y_m = y^{(m-1)}.$$

Then we obtain the system

$$(4) \qquad \begin{aligned} y_1' &= y_2 \\ y_2' &= y_3 \\ &\vdots \\ y_{m-1}' &= y_m \\ y_m' &= f(x, y_1, \cdots, y_m) \end{aligned}$$

and the initial conditions $y_1(x_0) = K_1, \quad y_2(x_0) = K_2, \quad \cdots, \quad y_m(x_0) = K_m$.

Euler Method for Systems

Methods for single first-order ODEs can be extended to systems (1) simply by writing vector functions $\mathbf{y}$ and $\mathbf{f}$ instead of scalar functions y and f, whereas x remains a scalar variable.

We begin with the Euler method. Just as for a single ODE this method will not be accurate enough for practical purposes, but it nicely illustrates the extension principle.

EXAMPLE 1 **Euler Method for a Second-Order ODE. Mass–Spring System**

Solve the initial value problem for a damped mass–spring system

$$y'' + 2y' + 0.75y = 0, \qquad y(0) = 3, \qquad y'(0) = -2.5$$

by the Euler method for systems with step $h = 0.2$ for x from 0 to 1 (where x is time).

Solution. The **Euler method** (3), Sec. 21.1, generalizes to systems in the form

$$(5) \qquad \mathbf{y}_{n+1} = \mathbf{y}_n + h\mathbf{f}(x_n, \mathbf{y}_n),$$

in components

$$\begin{aligned} y_{1,n+1} &= y_{1,n} + hf_1(x_n, y_{1,n}, y_{2,n}) \\ y_{2,n+1} &= y_{2,n} + hf_2(x_n, y_{1,n}, y_{2,n}) \end{aligned}$$

and similarly for systems of more than two equations. By (4) the given ODE converts to the system

$$\begin{aligned} y_1' &= f_1(x, y_1, y_2) = y_2 \\ y_2' &= f_2(x, y_1, y_2) = -2y_2 - 0.75y_1. \end{aligned}$$

Hence (5) becomes

$$\begin{aligned} y_{1,n+1} &= y_{1,n} + 0.2y_{2,n} \\ y_{2,n+1} &= y_{2,n} + 0.2(-2y_{2,n} - 0.75y_{1,n}). \end{aligned}$$

The initial conditions are $y(0) = y_1(0) = 3$, $y'(0) = y_2(0) = -2.5$. The calculations are shown in Table 21.11 on the next page. As for single ODEs, the results would not be accurate enough for practical purposes. The example merely serves to illustrate the method because the problem can be readily solved exactly,

$$y = y_1 = 2e^{-0.5x} + e^{-1.5x}, \qquad \text{thus} \qquad y' = y_2 = -e^{-0.5x} - 1.5e^{-1.5x}.$$

■

Table 21.11 Euler Method for Systems in Example 1 (Mass–Spring System)

n	x_n	$y_{1,n}$	y_1 Exact (5D)	Error $\epsilon_1 = y_1 - y_{1,n}$	$y_{2,n}$	y_2 Exact (5D)	Error $\epsilon_2 = y_2 - y_{2,n}$

Runge–Kutta Methods for Systems

As for Euler methods, we obtain RK methods for an initial value problem (1) simply by writing vector formulas for vectors with m components, which for $m = 1$ reduce to the previous scalar formulas.

Thus for the *classical* **RK method** *of fourth order* in Table 21.4 we obtain

(6a) $$\mathbf{y}(x_0) = \mathbf{y}_0 \qquad \text{(Initial values)}$$

and for each step $n = 0, 1, \cdorn, N - 1$ we obtain the 4 auxiliary quantities

(6b)
$$\begin{aligned}
\mathbf{k}_1 &= h\,\mathbf{f}(x_n, \quad \mathbf{y}_n) \\
\mathbf{k}_2 &= h\,\mathbf{f}(x_n + \tfrac{1}{2}h, \quad \mathbf{y}_n + \tfrac{1}{2}\mathbf{k}_1) \\
\mathbf{k}_3 &= h\,\mathbf{f}(x_n + \tfrac{1}{2}h, \quad \mathbf{y}_n + \tfrac{1}{2}\mathbf{k}_2) \\
\mathbf{k}_4 &= h\,\mathbf{f}(x_n + h, \quad \mathbf{y}_n + \mathbf{k}_3)
\end{aligned}$$

and the new value [approximation of the solution $\mathbf{y}(x)$ at $x_{n+1} = x_0 + (n + 1)h$]

(6c) $$\mathbf{y}_{n+1} = \mathbf{y}_n + \tfrac{1}{6}(\mathbf{k}_1 + 2\mathbf{k}_2 + 2\mathbf{k}_3 + \mathbf{k}_4).$$

EXAMPLE 2 RK Method for Systems. Airy's Equation. Airy Function Ai(x)

Solve the initial value problem

$$y'' = xy, \qquad y(0) = 1/(3^{2/3} \cdot \Gamma(2/3)) = 0.35502\,805, \qquad y'(0) = -1/(3^{1/3} \cdot \Gamma(1/3)) = -0.25881\,940$$

by the Runge–Kutta method for systems with $h = 0.2$; do 5 steps. This is **Airy's equation,**[2] which arose in optics (see Ref. [A13], p. 188, listed in App. 1). Γ is the gamma function (see App. A3.1). The initial conditions are such that we obtain a standard solution, the **Airy function** $\mathrm{Ai}(x)$, a special function that has been thoroughly investigated; for numeric values, see Ref. [GR1], pp. 446, 475.

[2]Named after Sir GEORGE BIDELL AIRY (1801–1892), English mathematician, who is known for his work in elasticity and in PDEs.

Solution. For $y'' = xy$, setting $y_1 = y$, $y_2 = y_1' = y'$ we obtain the system (4)

$$y_1' = y_2$$
$$y_2' = xy_1.$$

Hence $\mathbf{f} = [f_1 \quad f_2]^T$ in (1) has the components $f_1(x, y) = y_2$, $f_2(x, y) = xy_1$. We now write (6) in components. The initial conditions (6a) are $y_{1,0} = 0.35502\,805$, $y_{2,0} = -0.25881\,940$. In (6b) we have fewer subscripts by simply writing $\mathbf{k}_1 = \mathbf{a}$, $\mathbf{k}_2 = \mathbf{b}$, $\mathbf{k}_3 = \mathbf{c}$, $\mathbf{k}_4 = \mathbf{d}$, so that $\mathbf{a} = [a_1 \quad a_2]^T$, etc. Then (6b) takes the form

$$\mathbf{a} = h\begin{bmatrix} y_{2,n} \\ x_n y_{1,n} \end{bmatrix}$$

$$\mathbf{b} = h\begin{bmatrix} y_{2,n} + \frac{1}{2}a_2 \\ (x_n + \frac{1}{2}h)(y_{1,n} + \frac{1}{2}a_1) \end{bmatrix}$$

(6b*)

$$\mathbf{c} = h\begin{bmatrix} y_{2,n} + \frac{1}{2}b_2 \\ (x_n + \frac{1}{2}h)(y_{1,n} + \frac{1}{2}b_1) \end{bmatrix}$$

$$\mathbf{d} = h\begin{bmatrix} y_{2,n} + c_2 \\ (x_n + h)(y_{1,n} + c_1) \end{bmatrix}.$$

For example, the second component of $\mathbf{b}$ is obtained as follows. $\mathbf{f}(x, \mathbf{y})$ has the second component $f_2(x, \mathbf{y}) = xy_1$. Now in $\mathbf{b}$ $(= \mathbf{k}_2)$ the first argument is

$$x = x_n + \tfrac{1}{2}h.$$

The second argument in $\mathbf{b}$ is

$$\mathbf{y} = \mathbf{y}_n + \tfrac{1}{2}\mathbf{a},$$

and the first component of this is

$$y_1 = y_{1,n} + \tfrac{1}{2}a_1.$$

Together,

$$xy_1 = (x_n + \tfrac{1}{2}h)(y_{1,n} + \tfrac{1}{2}a_1).$$

Similarly for the other components in (6b*). Finally,

(6c*) $$\mathbf{y}_{n+1} = \mathbf{y}_n + \tfrac{1}{6}(\mathbf{a} + 2\mathbf{b} + 2\mathbf{c} + \mathbf{d}).$$

Table 21.12 shows the values $y(x) = y_1(x)$ of the Airy function $\mathrm{Ai}(x)$ and of its derivative $y'(x) = y_2(x)$ as well as of the (rather small!) error of $y(x)$. ■

Table 21.12 RK Method for Systems: Values $y_{1,n}(x_n)$ of the Airy Function Ai(x) in Example 2

n	x_n	$y_{1,n}(x_n)$	$y_1(x_n)$ Exact (8D)	$10^8 \cdot$ Error of y_1	$y_{2,n}(x_n)$

Runge–Kutta–Nyström Methods (RKN Methods)

RKN methods are direct extensions of RK methods (Runge–Kutta methods) to second-order ODEs $y'' = f(x, y, y')$, as given by the Finnish mathematician E. J. Nyström [*Acta Soc. Sci. fenn.*, 1925, L, No. 13]. The best known of these uses the following formulas, where $n = 0, 1, \cdots, N - 1$ (N the number of steps):

$$\textbf{(7a)}\qquad \begin{aligned} k_1 &= \tfrac{1}{2}hf(x_n, y_n, y_n') \\ k_2 &= \tfrac{1}{2}hf(x_n + \tfrac{1}{2}h, y_n + K, y_n' + k_1) \qquad \text{where } K = \tfrac{1}{2}h(y_n' + \tfrac{1}{2}k_1) \\ k_3 &= \tfrac{1}{2}hf(x_n + \tfrac{1}{2}h, y_n + K, y_n' + k_2) \\ k_4 &= \tfrac{1}{2}hf(x_n + h, y_n + L, y_n' + 2k_3) \qquad \text{where } L = h(y_n' + k_3). \end{aligned}$$

From this we compute the approximation y_{n+1} of $y(x_{n+1})$ at $x_{n+1} = x_0 + (n + 1)h$,

$$\textbf{(7b)}\qquad y_{n+1} = y_n + h(y_n' + \tfrac{1}{3}(k_1 + k_2 + k_3)),$$

and the approximation y_{n+1}' of the derivative $y'(x_{n+1})$ needed in the next step,

$$\textbf{(7c)}\qquad y_{n+1}' = y_n' + \tfrac{1}{3}(k_1 + 2k_2 + 2k_3 + k_4).$$

RKN for ODEs $y'' = f(x, y)$ Not Containing y'. Then $k_2 = k_3$ in (7), which makes the method particularly advantageous and reduces (7) to

$$\textbf{(7*)}\qquad \begin{aligned} k_1 &= \tfrac{1}{2}hf(x_n, y_n) \\ k_2 &= \tfrac{1}{2}hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}h(y_n' + \tfrac{1}{2}k_1)) = k_3 \\ k_4 &= \tfrac{1}{2}hf(x_n + h, y_n + h(y_n' + k_2)) \\ y_{n+1} &= y_n + h(y_n' + \tfrac{1}{3}(k_1 + 2k_2)) \\ y_{n+1}' &= y_n' + \tfrac{1}{3}(k_1 + 4k_2 + k_4). \end{aligned}$$

EXAMPLE 3 **RKN Method. Airy's Equation. Airy Function Ai(x)**

For the problem in Example 2 and $h = 0.2$ as before we obtain from (7*) simply $k_1 = 0.1x_n y_n$ and

$$k_2 = k_3 = 0.1(x_n + 0.1)(y_n + 0.1y_n' + 0.05k_1), \qquad k_4 = 0.1(x_n + 0.2)(y_n + 0.2y_n' + 0.2k_2).$$

Table 21.13 shows the results. The accuracy is the same as in Example 2, but the work was much less. ■

Table 21.13 **Runge–Kutta–Nyström Method Applied to Airy's Equation, Computation of the Airy Function y = Ai(x)**

x_n	y_n	y_n'	$y(x)$ Exact (8D)	$10^8 \cdot$ Error of y_n

0.6	0.209 799 74	−0.212 791 72	0.209 800 06	32
0.8	0.169 845 99	−0.186 411 34	0.169 846 32	33
1.0	0.135 292 18	−0.159 146 09	0.135 292 42	24

Our work in Examples 2 and 3 also illustrates that usefulness of methods for ODEs in the computation of values of **"higher transcendental functions."**

Backward Euler Method for Systems. Stiff Systems

The backward Euler formula (16) in Sec. 21.1 generalizes to systems in the form

$$\mathbf{y}_{n+1} = \mathbf{y}_n + h\,\mathbf{f}(x_{n+1}, \mathbf{y}_{n+1}) \qquad (n = 0, 1, \cdorn \cdorn \cdorn). \tag{8}$$

This is again an implicit method, giving $\mathbf{y}_{n+1}$ implicitly for given $\mathbf{y}_n$. Hence (8) must be solved for $\mathbf{y}_{n+1}$. For a linear system this is shown in the next example. This example also illustrates that, similar to the case of a single ODE in Sec. 21.1, the method is very useful for **stiff systems.** These are systems of ODEs whose matrix has eigenvalues λ of very different magnitudes, having the effect that, just as in Sec. 21.1, the step in direct methods, RK for example, cannot be increased beyond a certain threshold without losing stability. ($\lambda = -1$ and -10 in Example 4, but larger differences do occur in applications.)

EXAMPLE 4 Backward Euler Method for Systems of ODEs. Stiff Systems

Compare the backward Euler method (8) with the Euler and the RK methods for numerically solving the initial value problem

$$y'' + 11y' + 10y = 10x + 11, \qquad y(0) = 2, \qquad y'(0) = -10$$

converted to a system of first-order ODEs.

Solution. The given problem can easily be solved, obtaining

$$y = e^{-x} + e^{-10x} + x$$

so that we can compute errors. Conversion to a system by setting $y = y_1$, $y' = y_2$ [see (4)] gives

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= -10y_1 - 11y_2 + 10x + 11 & y_2(0) &= -10. \end{aligned}$$

The coefficient matrix

$$\mathbf{A} = \begin{bmatrix} 0 & 1 \\ -10 & -11 \end{bmatrix} \quad \text{has the characteristic determinant} \quad \begin{vmatrix} -\lambda & 1 \\ -10 & -\lambda - 11 \end{vmatrix}$$

whose value is $\lambda^2 + 11\lambda + 10 = (\lambda + 1)(\lambda + 10)$. Hence the eigenvalues are -1 and -10 as claimed above. The backward Euler formula is

$$\mathbf{y}_{n+1} = \begin{bmatrix} y_{1,n+1} \\ y_{2,n+1} \end{bmatrix} = \begin{bmatrix} y_{1,n} \\ y_{2,n} \end{bmatrix} + h \begin{bmatrix} y_{2,n+1} \\ -10y_{1,n+1} - 11y_{2,n+1} + 10x_{n+1} + 11 \end{bmatrix}.$$

Reordering terms gives the linear system in the unknowns $y_{1,n+1}$ and $y_{2,n+1}$

$$\begin{aligned} y_{1,n+1} - hy_{2,n+1} &= y_{1,n} \\ 10hy_{1,n+1} + (1 + 11h)y_{2,n+1} &= y_{2,n} + 10h(x_n + h) + 11h. \end{aligned}$$

The coefficient determinant is $D = 1 + 11h + 10h^2$, and Cramer's rule (in Sec. 7.6) gives the solution

$$\mathbf{y}_{n+1} = \frac{1}{D} \begin{bmatrix} (1 + 11h)y_{1,n} + hy_{2,n} + 10h^2x_n + 11h^2 + 10h^3 \\ -10hy_{1,n} + y_{2,n} + 10hx_n + 11h + 10h^2 \end{bmatrix}.$$

Table 21.14 Backward Euler Method (BEM) for Example 4. Comparison with Euler and RK

x	BEM $h = 0.2$	BEM $h = 0.4$	Euler $h = 0.1$	Euler $h = 0.2$	RK $h = 0.2$	RK $h = 0.3$	Exact

Table 21.14 shows the following.

Stability of the backward Euler method for $h = 0.2$ and 0.4 (and in fact for any h; try $h = 5.0$) with decreasing accuracy for increasing h,

Stability of the Euler method for $h = 0.1$ but instability for $h = 0.2$,

Stability of RK for $h = 0.2$ but instability for $h = 0.3$.

Figure 451 shows the Euler method for $h = 0.18$, an interesting case with initial jumping (for about $x < 3$) but later monotone following the solution curve of $y = y_1$. See also CAS Experiment 21. ■

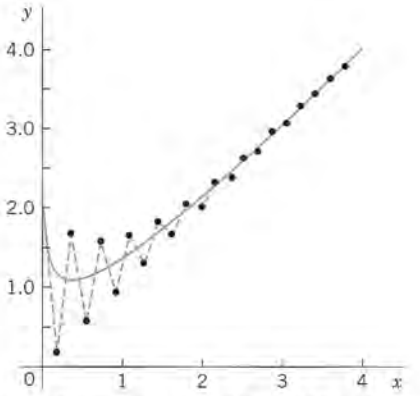

Fig. 451. Euler method with $h = 0.18$ in Example 4

PROBLEM SET 21.3

1. Verify the calculations in Example 1.

21.7 EULER FOR SYSTEMS AND SECOND-ORDER ODES

Solve by the Euler method:

2. $y_1' = -3y_1 + y_2$, $y_2' = y_1 - 3y_2$, $y_1(0) = 2$, $y_2(0) = 0$, $h = 0.1$, 5 steps

3. $y_1' = y_1$, $y_2' = y_2$, $y_1(0) = 1$, $y_2(0) = -1$, $h = 0.2$, 5 steps

4. $y_1' = y_1$, $y_2' = -y_2$, $y_1(0) = 2$, $y_2(0) = 2$, $h = 0.1$, 10 steps

5. $y'' + 4y = 0$, $y(0) = 1$, $y'(0) = 0$, $h = 0.2$, 5 steps

6. $y'' - y = x$, $y(0) = 1$, $y'(0) = -2$, $h = 0.1$, 5 steps

7. $y_1' = -y_1 + y_2$, $y_2' = -y_1 - y_2$, $y_1(0) = 0$, $y_2(0) = 4$, $h = 0.1$, 10 steps

8. Verify the formulas and calculations for the Airy equation in Example 2.

9–14 RK FOR SYSTEMS

Solve by the classical RK:

9. The system in Prob. 7. How much smaller is the error?
10. The ODE in Prob. 6. By what factor did the error decrease?
11. **Undamped Pendulum.** $y'' + \sin y = 0$, $y(\pi) = 0$, $y'(\pi) = 1$, $h = 0.2$, 5 steps. How does your result fit into Fig. 92 in Sec. 4.5?
12. **Bessel Function J_0.** $xy'' + y' + xy = 0$, $y(1) = 0.765198$, $y'(1) = -0.440051$, $h = 0.5$, 5 steps. (This gives the standard solution $J_0(x)$ in Fig. 107 in Sec. 5.5.)
13. $y_1' = -4y_1 + y_2$, $y_2' = y_1 - 4y_2$, $y_1(0) = 0$, $y_2(0) = 2$, $h = 0.1$, 5 steps
14. The system in Prob. 2. How much smaller is the error?

15. Verify the calculations for the Airy equation in Example 3.

16–19 RUNGE–KUTTA–NYSTRÖM METHOD

Do by RKN:

16. Prob. 12 (Bessel function J_0). Compare the results.
17. $y'' - xy' + 4y = 0$, $y(0) = 3$, $y'(0) = 0$, $h = 0.2$, 5 steps (Exact: $y = x^4 - 6x^2 + 3$.)
18. $(x^2 - x)y'' - xy' + y = 0$, $y(\frac{1}{2}) = 1 - \frac{1}{2}\ln 2$, $y'(\frac{1}{2}) = 1 - \ln 2$, $h = 0.1$, 4 steps
19. Prob. 11. Compare the results.

20. **CAS EXPERIMENT. Comparison of Methods. (a)** Write programs for RKN and RK for systems.

    (b) Try them out for second-order ODEs of your choice to find out empirically which is better in specific cases.

    (c) In using RKN, would it pay to first eliminate y' (see Prob. 29 in Problem Set 5.5)? Find out experimentally.

21. **CAS EXPERIMENT. Backward Euler and Stiffness.** Extend Example 4 as follows.

    (a) Verify the values in Table 21.14 and show them graphically as in Fig. 451.

    (b) Compute and graph Euler values for h near the "critical" $h = 0.18$ to determine more exactly when instability starts.

    (c) Compute and graph RK values for values of h between 0.2 and 0.3 to find h for which the RK approximation begins to increase away from the exact solution.

    (d) Compute and graph backward Euler values for large h; confirm stability and investigate the error increase for growing h.

21.4 Methods for Elliptic PDEs

The remaining sections of this chapter are devoted to numerics for PDEs (partial differential equations), particularly for the Laplace, Poisson, heat, and wave equations. These PDEs are basic in applications and, at the same time, are model cases of elliptic, parabolic, and hyperbolic PDEs, respectively. The definitions are as follows. (recall also Sec. 12.4).

A PDE is called **quasilinear** if it is linear in the highest derivatives. Hence a second-order quasilinear PDE in two independent variables x, y is of the form

$$au_{xx} + 2bu_{xy} + cu_{yy} = F(x, y, u, u_x, u_y). \tag{1}$$

u is an unknown function of x and y (a solution sought). F is a given function of the indicated variables.

Depending on the discriminant $ac - b^2$, the PDE (1) is said to be of

elliptic type if $ac - b^2 > 0$ (example: *Laplace equation*)

parabolic type if $ac - b^2 = 0$ (example: *heat equation*)

hyperbolic type if $ac - b^2 < 0$ (example: *wave equation*).

Here, in the heat and wave equations, y is time t. The *coefficients* a, b, c may be functions of x, y, so that the type of (1) may be different in different regions of the xy-plane. This classification is not merely a formal matter but is of great practical importance because the general behavior of solutions differs from type to type and so do the additional conditions (boundary and initial conditions) that must be taken into account.

Applications involving ***elliptic equations*** usually lead to boundary value problems in a region R, called a *first boundary value problem* or **Dirichlet problem** if u is prescribed on the boundary curve C of R, a *second boundary value problem* or **Neumann problem** if $u_n = \partial u/\partial n$ (normal derivative of u) is prescribed on C, and a *third* or **mixed problem** if u is prescribed on a part of C and u_n on the remaining part. C usually is a closed curve (or sometimes consists of two or more such curves).

Difference Equations for the Laplace and Poisson Equations

In this section we consider the **Laplace equation**

$$\nabla^2 u = u_{xx} + u_{yy} = 0 \tag{2}$$

and the **Poisson equation**

$$\nabla^2 u = u_{xx} + u_{yy} = f(x, y). \tag{3}$$

These are the most important elliptic PDEs in applications. To obtain methods of numeric solution, we replace the partial derivatives by corresponding **difference quotients,** as follows. By the Taylor formula,

$$\begin{aligned} &\text{(a)}\quad u(x + h, y) = u(x, y) + hu_x(x, y) + \tfrac{1}{2}h^2 u_{xx}(x, y) + \tfrac{1}{6}h^3 u_{xxx}(x, y) + \cdots \\ &\text{(b)}\quad u(x - h, y) = u(x, y) - hu_x(x, y) + \tfrac{1}{2}h^2 u_{xx}(x, y) - \tfrac{1}{6}h^3 u_{xxx}(x, y) + \cdots \end{aligned} \tag{4}$$

We subtract (4b) from (4a), neglect terms in h^3, h^4, $\cdots$, and solve for u_x. Then

$$u_x(x, y) \approx \frac{1}{2h}\,[u(x + h, y) - u(x - h, y)]. \tag{5a}$$

Similarly,

$$u(x, y + k) = u(x, y) + ku_y(x, y) + \tfrac{1}{2}k^2 u_{yy}(x, y) + \cdots$$

and

$$u(x, y - k) = u(x, y) - ku_y(x, y) + \tfrac{1}{2}k^2 u_{yy}(x, y) + \cdots.$$

By subtracting, neglecting terms in k^3, k^4, $\cdots$, and solving for u_y we obtain

$$u_y(x, y) \approx \frac{1}{2k}\,[u(x, y + k) - u(x, y - k)]. \tag{5b}$$

We now turn to second derivatives. Adding (4a) and (4b) and neglecting terms in $h^4, h^5, \cdots$, we obtain $u(x + h, y) + u(x - h, y) \approx 2u(x, y) + h^2 u_{xx}(x, y)$. Solving for u_{xx}, we have

$$\textbf{(6a)} \qquad u_{xx}(x, y) \approx \frac{1}{h^2}\,[u(x + h, y) - 2u(x, y) + u(x - h, y)].$$

Similarly,

$$\textbf{(6b)} \qquad u_{yy}(x, y) \approx \frac{1}{k^2}\,[u(x, y + k) - 2u(x, y) + u(x, y - k)].$$

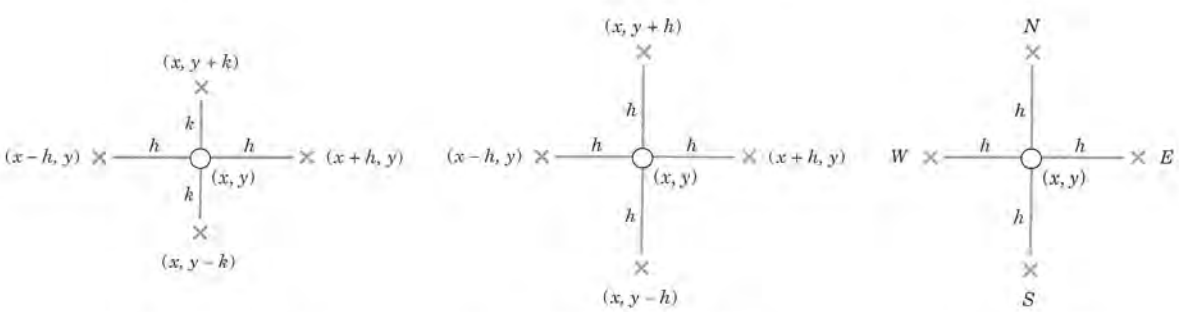
We shall not need (see Prob. 1)

$$\textbf{(6c)} \qquad u_{xy}(x, y) \approx \frac{1}{4hk}\,[u(x + h, y + k) - u(x - h, y + k) - u(x + h, y - k) + u(x - h, y - k)].$$

Figure 452a shows the points $(x + h, y)$, $(x - h, y)$, $\cdots$ in (5) and (6).

We now substitute (6a) and (6b) into the ***Poisson equation*** (3), choosing $k = h$ to obtain a simple formula:

$$\textbf{(7)} \qquad u(x + h, y) + u(x, y + h) + u(x - h, y) + u(x, y - h) - 4u(x, y) = h^2 f(x, y).$$



This is a **difference equation** corresponding to (3). Hence for the ***Laplace equation*** (2) the corresponding difference equation is

$$\textbf{(8)} \qquad u(x + h, y) + u(x, y + h) + u(x - h, y) + u(x, y - h) - 4u(x, y) = 0.$$

h is called the **mesh size.** Equation (8) relates u at (x, y) to u at the four neighboring points shown in Fig. 452b. It has a remarkable interpretation: u at (x, y) equals the mean of the values of u at the four neighboring points. This is an analog of the mean value property of harmonic functions (Sec. 18.6).

Those neighbors are often called E (East), N (North), W (West), S (South). Then Fig. 452b becomes Fig. 452c and (7) is

$$\textbf{(7*)} \qquad u(E) + u(N) + u(W) + u(S) - 4u(x, y) = h^2 f(x, y).$$

(a) Points in (5) and (6) (b) Points in (7) and (8) (c) Notation in (7*)

Fig. 452. Points and notation in (5)–(8) and (7*)

Our approximation of $h^2\nabla^2 u$ in (7) and (8) is a 5-point approximation with the coefficient scheme or **stencil** (also called *pattern, molecule,* or *star*)

$$\textbf{(9)}\quad \begin{Bmatrix} & 1 & \\ 1 & -4 & 1 \\ & 1 & \end{Bmatrix}. \quad \text{We may now write (7) as} \quad \begin{Bmatrix} & 1 & \\ 1 & -4 & 1 \\ & 1 & \end{Bmatrix} u = h^2 f(x, y).$$

Dirichlet Problem

In numerics for the Dirichlet problem in a region R we choose an h and introduce a square grid of horizontal and vertical straight lines of distance h. Their intersections are called **mesh points** (or *lattice points* or *nodes*). See Fig. 453.

Then we approximate the given PDE by a difference equation [(8) for the Laplace equation], which relates the unknown values of u at the mesh points in R to each other and to the given boundary values (details on p. 913). This gives a linear system of *algebraic* equations. By solving it we get approximations of the unknown values of u at the mesh points in R.

We shall see that the number of equations equals the number of unknowns. Now comes an important point. If the number of internal mesh points, call it p, is small, say, $p < 100$, then a direct solution method may be applied to that linear system of $p < 100$ equations in p unknowns. However, if p is large, a storage problem will arise. Now since each unknown u is related to only 4 of its neighbors, the coefficient matrix of the system is a **sparse matrix,** that is, a matrix with relatively few nonzero entries (for instance, 500 of 10000 when $p = 100$). Hence for large p we may avoid storage difficulties by using an iteration method, notably the Gauss–Seidel method (Sec. 20.3), which in PDEs is also called **Liebmann's method.** Remember that in this method we have the storage convenience that we can overwrite any solution component (value of u) as soon as a "new" value is available.

Both cases, large p and small p, are of interest to the engineer, large p if a fine grid is used to achieve high accuracy, and small p if the boundary values are known only rather inaccurately, so that a coarse grid will do it because in this case it would be meaningless to try for great accuracy in the interior of the region R.

We illustrate this approach with an example, keeping the number of equations small, for simplicity. As convenient ***notations for mesh points and corresponding values of the solution*** (and of approximate solutions) we use (see also Fig. 453)

$$\textbf{(10)}\qquad P_{ij} = (ih, jh), \qquad u_{ij} = u(ih, jh).$$

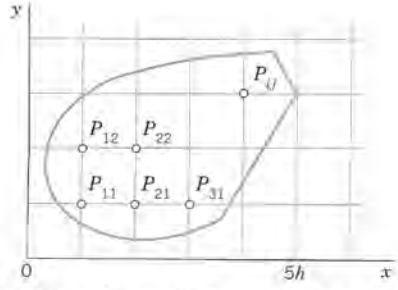


Fig. 453. Region in the xy-plane covered by a grid of mesh h, also showing mesh points $P_{11} = (h, h), \cdots, P_{ij} = (ih, jh), \cdots$

With this notation we can write (8) for any mesh point P_{ij} in the form

$$u_{i+1,j} + u_{i,j+1} + u_{i-1,j} + u_{i,j-1} - 4u_{ij} = 0. \tag{11}$$

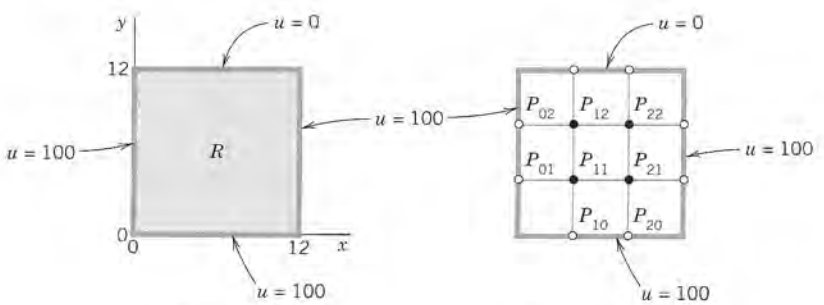
EXAMPLE 1 **Laplace Equation. Liebmann's Method**

The four sides of a square plate of side 12 cm made of homogeneous material are kept at constant temperature 0°C and 100°C as shown in Fig. 454a. Using a (very wide) grid of mesh 4 cm and applying Liebmann's method (that is, Gauss–Seidel iteration), find the (steady-state) temperature at the mesh points.

Solution. In the case of independence of time, the heat equation (see Sec. 10.8)

$$u_t = c^2(u_{xx} + u_{yy})$$

reduces to the Laplace equation. Hence our problem is a Dirichlet problem for the latter. We choose the grid shown in Fig. 454b and consider the mesh points in the order P_{11}, P_{21}, P_{12}, P_{22}. We use (11) and, in each equation, take to the right all the terms resulting from the given boundary values. Then we obtain the system



$$\begin{aligned} -4u_{11} + u_{21} + u_{12} &= -200 \\ u_{11} - 4u_{21} + u_{22} &= -200 \\ u_{11} - 4u_{12} + u_{22} &= -100 \\ u_{21} + u_{12} - 4u_{22} &= -100. \end{aligned} \tag{12}$$

In practice, one would solve such a small system by the Gauss elimination, finding $u_{11} = u_{21} = 87.5$, $u_{12} = u_{22} = 62.5$.

More exact values (exact to 3S) of the solution of the actual problem [as opposed to its model (12)] are 88.1 and 61.9, respectively. (These were obtained by using Fourier series.) Hence the error is about 1%, which is surprisingly accurate for a grid of such a large mesh size h. If the system of equations were large, one would solve it by an indirect method, such as Liebmann's method. For (12) this is as follows. We write (12) in the form (divide by -4 and take terms to the right)

$$\begin{aligned} u_{11} &= 0.25u_{21} + 0.25u_{12} + 50 \\ u_{21} &= 0.25u_{11} + 0.25u_{22} + 50 \\ u_{12} &= 0.25u_{11} + 0.25u_{22} + 25 \\ u_{22} &= 0.25u_{21} + 0.25u_{12} + 25. \end{aligned}$$

These equations are now used for the Gauss–Seidel iteration. They are identical with (2) in Sec. 20.3, where $u_{11} = x_1$, $u_{21} = x_2$, $u_{12} = x_3$, $u_{22} = x_4$, and the iteration is explained there, with 100, 100, 100, 100 chosen as starting values. Some work can be saved by better starting values, usually by taking the average of the boundary values that enter into the linear system. The exact solution of the system is $u_{11} = u_{21} = 87.5$, $u_{12} = u_{22} = 62.5$, as you may verify.

(a) Given problem (b) Grid and mesh points

Fig. 454. Example 1

Remark. It is interesting to note that if we choose mesh $h = L/n$ (L = side of R) and consider the $(n-1)^2$ internal mesh points (i.e., mesh points not on the boundary) row by row in the order

$$P_{11}, P_{21}, \cdots, P_{n-1,1}, P_{12}, P_{22}, \cdots, P_{n-1,2}, \cdots,$$

then the system of equations has the $(n-1)^2 \times (n-1)^2$ coefficient matrix

$$\text{(13)} \quad \mathbf{A} = \begin{bmatrix} \mathbf{B} & \mathbf{I} & & & & & \\ \mathbf{I} & \mathbf{B} & \mathbf{I} & & & & \\ & \cdot & \cdot & \cdot & & & \\ & & \cdot & \cdot & \cdot & & \\ & & & \mathbf{I} & \mathbf{B} & \mathbf{I} & \\ & & & & \mathbf{I} & \mathbf{B} \end{bmatrix}. \quad \text{Here} \quad \mathbf{B} = \begin{bmatrix} -4 & 1 & & & & & \\ 1 & -4 & 1 & & & & \\ & \cdot & \cdot & \cdot & & & \\ & & \cdot & \cdot & \cdot & & \\ & & & 1 & -4 & 1 & \\ & & & & 1 & -4 \end{bmatrix}$$

is an $(n-1) \times (n-1)$ matrix. (In (12) we have $n = 3$, $(n-1)^2 = 4$ internal mesh points, two submatrices **B**, and two submatrices **I**.) The matrix **A** is nonsingular. This follows by noting that the off-diagonal entries in each row of **A** have the sum 3 (or 2), whereas each diagonal entry of **A** equals -4, so that nonsingularity is implied by Gerschgorin's theorem in Sec. 20.7 because no Gerschgorin disk can include 0. ■

A matrix is called a **band matrix** if it has all its nonzero entries on the main diagonal and on sloping lines parallel to it (separated by sloping lines of zeros or not). For example, **A** in (13) is a band matrix. Although the Gauss elimination does not preserve zeros between bands, it does not introduce nonzero entries outside the limits defined by the original bands. Hence a band structure is advantageous. In (13) it has been achieved by carefully ordering the mesh points.

ADI Method

A matrix is called a **tridiagonal matrix** if it has all its nonzero entries on the main diagonal and on the two sloping parallels immediately above or below the diagonal. (See also Sec. 20.9.) In this case the Gauss elimination is particularly simple.

This raises the question of whether in the solution of the Dirichlet problem for the Laplace or Poisson equations one could obtain a system of equations whose coefficient matrix is tridiagonal. The answer is yes, and a popular method of that kind, called the **ADI method** (*alternating direction implicit method*) was developed by Peaceman and Rachford. The idea is as follows. The stencil in (9) shows that we could obtain a tridiagonal matrix if there were only the three points in a row (or only the three points in a column). This suggests that we write (11) in the form

$$\text{(14a)} \qquad u_{i-1,j} - 4u_{ij} + u_{i+1,j} = -u_{i,j-1} - u_{i,j+1}$$

so that the left side belongs to y-Row j only and the right side to x-Column i. Of course, we can also write (11) in the form

$$\text{(14b)} \qquad u_{i,j-1} - 4u_{ij} + u_{i,j+1} = -u_{i-1,j} - u_{i+1,j}$$

so that the left side belongs to Column i and the right side to Row j. In the ADI method we proceed by iteration. At every mesh point we choose an arbitrary starting value $u_{ij}^{(0)}$. In each step we compute new values at all mesh points. In one step we use an iteration

formula resulting from (14a) and in the next step an iteration formula resulting from (14b), and so on in alternating order.

In detail: suppose approximations $u_{ij}^{(m)}$ have been computed. Then, to obtain the next approximations $u_{ij}^{(m+1)}$, we substitute the $u_{ij}^{(m)}$ ***on the right*** side of (14a) and solve for the $u_{ij}^{(m+1)}$ on the left side; that is, we use

(15a)
$$u_{i-1,j}^{(m+1)} - 4u_{ij}^{(m+1)} + u_{i+1,j}^{(m+1)} = -u_{i,j-1}^{(m)} - u_{i,j+1}^{(m)}.$$

We use (15a) for a fixed j, that is, ***for a fixed row*** j, and for all internal mesh points in this row. This gives a linear system of N algebraic equations (N = number of internal mesh points per row) in N unknowns, the new approximations of u at these mesh points. Note that (15a) involves not only approximations computed in the previous step but also given boundary values. We solve the system (15a) (j fixed!) by Gauss elimination. Then we go to the next row, obtain another system of N equations and solve it by Gauss, and so on, until all rows are done. In the next step we ***alternate direction,*** that is, we compute the next approximations $u_{ij}^{(m+2)}$ column by column from the $u_{ij}^{(m+1)}$ and the given boundary values, using a formula obtained from (14b) by substituting the $u_{ij}^{(m+1)}$ ***on the right:***

(15b)
$$u_{i,j-1}^{(m+2)} - 4u_{ij}^{(m+2)} + u_{i,j+1}^{(m+2)} = -u_{i-1,j}^{(m+1)} - u_{i+1,j}^{(m+1)}.$$

For each fixed i, that is, ***for each column,*** this is a system of M equations (M = number of internal mesh points per column) in M unknowns, which we solve by Gauss elimination. Then we go to the next column, and so on, until all columns are done.

Let us consider an example that merely serves to explain the entire method.

EXAMPLE 2 **Dirichlet Problem. ADI Method**

Explain the procedure and formulas of the ADI method in terms of the problem in Example 1, using the same grid and starting values 100, 100, 100, 100.

Solution. While working, we keep an eye on Fig. 454b on p. 913 and the given boundary values. We obtain first approximations $u_{11}^{(1)}$, $u_{21}^{(1)}$, $u_{12}^{(1)}$, $u_{22}^{(1)}$ from (15a) with $m = 0$. We write boundary values contained in (15a) without an upper index, for better identification and to indicate that these given values remain the same during the iteration. From (15a) with $m = 0$ we have for $j = 1$ (first row) the system

$$\begin{aligned} (i = 1) \quad & u_{01} - 4u_{11}^{(1)} + u_{21}^{(1)} = -u_{10} - u_{12}^{(0)} \\ (i = 2) \quad & u_{11}^{(1)} - 4u_{21}^{(1)} + u_{31} = -u_{20} - u_{22}^{(0)}. \end{aligned}$$

The solution is $u_{11}^{(1)} = u_{21}^{(1)} = 100$. For $j = 2$ (second row) we obtain from (15a) the system

$$\begin{aligned} (i = 1) \quad & u_{02} - 4u_{12}^{(1)} + u_{22}^{(1)} = -u_{11}^{(0)} - u_{13} \\ (i = 2) \quad & u_{12}^{(1)} - 4u_{22}^{(1)} + u_{32} = -u_{21}^{(0)} - u_{23}. \end{aligned}$$

The solution is $u_{12}^{(1)} = u_{22}^{(1)} = 66.667$.

Second approximations $u_{11}^{(2)}$, $u_{21}^{(2)}$, $u_{12}^{(2)}$, $u_{22}^{(2)}$ are now obtained from (15b) with $m = 1$ by using the first approximations just computed and the boundary values. For $i = 1$ (first column) we obtain from (15b) the system

$$\begin{aligned} (j = 1) \quad & u_{10} - 4u_{11}^{(2)} + u_{12}^{(2)} = -u_{01} - u_{21}^{(1)} \\ (j = 2) \quad & u_{11}^{(2)} - 4u_{12}^{(2)} + u_{13} = -u_{02} - u_{22}^{(1)}. \end{aligned}$$

The solution is $u_{11}^{(2)} = 91.11$, $u_{12}^{(2)} = 64.44$. For $i = 2$ (second column) we obtain from (15b) the system

$$\begin{aligned} (j = 1) \quad & u_{20} - 4u_{21}^{(2)} + u_{22}^{(2)} = -u_{11}^{(1)} - u_{31} \\ (j = 2) \quad & u_{21}^{(2)} - 4u_{22}^{(2)} + u_{23} = -u_{12}^{(1)} - u_{32}. \end{aligned}$$

The solution is $u_{21}^{(2)} = 91.11$, $u_{22}^{(2)} = 64.44$.

In this example, which merely serves to explain the practical procedure in the ADI method, the accuracy of the second approximations is about the same as that of two Gauss–Seidel steps in Sec. 20.3 (where $u_{11} = x_1$, $u_{21} = x_2$, $u_{12} = x_3$, $u_{22} = x_4$), as the following table shows.

Method	u_{11}	u_{21}	u_{12}	u_{22}
ADI, 2nd approximations	91.11	91.11	64.44	64.44
Gauss–Seidel, 2nd approximations	93.75	90.62	65.62	64.06
Exact solution of (12)	87.50	87.50	62.50	62.50

Improving Convergence. Additional improvement of the convergence of the ADI method results from the following interesting idea. Introducing a parameter p, we can also write (11) in the form

$$\text{(16)} \quad \begin{aligned} &\text{(a)} \quad u_{i-1,j} - (2+p)u_{ij} + u_{i+1,j} = -u_{i,j-1} + (2-p)u_{ij} - u_{i,j+1} \\ &\text{(b)} \quad u_{i,j-1} - (2+p)u_{ij} + u_{i,j+1} = -u_{i-1,j} + (2-p)u_{ij} - u_{i+1,j}. \end{aligned}$$

This gives the more general ADI iteration formulas

$$\text{(17)} \quad \begin{aligned} &\textbf{(a)} \quad u_{i-1,j}^{(m+1)} - (2+p)u_{ij}^{(m+1)} + u_{i+1,j}^{(m+1)} = -u_{i,j-1}^{(m)} + (2-p)u_{ij}^{(m)} - u_{i,j+1}^{(m)} \\ &\textbf{(b)} \quad u_{i,j-1}^{(m+2)} - (2+p)u_{ij}^{(m+2)} + u_{i,j+1}^{(m+2)} = -u_{i-1,j}^{(m+1)} + (2-p)u_{ij}^{(m+1)} - u_{i+1,j}^{(m+1)}. \end{aligned}$$

For $p = 2$, this is (15). The parameter p may be used for improving convergence. Indeed, one can show that the ADI method converges for positive p, and that the optimum value for maximum rate of convergence is

$$\text{(18)} \qquad p_0 = 2 \sin \frac{\pi}{K}$$

where K is the larger of $M + 1$ and $N + 1$ (see above). Even better results can be achieved by letting p vary from step to step. More details of the ADI method and variants are discussed in Ref. [E25] listed in App. 1.

PROBLEM SET 21.4

1. Derive (5b), (6b), and (6c).

21.7 GAUSS ELIMINATION, GAUSS–SEIDEL ITERATION

For the grid in Fig. 455 compute the potential at the four internal points by Gauss and by 5 Gauss–Seidel steps with starting values 100, 100, 100, 100 (showing the details of your work) if the boundary values on the edges are:

2. $u = 0$ on the left, x^3 on the lower edge, $27 - 9y^2$ on the right, $x^3 - 27x$ on the upper edge.

3. $u(1, 0) = 60$, $u(2, 0) = 300$, $u = 100$ on the other three edges.

4. $u = x^4$ on the lower edge, $81 - 54y^2 + y^4$ on the right, $x^4 - 54x^2 + 81$ on the upper edge, y^4 on the left. Verify the exact solution $x^4 - 6x^2y^2 + y^4$ and determine the error.

5. $u = \sin \frac{1}{3}\pi x$ on the upper edge, 0 on the other edges. 10 steps.

6. $u = 220$ on the upper and lower edges, 110 on the left and right.

7. V_0 on the upper and lower edges, $-V_0$ on the left and right. Sketch the equipotential lines.

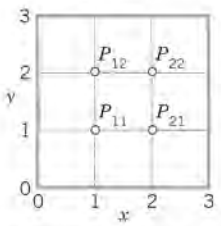


Fig. 455. Problems 2–7

8. Verify the calculations in Example 1. Find out experimentally how many steps are needed to obtain the solution of the linear system with an accuracy of 3S.

9. **(Use of symmetry)** Conclude from the boundary values in Example 1 that $u_{21} = u_{11}$ and $u_{22} = u_{12}$. Show that this leads to a system of two equations and solve it.

10. **(3 × 3 grid)** Solve Example 1, choosing $h = 3$ and starting values 100, 100, · · · .

11. For the square $0 \leqq x \leqq 4$, $0 \leqq y \leqq 4$ let the boundary temperatures be 0°C on the horizontal and 50°C on the vertical edges. Find the temperatures at the interior points of a square grid with $h = 1$.

12. Using the answer to Prob. 11, try to sketch some isotherms.

13. Find the isotherms for the square and grid in Prob. 11 if $u = \sin \frac{1}{4}\pi x$ on the horizontal and $-\sin \frac{1}{4}\pi y$ on the vertical edges. Try to sketch some isotherms.

14. **(Influence of starting values)** Do Prob. 5 by Gauss–Seidel, starting from **0**. Compare and comment.

15. Find the potential in Fig. 456 using (a) the coarse grid, (b) the fine grid, and Gauss elimination. *Hint.* In (b), use symmetry; take $u = 0$ as the boundary value at the two points at which the potential has a jump.

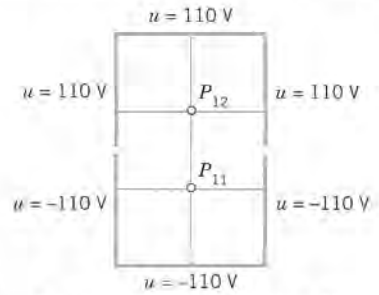

Fig. 456. Region and grids in Problem 15

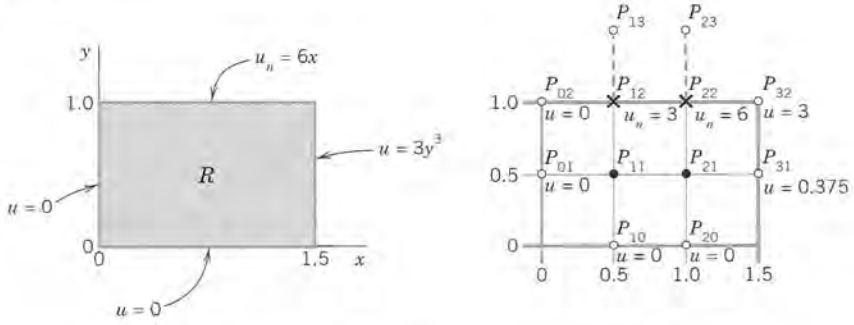
16. **(ADI)** Apply the ADI method to the Dirichlet problem in Prob. 5, using the grid in Fig. 455, as before and starting values zero.

17. What p_0 in (18) should we choose for Prob. 16? Apply the ADI formulas (17) with $p_0 = 1.7$ to Prob. 16, performing 1 step. Illustrate the improved convergence by comparing with the corresponding values 0.077, 0.308 after the first step in Prob. 16. (Use the starting values zero.)

18. **CAS PROJECT. Laplace Equation. (a)** Write a program for Gauss–Seidel with 16 equations in 16 unknowns, composing the matrix (13) from the indicated 4×4 submatrices and including a transformation of the vector of the boundary values into the vector **b** of $\mathbf{Ax} = \mathbf{b}$.

(b) Apply the program to the square grid in $0 \leqq x \leqq 5$, $0 \leqq y \leqq 5$ with $h = 1$ and $u = 220$ on the upper and lower edges, $u = 110$ on the left edge and $u = -10$ on the right edge. Solve the linear system also by Gauss elimination. What accuracy is reached in the 20th Gauss–Seidel step?

21.5 Neumann and Mixed Problems. Irregular Boundary



We continue our discussion of boundary value problems for elliptic PDEs in a region R in the xy-plane. The Dirichlet problem was studied in the last section. In solving **Neumann** and **mixed problems** (defined in the last section) we are confronted with a new situation, because there are boundary points at which the (outer) **normal derivative** $u_n = \partial u/\partial n$ of the solution is given, but u itself is unknown since it is not given. To handle such points we need a new idea. This idea is the same for Neumann and mixed problems. Hence we may explain it in connection with one of these two types of problems. We shall do so and consider a typical example as follows.

EXAMPLE 1 Mixed Boundary Value Problem for a Poisson Equation

Solve the mixed boundary value problem for the Poisson equation

$$\nabla^2 u = u_{xx} + u_{yy} = f(x, y) = 12xy$$

shown in Fig. 457a.

(a) Region R and boundary values (b) Grid ($h = 0.5$)

Fig. 457. Mixed boundary value problem in Example 1

Solution. We use the grid shown in Fig. 457b, where $h = 0.5$. We recall that (7) in Sec. 21.4 has the right side $h^2 f(x, y) = 0.5^2 \cdot 12xy = 3xy$. From the formulas $u = 3y^3$ and $u_n = 6x$ given on the boundary we compute the boundary data

$$(1) \qquad u_{31} = 0.375, \qquad u_{32} = 3, \qquad \frac{\partial u_{12}}{\partial n} = \frac{\partial u_{12}}{\partial y} = 6 \cdot 0.5 = 3, \qquad \frac{\partial u_{22}}{\partial n} = \frac{\partial u_{22}}{\partial y} = 6 \cdot 1 = 6.$$

P_{11} and P_{21} are internal mesh points and can be handled as in the last section. Indeed, from (7), Sec. 21.4, with $h^2 = 0.25$ and $h^2 f(x, y) = 3xy$ and from the given boundary values we obtain two equations corresponding to P_{11} and P_{21}, as follows (with -0 resulting from the left boundary).

$$(2a) \qquad \begin{aligned} -4u_{11} + u_{21} + u_{12} &= 12(0.5 \cdot 0.5) \cdot \tfrac{1}{4} - 0 = 0.75 \\ u_{11} - 4u_{21} + u_{22} &= 12(1 \cdot 0.5) \cdot \tfrac{1}{4} - 0.375 = 1.125 \end{aligned}$$

The only difficulty with these equations seems to be that they involve the unknown values u_{12} and u_{22} of u at P_{12} and P_{22} on the boundary, where the normal derivative $u_n = \partial u/\partial n = \partial u/\partial y$ is given, instead of u; but we shall overcome this difficulty as follows.

We consider P_{12} and P_{22}. The idea that will help us here is this. We imagine the region R to be extended above to the first row of external mesh points (corresponding to $y = 1.5$), and we assume that the Poisson equation also holds in the extended region. Then we can write down two more equations as before (Fig. 457b)

$$(2b) \qquad \begin{aligned} u_{11} - 4u_{12} + u_{22} + u_{13} &= 1.5 - 0 = 1.5 \\ u_{21} + u_{12} - 4u_{22} + u_{23} &= 3 - 3 = 0. \end{aligned}$$

On the right, 1.5 is $12xyh^2$ at (0.5, 1) and 3 is $12xyh^2$ at (1, 1) and 0 (at P_{02}) and 3 (at P_{32}) are given boundary values. We remember that we have not yet used the boundary condition on the upper part of the boundary of R, and we also notice that in (2b) we have introduced two more unknowns u_{13}, u_{23}. But we can now use that condition and get rid of u_{13}, u_{23} by applying the central difference formula for du/dy. From (1) we then obtain (see Fig. 457b)

$$3 = \frac{\partial u_{12}}{\partial y} \approx \frac{u_{13} - u_{11}}{2h} = u_{13} - u_{11}, \qquad \text{hence} \qquad u_{13} = u_{11} + 3$$

$$6 = \frac{\partial u_{22}}{\partial y} \approx \frac{u_{23} - u_{21}}{2h} = u_{23} - u_{21}, \qquad \text{hence} \qquad u_{23} = u_{21} + 6.$$

Substituting these results into (2b) and simplifying, we have

$$2u_{11} - 4u_{12} + u_{22} = 1.5 - 3 = -1.5$$
$$2u_{21} + u_{12} - 4u_{22} = 3 - 3 - 6 = -6.$$

Together with (2a) this yields, written in matrix form,

$$(3) \qquad \begin{bmatrix} -4 & 1 & 1 & 0 \\ 1 & -4 & 0 & 1 \\ 2 & 0 & -4 & 1 \\ 0 & 2 & 1 & -4 \end{bmatrix} \begin{bmatrix} u_{11} \\ u_{21} \\ u_{12} \\ u_{22} \end{bmatrix} = \begin{bmatrix} 0.75 \\ 1.125 \\ 1.5 - 3 \\ 0 - 6 \end{bmatrix} = \begin{bmatrix} 0.75 \\ 1.125 \\ -1.5 \\ -6 \end{bmatrix}.$$

(The entries 2 come from u_{13} and u_{23}, and so do -3 and -6 on the right). The solution of (3) (obtained by Gauss elimination) is as follows; the exact values of the problem are given in parentheses.

$$u_{12} = 0.866 \quad \text{(exact 1)} \qquad u_{22} = 1.812 \quad \text{(exact 2)}$$
$$u_{11} = 0.077 \quad \text{(exact 0.125)} \qquad u_{21} = 0.191 \quad \text{(exact 0.25).}$$

Irregular Boundary

We continue our discussion of boundary value problems for elliptic PDEs in a region R in the xy-plane. If R has a simple geometric shape, we can usually arrange for certain mesh points to lie on the boundary C of R, and then we can approximate partial derivatives as explained in the last section. However, if C intersects the grid at points that are not mesh points, then at points close to the boundary we must proceed differently, as follows.

The mesh point O in Fig. 458 is of that kind. For O and its neighbors A and P we obtain from Taylor's theorem

$$(4) \qquad \text{(a)} \quad u_A = u_O + ah \frac{\partial u_O}{\partial x} + \frac{1}{2}(ah)^2 \frac{\partial^2 u_O}{\partial x^2} + \cdots$$
$$\text{(b)} \quad u_P = u_O - h \frac{\partial u_O}{\partial x} + \frac{1}{2} h^2 \frac{\partial^2 u_O}{\partial x^2} + \cdots.$$

We disregard the terms marked by dots and eliminate $\partial u_O/\partial x$. Equation (4b) times a plus equation (4a) gives

$$u_A + a u_P \approx (1 + a)u_O + \frac{1}{2} a(a + 1)h^2 \frac{\partial^2 u_O}{\partial x^2}.$$

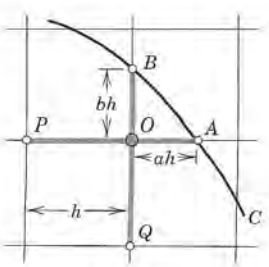


Fig. 458. Curved boundary C of a region R, a mesh point O near C, and neighbors A, B, P, Q

We solve this last equation algebraically for the derivative, obtaining

$$\frac{\partial^2 u_O}{\partial x^2} \approx \frac{2}{h^2}\left[\frac{1}{a(1+a)}\,u_A + \frac{1}{1+a}\,u_P - \frac{1}{a}\,u_O\right].$$

Similarly, by considering the points O, B, and Q,

$$\frac{\partial^2 u_O}{\partial y^2} \approx \frac{2}{h^2}\left[\frac{1}{b(1+b)}\,u_B + \frac{1}{1+b}\,u_Q - \frac{1}{b}\,u_O\right].$$

By addition,

$$\textbf{(5)}\quad \nabla^2 u_O \approx \frac{2}{h^2}\left[\frac{u_A}{a(1+a)} + \frac{u_B}{b(1+b)} + \frac{u_P}{1+a} + \frac{u_Q}{1+b} - \frac{(a+b)u_O}{ab}\right].$$

For example, if $a = \frac{1}{2}$, $b = \frac{1}{2}$, instead of the stencil (see Sec. 21.4)

$$\begin{Bmatrix} & 1 & \\ 1 & -4 & 1 \\ & 1 & \end{Bmatrix} \qquad \text{we now have} \qquad \begin{Bmatrix} & \frac{4}{3} & \\ \frac{2}{3} & -4 & \frac{4}{3} \\ & \frac{2}{3} & \end{Bmatrix}.$$

because $1/[a(1+a)] = \frac{4}{3}$, etc. The sum of all five terms still being zero (which is useful for checking).

Using the same ideas, you may show that in the case of Fig. 459,

$$\textbf{(6)}\quad \nabla^2 u_O \approx \frac{2}{h^2}\left[\frac{u_A}{a(a+p)} + \frac{u_B}{b(b+q)} + \frac{u_P}{p(p+a)} + \frac{u_Q}{q(q+b)} - \frac{ap+bq}{abpq}\,u_O\right],$$

a formula that takes care of all conceivable cases.

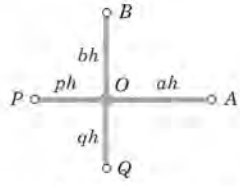

Fig. 459. Neighboring points A, B, P, Q of a mesh point O and notations in formula (6)

EXAMPLE 2 **Dirichlet Problem for the Laplace Equation. Curved Boundary**

Find the potential u in the region in Fig. 460 that has the boundary values given in that figure; here the curved portion of the boundary is an arc of the circle of radius 10 about (0, 0). Use the grid in the figure.

Solution. u is a solution of the Laplace equation. From the given formulas for the boundary values $u = x^3$, $u = 512 - 24y^2$, $\cdots$ we compute the values at the points where we need them; the result is shown in the figure. For P_{11} and P_{12} we have the usual regular stencil, and for P_{21} and P_{22} we use (6), obtaining

$$\text{(7)}\quad P_{11}, P_{12}: \begin{Bmatrix} & 1 & \\ 1 & -4 & 1 \\ & 1 & \end{Bmatrix}, \qquad P_{21}: \begin{Bmatrix} & 0.5 & \\ 0.6 & -2.5 & 0.9 \\ & 0.5 & \end{Bmatrix}, \qquad P_{22}: \begin{Bmatrix} & 0.9 & \\ 0.6 & -3 & 0.9 \\ & 0.6 & \end{Bmatrix}.$$

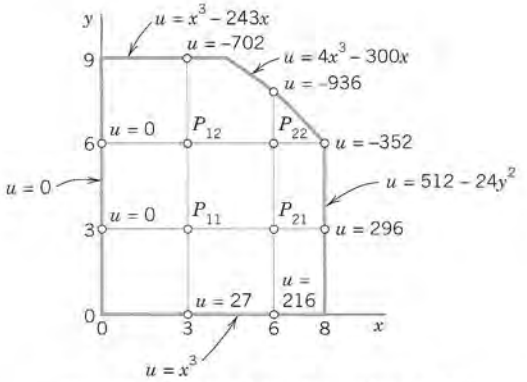

Fig. 460. Region, boundary values of the potential, and grid in Example 2

We use this and the boundary values and take the mesh points in the usual order P_{11}, P_{21}, P_{12}, P_{22}. Then we obtain the system

$$\begin{aligned}
-4u_{11} + u_{21} + u_{12} &= 0 - 27 &&= -27\\
0.6u_{11} - 2.5u_{21} + 0.5u_{22} &= -0.9 \cdot 296 - 0.5 \cdot 216 &&= -374.4\\
u_{11} - 4u_{12} + u_{22} &= 702 + 0 &&= 702\\
0.6u_{21} + 0.6u_{12} - 3u_{22} &= 0.9 \cdot 352 + 0.9 \cdot 936 &&= 1159.2.
\end{aligned}$$

In matrix form,

$$\begin{bmatrix} -4 & 1 & 1 & 0 \\ 0.6 & -2.5 & 0 & 0.5 \\ 1 & 0 & -4 & 1 \\ 0 & 0.6 & 0.6 & -3 \end{bmatrix} \begin{bmatrix} u_{11} \\ u_{21} \\ u_{12} \\ u_{22} \end{bmatrix} = \begin{bmatrix} -27 \\ -374.4 \\ 702 \\ 1159.2 \end{bmatrix}. \tag{8}$$

Gauss elimination yields the (rounded) values

$$u_{11} = -55.6, \quad u_{21} = 49.2, \quad u_{12} = -298.5, \quad u_{22} = -436.3.$$

Clearly, from a grid with so few mesh points we cannot expect great accuracy. The exact solution of the PDE (not of the difference equation) having the given boundary values is $u = x^3 - 3xy^2$ and yields the values

$$u_{11} = -54, \quad u_{21} = 54, \quad u_{12} = -297, \quad u_{22} = -432.$$

In practice one would use a much finer grid and solve the resulting large system by an indirect method. ■

PROBLEM SET 21.5

1. Verify the calculation for the Poisson equation in Example 1. Check the values for (3) at the end.
2. Derive (5) in particular when $a = b = \frac{1}{2}$.
3. Derive the general stencil formula (6) in all detail.
4. Verify the calculation for the boundary value problem in Example 2.
5. Do Example 1 in the text for $\nabla^2 u = 0$ with grid and boundary data as before.

MIXED BOUNDARY VALUE PROBLEMS

6. Solve the mixed boundary value problem for the Laplace equation $\nabla^2 u = 0$ in the rectangle in Fig. 457a (using the grid in Fig. 457b) and the boundary conditions $u_x = 0$ on the left edge, $u_x = 3$ on the right edge, $u = x^2$ on the lower edge, and $u = x^2 - 1$ on the upper edge.
7. Solve Prob. 6 when $u_n = 1$ on the upper edge and $u = 1$ on the other edges.

8. Solve the mixed boundary value problem for the Poisson equation $\nabla^2 u = 2(x^2 + y^2)$ in the region and for the boundary conditions shown in Fig. 461, using the indicated grid.

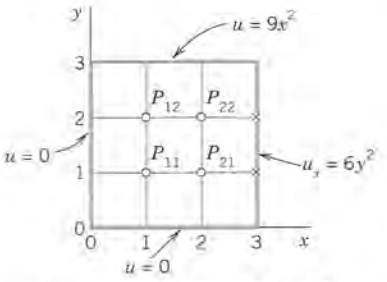

Fig. 461. Problems 8 and 10

9. CAS EXPERIMENT. Mixed Problem. Do Example 1 in the text with finer and finer grids of your choice and study the accuracy of the approximate values by comparing with the exact solution $u = 2xy^3$. Verify the latter.

10. Solve $\nabla^2 u = -\pi^2 y \sin \frac{1}{3}\pi x$ for the grid in Fig. 461 and $u_y(1, 3) = u_y(2, 3) = \frac{1}{2}\sqrt{243}$, $u = 0$ on the other three sides of the square.

IRREGULAR BOUNDARIES

11. Solve the Laplace equation in the region and for the boundary values shown in Fig. 462, using the indicated grid. (The sloping portion of the boundary is $y = 4.5 - x$.)

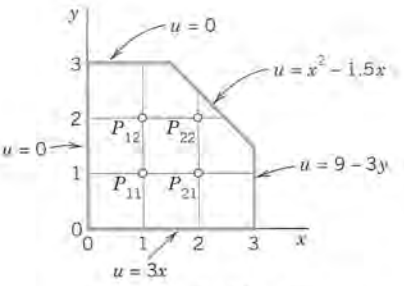

Fig. 462. Problem 11

12. If in Prob. 11 the axes are grounded ($u = 0$), what constant potential must the other portion of the boundary have in order to produce 100 volts at P_{11}?

13. What potential do we have in Prob. 11 if $u = 190$ volts on the axes and $u = 0$ on the other portion of the boundary?

14. Solve the Poisson equation $\nabla^2 u = 2$ in the region and for the boundary values shown in Fig. 463, using the grid also shown in the figure.

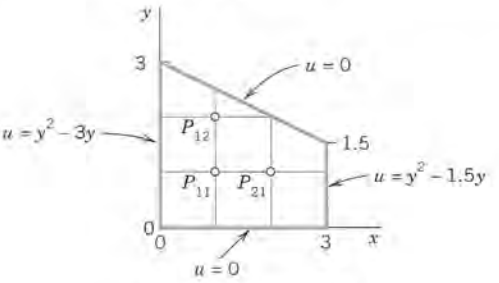

Fig. 463. Problem 14

21.6 Methods for Parabolic PDEs

The last two sections concerned elliptic PDEs, and we now turn to parabolic PDEs. Recall that the definitions of elliptic, parabolic, and hyperbolic PDEs were given in Sec. 21.4. There it was also mentioned that the general behavior of solutions differs from type to type, and so do the problems of practical interest. This reflects on numerics as follows.

For all three types, one replaces the PDE by a corresponding difference equation, but for *parabolic* and *hyperbolic* PDEs this does not automatically guarantee the **convergence** of the approximate solution to the exact solution as the mesh $h \to 0$; in fact, it does not even guarantee convergence at all. For these two types of PDEs one needs additional conditions (inequalities) to assure convergence and **stability,** the latter meaning that small perturbations in the initial data (or small errors at any time) cause only small changes at later times.

In this section we explain the numeric solution of the prototype of parabolic PDEs, the one-dimensional heat equation

$$u_t = c^2 u_{xx} \qquad (c \text{ constant}).$$

This PDE is usually considered for x in some fixed interval, say, $0 \leqq x \leqq L$, and time $t \geqq 0$, and one prescribes the initial temperature $u(x, 0) = f(x)$ (f given) and boundary conditions at $x = 0$ and $x = L$ for all $t \geqq 0$, for instance $u(0, t) = 0$, $u(L, t) = 0$. We may assume $c = 1$ and $L = 1$; this can always be accomplished by a linear transformation of x and t (Prob. 1). Then the **heat equation** and those conditions are

(1)	$u_t = u_{xx}$	$0 \leqq x \leqq 1, t \geqq 0$
(2)	$u(x, 0) = f(x)$	(Initial condition)
(3)	$u(0, t) = u(1, t) = 0$	(Boundary conditions).

A simple finite difference approximation of (1) is [see (6a) in Sec. 21.4; j is the number of the ***time step***]

$$\textbf{(4)} \qquad \frac{1}{k}\,(u_{i,j+1} - u_{ij}) = \frac{1}{h^2}\,(u_{i-1,j} - 2u_{ij} + u_{i-1,j}).$$

Figure 464 shows a corresponding grid and mesh points. The mesh size is h in the x-direction and k in the t-direction. Formula (4) involves the four points shown in Fig. 465. On the left in (4) we have used a *forward* difference quotient since we have no information for negative t at the start. From (4) we calculate $u_{i,j+1}$, which corresponds to time row $j + 1$, in terms of the three other u that correspond to time row j. Solving (4) for $u_{i,j+1}$, we have

$$\textbf{(5)} \qquad u_{i,j+1} = (1 - 2r)u_{ij} + r(u_{i+1,j} + u_{i-1,j}), \qquad r = \frac{k}{h^2}.$$

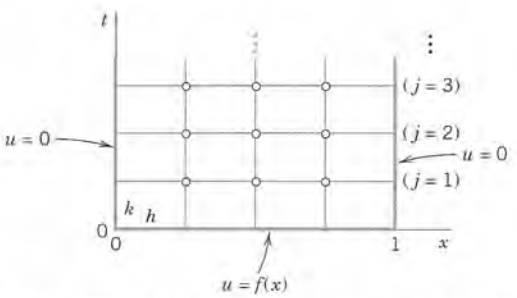

Fig. 464. Grid and mesh points corresponding to (4), (5)

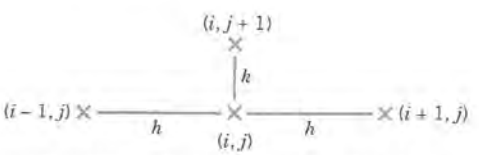

Fig. 465. The four points in (4) and (5)

Computations by this **explicit method** based on (5) are simple. However, it can be shown that crucial to the convergence of this method is the condition

$$r = \frac{k}{h^2} \leqq \frac{1}{2}. \tag{6}$$

That is, u_{ij} should have a positive coefficient in (5) or (for $r = \frac{1}{2}$) be absent from (5). Intuitively, (6) means that we should not move too fast in the t-direction. An example is given below.

Crank–Nicolson Method

Condition (6) is a handicap in practice. Indeed, to attain sufficient accuracy, we have to choose h small, which makes k very small by (6). For example, if $h = 0.1$, then $k \leqq 0.005$. Accordingly, we should look for a more satisfactory discretization of the heat equation.

A method that imposes no restriction on $r = k/h^2$ is the **Crank–Nicolson method,** which uses values of u at the six points in Fig. 466. The idea of the method is the replacement of the difference quotient on the right side of (4) by $\frac{1}{2}$ times the sum of two such difference quotients at two time rows (see Fig. 466). Instead of (4) we then have

$$\begin{aligned}\frac{1}{k}(u_{i,j+1} - u_{ij}) &= \frac{1}{2h^2}(u_{i+1,j} - 2u_{ij} + u_{i-1,j}) \\ &\quad + \frac{1}{2h^2}(u_{i+1,j+1} - 2u_{i,j+1} + u_{i-1,j+1}).\end{aligned} \tag{7}$$

Multiplying by $2k$ and writing $r = k/h^2$ as before, we collect the terms corresponding to time row $j + 1$ on the left and the terms corresponding to time row j on the right:

$$(2 + 2r)u_{i,j+1} - r(u_{i+1,j+1} + u_{i-1,j+1}) = (2 - 2r)u_{ij} + r(u_{i+1,j} + u_{i-1,j}). \tag{8}$$

How do we use (8)? In general, the three values on the left are unknown, whereas the three values on the right are known. If we divide the x-interval $0 \leqq x \leqq 1$ in (1) into n equal intervals, we have $n - 1$ internal mesh points per time row (see Fig. 464, where $n = 4$). Then for $j = 0$ and $i = 1, \cdots, n - 1$, formula (8) gives a linear system of $n - 1$ equations for the $n - 1$ unknown values $u_{11}, u_{21}, \cdots, u_{n-1,1}$ in the first time row in terms of the initial values $u_{00}, u_{10}, \cdots, u_{n0}$ and the boundary values u_{01} $(= 0)$, u_{n1} $(= 0)$. Similarly for $j = 1$, $j = 2$, and so on; that is, for each time row we have to solve such a linear system of $n - 1$ equations resulting from (8).

Although $r = k/h^2$ is no longer restricted, smaller r will still give better results. In practice, one chooses a k by which one can save a considerable amount of work, without making r too large. For instance, often a good choice is $r = 1$ (which would be impossible in the previous method). Then (8) becomes simply

$$4u_{i,j+1} - u_{i+1,j+1} - u_{i-1,j+1} = u_{i+1,j} + u_{i-1,j}. \tag{9}$$

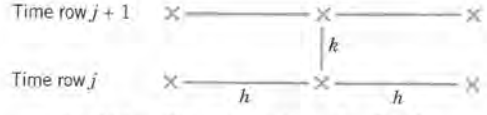

Fig. 466. The six points in the Crank–Nicolson formulas (7) and (8)

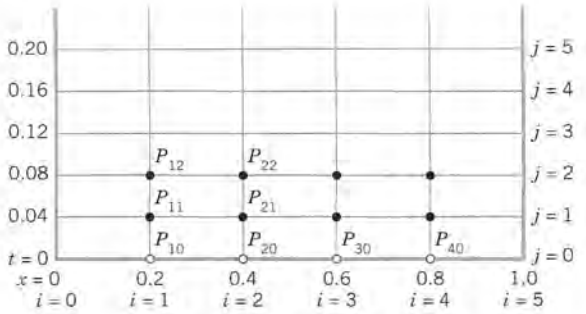

Fig. 467. Grid in Example 1

EXAMPLE 1 **Temperature in a Metal Bar. Crank–Nicolson Method, Explicit Method**

Consider a laterally insulated metal bar of length 1 and such that $c^2 = 1$ in the heat equation. Suppose that the ends of the bar are kept at temperature $u = 0°C$ and the temperature in the bar at some instant—call it $t = 0$—is $f(x) = \sin \pi x$. Applying the Crank–Nicolson method with $h = 0.2$ and $r = 1$, find the temperature $u(x, t)$ in the bar for $0 \leqq t \leqq 0.2$. Compare the results with the exact solution. Also apply (5) with an r satisfying (6), say, $r = 0.25$, and with values not satisfying (6), say, $r = 1$ and $r = 2.5$.

Solution by Crank–Nicolson. Since $r = 1$, formula (8) takes the form (9). Since $h = 0.2$ and $r = k/h^2 = 1$, we have $k = h^2 = 0.04$. Hence we have to do 5 steps. Figure 467 shows the grid. We shall need the initial values

$$u_{10} = \sin 0.2\pi = 0.587\,785, \qquad u_{20} = \sin 0.4\pi = 0.951\,057.$$

Also, $u_{30} = u_{20}$ and $u_{40} = u_{10}$. (Recall that u_{10} means u at P_{10} in Fig. 467, etc.) In each time row in Fig. 467 there are 4 internal mesh points. Hence in each time step we would have to solve 4 equations in 4 unknowns. But since the initial temperature distribution is symmetric with respect to $x = 0.5$, and $u = 0$ at both ends for all t, we have $u_{31} = u_{21}$, $u_{41} = u_{11}$ in the first time row and similarly for the other rows. This reduces each system to 2 equations in 2 unknowns. By (9), since $u_{31} = u_{21}$ and $u_{01} = 0$, for $j = 0$ these equations are

$$(i = 1) \qquad 4u_{11} - u_{21} = u_{00} + u_{20} = 0.951\,057$$
$$(i = 2) \qquad -u_{11} + 4u_{21} - u_{21} = u_{10} + u_{20} = 1.538\,842.$$

The solution is $u_{11} = 0.399\,274$, $u_{21} = 0.646\,039$. Similarly, for time row $j = 1$ we have the system

$$(i = 1) \qquad 4u_{12} - u_{22} = u_{01} + u_{21} = 0.646\,039$$
$$(i = 2) \qquad -u_{12} + 3u_{22} = u_{11} + u_{21} = 1.045\,313.$$

The solution is $u_{12} = 0.271\,221$, $u_{22} = 0.438\,844$, and so on. This gives the temperature distribution (Fig. 468):

t	$x = 0$	$x = 0.2$	$x = 0.4$	$x = 0.6$	$x = 0.8$	$x = 1$
0.00	0	0.588	0.951	0.951	0.588	0
0.04	0	0.399	0.646	0.646	0.399	0
0.08	0	0.271	0.439	0.439	0.271	0
0.12	0	0.184	0.298	0.298	0.184	0
0.16	0	0.125	0.202	0.202	0.125	0
0.20	0	0.085	0.138	0.138	0.085	0

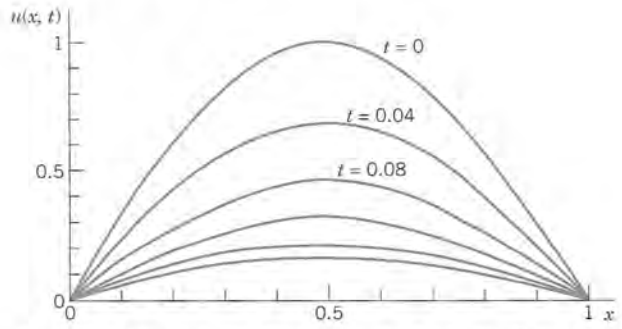

Fig. 468. Temperature distribution in the bar in Example 1

Comparison with the exact solution. The present problem can be solved exactly by separating variables (Sec. 12.5); the result is

$$u(x, t) = \sin \pi x \, e^{-\pi^2 t}. \tag{10}$$

Solution by the explicit method (5) with r = 0.25. For $h = 0.2$ and $r = k/h^2 = 0.25$ we have $k = rh^2 = 0.25 \cdot 0.04 = 0.01$. Hence we have to perform 4 times as many steps as with the Crank–Nicolson method! Formula (5) with $r = 0.25$ is

$$u_{i,j+1} = 0.25(u_{i-1,j} + 2u_{ij} + u_{i+1,j}). \tag{11}$$

We can again make use of the symmetry. For $j = 0$ we need $u_{00} = 0$, $u_{10} = 0.587\,785$ (see p. 925), $u_{20} = u_{30} = 0.951\,057$ and compute

$$u_{11} = 0.25(u_{00} + 2u_{10} + u_{20}) = 0.531\,657$$

$$u_{21} = 0.25(u_{10} + 2u_{20} + u_{30}) = 0.25(u_{10} + 3u_{20}) = 0.860\,239.$$

Of course we can omit the boundary terms $u_{01} = 0$, $u_{02} = 0, \cdots$ from the formulas. For $j = 1$ we compute

$$u_{12} = 0.25(2u_{11} + u_{21}) = 0.480\,888$$

$$u_{22} = 0.25(u_{11} + 3u_{21}) = 0.778\,094$$

and so on. We have to perform 20 steps instead of the 5 CN steps, but the numeric values show that the accuracy is only about the same as that of the Crank–Nicolson values CN. The exact 3D-values follow from (10).

t	$x = 0.2$			$x = 0.4$		
	CN	By (11)	Exact	CN	By (11)	Exact
0.04	0.399	0.393	0.396	0.646	0.637	0.641
0.08	0.271	0.263	0.267	0.439	0.426	0.432
0.12	0.184	0.176	0.180	0.298	0.285	0.291
0.16	0.125	0.118	0.121	0.202	0.191	0.196
0.20	0.085	0.079	0.082	0.138	0.128	0.132

Failure of (5) with r violating (6). Formula (5) with $h = 0.2$ and $r = 1$—which violates (6)—is

$$u_{i,j+1} = u_{i-1,j} - u_{ij} + u_{i+1,j}$$

and gives very poor values; some of these are

t	$x = 0.2$	Exact	$x = 0.4$	Exact
0.04	0.363	0.396	0.588	0.641
0.12	0.139	0.180	0.225	0.291
0.20	0.053	0.082	0.086	0.132

Formula (5) with an even larger $r = 2.5$ (and $h = 0.2$ as before) gives completely nonsensical results; some of these are

t	$x = 0.2$	Exact	$x = 0.4$	Exact
0.1	0.0265	0.2191	0.0429	0.3545
0.3	0.0001	0.0304	0.0001	0.0492

PROBLEM SET 21.6

1. **(Nondimensional form)** Show that the heat equation $\tilde{u}_{\tilde{t}} = c^2 \tilde{u}_{\tilde{x}\tilde{x}}$, $0 \leqq \tilde{x} \leqq L$, can be transformed to the "nondimensional" standard form $u_t = u_{xx}$, $0 \leqq x \leqq 1$, by setting $x = \tilde{x}/L$, $t = c^2\tilde{t}/L^2$, $u = \tilde{u}/u_0$, where u_0 is any constant temperature.
2. Derive the difference approximation (4) of the heat equation.
3. Derive (5) from (4).
4. Using the explicit method [(5) with $h = 1$ and $k = 0.5$], find the temperature at $t = 2$ in a laterally insulated bar of length 10 with ends kept at temperature 0 and initial temperature $f(x) = x - 0.1x^2$.
5. Solve the heat problem (1)–(3) by Crank–Nicolson for $0 \leqq t \leqq 0.20$ with $h = 0.2$ and $k = 0.04$ when $f(x) = x$ if $0 \leqq x < \frac{1}{2}$, $f(x) = 1 - x$ if $\frac{1}{2} \leqq x \leqq 1$. Compare with the exact values for $t = 0.20$ obtained from the series (2 terms) in Sec. 12.5.
6. Solve Prob. 5 by the explicit method with $h = 0.2$ and $k = 0.01$. Do 8 steps. Compare the last values with the Crank–Nicolson 3S-values 0.107, 0.175 and the exact 3S-values 0.108, 0.175.
7. The accuracy of the explicit method depends on r ($\leqq \frac{1}{2}$). Illustrate this for Prob. 6, choosing $r = \frac{1}{2}$ (and $h = 0.2$ as before). Do 4 steps. Compare the values for $t = 0.04$ and 0.08 with the 3S-values in Prob. 6, which are 0.156, 0.254 ($t = 0.04$), 0.105, 0.170 ($t = 0.08$).
8. If the left end of a laterally insulated bar extending from $x = 0$ to $x = 1$ is insulated, the boundary condition at $x = 0$ is $u_n(0, t) = u_x(0, t) = 0$. Show that in the application of the explicit method given by (5), we can compute $u_{0,j+1}$ by the formula

$$u_{0,j+1} = (1 - 2r)u_{0j} + 2ru_{1j}.$$

Apply this with $h = 0.2$ and $r = 0.25$ to determine the temperature $u(x, t)$ in a laterally insulated bar extending from $x = 0$ to 1 if $u(x, 0) = 0$, the left end is insulated and the right end is kept at temperature $g(t) = \sin \frac{50}{3}\pi t$. *Hint.* Use $0 = \partial u_{0j}/\partial x = (u_{1j} - u_{-1,j})/2h$.

9. In a laterally insulated bar of length 1 let the initial temperature be $f(x) = x$ if $0 \leqq x \leqq 0.2$, $f(x) = 0.25(1 - x)$ if $0.2 \leqq x \leqq 1$. Let $u(0, t) = 0$, $u(1, t) = 0$ for all t. Apply the explicit method with $h = 0.2$, $k = 0.01$. Do 5 steps.
10. Solve Prob. 9 for $f(x) = x$ if $0 \leqq x \leqq 0.5$, $f(x) = 1 - x$ if $0.5 \leqq x \leqq 1$, all the other data being as before. Can you expect the solution to satisfy $u(x, t) = u(1 - x, t)$ for all t?
11. Solve Prob. 9 by (9) with $h = 0.2$, 2 steps. Compare with exact values obtained from the series in Sec. 12.5 (2 terms) with suitable coefficients.
12. **CAS EXPERIMENT. Comparison of Methods.** **(a)** Write programs for the explicit and the Crank–Nicolson methods.

    (b) Apply the programs to the heat problem of a laterally insulated bar of length 1 with $u(x, 0) = \sin \pi x$ and $u(0, t) = u(1, t) = 0$ for all t, using $h = 0.2$, $k = 0.01$ for the explicit method (20 steps), $h = 0.2$ and (9) for the Crank–Nicolson method (5 steps). Obtain exact 6D-values from a suitable series and compare.

    (c) Graph temperature curves in (b) in two figures similar to Fig. 296 in Sec. 12.6.

    (d) Experiment with smaller h (0.1, 0.05, etc.) for both methods to find out to what extent accuracy increases under systematic changes of h and k.

13–15 CRANK–NICOLSON

Solve (1)–(3) by Crank–Nicolson with $r = 1$ (5 steps), where:

13. $f(x) = x(1 - x)$, $h = 0.2$
14. $f(x) = x(1 - x)$, $h = 0.1$ (Compare with Prob. 13.)
15. $f(x) = 5x$ if $0 \leqq x < 0.2$, $f(x) = 1.25(1 - x)$ if $0.2 \leqq x \leqq 1$, $h = 0.2$

21.7 Method for Hyperbolic PDEs

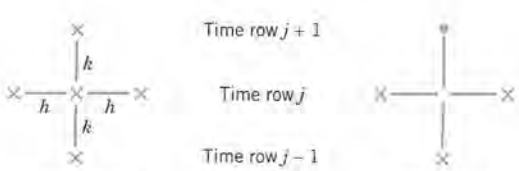
In this section we consider the numeric solution of problems involving hyperbolic PDEs. We explain a standard method in terms of a typical setting for the prototype of a hyperbolic PDE, the **wave equation:**

(1)	$u_{tt} = u_{xx}$	$0 \leqq x \leqq 1,\ t \geqq 0$
(2)	$u(x, 0) = f(x)$	(Given initial displacement)
(3)	$u_t(x, 0) = g(x)$	(Given initial velocity)
(4)	$u(0, t) = u(1, t) = 0$	(Boundary conditions).

Note that an equation $u_{tt} = c^2 u_{xx}$ and another x-interval can be reduced to the form (1) by a linear transformation of x and t. This is similar to Sec. 21.6, Prob. 1.

For instance, (1)–(4) is the model of a vibrating elastic string with fixed ends at $x = 0$ and $x = 1$ (see Sec. 12.2). Although an analytic solution of the problem is given in (13), Sec. 12.4, we use the problem for explaining basic ideas of the numeric approach that are also relevant for more complicated hyperbolic PDEs.

Replacing the derivatives by difference quotients as before, we obtain from (1) [see (6) in Sec. 21.4 with $y = t$]



$$\text{(5)} \qquad \frac{1}{k^2}\,(u_{i,j+1} - 2u_{ij} + u_{i,j-1}) = \frac{1}{h^2}\,(u_{i+1,j} - 2u_{ij} + u_{i-1,j})$$

where h is the mesh size in x, and k is the mesh size in t. This difference equation relates 5 points as shown in Fig. 469a. It suggests a rectangular grid similar to the grids for parabolic equations in the preceding section. We choose $r^* = k^2/h^2 = 1$. Then u_{ij} drops out and we have

$$\textbf{(6)} \qquad u_{i,j+1} = u_{i-1,j} + u_{i+1,j} - u_{i,j-1} \qquad \text{(Fig. 469b).}$$

It can be shown that for $0 < r^* \leqq 1$ the present **explicit method** is stable, so that from (6) we may expect reasonable results for initial data that have no discontinuities. (For a hyperbolic PDE the latter would propagate into the solution domain—a phenomenon that would be difficult to deal with on our present grid. For unconditionally stable **implicit methods** see [E1] in App. 1.)

Equation (6) still involves 3 time steps $j - 1, j, j + 1$, whereas the formulas in the parabolic case involved only 2 time steps. Furthermore, we now have 2 initial conditions.

(a) Formula (5) (b) Formula (6)

Fig. 469. Mesh points used in (5) and (6)

So we ask how we get started and how we can use the initial condition (3). This can be done as follows.

From $u_t(x, 0) = g(x)$ we derive the difference formula

$$(7) \qquad \frac{1}{2k}(u_{i1} - u_{i,-1}) = g_i, \qquad \text{hence} \qquad u_{i,-1} = u_{i1} - 2kg_i$$

where $g_i = g(ih)$. For $t = 0$, that is, $j = 0$, equation (6) is

$$u_{i1} = u_{i-1,0} + u_{i+1,0} - u_{i,-1}.$$

Into this we substitute $u_{i,-1}$ as given in (7). We obtain $u_{i1} = u_{i-1,0} + u_{i+1,0} - u_{i1} + 2kg_i$ and by simplification

$$\mathbf{(8)} \qquad u_{i1} = \tfrac{1}{2}(u_{i-1,0} + u_{i+1,0}) + kg_i.$$

This expresses u_{i1} in terms of the initial data. It is for the beginning only. Then use (6).

EXAMPLE 1 **Vibrating String, Wave Equation**

Apply the present method with $h = k = 0.2$ to the problem (1)–(4), where

$$f(x) = \sin \pi x, \qquad g(x) = 0.$$

Solution. The grid is the same as in Fig. 467, Sec. 21.6, except for the values of t, which now are 0.2, 0.4, $\cdots$ (instead of 0.04, 0.08, $\cdots$). The initial values $u_{00}, u_{10}, \cdots$ are the same as in Example 1, Sec. 21.6. From (8) and $g(x) = 0$ we have

$$u_{i1} = \tfrac{1}{2}(u_{i-1,0} + u_{i+1,0}).$$

From this we compute, using $u_{10} = u_{40} = \sin 0.2\pi = 0.587\,785$, $u_{20} = u_{30} = 0.951\,057$,

$$(i = 1) \quad u_{11} = \tfrac{1}{2}(u_{00} + u_{20}) = \tfrac{1}{2} \cdot 0.951\,057 = 0.475\,528$$

$$(i = 2) \quad u_{21} = \tfrac{1}{2}(u_{10} + u_{30}) = \tfrac{1}{2} \cdot 1.538\,842 = 0.769\,421$$

and $u_{31} = u_{21}$, $u_{41} = u_{11}$ by symmetry as in Sec. 21.6, Example 1. From (6) with $j = 1$ we now compute, using $u_{01} = u_{02} = \cdots = 0$,

$$(i = 1) \quad u_{12} = u_{01} + u_{21} - u_{10} = 0.769\,421 - 0.587\,785 = 0.181\,636$$

$$(i = 2) \quad u_{22} = u_{11} + u_{31} - u_{20} = 0.475\,528 + 0.769\,421 - 0.951\,057 = 0.293\,892,$$

and $u_{32} = u_{22}$, $u_{42} = u_{12}$ by symmetry; and so on. We thus obtain the following values of the displacement $u(x, t)$ of the string over the first half-cycle:

t	$x = 0$	$x = 0.2$	$x = 0.4$	$x = 0.6$	$x = 0.8$	$x = 1$
0.0	0	0.588	0.951	0.951	0.588	0
0.2	0	0.476	0.769	0.769	0.476	0
0.4	0	0.182	0.294	0.294	0.182	0
0.6	0	−0.182	−0.294	−0.294	−0.182	0
0.8	0	−0.476	−0.769	−0.769	−0.476	0
1.0	0	−0.588	−0.951	−0.951	−0.588	0

These values are exact to 3D (3 decimals), the exact solution of the problem being (see Sec. 12.3)

$$u(x, t) = \sin \pi x \cos \pi t.$$

The reason for the exactness follows from d'Alembert's solution (4), Sec. 12.4. (See Prob. 4, below.) ■

This is the end of Chap. 21 on numerics for ODEs and PDEs, a rapidly developing field of basic applications and interesting research, in which large-scale and complicated practical problems can now be attacked and solved by the computer.

PROBLEM SET 21.7

1–3 VIBRATING STRING

Solve (1)–(4) by the present method with $h = k = 0.2$ for the given initial deflection $f(x)$ and initial velocity 0 on the given t-interval.

1. $f(x) = 0.01x(1 - x)$, $0 \leqq t \leqq 2$
2. $f(x) = x^2(1 - x)$, $0 \leqq t \leqq 1$
3. $f(x) = x$ if $0 \leqq x \leqq 0.2$, $f(x) = 0.25(1 - x)$ if $0.2 < x \leqq 1$
4. Show that from d'Alembert's solution (13) in Sec. 12.4 with $c = 1$ it follows that (6) in the present section gives the exact value $u_{i,j+1} = u(ih, (j + 1)h)$.
5. If the string governed by the wave equation (1) starts from its equilibrium position with initial velocity $g(x) = \sin \pi x$, what is its displacement at time $t = 0.4$ and $x = 0.2, 0.4, 0.6, 0.8$? (Use the present method with $h = 0.2$, $k = 0.2$. Use (8). Compare with the exact values obtained from (12) in Sec. 12.4.)
6. Compute approximate values in Prob. 5, using a finer grid ($h = 0.1$, $k = 0.1$), and notice the increase in accuracy.
7. Illustrate the starting procedure when both f and g are not identically zero, say, $f(x) = 1 - \cos 2\pi x$, $g(x) = x - x^2$. Choose $h = k = 0.1$ and do 2 time steps.
8. Show that (12) in Sec. 12.4 gives as another starting formula

$$u_{i1} = \frac{1}{2}(u_{i+1,0} + u_{i-1,0}) + \frac{1}{2}\int_{x_i - k}^{x_i + k} g(s)\, ds$$

(where one can evaluate the integral numerically if necessary). In what case is this identical with (8)?

9. Compute u in Prob. 7 for $t = 0.1$ and $x = 0.1, 0.2, \cdots, 0.9$, using the formula in Prob. 8, and compare the values.
10. Solve (1)–(3) ($h = k = 0.2$, 5 time steps) subject to $f(x) = x^2$, $g(x) = 2x$, $u_x(0, t) = 2t$, $u(1, t) = (1 + t)^2$.

CHAPTER 21 REVIEW QUESTIONS AND PROBLEMS

1. Explain the Euler and Improved Euler methods in geometrical terms.
2. What are the local and global orders of a method? Give examples.
3. What do you know about error estimates? Why are they important?
4. How did we obtain numeric methods by using the Taylor series?
5. In each Runge–Kutta step we computed auxiliary values. How many? Why?
6. What are one-step and multistep methods? Give examples.
7. What is the idea of a predictor–corrector method? Mention some of these methods.
8. What is the idea of the Runge–Kutta–Fehlberg method?
9. How can Runge–Kutta be generalized to systems of ODEs?
10. What is automatic step size control? How is it done in practice?
11. Why and how did we use finite differences in this chapter?
12. Make a list of types of PDEs, corresponding problems, and methods for their numeric solution.
13. How did we approximate the Laplace equation? The Poisson equation?
14. Will a difference equation give exact solutions of a PDE?
15. How did we handle (a) irregularly shaped domains, (b) given normal derivatives at the boundary?
16. Solve $y' = 2xy$, $y(0) = 1$, by the Euler method with $h = 0.1$, 10 steps. Compute the error.
17. Solve $y' = 1 + y^2$, $y(0) = 0$, by the improved Euler method with $h = 0.1$, 5 steps. Compute the error.
18. Solve $y' = (x + y - 4)^2$, $y(0) = 4$, by RK with $h = 0.2$, 7 steps.

19. Solve Prob. 17 by RK with $h = 0.1$, 5 steps. Compute the error. Compare with Prob. 17.

20. **(Fair comparison)** Solve $y' = 2x^{-1}\sqrt{y - \ln x} + x^{-1}$, $y(1) = 0$ for $1 \leqq x \leqq 1.8$ (a) by the Euler method with $h = 0.1$, (b) by the improved Euler method with $h = 0.2$, (c) by RK with $h = 0.4$. Verify that the exact solution is $y = (\ln x)^2 + \ln x$. Compute and compare the errors. Why is the comparison fair?

21. Compute e^x for $x = 0, 0.1, \cdots, 1.0$ by applying RK to $y' = y$, $y(0) = 1$, $h = 0.1$. Show that the result is 5D-exact.

22. Solve $y' = (x + y)^2$, $y(0) = 0$ by RK with $h = 0.2$, 5 steps.

23. Show that by applying the method in Sec. 21.2 to a polynomial of first degree we obtain the multistep predictor and corrector formulas

$$y^*_{n+1} = y_n + \frac{h}{2}(3f_n - f_{n-1})$$

$$y_{n+1} = y_n + \frac{h}{2}(f^*_{n+1} + f_n)$$

where $f^*_{n+1} = f(x_{n+1}, y^*_{n+1})$.

24. Apply the multistep method in Prob. 23 to the initial value problem $y' = x + y$, $y(0) = 0$, choosing $h = 0.2$ and doing 5 steps. Compare with the exact values.

25. Solve $y' = (y - x - 1)^2 + 2$, $y(0) = 1$ for $0 \leqq x \leqq 1$ by Adams–Moulton with $h = 0.1$ and starting values 1, 1.200334589, 1.402709878, 1.609336039.

26. Solve $y'' + y = 0$, $y(0) = 0$, $y'(0) = 1$ by RKN with $h = 0.2$, 5 steps. Find the error.

27. Solve $y_1' = -4y_1 + 3y_2$, $y_2' = 5y_1 - 6y_2$, $y_1(0) = 3$, $y_2(0) = -5$, by RK for systems, $h = 0.1$, 5 steps.

28. Solve $y_1' = -5y_1 + 3y_2$, $y_2' = -3y_1 - 5y_2$, $y_1(0) = 2$, $y_2(0) = 2$ by RK for systems, $h = 0.1$, 5 steps.

29. Find rough approximate values of the electrostatic potential at P_{11}, P_{12}, P_{13} in Fig. 470 that lie in a field between conducting plates (in Fig. 470 appearing as sides of a rectangle) kept at potentials 0 and 110 volts as shown. (Use the indicated grid.)

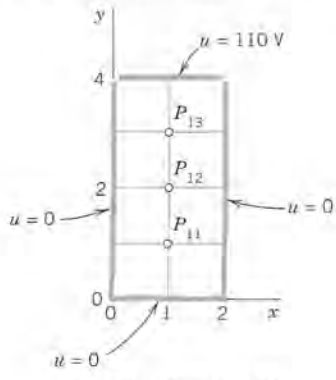


Fig. 470. Problem 29

30–32 POTENTIAL

Find the potential in Fig. 471, using the given grid and the boundary values:

30. $u = 70$ on the upper and left sides, $u = 0$ on the lower and right sides

31. $u(P_{10}) = u(P_{30}) = 960$, $u(P_{20}) = -480$, $u = 0$ elsewhere on the boundary

32. $u(P_{01}) = u(P_{03}) = u(P_{41}) = u(P_{43}) = 200$, $u(P_{10}) = u(P_{30}) = -400$, $u(P_{20}) = 1600$, $u(P_{02}) = u(P_{42}) = u(P_{14}) = u(P_{24}) = u(P_{34}) = 0$

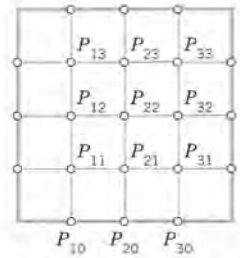

Fig. 471. Problems 30–32

33. Verify (13) in Sec. 21.4 for the system (12) and show that **A** in (12) is nonsingular.

34. Derive the difference approximation of the heat equation.

35. Solve the heat equation (1), Sec. 21.6, for the initial condition $f(x) = x$ if $0 \leqq x \leqq 0.2$, $f(x) = 0.25(1 - x)$ if $0.2 < x \leqq 1$ and boundary condition (3), Sec. 21.6, by the explicit method [formula (5) in Sec. 21.6] with $h = 0.2$ and $k = 0.01$ so that you get values of the temperature at time $t = 0.05$ as the answer.

36. A laterally insulated homogeneous bar with ends at $x = 0$ and $x = 1$ has initial temperature 0. Its left end is kept at 0, whereas the temperature at the right end varies sinusoidally according to

$$u(t, 1) = g(t) = \sin \tfrac{25}{3}\pi t.$$

Find the temperature $u(x, t)$ in the bar [solution of (1) in Sec. 21.6] by the explicit method with $h = 0.2$ and $r = 0.5$ (one period, that is, $0 \leqq t \leqq 0.24$).

37. Find $u(x, 0.12)$ and $u(x, 0.24)$ in Prob. 36 if the left end of the bar is kept at $-g(t)$ (instead of 0), all the other data being as before.

38. Find out how the results of Prob. 36 can be used for obtaining the results in Prob. 37. Use the values 0.054, 0.172, 0.325, 0.406 ($t = 0.12$, $x = 0.2, 0.4, 0.6, 0.8$) and -0.009, -0.086, -0.252, -0.353 ($t = 0.24$) from the answer to Prob. 36 to check your answer to Prob. 37.

39. Solve $u_t = u_{xx}$ ($0 \leqq x \leqq 1$, $t \geqq 0$), $u(x, 0) = x^2(1 - x)$, $u(0, t) = u(1, t) = 0$ by Crank–Nicolson with $h = 0.2$, $k = 0.04$, 5 time steps.

40. Find the solution of the vibrating string problem $u_{tt} = u_{xx}$, $u(x, 0) = x(1 - x)$, $u_t = 0$, $u(0, t) = u(1, t) = 0$ by the method in Sec. 21.7 with $h = 0.1$ and $k = 0.1$ for $t = 0.3$.

SUMMARY OF CHAPTER 21
Numerics for ODEs and PDEs

In this chapter we discussed numerics for ODEs (Secs. 21.1–21.3) and PDEs (Secs. 21.4–21.7). Methods for initial value problems

$$(1) \qquad y' = f(x, y), \qquad y(x_0) = y_0$$

involving a first-order ODE are obtained by truncating the Taylor series

$$y(x + h) = y(x) + hy'(x) + \frac{h^2}{2} y''(x) + \cdots$$

where, by (1), $y' = f$, $y'' = f' = \partial f/\partial x + (\partial f/\partial y)y'$, etc. Truncating after the term hy', we get the *Euler method*, in which we compute step by step

$$(2) \qquad y_{n+1} = y_n + hf(x_n, y_n) \qquad (n = 0, 1, \cdots).$$

Taking one more term into account, we obtain the *improved Euler method*. Both methods show the basic idea but are too inaccurate in most cases.

Truncating after the term in h^4, we get the important classical **Runge–Kutta (RK) method** of fourth order. The crucial idea in this method is the replacement of the cumbersome evaluation of derivatives by the evaluation of $f(x, y)$ at suitable points (x, y); thus in each step we first compute four auxiliary quantities (Sec. 21.1)

$$(3a) \qquad \begin{aligned} k_1 &= hf(x_n, y_n) \\ k_2 &= hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_1) \\ k_3 &= hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_2) \\ k_4 &= hf(x_n + h, y_n + k_3) \end{aligned}$$

and then the new value

$$(3b) \qquad y_{n+1} = y_n + \tfrac{1}{6}(k_1 + 2k_2 + 2k_3 + k_4).$$

Error and step size control are possible by step halving or by **RKF** (Runge–Kutta–Fehlberg).

The methods in Sec. 21.1 are **one-step methods** since they get y_{n+1} from the result y_n of a single step. A **multistep method** (Sec. 21.2) uses the values of $y_n, y_{n-1}, \cdots$ of several steps for computing y_{n+1}. Integrating cubic interpolation polynomials gives the **Adams–Bashforth predictor** (Sec. 21.2)

$$(4a) \qquad y^*_{n+1} = y_n + \frac{1}{24} h(55f_n - 59f_{n-1} + 37f_{n-2} - 9f_{n-3})$$

where $f_j = f(x_j, y_j)$, and an **Adams–Moulton corrector** (the actual new value)

$$(4b) \qquad y_{n+1} = y_n + \frac{1}{24} h(9f^*_{n+1} + 19f_n - 5f_{n-1} + f_{n-2}),$$

where $f^*_{n+1} = f(x_{n+1}, y^*_{n+1})$. Here, to get started, y_1, y_2, y_3 must be computed by the Runge–Kutta method or by some other accurate method.

Section 19.3 concerned the extension of Euler and RK methods to systems

$$\mathbf{y}' = \mathbf{f}(x, \mathbf{y}), \qquad \text{thus} \qquad y_j' = f_j(x, y_1, \cdots, y_m), \qquad j = 1, \cdots, m.$$

This includes single mth order ODEs, which are reduced to systems. Second-order equations can also be solved by **RKN** (Runge–Kutta–Nyström) **methods.** These are particularly advantageous for $y'' = f(x, y)$ with f not containing y'.

Numeric methods for PDEs are obtained by replacing partial derivatives by difference quotients. This leads to approximating difference equations, for the **Laplace equation** to

$$(5) \qquad u_{i+1,j} + u_{i,j+1} + u_{i-1,j} + u_{i,j-1} - 4u_{ij} = 0 \qquad \text{(Sec. 21.4)}$$

for the **heat equation** to

$$(6) \qquad \frac{1}{k}(u_{i,j+1} - u_{ij}) = \frac{1}{h^2}(u_{i+1,j} - 2u_{ij} + u_{i-1,j}) \qquad \text{(Sec. 21.6)}$$

and for the **wave equation** to

$$(7) \qquad \frac{1}{k^2}(u_{i,j+1} - 2u_{ij} + u_{i,j-1}) = \frac{1}{h^2}(u_{i+1,j} - 2u_{ij} + u_{i-1,j}) \qquad \text{(Sec. 21.7);}$$

here h and k are the mesh sizes of a grid in the x- and y-directions, respectively, where in (6) and (7) the variable y is time t.

These PDEs are *elliptic*, *parabolic*, and *hyperbolic*, respectively. Corresponding numeric methods differ, for the following reason. For elliptic PDEs we have boundary value problems, and we discussed for them the **Gauss–Seidel method** (also known as **Liebmann's method**) and the **ADI method** (Secs. 21.4, 21.5). For parabolic PDEs we are given one initial condition and boundary conditions, and we discussed an *explicit method* and the **Crank–Nicolson method** (Sec. 21.6). For hyperbolic PDEs, the problems are similar but we are given a second initial condition (Sec. 21.7).

PART F

Optimization, Graphs

CHAPTER 22 Unconstrained Optimization. Linear Programming

CHAPTER 23 Graphs. Combinatorial Optimization

Ideas of optimization and application of graphs play an increasing role in engineering, computer science, systems theory, economics, and other areas. In the first chapter of this part we explain some basic concepts, methods, and results in unconstrained and constrained optimization. The second chapter is devoted to graphs and the corresponding so-called combinatorial optimization, a relatively new interesting area of ongoing applied and theoretical research.

CHAPTER 22

Unconstrained Optimization. Linear Programming

Optimization principles are of basic importance in modern engineering design and systems operation in various areas. The recent development has been influenced by computers capable of solving large-scale problems and by the creation of corresponding new optimization techniques, so that the entire field has become a large area of its own.

In the present chapter we give an introduction to the more important concepts, methods, and results on unconstrained optimization (the so-called **gradient method**) and constrained optimization (**linear programming**).

Prerequisite: a modest working knowledge of linear systems of equations
References and Answers to Problems: App. 1 Part F, App. 2.

22.1 Basic Concepts. Unconstrained Optimization

In an **optimization problem** the objective is to *optimize* (*maximize* or *minimize*) some function f. This function f is called the **objective function.**

For example, an objective function f to be *maximized* may be the revenue in a production of TV sets, the yield per minute in a chemical process, the mileage per gallon of a certain type of car, the hourly number of customers served in a bank, the hardness of steel, or the tensile strength of a rope.

Similarly, we may want to *minimize* f if f is the cost per unit of producing certain cameras, the operating cost of some power plant, the daily loss of heat in a heating system, the idling time of some lathe, or the time needed to produce a fender.

In most optimization problems the objective function f depends on several variables

$$x_1 \cdot \cdot \cdot, x_n.$$

These are called **control variables** because we can "control" them, that is, choose their values.

For example, the yield of a chemical process may depend on pressure x_1 and temperature x_2. The efficiency of a certain air-conditioning system may depend on temperature x_1, air pressure x_2, moisture content x_3, cross-sectional area of outlet x_4, and so on.

Optimization theory develops methods for optimal choices of $x_1, \cdot \cdot \cdot, x_n$, which maximize (or minimize) the objective function f, that is, methods for finding optimal values of $x_1, \cdot \cdot \cdot, x_n$.

In many problems the choice of values of $x_1, \cdots, x_n$ is not entirely free but is subject to some **constraints,** that is, additional restrictions arising from the nature of the problem and the variables.

For example, if x_1 is production cost, then $x_1 \geqq 0$, and there are many other variables (time, weight, distance traveled by a salesman, etc.) that can take nonnegative values only. Constraints can also have the form of equations (instead of inequalities).

We first consider **unconstrained optimization** in the case of a function $f(x_1, \cdots, x_n)$. We also write $\mathbf{x} = (x_1, \cdots, x_n)$ and $f(\mathbf{x})$, for convenience.

By definition, f has a **minimum** at a point $\mathbf{x} = \mathbf{X}_0$ in a region R (where f is defined) if

$$f(\mathbf{x}) \geqq f(\mathbf{X}_0)$$

for all $\mathbf{x}$ in R. Similarly, f has a **maximum** at $\mathbf{X}_0$ in R if

$$f(\mathbf{x}) \leqq f(\mathbf{X}_0)$$

for all $\mathbf{x}$ in R. Minima and maxima together are called **extrema.**

Furthermore, f is said to have a **local minimum** at $\mathbf{X}_0$ if

$$f(\mathbf{x}) \geqq f(\mathbf{X}_0)$$

for all $\mathbf{x}$ in a neighborhood of $\mathbf{X}_0$, say, for all $\mathbf{x}$ satisfying

$$|\mathbf{x} - \mathbf{X}_0| = [(x_1 - X_1)^2 + \cdots + (x_n - X_n)^2]^{1/2} < r,$$

where $\mathbf{X}_0 = (X_1, \cdots, X_n)$ and $r > 0$ is sufficiently small.

Similarly, f has a **local maximum** at $\mathbf{X}_0$ if $f(\mathbf{x}) \leqq f(\mathbf{X}_0)$ for all $\mathbf{x}$ satisfying $|\mathbf{x} - \mathbf{X}_0| < r$.

If f is differentiable and has an extremum at a point $\mathbf{X}_0$ in the *interior of a region* R (that is, not on the boundary), then the partial derivatives $\partial f/\partial x_1, \cdots, \partial f/\partial x_n$ must be zero at $\mathbf{X}_0$. These are the components of a vector that is called the **gradient** of f and denoted by grad f or ∇f. (For $n = 3$ this agrees with Sec. 9.7.) Thus

$$\nabla f(\mathbf{X}_0) = \mathbf{0}. \tag{1}$$

A point $\mathbf{X}_0$ at which (1) holds is called a **stationary point** of f.

Condition (1) is necessary for an extremum of f at $\mathbf{X}_0$ in the interior of R, but is not sufficient. Indeed, if $n = 1$, then for $y = f(x)$, condition (1) is $y' = f'(X_0) = 0$; and, for instance, $y = x^3$ satisfies $y' = 3x^2 = 0$ at $x = X_0 = 0$ where f has no extremum but a point of inflection. Similarly, for $f(\mathbf{x}) = x_1x_2$ we have $\nabla f(\mathbf{0}) = \mathbf{0}$, and f does not have an extremum but has a saddle point at $\mathbf{0}$. Hence after solving (1), one must still find out whether one has obtained an extremum. In the case $n = 1$ the conditions $y'(X_0) = 0$, $y''(X_0) > 0$ guarantee a local minimum at X_0 and the conditions $y'(X_0) = 0$, $y''(X_0) < 0$ a local maximum, as is known from calculus. For $n > 1$ there exist similar criteria. However, in practice even solving (1) will often be difficult. For this reason, one generally prefers solution by iteration, that is, by a search process that starts at some point and moves stepwise to points at which f is smaller (if a minimum of f is wanted) or larger (in the case of a maximum).

The **method of steepest descent** or **gradient method** is of this type. We present it here in its standard form. (For refinements see Ref. [E25] listed in App. 1.)

The idea of this method is to find a minimum of $f(\mathbf{x})$ by repeatedly computing minima of a function $g(t)$ of a single variable t, as follows. Suppose that f has a minimum at $\mathbf{X}_0$ and we start at a point $\mathbf{x}$. Then we look for a minimum of f closest to $\mathbf{x}$ along the straight line in the direction of $-\nabla f(\mathbf{x})$, which is the direction of steepest descent (= direction of maximum decrease) of f at $\mathbf{x}$. That is, we determine the value of t and the corresponding point

$$\mathbf{z}(t) = \mathbf{x} - t\nabla f(\mathbf{x}) \tag{2}$$

at which the function

$$g(t) = f(\mathbf{z}(t)) \tag{3}$$

has a minimum. We take this $\mathbf{z}(t)$ as our next approximation to $\mathbf{X}_0$.

EXAMPLE 1 **Method of Steepest Descent**

Determine a minimum of

$$f(\mathbf{x}) = x_1^2 + 3x_2^2, \tag{4}$$

starting from $\mathbf{x}_0 = (6, 3) = 6\mathbf{i} + 3\mathbf{j}$ and applying the method of steepest descent.

Solution. Clearly, inspection shows that $f(\mathbf{x})$ has a minimum at $\mathbf{0}$. Knowing the solution gives us a better feel of how the method works. We obtain $\nabla f(\mathbf{x}) = 2x_1\mathbf{i} + 6x_2\mathbf{j}$ and from this

$$\mathbf{z}(t) = \mathbf{x} - t\nabla f(\mathbf{x}) = (1 - 2t)x_1\mathbf{i} + (1 - 6t)x_2\mathbf{j}$$

$$g(t) = f(\mathbf{z}(t)) = (1 - 2t)^2x_1^2 + 3(1 - 6t)^2x_2^2.$$

We now calculate the derivative

$$g'(t) = 2(1 - 2t)x_1^2(-2) + 6(1 - 6t)x_2^2(-6),$$

set $g'(t) = 0$, and solve for t, finding

$$t = \frac{x_1^2 + 9x_2^2}{2x_1^2 + 54x_2^2}.$$

Starting from $\mathbf{x}_0 = 6\mathbf{i} + 3\mathbf{j}$, we compute the values in Table 22.1, which are shown in Fig. 472.

Figure 472 suggests that in the case of slimmer ellipses ("a long narrow valley"), convergence would be poor. You may confirm this by replacing the coefficient 3 in (4) with a large coefficient. For more sophisticated descent and other methods, some of them also applicable to vector functions of vector variables, we refer to the references listed in Part F of App. 1; see also [E25]. ■

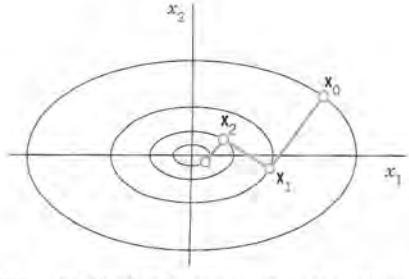

Fig. 472. Method of steepest descent in Example 1

Table 22.1 **Method of Steepest Descent, Computations in Example 1**

n	$\mathbf{x}$		t	$1 - 2t$	$1 - 6t$
0	6.000	3.000	0.210	0.581	−0.258
1	3.484	−0.774	0.310	0.381	−0.857
2	1.327	0.664	0.210	0.581	−0.258
3	0.771	−0.171	0.310	0.381	−0.857
4	0.294	0.147	0.210	0.581	−0.258
5	0.170	−0.038	0.310	0.381	−0.857
6	0.065	0.032			

PROBLEM SET 22.1

1. What happens if you apply the method of steepest descent to $f(x) = x_1^2 + x_2^2$?
2. Verify that in Example 1, successive gradients are orthogonal. What is the reason?

3–11 STEEPEST DESCENT

Do 3 steepest descent steps when:

3. $f(x) = 3x_1^2 + 2x_2^2 - 12x_1 + 16x_2$, $\mathbf{x}_0 = [1 \quad 1]^\mathsf{T}$
4. $f(x) = x_1^2 + 2x_2^2 - x_1 - 6x_2$, $\mathbf{x}_0 = [0 \quad 0]^\mathsf{T}$
5. $f(\mathbf{x}) = 0.5x_1^2 + 0.7x_2^2 - x_1 + 4.2x_2 + 1$, $x_0 = [-1 \quad 1]^\mathsf{T}$
6. $f(\mathbf{x}) = x_1^2 + 0.1x_2^2 + 8x_1 + x_2 + 22.5$, $x_0 = [2 \quad -1]^\mathsf{T}$
7. $f(\mathbf{x}) = 0.2x_1^2 + x_2^2 - 0.08x_1$, $x_0 = [4 \quad 4]^\mathsf{T}$
8. $f(\mathbf{x}) = x_1^2 - x_2^2$, $\mathbf{x}_0 = [2 \quad 1]^\mathsf{T}$, 5 steps. First guess. Then compute. Sketch your path.
9. $f(x) = x_1^2 + cx_2^2$, $\mathbf{x}_0 = [c \quad 1]^\mathsf{T}$. Show that 2 steps give $[c \quad 1]^\mathsf{T}$ times a factor, $-4c^2/(c^2 - 1)^2$. What can you conclude from this about the speed of convergence?
10. $f(\mathbf{x}) = x_1^2 - x_2$, $\mathbf{x}_0 = [1 \quad 1]^\mathsf{T}$. Sketch your path. Predict the outcome of further steps.
11. $f(\mathbf{x}) = ax_1 + bx_2$, any $\mathbf{x}_0$. First guess, then compute.
12. **CAS EXPERIMENT. Steepest Descent. (a)** Write a program for the method.

    (b) Apply your program to $f(\mathbf{x}) = x_1^2 + 4x_2^2$, experimenting with respect to speed of convergence depending on the choice of $\mathbf{x}_0$.

    (c) Apply your program to $f(\mathbf{x}) = x_1^2 + x_2^4$ and to $f(\mathbf{x}) = x_1^4 + x_2^4$, $\mathbf{x}_0 = [2 \quad 1]^\mathsf{T}$. Graph level curves and your path of descent. (Try to include graphing directly in your program.)

22.2 Linear Programming

Linear programming or **linear optimization** consists of methods for solving optimization problems ***with constraints,*** that is, methods for finding a maximum (or a minimum) $\mathbf{x} = [x_1, \cdots, x_n]$ of a ***linear*** objective function

$$z = f(x) = a_1x_1 + a_2x_2 + \cdots + a_nx_n$$

satisfying the constraints. The latter are **linear inequalities,** such as $3x_1 + 4x_2 \leqq 36$, or $x_1 \geqq 0$, etc. (examples below). Problems of this kind arise frequently, almost daily, for instance, in production, inventory management, bond trading, operation of power plants, routing delivery vehicles, airplane scheduling, and so on. Progress in computer technology has made it possible to solve programming problems involving hundreds or thousands or more variables. Let us explain the setting of a linear programming problem and the idea of a "geometric" solution, so that we shall see what is going on.

EXAMPLE 1 **Production Plan**

Energy Savers, Inc., produces heaters of types S and L. The wholesale price is \$40 per heater for S and \$88 for L. Two time constraints result from the use of two machines M_1 and M_2. On M_1 one needs 2 min for an S heater and 8 min for an L heater. On M_2 one needs 5 min for an S heater and 2 min for an L heater. Determine production figures x_1 and x_2 for S and L, respectively (number of heaters produced per hour) so that the hourly revenue

$$z = f(x) = 40x_1 + 88x_2$$

is maximum.

Solution. Production figures x_1 and x_2 must be nonnegative. Hence the objective function (to be maximized) and the four constraints are

$$\text{(0)} \qquad z = 40x_1 + 88x_2$$

$$\text{(1)} \qquad 2x_1 + 8x_2 \leqq 60 \text{ min time on machine } M_1$$

$$\text{(2)} \qquad 5x_1 + 2x_2 \leqq 60 \text{ min time on machine } M_2$$

$$\text{(3)} \qquad x_1 \geqq 0$$

$$\text{(4)} \qquad x_2 \geqq 0.$$

Figure 473 shows (0)–(4) as follows. Constancy lines

$$z = const$$

are marked (0). These are **lines of constant revenue.** Their slope is $-40/88 = -5/11$. To increase z we must move the line upward (parallel to itself), as the arrow shows. Equation (1) with the equality sign is marked (1). It intersects the coordinate axes at $x_1 = 60/2 = 30$ (set $x_2 = 0$) and $x_2 = 60/8 = 7.5$ (set $x_1 = 0$). The arrow marks the side on which the points (x_1, x_2) lie that satisfy the inequality in (1). Similarly for Eqs. (2)–(4). The blue quadrangle thus obtained is called the **feasibility region.** It is the set of all **feasible solutions,** meaning solutions that satisfy all four constraints. The figure also lists the revenue at O, A, B, C. The optimal solution is obtained by moving the line of constant revenue up as much as possible without leaving the feasibility region completely. Obviously, this optimum is reached when that line passes through B, the intersection (10, 5) of (1) and (2). We see that the optimal revenue

$$z_{\max} = 40 \cdot 10 + 88 \cdot 5 = \$840$$

is obtained by producing twice as many S heaters as L heaters. ■

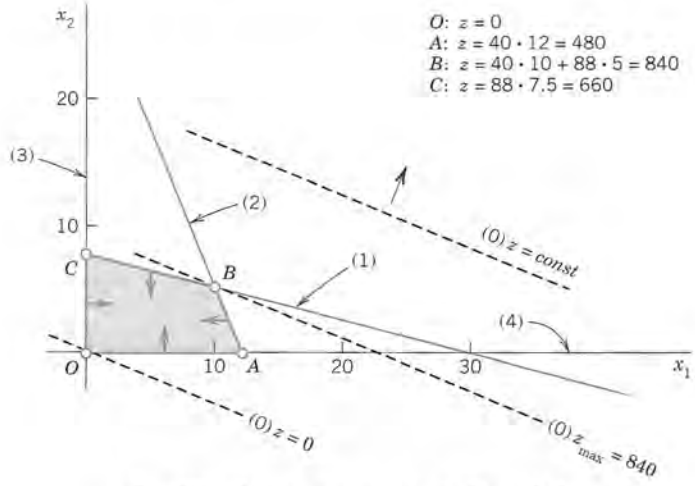

Fig. 473. Linear programming in Example 1

Note well that the problem in Example 1 or similar optimization problems *cannot* be solved by setting certain partial derivatives equal to zero, because crucial to such problems is the region in which the control variables are allowed to vary.

Furthermore, our "geometric" or graphic method illustrated in Example 1 is confined to two variables x_1, x_2. However, most practical problems involve much more than two variables, so that we need other methods of solution.

Normal Form of a Linear Programming Problem

To prepare for general solution methods, we show that constraints can be written more uniformly. Let us explain the idea in terms of (1),

$$2x_1 + 8x_2 \leqq 60.$$

This inequality implies $60 - 2x_1 - 8x_2 \geqq 0$ (and conversely), that is, the quantity

$$x_3 = 60 - 2x_1 - 8x_2$$

is nonnegative. Hence, our original inequality can now be written as an equation

$$2x_1 + 8x_2 + x_3 = 60,$$

where

$$x_3 \geqq 0.$$

x_3 is a nonnegative auxiliary variable introduced for converting inequalities to equations. Such a variable is called a **slack variable,** because it "takes up the slack" or difference between the two sides of the inequality.

EXAMPLE 2 **Conversion of Inequalities by the Use of Slack Variables**

With the help of two slack variables x_3, x_4 we can write the linear programming problem in Example 1 in the following form. ***Maximize***

$$f = 40x_1 + 88x_2$$

subject to the constraints

$$\begin{aligned} 2x_1 + 8x_2 + x_3 &= 60 \\ 5x_1 + 2x_2 + x_4 &= 60 \\ x_i &\geqq 0 \quad (i = 1, \cdots, 4). \end{aligned}$$

We now have $n = 4$ variables and $m = 2$ (linearly independent) equations, so that two of the four variables, for example, x_1, x_2, determine the others. Also note that each of the four sides of the quadrangle in Fig. 473 now has an equation of the form $x_i = 0$:

$$\begin{aligned} &OA\text{:}\ x_2 = 0. \\ &AB\text{:}\ x_4 = 0, \\ &BC\text{:}\ x_3 = 0, \\ &CO\text{:}\ x_1 = 0. \end{aligned}$$

A vertex of the quadrangle is the intersection of two sides. Hence at a vertex, $n - m = 4 - 2 = 2$ of the variables are zero and the others are nonnegative. Thus at A we have $x_2 = 0$, $x_4 = 0$, and so on. ■

Our example suggests that a general linear optimization problem can be brought to the following **normal form.** *Maximize*

$$f = c_1x_1 + c_2x_2 + \cdots + c_nx_n \tag{5}$$

subject to the constraints

$$\begin{aligned} a_{11}x_1 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + \cdots + a_{2n}x_n &= b_2 \\ &\cdots\cdots\cdots\cdots\cdots \\ a_{m1}x_1 + \cdots + a_{mn}x_n &= b_m \\ x_i \geqq 0 \qquad (i &= 1, \cdots, n) \end{aligned} \tag{6}$$

with all b_j nonnegative. (If a $b_j < 0$, multiply the equation by -1.) Here $x_1, \cdots, x_n$ include the slack variables (for which the c_j's in f are zero). We assume that the equations in (6) are linearly independent. Then, if we choose values for $n - m$ of the variables, the system uniquely determines the others. Of course, since we must have

$$x_1 \geqq 0, \cdots, x_n \geqq 0,$$

this choice is not entirely free.

Our problem also includes the **minimization** of an objective function f since this corresponds to maximizing $-f$ and thus needs no separate consideration.

An n-tuple $(x_1, \cdots, x_n)$ that satisfies all the constraints in (6) is called a *feasible point* or **feasible solution.** A feasible solution is called an **optimal solution** if for it the objective function f becomes maximum, compared with the values of f at all feasible solutions.

Finally, by a **basic feasible solution** we mean a feasible solution for which at least $n - m$ of the variables $x_1, \cdots, x_n$ are zero. For instance, in Example 2 we have $n = 4$, $m = 2$, and the basic feasible solutions are the four vertices O, A, B, C in Fig. 473. Here B is an optimal solution (the only one in this example).

The following theorem is fundamental.

THEOREM 1

Optimal Solution

Some optimal solution of a linear programming problem (5), (6) *is also a basic feasible solution of* (5), (6).

For a proof, see Ref. [F5], Chap. 3 (listed in App. 1). A problem can have many optimal solutions and not all of them may be *basic* feasible solutions; but the theorem guarantees that we can find an optimal solution by searching through the basic feasible solutions only. This is a great simplification; but since there are $\binom{n}{n-m} = \binom{n}{m}$ different ways of equating $n - m$ of the n variables to zero, considering all these possibilities, dropping those which are not feasible and then searching through the rest would still involve very much work, even when n and m are relatively small. Hence a systematic search is needed. We shall explain an important method of this type in the next section.

PROBLEM SET 22.2

1. What is the meaning of the slack variables x_3, x_4 in Example 2 in terms of the problem in Example 1?
2. Can we always expect a unique solution (as is the case in Example 1)?
3. Could we find a profit $f(x_1, x_2) = a_1x_1 + a_2x_2$ whose maximum is at an interior point of the quadrangle in Fig. 473? (Give a reason for your answer.)
4. Why are slack variables always nonnegative? How many of them do we need?

5–10 REGIONS AND CONSTRAINTS

Describe and graph the region in the first quadrant of the x_1x_2-plane determined by the inequalities:

5. $x_1 + 2x_2 \leqq 10$
   $x_1 - x_2 \leqq 0$
   $x_2 \geqq 2$

6. $-x_1 + x_2 \geqq 0$
   $x_1 + x_2 \leqq 5$
   $-2x_1 + x_2 \leqq 16$

7. $2.0x_1 + 6.0x_2 \leqq 18.0$
   $5.0x_1 + 2.5x_2 \leqq 20.0$

8. $2x_1 - x_2 \geqq 6$
   $4x_1 + 5x_2 \leqq 40$
   $x_1 - 2x_2 \geqq -3$

9. $x_1 + x_2 \geqq 3$
   $x_1 + x_2 \leqq 9$
   $-x_1 + x_2 \geqq -3$
   $-x_1 + x_2 \leqq 3$

10. $x_1 + x_2 \geqq 2$
    $3x_1 + 5x_2 \geqq 15$
    $2x_1 - x_2 \geqq -2$
    $-x_1 + 2x_2 \leqq 10$

11–15 MAXIMIZATION AND MINIMIZATION

Maximize the given objective function f subject to the given constraints.

11. $f = -10x_1 + 2x_2$, $x_1 \geqq 0$, $x_2 \geqq 0$,
    $-x_1 + x_2 \geqq -1$, $x_1 + x_2 \leqq 6$, $x_2 \leqq 5$

12. $f = 3x_1 - 6x_2$, $4x_1 + x_2 \geqq 4$,
    $-x_1 + 2x_2 \geqq 6$, $x_1 + 2x_2 \leqq 14$

13. $f = 2x_1 + 3x_2$, $4x_1 + 3x_2 \geqq 12$,
    $x_1 - x_2 \geqq -3$, $x_2 \leqq 6$, $2x_1 - 3x_2 \leqq 0$

14. Minimize f in Prob. 13.

15. Minimize f in Prob. 11.

16. **(Maximum output)** Giant Ladders, Inc., wants to maximize its daily total output of large step ladders by producing x_1 of them by a process P_1 and x_2 by a process P_2, where P_1 requires 2 hours of labor and 4 machine hours per ladder, and P_2 requires 3 hours of labor and 2 machine hours. For this kind of work, 1200 hours of labor and 1600 hours on the machines are at most available per day. Find the optimal x_1 and x_2.

17. **(Maximum profit)** Universal Electric, Inc., manufactures and sells two models of lamps, L_1 and L_2, the profit being \$150 and \$100, respectively. The process involves two workers W_1 and W_2 who are available for this kind of work 100 and 80 hours per month, respectively. W_1 assembles L_1 in 20 min and L_2 in 30 min. W_2 paints L_1 in 20 min and L_2 in 10 min. Assuming that all lamps made can be sold without difficulty, determine production figures that maximize the profit.

18. **(Minimum cost)** Hardbrick, Inc., has two kilns. Kiln I can produce 3000 grey bricks, 2000 red bricks, and 300 glazed bricks daily. For Kiln II the corresponding figures are 2000, 5000, and 1500. Daily operating costs of Kilns I and II are \$400 and \$600, respectively. Find the number of days of operation of each kiln so that the operation cost in filling an order of 18000 grey, 34000 red, and 9000 glazed bricks is minimized.

19. **(Maximum profit)** United Metal, Inc., produces alloys B_1 (special brass) and B_2 (yellow tombac). B_1 contains 50% copper and 50% zinc. (Ordinary brass contains about 65% copper and 35% zinc.) B_2 contains 75% copper and 25% zinc. Net profits are \$120 per ton of B_1 and \$100 per ton of B_2. The daily copper supply is 45 tons. The daily zinc supply is 30 tons. Maximize the net profit of the daily production.

20. **(Nutrition)** Foods A and B have 600 and 500 calories, contain 15 g and 30 g of protein, and cost \$1.80 and \$2.10 per unit, respectively. Find the minimum cost diet of at least 3900 calories containing at least 150 g of protein.

22.3 Simplex Method

From the last section we recall the following. A linear optimization problem (linear programming problem) can be written in normal form; that is:

Maximize

$$z = f(\mathbf{x}) = c_1x_1 + \cdots + c_nx_n \tag{1}$$

subject to the constraints

$$\begin{aligned} a_{11}x_1 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + \cdots + a_{2n}x_n &= b_2 \\ &\cdots\cdots\cdots\cdots \\ a_{m1}x_1 + \cdots + a_{mn}x_n &= b_m \\ x_i \geqq 0 \qquad (i = 1, \cdots, n). & \end{aligned} \tag{2}$$

For finding an optimal solution of this problem, we need to consider only the **basic feasible solutions** (defined in Sec. 22.2), but there are still so many that we have to follow a systematic search procedure. In 1948 G. B. Dantzig published an iterative method, called the **simplex method,** for that purpose. In this method, one proceeds stepwise from one basic feasible solution to another in such a way that the objective function f always increases its value. Let us explain this method in terms of the example in the last section.

In its original form the problem concerned the maximization of the objective function

$$z = 40x_1 + 88x_2$$

subject to

$$\begin{aligned} 2x_1 + 8x_2 &\leqq 60 \\ 5x_1 + 2x_2 &\leqq 60 \\ x_1 &\geqq 0 \\ x_2 &\geqq 0. \end{aligned}$$

Converting the first two inequalities to equations by introducing two slack variables x_3, x_4, we obtained the **normal form** of the problem in Example 2. Together with the objective function (written as an equation $z - 40x_1 - 88x_2 = 0$) this normal form is

$$\begin{aligned} z - 40x_1 - 88x_2 &= 0 \\ 2x_1 + 8x_2 + x_3 &= 60 \\ 5x_1 + 2x_2 + x_4 &= 60 \end{aligned} \tag{3}$$

where $x_1 \geqq 0, \cdots, x_4 \geqq 0$. This is a linear system of equations. To find an optimal solution of it, we may consider its **augmented matrix** (see Sec. 7.3)

$$\mathbf{T}_0 = \begin{array}{c} \begin{array}{cccccc} z & x_1 & x_2 & x_3 & x_4 & b \end{array} \\ \left[\begin{array}{c|cc|c|c|c} 1 & -40 & -88 & 0 & 0 & 0 \\ \hline 0 & 2 & 8 & 1 & 0 & 60 \\ 0 & 5 & 2 & 0 & 1 & 60 \end{array}\right] \end{array} \tag{4}$$

This matrix is called a **simplex tableau** or **simplex table** (the ***initial*** *simplex table*). These are standard names. The dashed lines and the letters

$$z, \quad x_1, \quad \cdots, \quad b$$

are for ease in further manipulation.

Every simplex table contains two kinds of variables x_j. By **basic variables** we mean those whose columns have only one nonzero entry. Thus x_3, x_4 in (4) are basic variables and x_1, x_2 are **nonbasic variables.**

Every simplex table gives a basic feasible solution. It is obtained by setting the nonbasic variables to zero. Thus (4) gives the basic feasible solution

$$x_1 = 0, \qquad x_2 = 0, \qquad x_3 = 60/1 = 60, \qquad x_4 = 60/1 = 60, \qquad z = 0$$

with x_3 obtained from the second row and x_4 from the third.

The optimal solution (its location and value) is now obtained stepwise by pivoting, designed to take us to basic feasible solutions with higher and higher values of z until the maximum of z is reached. Here, the choice of the **pivot equation** and **pivot** are quite different from that in the Gauss elimination. The reason is that x_1, x_2, x_3, x_4 are restricted to nonnegative values.

***Step 1. Operation O_1*: Selection of the *Column* of the Pivot**
Select as the column of the pivot the first column with a negative entry in Row 1. In (4) this is Column 2 (because of the -40).

Operation O_2*: Selection of the *Row* of the Pivot.** Divide the right sides [60 and 60 in (4)] by the corresponding entries of the column just selected ($60/2 = 30$, $60/5 = 12$). Take as the pivot equation the equation that gives the ***smallest quotient. Thus the pivot is 5 because 60/5 is smallest.

***Operation O_3*: Elimination by Row Operations.** This gives zeros above and below the pivot (as in Gauss–Jordan, Sec. 7.8).

With the notation for row operations as introduced in Sec. 7.3, the calculations in Step 1 give from the simplex table $\mathbf{T}_0$ in (4) the following simplex table (augmented matrix), with the blue letters referring to the ***previous table.***

(5)
$$\mathbf{T}_1 = \begin{array}{c} \begin{array}{cccccc} z & x_1 & x_2 & x_3 & x_4 & b \end{array} \\ \left[\begin{array}{c:cccc:c} 1 & 0 & -72 & 0 & 8 & 480 \\ \hdashline 0 & 0 & 7.2 & 1 & -0.4 & 36 \\ 0 & 5 & 2 & 0 & 1 & 60 \end{array}\right] \end{array} \begin{array}{l} \\ \text{Row 1} + 8 \text{ Row 3} \\ \text{Row 2} - 0.4 \text{ Row 3} \end{array}$$

We see that basic variables are now x_1, x_3 and nonbasic variables are x_2, x_4. Setting the latter to zero, we obtain the basic feasible solution given by $\mathbf{T}_1$,

$$x_1 = 60/5 = 12, \qquad x_2 = 0, \qquad x_3 = 36/1 = 36, \qquad x_4 = 0, \qquad z = 480.$$

This is A in Fig. 473 (Sec. 22.2). We thus have moved from O: (0, 0) with $z = 0$ to A: (12, 0) with the greater $z = 480$. The reason for this increase is our elimination of a term $(-40x_1)$ with a negative coefficient. Hence ***elimination is applied only to negative entries*** in Row 1 but to no others. This motivates the selection of the *column* of the pivot.

We now motivate the selection of the *row* of the pivot. Had we taken the second row of $\mathbf{T}_0$ instead (thus 2 as the pivot), we would have obtained $z = 1200$ (verify!), but this line of constant revenue $z = 1200$ lies entirely outside the feasibility region in Fig. 473. This motivates our cautious choice of the entry 5 as our pivot because it gave the smallest quotient ($60/5 = 12$).

Step 2. The basic feasible solution given by (5) is not yet optimal because of the negative entry -72 in Row 1. Accordingly, we perform the operations O_1 to O_3 again, choosing a pivot in the column of -72.

Operation O_1. Select Column 3 of $\mathbf{T}_1$ in (5) as the column of the pivot (because $-72 < 0$).

Operation O_2. We have $36/7.2 = 5$ and $60/2 = 30$. Select 7.2 as the pivot (because $5 < 30$).

Operation O_3. Elimination by row operations gives

(6)
$$\mathbf{T}_2 = \begin{array}{c} \\ \\ \\ \end{array} \begin{array}{c} \begin{array}{cccccc} z & x_1 & x_2 & x_3 & x_4 & b \end{array} \\ \left[\begin{array}{cccccc} 1 & 0 & 0 & 10 & 4 & 840 \\ 0 & 0 & 7.2 & 1 & -0.4 & 36 \\ 0 & 5 & 0 & -\dfrac{1}{3.6} & \dfrac{1}{0.9} & 50 \end{array}\right] \end{array} \begin{array}{l} \text{Row 1} - 10\,\text{Row 2} \\ \\ \text{Row 3} - \dfrac{2}{7.2}\,\text{Row 2} \end{array}$$

We see that now x_1, x_2 are basic and x_3, x_4 nonbasic. Setting the latter to zero, we obtain from $\mathbf{T}_2$ the basic feasible solution

$$x_1 = 50/5 = 10, \qquad x_2 = 36/7.2 = 5, \qquad x_3 = 0, \qquad x_4 = 0, \qquad z = 840.$$

This is B in Fig. 473 (Sec. 22.2). In this step, z has increased from 480 to 840, due to the elimination of -72 in $\mathbf{T}_1$. Since $\mathbf{T}_2$ contains no more negative entries in Row 1, we conclude that $z = f(10, 5) = 40 \cdot 10 + 88 \cdot 5 = 840$ is the maximum possible revenue. It is obtained if we produce twice as many S heaters as L heaters. This is the solution of our problem by the simplex method of linear programming. ■

Minimization. If we want to ***minimize*** $z = f(\mathbf{x})$ (instead of maximize), we take as the columns of the pivots those whose entry in Row 1 is ***positive*** (instead of negative). In such a Column k we consider only positive entries t_{jk} and take as pivot a t_{jk} for which b_j/t_{jk} is smallest (as before). For examples, see the problem set.

PROBLEM SET 22.3

1–9 SIMPLEX METHOD

Write in normal form and solve by the simplex method, assuming all x_j to be nonnegative.

1. Maximize $f = 3x_1 + 2x_2$ subject to $3x_1 + 4x_2 \leqq 60$, $4x_1 + 3x_2 \leqq 60$, $10x_1 + 2x_2 \leqq 120$.
2. Prob. 16 in Problem Set 22.2.
3. Maximize the profit in the daily production of x_1 metal frames F_1 (\$90 profit/frame) and x_2 frames F_2 (\$50 profit/frame) under the restrictions $x_1 + 3x_2 \leqq 1800$ (material), $x_1 + x_2 \leqq 1000$ (machine hours), $3x_1 + x_2 \leqq 2400$ (labor).
4. Maximize $f = 2x_1 + 3x_2 + x_3$ subject to $x_1 + x_2 + x_3 \leqq 4.8$, $10x_1 + x_3 \leqq 9.9$, $x_2 - x_3 \leqq 0.2$.
5. The problem in the text with the order of the constraints interchanged.
6. Minimize $f = 4x_1 - 10x_2 - 20x_3$ subject to $3x_1 + 4x_2 + 5x_3 \leqq 60$, $2x_1 + x_2 \leqq 20$, $2x_1 + 3x_3 \leqq 30$.
7. Minimize $f = 5x_1 - 20x_2$ subject to $-2x_1 + 10x_2 \leqq 5$, $2x_1 + 5x_2 \leqq 10$.
8. Prob. 20 in Problem Set 22.2.

9. Maximize $f = 34x_1 + 29x_2 + 32x_3$ subject to $8x_1 + 2x_2 + x_3 \leqq 54$, $3x_1 + 8x_2 + 2x_3 \leqq 59$, $x_1 + x_2 + 5x_3 \leqq 39$.

10. **CAS PROJECT. Simplex Method.** (a) Write a program for graphing a region R in the first quadrant of the x_1x_2-plane determined by linear constraints.

(b) Write a program for maximizing $z = a_1x_1 + a_2x_2$ in R.

(c) Write a program for maximizing $z = a_1x_1 + \cdots + a_nx_n$ subject to linear constraints.

(d) Apply your programs to problems in this problem set and the previous one.

22.4 Simplex Method: Difficulties

We recall from the last section that in the simplex method we proceed stepwise from one basic feasible solution to another, thereby increasing the value of the objective function f until we reach an optimal solution. Occasionally (but rather infrequently in practice), two kinds of difficulties may occur.

The first of these is degeneracy. A **degenerate feasible solution** is a feasible solution at which more than the usual number $n - m$ of variables are zero. Here n is the number of variables (slack and others) and m the number of constraints (not counting the $x_j \geqq 0$ conditions). In the last section, $n = 4$ and $m = 2$, and the occurring basic feasible solutions were nondegenerate; $n - m = 2$ variables were zero in each such solution.

In the case of a degenerate feasible solution we do an extra elimination step in which a basic variable that is zero for that solution becomes nonbasic (and a nonbasic variable becomes basic instead). We explain this in a typical case. For more complicated cases and techniques (rarely needed in practice) see Ref. [F5] in App. 1.

EXAMPLE 1 **Simplex Method, Degenerate Feasible Solution**

AB Steel, Inc., produces two kinds of iron I_1, I_2 by using three kinds of raw material R_1, R_2, R_3 (scrap iron and two kinds of ore) as shown. Maximize the daily profit.

Raw Material	Raw Material Needed per Ton		Raw Material Available per Day (tons)
	Iron I_1	Iron I_2	
R_1	2	1	16
R_2	1	1	8
R_3	0	1	3.5
Net profit per ton	\$150	\$300	

Solution. Let x_1 and x_2 denote the amount (in tons) of iron I_1 and I_2, respectively, produced per day. Then our problem is as follows. Maximize

$$z = f(\mathbf{x}) = 150x_1 + 300x_2 \tag{1}$$

subject to the constraints $x_1 \geqq 0$, $x_2 \geqq 0$ and

$$2x_1 + x_2 \leqq 16 \qquad \text{(raw material } R_1\text{)}$$

$$x_1 + x_2 \leqq 8 \qquad \text{(raw material } R_2\text{)}$$

$$x_2 \leqq 3.5 \qquad \text{(raw material } R_3\text{)}.$$

By introducing slack variables x_3, x_4, x_5 we obtain the normal form of the constraints

$$
\begin{aligned}
2x_1 + x_2 + x_3 &= 16 \\
x_1 + x_2 + x_4 &= 8 \\
x_2 + x_5 &= 3.5 \\
x_j \geqq 0 \quad (j &= 1, \cdots, 5).
\end{aligned} \tag{2}
$$

As in the last section we obtain from (1) and (2) the initial simplex table

$$
\mathbf{T}_0 = \begin{array}{c} \begin{array}{ccccccc} z & x_1 & x_2 & x_3 & x_4 & x_5 & b \end{array} \\ \left[\begin{array}{c|cc|ccc|c} 1 & -150 & -300 & 0 & 0 & 0 & 0 \\ \hline 0 & 2 & 1 & 1 & 0 & 0 & 16 \\ 0 & 1 & 1 & 0 & 1 & 0 & 8 \\ 0 & 0 & 1 & 0 & 0 & 1 & 3.5 \end{array}\right] \end{array} . \tag{3}
$$

We see that x_1, x_2 are nonbasic variables and x_3, x_4, x_5 are basic. With $x_1 = x_2 = 0$ we have from (3) the basic feasible solution

$$
x_1 = 0, \quad x_2 = 0, \quad x_3 = 16/1 = 16, \quad x_4 = 8/1 = 8, \quad x_5 = 3.5/1 = 3.5, \quad z = 0.
$$

This is O: (0, 0) in Fig. 474. We have $n = 5$ variables x_j, $m = 3$ constraints, and $n - m = 2$ variables equal to zero in our solution, which thus is nondegenerate.

Step 1 of Pivoting

Operation O_1: Column Selection of Pivot. Column 2 (since $-150 < 0$).

Operation O_2: Row Selection of Pivot. $16/2 = 8$, $8/1 = 8$; $3.5/0$ is not possible. Hence we could choose Row 2 or Row 3. We choose Row 2. The pivot is 2.

Operation O_3: Elimination by Row Operations. This gives the simplex table

$$
\mathbf{T}_1 = \begin{array}{c} \begin{array}{ccccccc} z & x_1 & x_2 & x_3 & x_4 & x_5 & b \end{array} \\ \left[\begin{array}{c|cc|ccc|c} 1 & 0 & -225 & 75 & 0 & 0 & 1200 \\ \hline 0 & 2 & 1 & 1 & 0 & 0 & 16 \\ 0 & 0 & \frac{1}{2} & -\frac{1}{2} & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 3.5 \end{array}\right] \end{array} \begin{array}{l} \text{Row 1} + 75 \text{ Row 2} \\ \\ \text{Row 3} - \frac{1}{2} \text{ Row 2} \\ \text{Row 4} \end{array} \tag{4}
$$

We see that the basic variables are x_1, x_4, x_5 and the nonbasic are x_2, x_3. Setting the nonbasic variables to zero, we obtain from $\mathbf{T}_1$ the basic feasible solution

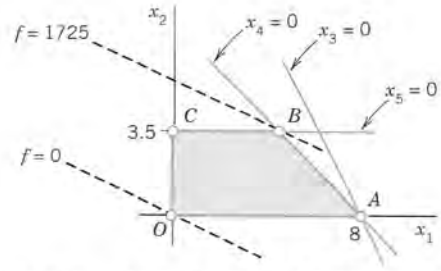

Fig. 474. Example 1, where A is degenerate

$$x_1 = 16/2 = 8, \quad x_2 = 0, \quad x_3 = 0, \quad x_4 = 0/1 = 0, \quad x_5 = 3.5/1 = 3.5, \quad z = 1200$$

This is A: (8, 0) in Fig. 474. This solution in degenerate because $x_4 = 0$ (in addition to $x_2 = 0$, $x_3 = 0$); geometrically: the straight line $x_4 = 0$ also passes through A. This requires the next step, in which x_4 will become nonbasic.

Step 2 of Pivoting

Operation O_1: Column Selection of Pivot. Column 3 (since $-225 < 0$).

Operation O_2: Row Selection of Pivot. $16/1 = 16$, $0/\frac{1}{2} = 0$. Hence $\frac{1}{2}$ must serve as the pivot.

Operation O_3: Elimination by Row Operations. This gives the following simplex table.

(5)
$$\mathbf{T}_2 = \begin{array}{c} \begin{array}{ccccccc} z & x_1 & x_2 & x_3 & x_4 & x_5 & b \end{array} \\ \left[\begin{array}{c|cc|cc|c} 1 & 0 & 0 & -150 & 450 & 0 & 1200 \\ \hline 0 & 2 & 0 & 2 & -2 & 0 & 16 \\ 0 & 0 & \frac{1}{2} & -\frac{1}{2} & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & -2 & 1 & 3.5 \end{array}\right] \end{array} \begin{array}{l} \text{Row 1} + 450\,\text{Row 3} \\ \text{Row 2} - 2\,\text{Row 3} \\ \\ \text{Row 4} - 2\,\text{Row 3} \end{array}$$

We see that the basic variables are x_1, x_2, x_5 and the nonbasic are x_3, x_4. Hence x_4 has become nonbasic, as intended. By equating the nonbasic variables to zero we obtain from $\mathbf{T}_2$ the basic feasible solution

$$x_1 = 16/2 = 8, \quad x_2 = 0/\tfrac{1}{2} = 0, \quad x_3 = 0, \quad x_4 = 0, \quad x_5 = 3.5/1 = 3.5, \quad z = 1200.$$

This is still A: (8, 0) in Fig. 474 and z has not increased. But this opens the way to the maximum, which we reach in the next step.

Step 3 of Pivoting

Operation O_1: Column Selection of Pivot. Column 4 (since $-150 < 0$).

Operation O_2: Row Selection of Pivot. $16/2 = 8$, $0/(-\frac{1}{2}) = 0$, $3.5/1 = 3.5$. We can take 1 as the pivot. (With $-\frac{1}{2}$ as the pivot we would not leave A. Try it.)

Operation O_3: Elimination by Row Operations. This gives the simplex table

(6)
$$\mathbf{T}_3 = \begin{array}{c} \begin{array}{ccccccc} z & x_1 & x_2 & x_3 & x_4 & x_5 & b \end{array} \\ \left[\begin{array}{c|cc|cc|c} 1 & 0 & 0 & 0 & 150 & 150 & 1725 \\ \hline 0 & 2 & 0 & 0 & 2 & -2 & 9 \\ 0 & 0 & \frac{1}{2} & 0 & 0 & \frac{1}{2} & 1.75 \\ 0 & 0 & 0 & 1 & -2 & 1 & 3.5 \end{array}\right] \end{array} \begin{array}{l} \text{Row 1} + 150\,\text{Row 4} \\ \text{Row 2} - 2\,\text{Row 1} \\ \text{Row 3} - \frac{1}{2}\,\text{Row 2} \\ \\ \end{array}$$

We see that basic variables are x_1, x_2, x_3 and nonbasic x_4, x_5. Equating the latter to zero we obtain from $\mathbf{T}_3$ the basic feasible solution

$$x_1 = 9/2 = 4.5, \quad x_2 = 1.75/\tfrac{1}{2} = 3.5, \quad x_3 = 3.5/1 = 3.5, \quad x_4 = 0, \quad x_5 = 0, \quad z = 1725.$$

This is B: (4.5, 3.5) in Fig. 474. Since Row 1 of $\mathbf{T}_3$ has no negative entries, we have reached the maximum daily profit $z_{\max} = f(4.5, 3.5) = 150 \cdot 4.5 + 300 \cdot 3.5 = \$1725$. This is obtained by using 4.5 tons of iron I_1 and 3.5 tons of iron I_2. ■

Difficulties in Starting

As a second kind of difficulty, it may sometimes be hard to find a basic feasible solution to start from. In such a case the idea of an **artificial variable** (or several such variables) is helpful. We explain this method in terms of a typical example.

EXAMPLE 2 **Simplex Method: Difficult Start, Artificial Variable**

Maximize

$$z = f(\mathbf{x}) = 2x_1 + x_2 \tag{7}$$

subject to the constraints $x_1 \geqq 0$, $x_2 \geqq 0$ and (Fig. 475)

$$\begin{aligned} x_1 - \tfrac{1}{2}x_2 &\geqq 1 \\ x_1 - x_2 &\leqq 2 \\ x_1 + x_2 &\leqq 4. \end{aligned}$$

Solution. By means of slack variables we achieve the normal form of the constraints

$$\begin{aligned} z - 2x_1 - x_2 &= 0 \\ x_1 - \tfrac{1}{2}x_2 - x_3 &= 1 \\ x_1 - x_2 + x_4 &= 2 \\ x_1 + x_2 + x_5 &= 4 \\ x_j &\geqq 0 \quad (j = 1, \cdots, 5). \end{aligned} \tag{8}$$

Note that the first slack variable is negative (or zero), which makes x_3 nonnegative within the feasibility region (and negative outside). From (7) and (8) we obtain the simplex table

z	x_1	x_2	x_3	x_4	x_5	b
1	−2	−1	0	0	0	0
0	1	$-\frac{1}{2}$	−1	0	0	1
0	1	−1	0	1	0	2
0	1	1	0	0	1	4

x_1, x_2 are nonbasic, and we would like to take x_3, x_4, x_5 as basic variables. By our usual process of equating the nonbasic variables to zero we obtain from this table

$$x_1 = 0, \quad x_2 = 0, \quad x_3 = 1/(-1) = -1, \quad x_4 = 2/1 = 2, \quad x_5 = 4/1 = 4, \quad z = 0.$$

$x_3 < 0$ indicates that (0, 0) lies outside the feasibility region. Since $x_3 < 0$, we cannot proceed immediately. Now, instead of searching for other basic variables, we use the following idea. Solving the second equation in (8) for x_3, we have

$$x_3 = -1 + x_1 - \tfrac{1}{2}x_2.$$

To this we now add a variable x_6 on the right,

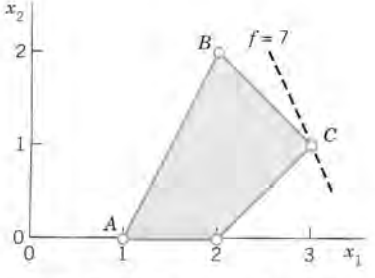

Fig. 475. Feasibility region in Example 2

(9) $$x_3 = -1 + x_1 - \tfrac{1}{2}x_2 + x_6.$$

x_6 is called an **artificial variable** and is subject to the constraint $x_6 \geqq 0$.

We must take care that x_6 (which is not part of the given problem!) will disappear eventually. We shall see that we can accomplish this by adding a term $-Mx_6$ with very large M to the objective function. Because of (7) and (9) (solved for x_6) this gives the modified objective function for this **"extended problem"**

(10) $$\hat{z} = z - Mx_6 = 2x_1 + x_2 - Mx_6 = (2 + M)x_1 + (1 - \tfrac{1}{2}M)x_2 - Mx_3 - M.$$

We see that the simplex table corresponding to (10) and (8) is

$$\mathbf{T}_0 = \begin{array}{c} \begin{array}{cccccccc} \hat{z} & x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & b \end{array} \\ \left[\begin{array}{c|c|c|c|c|c|c|c} 1 & -2-M & -1+\frac{1}{2}M & M & 0 & 0 & 0 & -M \\ \hline 0 & 1 & -\frac{1}{2} & -1 & 0 & 0 & 0 & 1 \\ 0 & 1 & -1 & 0 & 1 & 0 & 0 & 2 \\ 0 & 1 & 1 & 0 & 0 & 1 & 0 & 4 \\ 0 & 1 & -\frac{1}{2} & -1 & 0 & 0 & 1 & 1 \end{array}\right] \end{array}.$$

The last row of this table results from (9) written as $x_1 - \frac{1}{2}x_2 - x_3 + x_6 = 1$. We see that we can now start, taking x_4, x_5, x_6 as the basic variables and x_1, x_2, x_3 as the nonbasic variables. Column 2 has a negative first entry. We can take the second entry (1 in Row 2) as the pivot. This gives

$$\mathbf{T}_1 = \begin{array}{c} \begin{array}{cccccccc} \hat{z} & x_1 & x_2 & x_3 & x_4 & x_5 & x_6 & b \end{array} \\ \left[\begin{array}{c|c|c|c|c|c|c|c} 1 & 0 & -2 & -2 & 0 & 0 & 0 & 2 \\ \hline 0 & 1 & -\frac{1}{2} & -1 & 0 & 0 & 0 & 1 \\ 0 & 0 & -\frac{1}{2} & 1 & 1 & 0 & 0 & 1 \\ 0 & 0 & \frac{3}{2} & 1 & 0 & 1 & 0 & 3 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{array}\right] \end{array}.$$

This corresponds to $x_1 = 1, x_2 = 0$ (point A in Fig. 475), $x_3 = 0, x_4 = 1, x_5 = 3, x_6 = 0$. We can now drop Row 5 and Column 7. In this way we get rid of x_6, as wanted, and obtain

$$\mathbf{T}_2 = \begin{array}{c} \begin{array}{ccccccc} z & x_1 & x_2 & x_3 & x_4 & x_5 & b \end{array} \\ \left[\begin{array}{c|c|c|c|c|c|c} 1 & 0 & -2 & -2 & 0 & 0 & 2 \\ \hline 0 & 1 & -\frac{1}{2} & -1 & 0 & 0 & 1 \\ 0 & 0 & -\frac{1}{2} & 1 & 1 & 0 & 1 \\ 0 & 0 & \frac{3}{2} & 1 & 0 & 1 & 3 \end{array}\right] \end{array}.$$

In Column 3 we choose 3/2 as the next pivot. We obtain

$$\mathbf{T}_3 = \begin{array}{c} \begin{array}{ccccccc} z & x_1 & x_2 & x_3 & x_4 & x_5 & b \end{array} \\ \left[\begin{array}{c|c|c|c|c|c|c} 1 & 0 & 0 & -\frac{2}{3} & 0 & \frac{4}{3} & 6 \\ \hline 0 & 1 & 0 & -\frac{2}{3} & 0 & \frac{1}{3} & 2 \\ 0 & 0 & 0 & \frac{4}{3} & 1 & \frac{1}{3} & 2 \\ 0 & 0 & \frac{3}{2} & 1 & 0 & 1 & 3 \end{array}\right] \end{array}.$$

This corresponds to $x_1 = 2, x_2 = 2$ (this is B in Fig. 475), $x_3 = 0, x_4 = 2, x_5 = 0$. In Column 4 we choose 4/3 as the pivot, by the usual principle. This gives

$$\mathbf{T}_4 = \begin{array}{c} \begin{array}{ccccccc} z & x_1 & x_2 & x_3 & x_4 & x_5 & b \end{array} \\ \left[\begin{array}{c|cc|c|cc|c} 1 & 0 & 0 & 0 & \frac{1}{2} & \frac{3}{2} & 7 \\ \hline 0 & 1 & 0 & 0 & \frac{1}{2} & \frac{1}{2} & 3 \\ 0 & 0 & 0 & \frac{4}{3} & 1 & \frac{1}{3} & 2 \\ 0 & 0 & \frac{3}{2} & 0 & -\frac{3}{4} & \frac{3}{4} & \frac{3}{2} \end{array}\right] \end{array}.$$

This corresponds to $x_1 = 3$, $x_2 = 1$ (point C in Fig. 475), $x_3 = \frac{3}{2}$, $x_4 = 0$, $x_5 = 0$. This is the maximum $f_{\max} = f(3, 1) = 7$. ■

PROBLEM SET 22.4

If in a step you have a choice between pivots, take the one that comes first in the column considered.

1. Maximize $z = f_1(\mathbf{x}) = 6x_1 + 12x_2$ subject to $0 \leqq x_1 \leqq 4$, $0 \leqq x_2 \leqq 4$, $6x_1 + 12x_2 \leqq 72$.
2. Do Prob. 1 with the last two constraints interchanged.
3. Maximize the daily output in producing x_1 glass plates by a process P_1 and x_2 glass plates by a process P_2 subject to the constraints (labor hours, machine hours, raw material supply)

$$2x_1 + 3x_2 \leqq 130, \qquad 3x_1 + 8x_2 \leqq 300,$$
$$4x_1 + 2x_2 \leqq 140.$$

4. Maximize $z = 300x_1 + 500x_2$ subject to $2x_1 + 8x_2 \leqq 60$, $2x_1 + x_2 \leqq 30$, $4x_1 + 4x_2 \leqq 60$.
5. Do Prob. 4 with the last two constraints interchanged. Comment on the resulting simplification.
6. Maximize the total output $f = x_1 + x_2 + x_3$ (production figures of three different production processes) subject to input constraints (limitation of machine time)

$$4x_1 + 5x_2 + 8x_3 \leqq 12,$$
$$8x_1 + 5x_2 + 4x_3 \leqq 12.$$

7. Maximize $f = 6x_1 + 6x_2 + 9x_3$ subject to $x_j \geqq 0$ $(j = 1, \cdots, 5)$, and $x_1 + x_3 + x_4 = 1$, $x_2 + x_3 + x_5 = 1$.
8. Using an artificial variable, minimize $f = 2x_1 - x_2$ subject to $x_1 \geqq 0$, $x_2 \geqq 0$, $x_1 + x_2 \geqq 5$, $-x_1 + x_2 \leqq 1$, $5x_1 + 4x_2 \leqq 40$.
9. Maximize $f = 4x_1 + x_2 + 2x_3$ subject to $x_1 \geqq 0$, $x_2 \geqq 0$, $x_3 \leqq 0$, $x_1 + x_2 + x_3 \leqq 1$, $x_1 + x_2 - x_3 \leqq 0$.
10. If one uses the method of artificial variables in a problem without solution, this nonexistence will become apparent by the fact that one cannot get rid of the artificial variable. Illustrate this by trying to maximize $f = 2x_1 + x_2$ subject to $x_1 \geqq 0$, $x_2 \geqq 0$, $2x_1 + x_2 \leqq 2$, $x_1 + 2x_2 \geqq 6$, $x_1 + x_2 \leqq 4$.

CHAPTER 22 REVIEW QUESTIONS AND PROBLEMS

1. What is the difference between constrained and unconstrained optimization?
2. State the idea and the basic formulas of the method of steepest descent.
3. Write down an algorithm for the method of steepest descent.
4. Design a "method of steepest ascent" for determining maxima.
5. What is linear programming? Its basic idea? An objective function?
6. Why can we not use methods of calculus for extrema in linear programming?
7. What are slack variables? Artificial variables? Why did we use them?
8. Apply the method of steepest descent to $f(\mathbf{x}) = x_1^2 + 1.5x_2^2$, starting from (6, 3). Do 3 steps. Why is the convergence faster than in Example 1, Sec. 22.1?
9. What does the method of steepest descent amount to in the case of a single variable?
10. In Prob. 8 start from $\mathbf{x}_0 = [1.5 \quad 1]^T$. Show that the next even-numbered approximations are $\mathbf{x}_2 = k\mathbf{x}_0$, $\mathbf{x}_4 = k^2\mathbf{x}_0$, etc., where $k = 0.04$.
11. What happens in Example 1 of Sec. 22.1 if you replace the function $f(\mathbf{x}) = x_1^2 + 3x_2^2$ by $f(\mathbf{x}) = x_1^2 + 5x_2^2$? Do 5 steps, starting from $\mathbf{x}_0 = [6 \quad 3]^T$. Is the convergence faster or slower?
12. Apply the method of steepest descent to $f(\mathbf{x}) = 9x_1^2 + x_2^2 + 18x_1 - 4x_2$, 5 steps, starting from $\mathbf{x}_0 = [2 \quad 4]^T$.
13. In Prob. 12, could you start from $[0 \quad 0]^T$ and do 5 steps?

14. Show that the gradients in Prob. 13 are orthogonal. Give a reason.

15–20 Graph or sketch the region in the first quadrant of the x_1x_2-plane determined by the following inequalities.

15. $x_1 + 3x_2 \leqq 6$, $2x_1 + x_2 \leqq 4$

16. $x_1 - 2x_2 \leqq -2$, $0.8x_1 + x_2 \leqq 6$

17. $-x_1 + x_2 \geqq 0$, $x_1 + x_2 \leqq 4$

18. $x_1 - 2x_2 \geqq -4$, $2x_1 + x_2 \leqq 12$, $x_1 + x_2 \leqq 8$

19. $x_1 + x_2 \leqq 5$, $x_2 \leqq 3$, $-x_1 + x_2 \leqq 2$

20. $x_1 + x_2 \geqq 2$, $2x_1 - 3x_2 \geqq -12$, $x_1 \leqq 15$

21–25 Maximize or minimize as indicated.

21. Maximize $f = 10x_1 + 20x_2$ subject to $x_1 \leqq 5$, $x_1 + x_2 \leqq 6$, $x_2 \leqq 4$.

22. Maximize $f = x_1 + x_2$ subject to $x_1 + 2x_2 \leqq 10$, $2x_1 + x_2 \leqq 10$, $x_2 \leqq 4$.

23. Minimize $f = 2x_1 - 10x_2$ subject to $x_1 - x_2 \leqq 4$, $2x_1 + x_2 \leqq 14$, $x_1 + x_2 \leqq 9$, $-x_1 + 3x_2 \leqq 15$.

24. A factory produces two kinds of gaskets, G_1, G_2, with net profit of \$60 and \$30, respectively. Maximize the total daily profit subject to the constraints (x_j = number of gaskets G_j produced per day)

$$40x_1 + 40x_2 \leqq 1800 \quad \text{(Machine hours)},$$

$$200x_1 + 20x_2 \leqq 6300 \quad \text{(Labor)}.$$

25. Maximize the daily output in producing x_1 chairs by a process P_1 and x_2 chairs by a process P_2 subject to $3x_1 + 4x_2 \leqq 550$ (machine hours), $5x_1 + 4x_2 \leqq 650$ (labor).

SUMMARY OF CHAPTER 22
Unconstrained Optimization. Linear Programming

In optimization problems we maximize or minimize an **objective function** $z = f(\mathbf{x})$ depending on control variables $x_1, \cdots, x_m$ whose domain is either unrestricted (**"unconstrained optimization,"** Sec. 22.1) or restricted by constraints in the form of inequalities or equations or both (**"constrained optimization,"** Sec. 22.2).

If the objective function is *linear* and the constraints are *linear inequalities* in $x_1, \cdots, x_m$, then by introducing **slack variables** $x_{m+1}, \cdots, x_n$ we can write the optimization problem in **normal form** with the objective function given by

$$f_1 = c_1x_1 + \cdots + c_nx_n \tag{1}$$

(where $c_{m+1} = \cdots = c_n = 0$) and the constraints given by

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ &\cdots\cdots\cdots \\ &\cdots\cdots\cdots \\ a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n &= b_m \end{aligned} \tag{2}$$

$$x_1 \geqq 0, \cdots, x_n \geqq 0.$$

In this case we can then apply the widely used **simplex method** (Sec. 22.3), a systematic stepwise search through a very much reduced subset of all feasible solutions. Section 22.4 shows how to overcome difficulties with this method.

CHAPTER 23

Graphs. Combinatorial Optimization

Graphs and **digraphs** (= directed graphs) have developed into powerful tools in areas, such as electrical and civil engineering, communication networks, operations research, computer science, economics, industrial management, and marketing. An essential factor of this growth is the use of computers in large-scale optimization problems that can be modeled by graphs and solved by algorithms provided by graph theory. This approach yields models of general applicability and economic importance. It lies in the center of **combinatorial optimization,** a term denoting optimization problems that are of pronounced discrete or combinatorial structure.

This chapter gives an introduction to this wide area, which constitutes a shift of emphasis away from differential equations, eigenvalues, and so on, and is full of new ideas as well as open problems—in connection, for instance, with efficient computer algorithms. The classes of problems we shall consider include transportation of minimum cost or time, best assignment of workers to jobs, most efficient use of communication networks, and many others. Problems for these classes often form the core of larger and more involved practical problems.

Prerequisite: none.
References and Answers to Problems: App. 1 Part F, App. 2.

23.1 Graphs and Digraphs

Roughly, a *graph* consists of points, called *vertices,* and lines connecting them, called *edges.* For example, these may be four cities and five highways connecting them, as in Fig. 476. Or the points may represent some people, and we connect by an edge those who do business with each other. Or the vertices may represent computers in a network and the edges connections between them. Let us now give a formal definition.

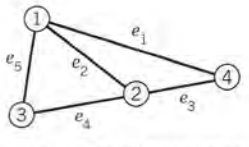

Fig. 476. Graph consisting of 4 vertices and 5 edges

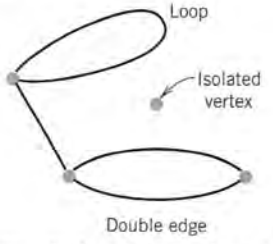

Fig. 477. Isolated vertex, loop, double edge. (Excluded by definition.)

DEFINITION

Graph

A **graph** G consists of two finite sets (sets having finitely many elements), a set V of points, called **vertices,** and a set E of connecting lines, called **edges,** such that each edge connects two vertices, called the *endpoints* of the edge. We write

$$G = (V, E).$$

Excluded are *isolated vertices* (vertices that are not endpoints of any edge), *loops* (edges whose endpoints coincide), and *multiple edges* (edges that have both endpoints in common. See Fig. 477.

CAUTION! Our three exclusions are practical and widely accepted, but not uniformly. For instance, some authors permit multiple edges and call graphs without them *simple graphs.* ■

We denote vertices by letters, $u, v, \cdots$ or $v_1, v_2, \cdots$ or simply by numbers $1, 2, \cdots$ (as in Fig. 476). We denote edges by $e_1, e_2, \cdots$ or by their two endpoints; for instance, $e_1 = (1, 4)$, $e_2 = (1, 2)$ in Fig. 476.

An edge (v_i, v_j) is called **incident** with the vertex v_i (and conversely); similarly, (v_i, v_j) is *incident* with v_j. The number of edges incident with a vertex v is called the **degree** of v. Two vertices are called **adjacent** in G if they are connected by an edge in G (that is, if they are the two endpoints of some edge in G).

We meet graphs in different fields under different names: as "networks" in electrical engineering, "structures" in civil engineering, "molecular structures" in chemistry, "organizational structures" in economics, "sociograms," "road maps," "telecommunication networks," and so on.

Digraphs (Directed Graphs)

Nets of one-way streets, pipeline networks, sequences of jobs in construction work, flows of computation in a computer, producer–consumer relations, and many other applications suggest the idea of a "digraph" (= directed graph), in which each edge has a direction (indicated by an arrow, as in Fig. 478).

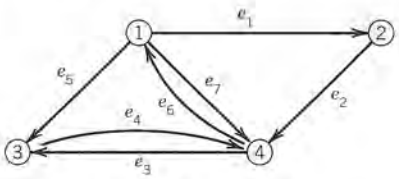

Fig. 478. Digraph

DEFINITION

Digraph (Directed Graph)

A **digraph** $G = (V, E)$ is a graph in which each edge $e = (i, j)$ has a direction from its *"initial point" i* to its *"terminal point" j.*

Two edges connecting the same two points i, j are now permitted, provided they have opposite directions, that is, they are (i, j) and (j, i). *Example.* (1, 4) and (4, 1) in Fig. 478.

A **subgraph** or subdigraph of a given graph or digraph $G = (V, E)$, respectively, is a graph or digraph obtained by deleting some of the edges and vertices of G, retaining the other edges of G (together with their pairs of endpoints). For instance, e_1, e_3 (together with the vertices 1, 2, 4) form a subgraph in Fig. 476, and e_3, e_4, e_5 (together with the vertices 1, 3, 4) form a subdigraph in Fig. 478.

Computer Representation of Graphs and Digraphs

Drawings of graphs are useful to people in explaining or illustrating specific situations. Here one should be aware that a graph may be sketched in various ways; see Fig. 479. For handling graphs and digraphs in computers, one uses matrices or lists as appropriate data structures, as follows.

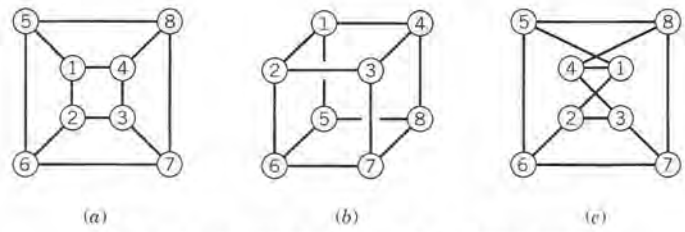

Fig. 479. Different sketches of the same graph

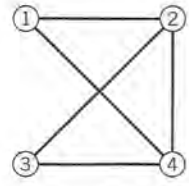


Adjacency Matrix of a Graph G: Matrix $\mathbf{A} = [a_{ij}]$ with entries

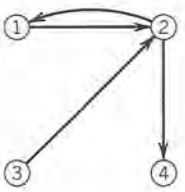
$$a_{ij} = \begin{cases} 1 & \text{if } G \text{ has an edge } (i, j), \\ 0 & \text{else.} \end{cases}$$

Thus $a_{ij} = 1$ if and only if two vertices i and j are adjacent in G. Here, by definition, no vertex is considered to be adjacent to itself; thus, $a_{ii} = 0$. $\mathbf{A}$ is symmetric, $a_{ij} = a_{ji}$. (Why?)

The adjacency matrix of a graph is generally much smaller than the so-called *incidence matrix* (see Probs. 21, 22) and is preferred over the latter if one decides to store a graph in a computer in matrix form.

EXAMPLE 1 **Adjacency Matrix of a Graph**

$$\begin{array}{c} \text{Vertex} \\ \text{Vertex } 1 \\ 2 \\ 3 \\ 4 \end{array} \begin{array}{c} \begin{array}{cccc} 1 & 2 & 3 & 4 \end{array} \\ \begin{bmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix} \end{array}$$



■

Adjacency Matrix of a Digraph G: Matrix $\mathbf{A} = [a_{ij}]$ with entries

$$a_{ij} = \begin{cases} 1 & \text{if } G \text{ has a directed edge } (i, j), \\ 0 & \text{else.} \end{cases}$$

This matrix $\mathbf{A}$ is not symmetric. (Why?)

EXAMPLE 2 Adjacency Matrix of a Digraph

	To vertex 1	2	3	4
From vertex 1	0	1	0	0
2	1	0	0	1
3	0	1	0	0
4	0	0	0	0

■

Lists. The **vertex incidence list** of a graph shows for each vertex the incident edges. The **edge incidence list** shows for each edge its two endpoints. Similarly for a *digraph;* in the vertex list, outgoing edges then get a minus sign, and in the edge list we now have *ordered* pairs of vertices.

EXAMPLE 3 Vertex Incidence List and Edge Incidence List of a Graph

This graph is the same as in Example 1, except for notation.

Vertex	Incident Edges
v_1	e_1, e_5
v_2	e_1, e_2, e_3
v_3	e_2, e_4
v_4	e_3, e_4, e_5

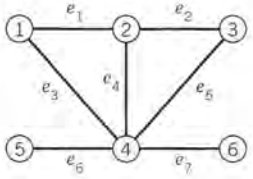
Edge	Endpoints
e_1	v_1, v_2
e_2	v_2, v_3
e_3	v_2, v_4
e_4	v_3, v_4
e_5	v_1, v_4

■

"Sparse graphs" are graphs with few edges (far fewer than the maximum possible number $n(n-1)/2$, where n is the number of vertices). For these graphs, matrices are not efficient. *Lists* then have the advantage of requiring much less storage and being easier to handle; they can be ordered, sorted, or manipulated in various other ways directly within the computer. For instance, in tracing a "walk" (a connected sequence of edges with pairwise common endpoints), one can easily go back and forth between the two lists just discussed, instead of scanning a large column of a matrix for a single 1.

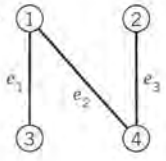
Computer science has developed more refined lists, which, in addition to the actual content, contain "pointers" indicating the preceding item or the next item to be scanned or both items (in the case of a "walk": the preceding edge or the subsequent one). For details, see Refs. [E16] and [F7].

This section was devoted to basic concepts and notations needed throughout this chapter, in which we shall discuss some of the most important classes of combinatorial optimization problems. This will at the same time help us to become more and more familiar with graphs and digraphs.



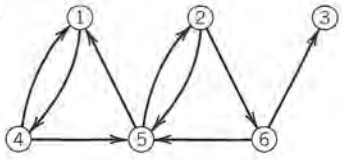
PROBLEM SET 23.1

1. Sketch the graph consisting of the vertices and edges of a square. Of a tetrahedron.
2. Worker W_1 can do jobs J_1 and J_3, worker W_2 job J_4, worker W_3 jobs J_2 and J_3. Represent this by a graph.
3. Explain how the following may be regarded as graphs or digraphs: flight connections between given cities; memberships of some persons in some committees; relations between chapters of a book; a tennis tournament; a family tree.
4. How would you represent a net of one-way and two-way streets by a digraph?
5. Give further examples of situations that could be represented by a graph or digraph.
6. Find the adjacency matrix of the graph in Fig. 476.
7. When will the adjacency matrix of a graph be symmetric? Of a digraph?

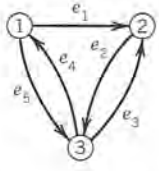


8–13 ADJACENCY MATRIX

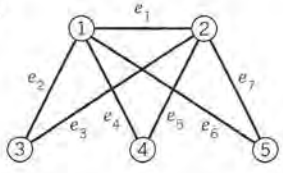
Find the adjacency matrix of the graph or digraph.



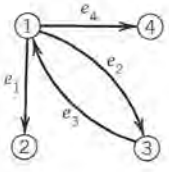
8.



9.



10.



11.

12.

13.

Sketch the graph whose adjacency matrix is:

14.
$$\begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix}$$

15.
$$\begin{bmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

16.
$$\begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix}$$

Sketch the digraph whose adjacency matrix is:

17. The matrix in Prob. 14.

18. The matrix in Prob. 16.

19. **(Complete graph)** Show that a graph G with n vertices can have at most $n(n-1)/2$ edges, and G has exactly $n(n-1)/2$ edges if G is *complete*, that is, if every pair of vertices of G is joined by an edge. (Recall that loops and multiple edges are excluded.)

20. In what case are all the off-diagonal entries of the adjacency matrix of a graph G equal to 1?

Incidence Matrix of a Graph: Matrix $\mathbf{B} = [b_{jk}]$ with entries

$$b_{jk} = \begin{cases} 1 & \text{if vertex } j \text{ is an endpoint of edge } e_k \\ 0 & \text{otherwise.} \end{cases}$$

Find the incidence matrix of:

21. The graph in Prob. 9.

22. The graph in Prob. 8.

Incidence Matrix of a Digraph: Matrix $\widetilde{\mathbf{B}} = [\widetilde{b}_{jk}]$ with entries

$$\widetilde{b}_{jk} = \begin{cases} -1 & \text{if edge } e_k \text{ leaves vertex } j \\ 1 & \text{if edge } e_k \text{ enters vertex } j \\ 0 & \text{otherwise.} \end{cases}$$

Find the incidence matrix of:

23. The digraph in Prob. 11.

24. The digraph in Prob. 13.

25. Make a vertex incidence list of the digraph in Prob. 13.

23.2 Shortest Path Problems. Complexity

Beginning in this section, we shall discuss some of the most important classes of optimization problems that concern graphs and digraphs as they arise in applications. Basic ideas and algorithms will be explained and illustrated by small graphs, but you should keep in mind that real-life problems may often involve many ***thousands or even millions of vertices and edges*** (think of telephone networks, worldwide air travel, companies that have offices and stores in all larger cities). Then reliable and efficient systematic methods are an absolute necessity—solution by inspection or by trial and error would no longer work, even if "nearly optimal" solutions are acceptable.

We begin with **shortest path problems,** as they arise, for instance, in designing shortest (or least expensive, or fastest) routes for a traveling salesman, for a cargo ship, etc. Let us first explain what we mean by a path.

In a graph $G = (V, E)$ we can walk from a vertex v_1 along some edges to some other vertex v_k. Here we can

(A) make no restrictions, or

(B) require that each *edge* of G be traversed at most once, or

(C) require that each *vertex* be visited at most once.

In case (A) we call this a **walk.** Thus a walk from v_1 to v_k is of the form

$$(1) \qquad (v_1, v_2), (v_2, v_3), \cdots, (v_{k-1}, v_k),$$

where some of these edges or vertices may be the same. In case (B), where each *edge* may occur at most once, we call the walk a **trail.** Finally, in case (C), where each *vertex* may occur at most once (and thus each edge automatically occurs at most once), we call the trail a **path.**

We admit that a walk, trail, or path may end at the vertex it started from, in which case we call it **closed;** then $v_k = v_1$ in (1).

A closed path is called a **cycle.** *A cycle has at least three edges* (because we do not have double edges; see Sec. 23.1). Figure 480 illustrates all these concepts.

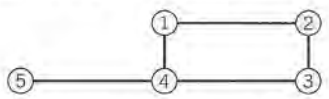


Fig. 480. Walk, trail, path, cycle

1 − 2 − 3 − 2 is a walk (not a trail).
4 − 1 − 2 − 3 − 4 − 5 is a trail (not a path).
1 − 2 − 3 − 4 − 5 is a path (not a cycle).
1 − 2 − 3 − 4 − 1 is a cycle.

Shortest Path

To define the concept of a shortest path, we assume that $G = (V, E)$ is a **weighted graph,** that is, each edge (v_i, v_j) in G has a given *weight* or *length* $l_{ij} > 0$. Then a **shortest path** $v_1 \to v_k$ (with fixed v_1 and v_k) is a path (1) such that the sum of the lengths of its edges

$$l_{12} + l_{23} + l_{34} + \cdots + l_{k-1,k}$$

(l_{12} = length of (v_1, v_2), etc.) is minimum (as small as possible among all paths from v_1 to v_k). Similarly, a **longest path** $v_1 \to v_k$ is one for which that sum is maximum.

Shortest (and longest) path problems are among the most important optimization problems. Here, "length" l_{ij} (often also called "cost" or "weight") can be an actual length measured in miles or travel time or gasoline expenses, but it may also be something entirely different.

For instance, the *"traveling salesman problem"* requires the determination of a shortest **Hamiltonian**[1] **cycle** in a graph, that is, a cycle that contains all the vertices of the graph.

As another example, by choosing the "most profitable" route $v_1 \to v_k$, a salesman may want to maximize Σl_{ij}, where l_{ij} is his expected commission minus his travel expenses for going from town i to town j.

In an investment problem, i may be the day an investment is made, j the day it matures, and l_{ij} the resulting profit, and one gets a graph by considering the various possibilities of investing and reinvesting over a given period of time.

Shortest Path if All Edges Have Length $l = 1$

Obviously, if all edges have length 1, then a shortest path $v_1 \to v_k$ is one that has the smallest number of edges among all paths $v_1 \to v_k$ in a given graph G. For this problem we discuss a BFS algorithm. BFS stands for **Breadth First Search.** This means that in each step the algorithm visits *all neighboring* (all adjacent) vertices of a vertex reached, as opposed to a DFS algorithm (**Depth First Search** algorithm), which makes a long trail (as in a maze). This widely used BFS algorithm is shown in Table 23.1.

We want to find a shortest path in G from a vertex s (***start***) to a vertex t (***terminal***). To guarantee that there is a path from s to t, we make sure that G does not consist of separate portions. Thus we assume that G is **connected,** that is, for any two vertices v and w there is a path $v \to w$ in G. (Recall that a vertex v is called **adjacent** to a vertex u if there is an edge (u, v) in G.)

Table 23.1 Moore's BFS for Shortest Path (All Lengths One)

Proceedings of the International Symposium for Switching Theory, Part II, pp. 285–292. Cambridge: Harvard University Press, 1959.

ALGORITHM MOORE $[G = (V, E), s, t]$

This algorithm determines a shortest path in a connected graph $G = (V, E)$ from a vertex s to a vertex t.

INPUT: Connected graph $G = (V, E)$, in which one vertex is denoted by s and one by t, and each edge (i, j) has length $l_{ij} = 1$. Initially all vertices are unlabeled.

OUTPUT: A shortest path $s \to t$ in $G = (V, E)$

1. Label s with 0.
2. Set $i = 0$.
3. Find all *unlabeled* vertices adjacent to a vertex labeled i.
4. Label the vertices just found with $i + 1$.
5. If vertex t is labeled, then "backtracking" gives the shortest path

$$k\ (=\text{label of } t),\ k-1,\ k-2,\ \cdots,\ 0$$

OUTPUT $k, k-1, k-2, \cdots, 0$. Stop

Else increase i by 1. Go to Step 3.

End MOORE

[1]WILLIAM ROWAN HAMILTON (1805–1865), Irish mathematician, known for his work in dynamics.

EXAMPLE 1 Application of Moore's BFS Algorithm

Find a shortest path $s \to t$ in the graph G shown in Fig. 481.

Solution. Figure 481 shows the labels. The blue edges form a shortest path (length 4). There is another shortest path $s \to t$. (Can you find it?) Hence in the program we must introduce a rule that makes backtracking unique because otherwise the computer would not know what to do next if at some step there is a choice (for instance, in Fig. 481 when it got back to the vertex labeled 2). The following rule seems to be natural.

Backtracking rule. Using the numbering of the vertices from 1 to n (not the labeling!), at each step, if a vertex labeled i is reached, take as the next vertex that with the smallest number (not label!) among all the vertices labeled $i - 1$. ■

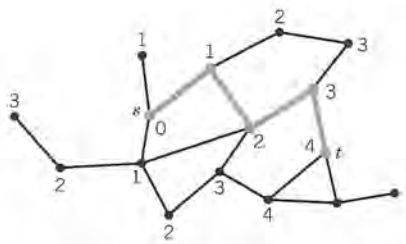

Fig. 481. Example 1, given graph and result of labeling

Complexity of an Algorithm

Complexity *of Moore's algorithm.* To find the vertices to be labeled 1, we have to scan all edges incident with s. Next, when $i = 1$, we have to scan all edges incident with vertices labeled 1, etc. Hence each edge is scanned twice. These are $2m$ operations (m = number of edges of G). This is a function $c(m)$. Whether it is $2m$ or $5m + 3$ or $12m$ is not so essential; it *is* essential that $c(m)$ is proportional to m (not m^2, for example); it is of the "order" m. We write for any function $am + b$ simply $O(m)$, for any function $am^2 + bm + d$ simply $O(m^2)$, and so on; here, O suggests **order**. The underlying idea and practical aspect are as follows.

In judging an algorithm, we are mostly interested in its behavior for very large problems (large m in the present case), since these are going to determine the limits of the applicability of the algorithm. Thus, the essential item is the fastest growing term (am^2 in $am^2 + bm + d$, etc.) since it will overwhelm the others when m is large enough. Also, a constant factor in this term is not very essential; for instance, the difference between two algorithms of orders, say, $5m^2$ and $8m^2$ is generally not very essential and can be made irrelevant by a modest increase in the speed of computers. However, it does make a great practical difference whether an algorithm is of order m or m^2 or of a still higher power m^p. And the biggest difference occurs between these "polynomial orders" and "exponential orders," such as 2^m.

For instance, on a computer that does 10^9 operations per second, a problem of size $m = 50$ will take 0.3 second with an algorithm that requires m^5 operations, but 13 days with an algorithm that requires 2^m operations. But this is not our only reason for regarding polynomial orders as good and exponential orders as bad. Another reason is the ***gain in using a faster computer.*** For example let two algorithms be $O(m)$ and $O(m^2)$. Then, since $1000 = 31.6^2$, an increase in speed by a factor 1000 has the effect that per hour we can do problems 1000 and 31.6 times as big, respectively. But since $1000 = 2^{9.97}$, with an algorithm that is $O(2^m)$, all we gain is a relatively modest increase of 10 in problem size because $2^{9.97} \cdot 2^m = 2^{m+9.97}$.

The **symbol O** is quite practical and commonly used whenever the order of growth is essential, but not the specific form of a function. Thus if a function $g(m)$ is of the form

$$g(m) = kh(m) + \text{more slowly growing terms} \qquad (k \neq 0, \text{ constant}),$$

we say that $g(m)$ is of the *order* $h(m)$ and write

$$g(m) = O(h(m)).$$

For instance,

$$am + b = O(m), \qquad am^2 + bm + d = O(m^2), \qquad 5 \cdot 2^m + 3m^2 = O(2^m).$$

We want an algorithm $\mathcal{A}$ to be "efficient," that is, "good" with respect to

(i) *Time* (number $c_{\mathcal{A}}(m)$ of computer operations), or

(ii) *Space* (storage needed in the internal memory)

or both. Here $c_{\mathcal{A}}$ suggests **"complexity"** of $\mathcal{A}$. Two popular choices for $c_{\mathcal{A}}$ are

(*Worst case*) $c_{\mathcal{A}}(m)$ = longest time $\mathcal{A}$ takes for a problem of size m,

(*Average case*) $c_{\mathcal{A}}(m)$ = average time $\mathcal{A}$ takes for a problem of size m.

In problems on graphs, the "size" will often be m (number of edges) or n (number of vertices). For our present simple algorithm, $c_{\mathcal{A}}(m) = 2m$ in both cases.

For a "good" algorithm $\mathcal{A}$, we want that $c_{\mathcal{A}}(m)$ does not grow too fast. Accordingly, we call $\mathcal{A}$ **efficient** if $c_{\mathcal{A}}(m) = O(m^k)$ for some integer $k \geqq 0$; that is, $c_{\mathcal{A}}$ may contain only powers of m (or functions that grow even more slowly, such as $\ln m$), but no exponential functions. Furthermore, we call $\mathcal{A}$ **polynomially bounded** if $\mathcal{A}$ is efficient when we choose the "worst case" $c_{\mathcal{A}}(m)$. These conventional concepts have intuitive appeal, as our discussion shows.

Complexity should be investigated for every algorithm, so that one can also compare different algorithms for the same task. This may often exceed the level in this chapter; accordingly, we shall confine ourselves to a few occasional comments in this direction.

PROBLEM SET 23.2

1–6 SHORTEST PATH

Find a shortest path P: $s \to t$ and its length by Moore's BFS algorithm; sketch the graph with the labels and indicate P by heavier lines (as in Fig. 481).

1.

2.

3.

4.

5.

6.

7. (Nonuniqueness) A shortest path $s \to t$ for given s and t need not be unique. Illustrate this by finding another shortest path $s \to t$ in Example 1 in the text.

8. (Maximum length) If P is a shortest path between any two vertices in a graph with n vertices, how many edges can P at most have? In a complete graph (with all edges of length 1)? Give a reason.

9. (Moore's algorithm) Show that if a vertex v has label $\lambda(v) = k$, then there is a path $s \to v$ of length k.

10. Call the length of a shortest path $s \to v$ the **distance** of v from s. Show that if v has distance l, it has label $\lambda(v) = l$.

11. **(Hamiltonian cycle)** Find and sketch a Hamiltonian cycle in the graph of Prob. 3.

12. Find and sketch a Hamiltonian cycle in the graph of a dodecahedron, which has 12 pentagonal faces and 20 vertices (Fig. 482). This is a problem Hamilton himself considered.

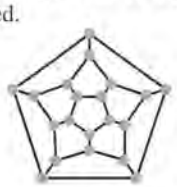

Fig. 482. Problem 12

13. Find and sketch a Hamiltonian cycle in Fig. 479, Sec. 23.1.

14. **(Euler graph)** An *Euler graph* G is a graph that has a closed Euler trail. An **Euler trail** is a trail that contains every edge of G exactly once. Which subgraph with four edges of the graph in Example 1, Sec. 23.1, is an Euler graph?

15. Is the graph in Fig. 483 an Euler graph? (Give a reason.)

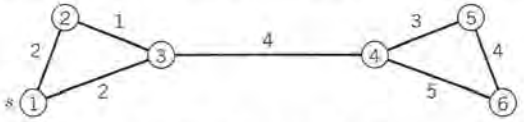

Fig. 483. Problems 15, 17

16. Find 4 different closed Euler trails in Fig. 484.

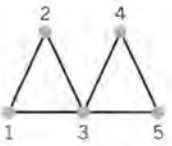

Fig. 484. Problem 16

17. The **postman problem** is the problem of finding a closed walk W: $s \to s$ (s the post office) in a graph G with edges (i, j) of length $l_{ij} > 0$ such that every edge of G is traversed at least once and the length of W is minimum. Find a solution for the graph in Fig. 483 by inspection. (The problem is also called the *Chinese postman problem* since it was published in the journal *Chinese Mathematics* 1 (1962), 273–277.)

18. Show that the length of a shortest postman trail is the same for every starting vertex.

19. **(Order)** Show that $O(m^3) + O(m^3) = O(m^3)$ and $kO(m^p) = O(m^p)$.

20. Show that $\sqrt{1 + m^2} = O(m)$, $0.02e^m + 100m^2 = O(e^m)$.

21. If we switch from one computer to another that is 100 times as fast, what is our gain in problem size per hour in the use of an algorithm that is $O(m)$, $O(m^2)$, $O(m^5)$, $O(e^m)$?

22. **CAS PROBLEM. Moore's Algorithm.** Write a computer program for the algorithm in Table 23.1. Test the program with the graph in Example 1. Apply it to Probs. 1–3 and to some graphs of your own choice.

23.3 Bellman's Principle. Dijkstra's Algorithm

We continue our discussion of the shortest path problem in a graph G. The last section concerned the special case that all edges had length 1. But in most applications the edges (i, j) will have any lengths $l_{ij} > 0$, and we now turn to this general case, which is of greater practical importance. We write $l_{ij} = \infty$ for any edge (i, j) that does not exist in G (setting $\infty + a = \infty$ for any number a, as usual).

We consider the problem of finding shortest paths from a given vertex, denoted by 1 and called the **origin,** to ***all*** other vertices 2, 3, $\cdots$, n of G. We let L_j denote the length of a shortest path P_j: $1 \to j$ in G.

THEOREM 1

Bellman's Minimality Principle or Optimality Principle[2]

If P_j: $1 \to j$ is a shortest path from 1 to j in G and (i, j) is the last edge of P_j (Fig. 485), *then P_i: $1 \to i$ [obtained by dropping (i, j) from P_j] is a shortest path $1 \to i$.*

[2]RICHARD BELLMAN (1920–1984), American mathematician, known for his work in dynamic programming.

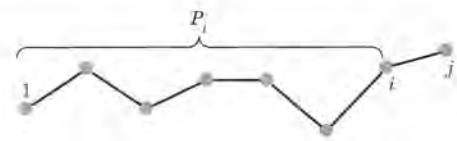

Fig. 485. Paths P and P_i in Bellman's minimality principle

PROOF Suppose that the conclusion is false. Then there is a path P_i^*: $1 \to i$ that is shorter than P_i. Hence if we now add (i, j) to P_i^*, we get a path $1 \to j$ that is shorter than P_j. This contradicts our assumption that P_j is shortest. ∎

From Bellman's principle we can derive basic equations as follows. For fixed j we may obtain various paths $1 \to j$ by taking shortest paths P_i for various i for which there is in G an edge (i, j), and add (i, j) to the corresponding P_i. These paths obviously have lengths $L_i + l_{ij}$ (L_i = length of P_i). We can now take the minimum over i, that is, pick an i for which $L_i + l_{ij}$ is smallest. By the Bellman principle, this gives a shortest path $1 \to j$. It has the length

$$\text{(1)} \qquad \begin{aligned} L_1 &= 0 \\ L_j &= \min_{i \neq j} (L_i + l_{ij}), \end{aligned} \qquad j = 2, \cdots, n.$$

These are the **Bellman equations.** Since $l_{ii} = 0$ by definition, instead of $\min_{i \neq j}$ we can simply write $\min_i$. These equations suggest the idea of one of the best-known algorithms for the shortest path problem, as follows.

Dijkstra's Algorithm for Shortest Paths

Dijkstra's[3] algorithm is shown in Table 23.2, where a **connected graph** G is a graph in which for any two vertices v and w in G there is a path $v \to w$. The algorithm is a labeling procedure. At each stage of the computation, each vertex v gets a label, either

(PL) a *permanent label* = length L_v of a shortest path $1 \to v$

or

(TL) a *temporary label* = upper bound $\widetilde{L}_v$ for the length of a shortest path $1 \to v$.

We denote by $\mathcal{PL}$ and $\mathcal{TL}$ the sets of vertices with a permanent label and with a temporary label, respectively. The algorithm has an initial step in which vertex 1 gets the permanent label $L_1 = 0$ and the other vertices get temporary labels, and then the algorithm alternates between Steps 2 and 3. In Step 2 the idea is to pick k "minimally." In Step 3 the idea is that the upper bounds will in general improve (decrease) and must be updated accordingly. Namely, the new temporary label $\widetilde{L}_j$ of vertex j will be the old one if there is no improvement or it will be $L_k + l_{kj}$ if there is.

[3]EDSGER WYBE DIJKSTRA (1930–2002), Dutch computer scientist, 1972 recipient of the ACM Turing Award. His algorithm appeared in *Numerische Mathematik* **1** (1959), 269–271.

Table 23.2 Dijkstra's Algorithm for Shortest Paths

ALGORITHM DIJKSTRA [$G = (V, E)$, $V = \{1, \cdots, n\}$, l_{ij} for all (i, j) in E]

Given a connected graph $G = (V, E)$ with vertices $1, \cdots, n$ and edges (i, j) having lengths $l_{ij} > 0$, this algorithm determines the lengths of shortest paths from vertex 1 to the vertices $2, \cdots, n$.

INPUT: Number of vertices n, edges (i, j), and lengths l_{ij}

OUTPUT: Lengths L_j of shortest paths $1 \to j$, $j = 2, \cdots, n$

1. *Initial step*

Vertex 1 gets PL: $L_1 = 0$.
Vertex j ($= 2, \cdots, n$) gets TL: $\tilde{L}_j = l_{1j}$ ($= \infty$ if there is no edge $(1, j)$ in G).
Set $\mathcal{PL} = \{1\}$, $\mathcal{TL} = \{2, 3, \cdots, n\}$.

2. *Fixing a permanent label*

Find a k in $\mathcal{TL}$ for which $\tilde{L}_k$ is miminum, set $L_k = \tilde{L}_k$. Take the smallest k if there are several. Delete k from $\mathcal{TL}$ and include it in $\mathcal{PL}$.
If $\mathcal{TL} = \emptyset$ (that is, $\mathcal{TL}$ is empty) then

OUTPUT $L_2, \cdots, L_n$. Stop

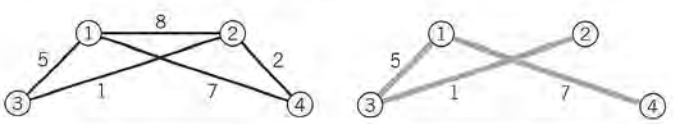
Else continue (that is, go to Step 3).

3. *Updating temporary labels*

For all j in $\mathcal{TL}$, set $\tilde{L}_j = \min_k \{\tilde{L}_j, L_k + l_{kj}\}$ (that is, take the smaller of $\tilde{L}_j$ and $L_k + l_{kj}$ as your new $\tilde{L}_j$).

Go to Step 2.

End DIJKSTRA



EXAMPLE 1 **Application of Dijkstra's Algorithm**

Applying Dijkstra's algorithm to the graph in Fig. 486a, find shortest paths from vertex 1 to vertices 2, 3, 4.

Solution. We list the steps and computations.

1.	$L_1 = 0, \tilde{L}_2 = 8, \tilde{L}_3 = 5, \tilde{L}_4 = 7,$	$\mathcal{PL} = \{1\},$	$\mathcal{TL} = \{2, 3, 4\}$
2.	$L_3 = \min\{\tilde{L}_2, \tilde{L}_3, \tilde{L}_4\} = 5, k = 3,$	$\mathcal{PL} = \{1, 3\},$	$\mathcal{TL} = \{2, 4\}$
3.	$\tilde{L}_2 = \min\{8, L_3 + l_{32}\} = \min\{8, 5 + 1\} = 6$		
	$\tilde{L}_4 = \min\{7, L_3 + l_{34}\} = \min\{7, \infty\} = 7$		
2.	$L_2 = \min\{\tilde{L}_2, \tilde{L}_4\} = \min\{6, 7\} = 6, k = 2,$	$\mathcal{PL} = \{1, 2, 3\},$	$\mathcal{TL} = \{4\}$
3.	$\tilde{L}_4 = \min\{7, L_2 + l_{24}\} = \min\{7, 6 + 2\} = 7$		
2.	$L_4 = 7, k = 4$	$\mathcal{PL} = \{1, 2, 3, 4\},$	$\mathcal{TL} = \emptyset.$

Figure 486b shows the resulting shortest paths, of lengths $L_2 = 6$, $L_3 = 5$, $L_4 = 7$. ■

(a) Given graph G (b) Shortest paths in G

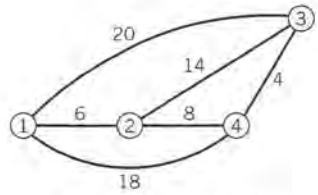
Fig. 486. Example 1

Complexity. *Dijkstra's algorithm is* $O(n^2)$.

PROOF Step 2 requires comparison of elements, first $n - 2$, the next time $n - 3$, etc., a total of $(n - 2)(n - 1)/2$. Step 3 requires the same number of comparisons, a total of $(n - 2)(n - 1)/2$, as well as additions, first $n - 2$, the next time $n - 3$, etc., again a total of $(n - 2)(n - 1)/2$. Hence the total number of operations is $3(n - 2)(n - 1)/2 = O(n^2)$. ■

PROBLEM SET 23.3

1. The net of roads in Fig. 487 connecting four villages is to be reduced to minimum length, but so that one can still reach every village from every other village. Which of the roads should be retained? Find the solution (a) by inspection, (b) by Dijkstra's algorithm.



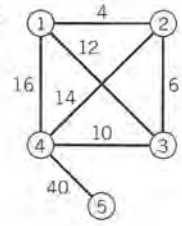


Fig. 487. Problem 1

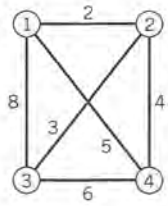
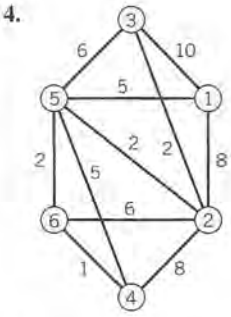
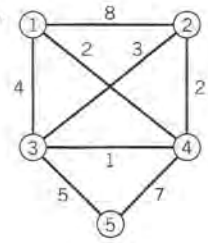


2–7 DIJKSTRA'S ALGORITHM

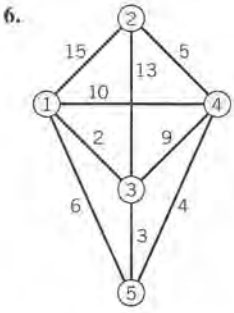
Find shortest paths for the following graphs.



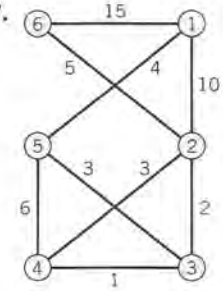
2.



3.



4.



5.

6.

7.

8. Show that in Dijkstra's algorithm, for L_k there is a path P: $1 \to k$ of length L_k.

9. Show that in Dijkstra's algorithm, at each instant the demand on storage is light (data for less than n edges).

10. CAS PROBLEM. Dijkstra's Algorithm. Write a program and apply it to Probs. 2–4.

23.4 Shortest Spanning Trees: Greedy Algorithm

So far we have discussed shortest path problems. We now turn to a particularly important kind of graph, called a tree, along with related optimization problems that arise quite often in practice.

By definition, a **tree** T is a graph that is connected and has no cycles. **"Connected"** was defined in Sec. 23.3; it means that there is a path from any vertex in T to any other vertex in T. A **cycle** is a path $s \to t$ of at least three edges that is closed ($t = s$); see also Sec. 23.2. Figure 488a shows an example.

CAUTION! The terminology varies; *cycles* are sometimes also called *circuits*.

A **spanning tree** T in a given connected graph $G = (V, E)$ is a tree containing *all* the n vertices of G. See Fig. 488b. Such a tree has $n - 1$ edges. (Proof?)

A **shortest spanning tree** T in a connected graph G (whose edges (i, j) have lengths $l_{ij} > 0$) is a spanning tree for which Σl_{ij} (sum over all edges of T) is minimum compared to Σl_{ij} for any other spanning tree in G.

Trees are among the most important types of graphs, and they occur in various applications. Familiar examples are family trees and organization charts. Trees can be used to exhibit, organize, or analyze electrical networks, producer–consumer and other business relations, information in database systems, syntactic structure of computer programs, etc. We mention a few specific applications that need no lengthy additional explanations.

The set of shortest paths from vertex 1 to the vertices $2, \cdots, n$ in the last section forms a spanning tree.

Railway lines connecting a number of cities (the vertices) can be set up in the form of a spanning tree, the "length" of a line (edge) being the construction cost, and one wants to minimize the total construction cost. Similarly for bus lines, where "length" may be the average annual operating cost. Or for steamship lines (freight lines), where "length" may be profit and the goal is the maximization of total profit. Or in a network of telephone lines between some cities, a shortest spanning tree may simply represent a selection of lines that connect all the cities at minimal cost. In addition to these examples we could mention others from distribution networks, and so on.

We shall now discuss a simple algorithm for the problem of finding a shortest spanning tree. This algorithm (Table 23.3) is particularly suitable for sparse graphs (graphs with very few edges; see Sec. 23.1).

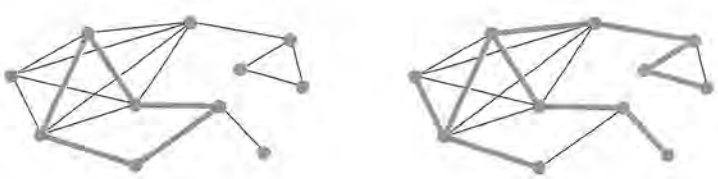
Table 23.3 Kruskal's Greedy Algorithm for Shortest Spanning Trees

Proceedings of the American Mathematical Society **7** (1956), 48–50.

ALGORITHM KRUSKAL [$G = (V, E)$, l_{ij} for all (i, j) in E]

Given a connected graph $G = (V, E)$ with edges (i, j) having length $l_{ij} > 0$, the algorithm determines a shortest spanning tree T in G.

INPUT: Edges (i, j) of G and their lengths l_{ij}



OUTPUT: Shortest spanning tree T in G

1. Order the edges of G in ascending order of length.
2. Choose them in this order as edges of T, rejecting an edge only if it forms a cycle with edges already chosen.

If $n - 1$ edges have been chosen, then

OUTPUT T (= the set of edges chosen). Stop

End KRUSKAL

(a) A cycle (b) A spanning tree

Fig. 488. Example of (a) a cycle, (b) a spanning tree in a graph

EXAMPLE 1 **Application of Kruskal's Algorithm**

Using Kruskal's algorithm, we shall determine a shortest spanning tree in the graph in Fig. 489.

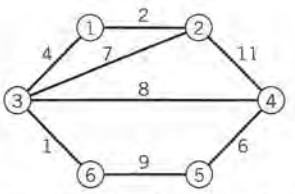


Fig. 489. Graph in Example 1

Solution. See Table 23.4. In some of the intermediate stages the edges chosen form a *disconnected* graph (see Fig. 490); this is typical. We stop after $n - 1 = 5$ choices since a spanning tree has $n - 1$ edges. In our problem the edges chosen are in the upper part of the list. This is typical of problems of any size; in general, edges farther down in the list have a smaller chance of being chosen. ■

Table 23.4 **Solution in Example 1**

Edge	Length	Choice
(3, 6)	1	1st
(1, 2)	2	2nd
(1, 3)	4	3rd
(4, 5)	6	4th
(2, 3)	7	Reject
(3, 4)	8	5th
(5, 6)	9	
(2, 4)	11	

The efficiency of Kruskal's method is greatly increased by

Double Labeling of Vertices. *Each vertex i carries a double label (r_i, p_i), where*

r_i = *Root of the subtree to which i belongs,*
p_i = *Predecessor of i in its subtree,*
$p_i = 0$ *for roots.*

This simplifies

Rejecting. If (i, j) *is next in the list to be considered, reject* (i, j) *if* $r_i = r_j$ (that is, i and j are in the same subtree, so that they are already joined by edges and (i, j) would thus create a cycle). *If* $r_i \neq r_j$, *include* (i, j) *in* T.

If there are several choices for r_i, choose the smallest. If subtrees merge (become a single tree), retain the smallest root as the root of the new subtree.

For Example 1 the double-label list is shown in Table 23.5. In storing it, at each instant one may retain only the latest double label. We show all double labels in order to exhibit the process in all its stages. Labels that remain unchanged are not listed again. Underscored are the two 1's that are the common root of vertices 2 and 3, the reason for rejecting the edge (2, 3). By reading for each vertex the latest label we can read from this list that 1 is the vertex we have chosen as a root and the tree is as shown in the last part of Fig. 490.

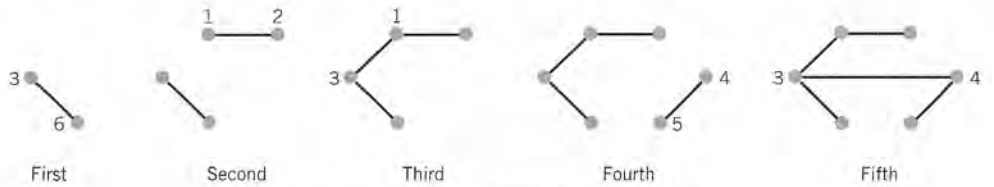

Fig. 490. Choice process in Example 1

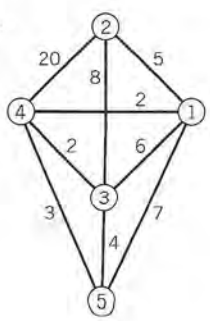
This is made possible by the predecessor label that each vertex carries. Also, for accepting or rejecting an edge we have to make only one comparison (the roots of the two endpoints of the edge).

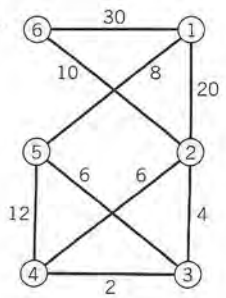
Ordering is the more expensive part of the algorithm. It is a standard process in data processing for which various methods have been suggested (see **Sorting** in Ref. [E25] listed in App. 1). For a complete list of m edges, an algorithm would be $O(m \log_2 m)$, but since the $n - 1$ edges of the tree are most likely to be found earlier, by inspecting the q ($< m$) topmost edges, for such a list of q edges one would have $O(q \log_2 m)$.

Table 23.5 **List of Double Labels in Example 1**



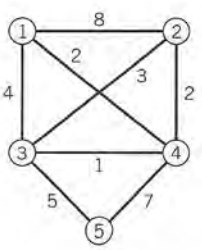
Vertex	Choice 1 (3, 6)	Choice 2 (1, 2)	Choice 3 (1, 3)	Choice 4 (4, 5)	Choice 5 (3, 4)
1		(1, 0)			
2		(1, 1)			
3	(3, 0)		(1, 1)		
4				(4, 0)	(1, 3)
5				(4, 4)	(1, 4)
6	(3, 3)		(1, 3)		

PROBLEM SET 23.4

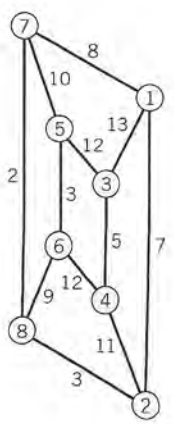


1–6 KRUSKAL'S ALGORITHM

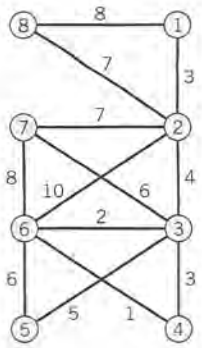
Find a shortest spanning tree by Kruskal's algorithm.



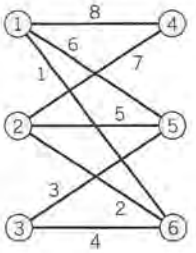
1.



2.



3.



4.

5.

6.

7. CAS PROBLEM. Kruskal's Algorithm. Write a corresponding program. (Sorting is discussed in Ref. [E25] listed in App. 1.)

8. Design an algorithm for obtaining longest spanning trees.

9. Apply the algorithm in Prob. 8 to the graph in Example 1. Compare with the result in Example 1.

10. To get a minimum spanning tree, instead of adding shortest edges, one could think of deleting longest edges. For what graphs would this be feasible? Describe an algorithm for this.

11. Apply the method suggested in Prob. 10 to the graph in Example 1. Do you get the same tree?

12. Find a shortest spanning tree in the complete graph of all possible 15 connections between the six cities given (distances by airplane, in miles, rounded). Can you think of a practical application of the result?

	Dallas	Denver	Los Angeles	New York	Washington, DC
Chicago	800	900	1800	700	650
Dallas		650	1300	1350	1200

Los Angeles				2500	2350
New York					200

13. (Forest) A (not necessarily connected) graph without cycles is called a *forest*. Give typical examples of applications in which graphs occur that are forests or trees.

14–20 GENERAL PROPERTIES OF TREES

Prove:

14. (Uniqueness) The path connecting any two vertices u and v in a tree is unique.

15. If in a graph any two vertices are connected by a unique path, the graph is a tree.

16. If a graph has no cycles, it must have at least 2 vertices of degree 1 (definition in Sec. 23.1).

17. A tree with exactly two vertices of degree 1 must be a path.

18. A tree with n vertices has $n - 1$ edges. (Proof by induction.)

19. If two vertices in a tree are joined by a new edge, a cycle is formed.

20. A graph with n vertices is a tree if and only if it has $n - 1$ edges and has no cycles.

23.5 Shortest Spanning Trees: Prim's Algorithm

Prim's algorithm shown in Table 23.6 is another popular algorithm for the shortest spanning tree problem (see Sec. 23.4). This algorithm avoids ordering edges and gives a tree T at each stage, a property that Kruskal's algorithm in the last section did not have (look back at Fig. 490 if you did not notice it).

In Prim's algorithm, starting from any single vertex, which we call 1, we "grow" the tree T by adding edges to it, one at a time, according to some rule (in Table 23.6) until T finally becomes a *spanning* tree, which is shortest.

We denote by U the set of vertices of the growing tree T and by S the set of its edges. Thus, initially $U = \{1\}$ and $S = \varnothing$; at the end, $U = V$, the vertex set of the given graph $G = (V, E)$, whose edges (i, j) have length $l_{ij} > 0$, as before.

Thus at the beginning (Step 1) the labels

$$\lambda_2, \cdots, \lambda_n \qquad \text{of the vertices} \qquad 2, \cdots, n$$

are the lengths of the edges connecting them to vertex 1 (or ∞ if there is no such edge in G). And we pick (Step 2) the shortest of these as the first edge of the growing tree T and include its other end j in U (choosing the smallest j if there are several, to make the process unique). Updating labels in Step 3 (at this stage and at any later stage) concerns each vertex k not yet in U. Vertex k has label $\lambda_k = l_{i(k),k}$ from before. If $l_{jk} < \lambda_k$, this means that k is closer to the new member j just included in U than k is to its old "closest neighbor" $i(k)$ in U. Then we update the label of k, replacing $\lambda_k = l_{i(k),k}$ by $\lambda_k = l_{jk}$ and setting $i(k) = j$. If, however, $l_{jk} \geqq \lambda_k$ (the *old* label of k), we don't touch the old label. Thus the label λ_k always identifies the closest neighbor of k in U, and this is updated in Step 3 as U and the tree T grow. From the final labels we can backtrack the final tree, and from their numeric values we compute the total length (sum of the lengths of the edges) of this tree.

Table 23.6 Prim's Algorithm for Shortest Spanning Trees

Bell System Technical Journal **36** (1957), 1389–1401.

For an improved version of the algorithm, see Cheriton and Tarjan, *SIAM Journal on Computation* **5** (1976), 724–742.

ALGORITHM PRIM [$G = (V, E)$, $V = \{1, \cdots, n\}$, l_{ij} for all (i, j) in E]

Given a connected graph $G = (V, E)$ with vertices $1, 2, \cdots, n$ and edges (i, j) having length $l_{ij} > 0$, this algorithm determines a shortest spanning tree T in G and its length $L(T)$.

INPUT: n, edges (i, j) of G and their lengths l_{ij}
OUTPUT: Edge set S of a shortest spanning tree T in G; $L(T)$
[*Initially, all vertices are unlabeled.*]

1. *Initial step*
Set $i(k) = 1$, $U = \{1\}$, $S = \varnothing$.
Label vertex k ($= 2, \cdots, n$) with $\lambda_k = l_{1k}$ [$= \infty$ if G has no edge $(1, k)$].

2. *Addition of an edge to the tree T*
Let λ_j be the smallest λ_k for vertex k not in U. Include vertex j in U and edge $(i(j), j)$ in S.
If $U = V$ then compute
$L(T) = \Sigma l_{ij}$ (sum over all edges in S)
OUTPUT S, $L(T)$. Stop
[*S is the edge set of a shortest spanning tree T in G.*]
Else continue (that is, go to Step 3).

3. *Label updating*
For every k not in U, if $l_{jk} < \lambda_k$, then set $\lambda_k = l_{jk}$ and $i(k) = j$.
Go to Step 2.

End PRIM

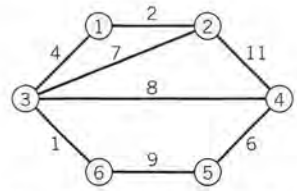

Fig. 491. Graph in Example 1

EXAMPLE 1 **Application of Prim's Algorithm**

Find a shortest spanning tree in the graph in Fig. 491 (which is the same as in Example 1, Sec. 23.4, so that we can compare).

Solution. The steps are as follows.

1. $i(k) = 1$, $U = \{1\}$, $S = \emptyset$, initial labels see Table 23.7.
2. $\lambda_2 = l_{12} = 2$ is smallest, $U = \{1, 2\}$, $S = \{(1, 2)\}$
3. Update labels as shown in Table 23.7, column (I).
2. $\lambda_3 = l_{13} = 4$ is smallest, $U = \{1, 2, 3\}$, $S = \{(1, 2), (1, 3)\}$
3. Update labels as shown in Table 23.7, column (II).
2. $\lambda_6 = l_{36} = 1$ is smallest, $U = \{1, 2, 3, 6\}$, $S = \{(1, 2), (1, 3), (3, 6)\}$
3. Update labels as shown in Table 23.7, column (III).
2. $\lambda_4 = l_{34} = 8$ is smallest, $U = \{1, 2, 3, 4, 6\}$, $S = \{(1, 2), (1, 3), (3, 4), (3, 6)\}$
3. Update labels as shown in Table 23.7, column (IV).
2. $\lambda_5 = l_{45} = 6$ is smallest, $U = V$, $S = (1, 2), (1, 3), (3, 4), (3, 6), (4, 5)$. Stop.

The tree is the same as in Example 1, Sec. 23.4. Its length is 21. You will find it interesting to compare the growth process of the present tree with that in Sec. 23.4. ■

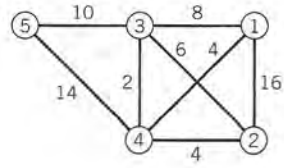
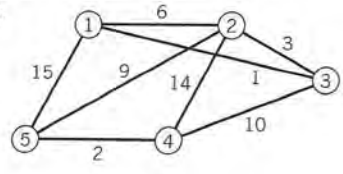
PROBLEM SET 23.5

1–7 PRIM'S ALGORITHM

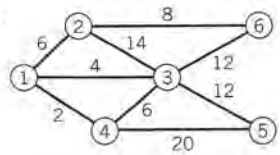


Find a shortest spanning tree by Prim's algorithm. Sketch it.

1. For the graph in Prob. 1, Sec. 23.4
2. For the graph in Prob. 2, Sec. 23.4
3. For the graph in Prob. 4, Sec. 23.4



4.



5.

6.

7.

8. (Complexity) Show that Prim's algorithm has complexity $O(n^2)$.

9. How does Prim's algorithm prevent the formation of cycles as one grows T?

10. For a complete graph (or one that is almost complete), if our data is an $n \times n$ distance table (as in Prob. 12, Sec. 23.4), show that the present algorithm [which is $O(n^2)$] cannot easily be replaced by an algorithm of order less than $O(n^2)$.

11. In what case will Prim's algorithm give $S = E$ as the final result?

12. TEAM PROJECT. Center of a Graph and Related Concepts. (a) Distance, eccentricity. Call the length of a shortest path $u \to v$ in a graph $G = (V, E)$ the *distance* $d(u, v)$ from u to v. For fixed u, call the greatest $d(u, v)$ as v ranges over V the *eccentricity* $\epsilon(u)$ of u. Find the eccentricity of vertices 1, 2, 3 in the graph in Prob. 7.

(b) Diameter, radius, center. The *diameter* $d(G)$ of a graph $G = (V, E)$ is the maximum of $d(u, v)$ as u and v vary over V, and the *radius* $r(G)$ is the smallest eccentricity $\epsilon(v)$ of the vertices v. A vertex v with $\epsilon(v) = r(G)$ is called a *central vertex*. The set of all central vertices is called the *center* of G. Find $d(G)$, $r(G)$ and the center of the graph in Prob. 7.

(c) What are the diameter, radius, and center of the spanning tree in Example 1?

(d) Explain how the idea of a center can be used in setting up an emergency service facility on a transportation network. In setting up a fire station, a shopping center. How would you generalize the concepts in the case of two or more such facilities?

(e) Show that a tree T whose edges all have length 1 has center consisting of either one vertex or two adjacent vertices.

(f) Set up an algorithm of complexity $O(n)$ for finding the center of a tree T.

13. What would the result be if you applied Prim's algorithm to a graph that is not connected?

14. CAS PROBLEM. Prim's Algorithm. Write a program and apply it to Probs. 4–6.

23.6 Flows in Networks

After shortest path problems and problems for trees, as a third large area in combinatorial optimization we discuss **flow problems in networks** (electrical, water, communication, traffic, business connections, etc.), turning from graphs to digraphs (directed graphs; see Sec. 23.1).

By definition, a **network** is a digraph $G = (V, E)$ in which each edge (i, j) has assigned to it a **capacity** $c_{ij} > 0$ [= maximum possible flow along (i, j)], and at one vertex, s, called the **source,** a flow is produced that flows along the edges of the digraph G to another vertex, t, called the **target** or **sink,** where the flow disappears.

In applications, this may be the flow of electricity in wires, of water in pipes, of cars on roads, of people in a public transportation system, of goods from a producer to consumers, of e-mail from senders to recipients over the Internet, and so on.

We denote the flow along a (directed!) edge (i, j) by f_{ij} and impose two conditions:

1. For each edge (i, j) in G the flow does not exceed the capacity c_{ij},

$$\textbf{(1)} \qquad 0 \leqq f_{ij} \leqq c_{ij} \qquad \textbf{("Edge condition").}$$

2. For each vertex i, not s or t,

$$\text{Inflow} = \text{Outflow} \qquad \textbf{("Vertex condition," "Kirchhoff's law");}$$

in a formula,

$$\text{(2)} \qquad \underbrace{\sum_k f_{ki}}_{\text{Inflow}} - \underbrace{\sum_j f_{ij}}_{\text{Outflow}} = \begin{cases} 0 \text{ if vertex } i \neq s,\ i \neq t, \\ -f \text{ at the source } s, \\ f \text{ at the target (sink) } t, \end{cases}$$

where f is the total flow (and at s the inflow is zero, whereas at t the outflow is zero). Figure 492 illustrates the notation (for some hypothetical figures).

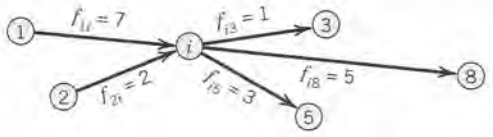


Fig. 492. Notation in (2): inflow and outflow for a vertex i (not s or t)

Paths

By a **path** $v_1 \to v_k$ from a vertex v_1 to a vertex v_k in a digraph G we mean a sequence of edges

$$(v_1, v_2), (v_2, v_3), \cdots, (v_{k-1}, v_k),$$

regardless of their directions in G, that forms a path as in a graph (see Sec. 23.2). Hence when we travel along this path from v_1 to v_k we may traverse some edge ***in*** its given direction—then we call it a **forward edge** of our path—or ***opposite to*** its given direction—then we call it a **backward edge** of our path. In other words, our path consists of one-way streets, and forward edges (backward edges) are those that we travel *in the right direction* (*in the wrong direction*). Figure 493 shows a forward edge (u, v) and a backward edge (w, v) of a path $v_1 \to v_k$.

CAUTION! Each edge in a network has a given direction, *which we cannot change.* Accordingly, if (u, v) is a forward edge in a path $v_1 \to v_k$, then (u, v) can become a backward edge only in another path $x_1 \to x_j$ in which it is an edge and is traversed in the opposite direction as one goes from x_1 to x_j; see Fig. 494. Keep this in mind, to avoid misunderstandings.

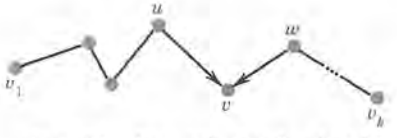

Fig. 493. Forward edge (u, v) and backward edge (w, v) of a path $v_1 \to v_k$

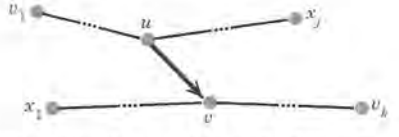

Fig. 494. Edge (u, v) as forward edge in the path $v_1 \to v_k$ and as backward edge in the path $x_1 \to x_j$

Flow Augmenting Paths

Our goal will be to ***maximize the flow*** from the source s to the target t of a given network. We shall do this by developing methods for increasing an existing flow (including the special case in which the latter is zero). The idea then is to find a path P: $s \to t$ all of whose edges are not fully used, so that we can push additional flow through P. This suggests the following concept.

DEFINITION

Flow Augmenting Path

A *flow augmenting path* in a network with a given flow f_{ij} on each edge (i, j) is a path P: $s \to t$ such that

(i) no forward edge is used to capacity; thus $f_{ij} < c_{ij}$ for these;

(ii) no backward edge has flow 0; thus $f_{ij} > 0$ for these.

EXAMPLE 1 **Flow Augmenting Paths**

Find flow augmenting paths in the network in Fig. 495, where the first number is the capacity and the second number a given flow.

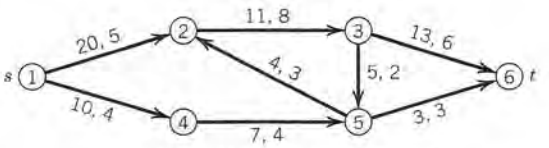

Fig. 495. Network in Example 1
First number = Capacity, Second number = Given flow

Solution. In practical problems, networks are large and one needs a ***systematic method for augmenting flows, which we discuss in the next section.*** In our small network, which should help to illustrate and clarify the concepts and ideas, we can find flow augmenting paths by inspection and augment the existing flow $f = 9$ in Fig. 495. (The outflow from s is $5 + 4 = 9$, which equals the inflow $6 + 3$ into t.)

We use the notation

$$\Delta_{ij} = c_{ij} - f_{ij} \qquad \text{for forward edges}$$

$$\Delta_{ij} = f_{ij} \qquad \text{for backward edges}$$

$$\Delta = \min \Delta_{ij} \qquad \text{taken over all edges of a path.}$$

From Fig. 495 we see that a flow augmenting path P_1: $s \to t$ is P_1: $1 - 2 - 3 - 6$ (Fig. 496), with $\Delta_{12} = 20 - 5 = 15$, etc., and $\Delta = 3$. Hence we can use P_1 to increase the given flow 9 to $f = 9 + 3 = 12$. All three edges of P_1 are forward edges. We augment the flow by 3. Then the flow in each of the edges of P_1 is increased by 3, so that we now have $f_{12} = 8$ (instead of 5), $f_{23} = 11$ (instead of 8), and $f_{36} = 9$ (instead of 6). Edge (2, 3) is now used to capacity. The flow in the other edges remains as before.

We shall now try to increase the flow in this network in Fig. 495 beyond $f = 12$.

There is another flow augmenting path P_2: $s \to t$, namely, P_2: $1 - 4 - 5 - 3 - 6$ (Fig. 496). It shows how a backward edge comes in and how it is handled. Edge (3, 5) is a backward edge. It has flow 2, so that $\Delta_{35} = 2$. We compute $\Delta_{14} = 10 - 4 = 6$, etc. (Fig. 496) and $\Delta = 2$. Hence we can use P_2 for another augmentation to get $f = 12 + 2 = 14$. The new flow is shown in Fig. 497. No further augmentation is possible. We shall confirm later that $f = 14$ is maximum. ■

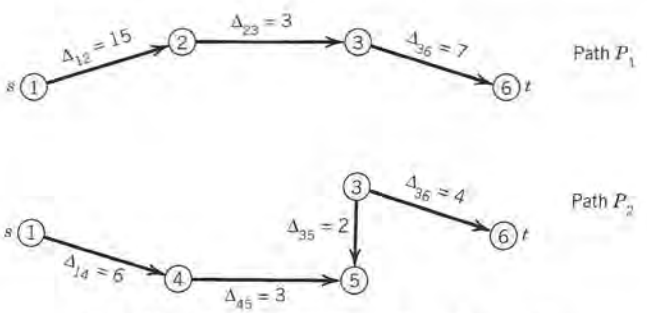

Fig. 496. Flow augmenting paths in Example 1

Cut Sets

A "cut set" is a set of edges in a network. The underlying idea is simple and natural. If we want to find out what is flowing from s to t in a network, we may cut the network somewhere between s and t (Fig. 497 shows an example) and see what is flowing in the edges hit by the cut, because any flow from s to t must sometimes pass through some of these edges. These form what is called a **cut set.** [In Fig. 497, the cut set consists of the edges (2, 3), (5, 2), (4, 5).] We denote this cut set by (S, T). Here S is the set of vertices on that side of the cut on which s lies ($S = \{s, 2, 4\}$ for the cut in Fig. 497) and T is the set of the other vertices ($T = \{3, 5, t\}$ in Fig. 497). We say that a cut ***"partitions"*** the vertex set V into two parts S and T. Obviously, the corresponding cut set (S, T) consists of all the edges in the network with one end in S and the other end in T.

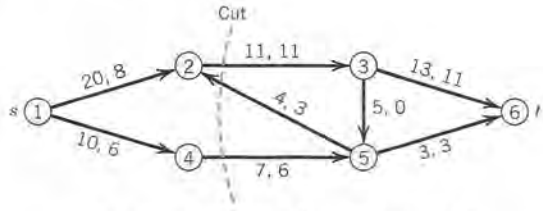

Fig. 497. Maximum flow in Example 1

By definition, the **capacity** cap (S, T) of a cut set (S, T) is the sum of the capacities of all **forward edges** in (S, T) (forward edges only!), that is, the edges that are directed *from S to T*,

$$\text{cap}\,(S, T) = \Sigma c_{ij} \qquad \text{[sum over the forward edges of } (S, T)\text{]}. \tag{3}$$

Thus, cap $(S, T) = 11 + 7 = 18$ in Fig. 497.

The other edges (directed *from T to S*) are called **backward edges** of the cut set (S, T), and by the **net flow** through a cut set we mean the sum of the flows in the forward edges minus the sum of the flows in the backward edges of the cut set.

CAUTION! Distinguish well between forward and backward edges in a cut set and in a path: (5, 2) in Fig. 497 is a backward edge for the cut shown but a forward edge in the path $1 - 4 - 5 - 2 - 3 - 6$.

For the cut in Fig. 497 the net flow is $11 + 6 - 3 = 14$. For the same cut in Fig. 495 (not indicated there), the net flow is $8 + 4 - 3 = 9$. In both cases it equals the flow f. We claim that this is not just by chance, but cuts do serve the purpose for which we have introduced them:

THEOREM 1

Net Flow in Cut Sets

Any given flow in a network G is the net flow through any cut set (S, T) of G.

PROOF By Kirchhoff's law (2), multiplied by -1, at a vertex i we have

$$\underbrace{\sum_j f_{ij}}_{\text{Outflow}} - \underbrace{\sum_l f_{li}}_{\text{Inflow}} = \begin{cases} 0 & \text{if } i \neq s, t, \\ f & \text{if } i = s. \end{cases} \tag{4}$$

Here we can sum over j and l from 1 to n (= number of vertices) by putting $f_{ij} = 0$ for $j = i$ and also for edges without flow or nonexisting edges; hence we can write the two sums as one,

$$\sum_j (f_{ij} - f_{ji}) = \begin{cases} 0 & \text{if } i \neq s, t, \\ f & \text{if } i = s. \end{cases}$$

We now sum over all i in S. Since s is in S, this sum equals f:

$$\sum_{i \in S} \sum_{j \in V} (f_{ij} - f_{ji}) = f. \tag{5}$$

We claim that in this sum, only the edges belonging to the cut set contribute. Indeed, edges with both ends in T cannot contribute, since we sum only over i in S; but edges (i, j) with both ends in S contribute $+f_{ij}$ at one end and $-f_{ij}$ at the other, a total contribution of 0. Hence the left side of (5) equals the net flow through the cut set. By (5), this is equal to the flow f and proves the theorem. ∎

This theorem has the following consequence, which we shall also need later in this section.

THEOREM 2

Upper Bound for Flows

A flow f in a network G cannot exceed the capacity of any cut set (S, T) in G.

PROOF By Theorem 1 the flow f equals the net flow through the cut set, $f = f_1 - f_2$, where f_1 is the sum of the flows through the forward edges and f_2 ($\geqq 0$) is the sum of the flows through the backward edges of the cut set. Thus $f \leqq f_1$. Now f_1 cannot exceed the sum of the capacities of the forward edges; but this sum equals the capacity of the cut set, by definition. Together, $f \leqq \text{cap}\ (S, T)$, as asserted. ∎

Cut sets will now bring out the full importance of augmenting paths:

THEOREM 3

Main Theorem. Augmenting Path Theorem for Flows

A flow from s to t in a network G is maximum if and only if there does not exist a flow augmenting path $s \to t$ in G.

PROOF **(a)** If there is a flow augmenting path P: $s \to t$, we can use it to push through it an additional flow. Hence the given flow cannot be maximum.

(b) On the other hand, suppose that there is no flow augmenting path $s \to t$ in G. Let S_0 be the set of all vertices i (including s) such that there is a flow augmenting path $s \to i$, and let T_0 be the set of the other vertices in G. Consider any edge (i, j) with i in S_0 and j in T_0. Then we have a flow augmenting path $s \to i$ since i is in S_0, but $s \to i \to j$ is not flow augmenting because j is not in S_0. Hence we must have

$$f_{ij} = \begin{cases} c_{ij} \\ 0 \end{cases} \quad \text{if } (i, j) \text{ is a } \begin{cases} \text{forward} \\ \text{backward} \end{cases} \text{ edge of the path } s \to i \to j. \tag{6}$$

Otherwise we could use (i, j) to get a flow augmenting path $s \to i \to j$. Now (S_0, T_0) defines a cut set (since t is in T_0; why?). Since by (6), forward edges are used to capacity and backward edges carry no flow, the net flow through the cut set (S_0, T_0) equals the sum of the capacities of the forward edges, which is cap (S_0, T_0) by definition. This net flow equals the given flow f by Theorem 1. Thus f = cap (S_0, T_0). We also have $f \leqq$ cap (S_0, T_0) by Theorem 2. Hence f must be maximum since we have reached equality. ■

The end of this proof yields another basic result (by Ford and Fulkerson, *Canadian Journal of Mathematics* **8** (1956), 399–404), namely, the so-called

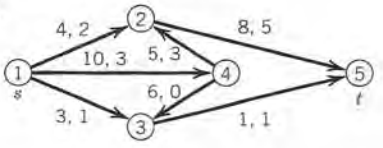
THEOREM 4

Max-Flow Min-Cut Theorem

The maximum flow in any network G equals the capacity of a **"minimum cut set"** (= a cut set of minimum capacity) *in G.*

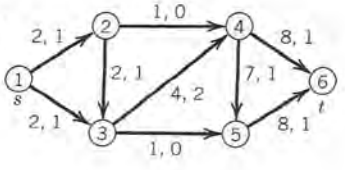
PROOF We have just seen that f = cap (S_0, T_0) for a maximum flow f and a suitable cut set (S_0, T_0). Now by Theorem 2 we also have $f \leqq$ cap (S, T) for this f and any cut set (S, T) in G. Together, cap $(S_0, T_0) \leqq$ cap (S, T). Hence (S_0, T_0) is a minimum cut set.

The existence of a maximum flow in this theorem follows for rational capacities from the algorithm in the next section and for arbitrary capacities from the Edmonds–Karp BFS also in that section. ■



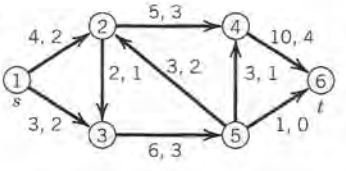
The two basic tools in connection with networks are flow augmenting paths and cut sets. In the next section we show how flow augmenting paths can be used in an algorithm for maximum flows.

PROBLEM SET 23.6

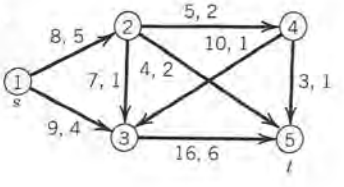


1–4 FLOW AUGMENTING PATHS

Find flow augmenting paths:



1.



2.

3.

4.

5–8 MAXIMUM FLOW

Find the maximum flow by inspection:

5. In Prob. 1.

6. In Prob. 2.

7. In Prob. 3.

8. In Prob. 4.

9–11 CAPACITY

In Fig. 495 find T and cap (S, T) if S equals

9. {1, 2, 3}

10. {1, 2, 4, 5}

11. {1, 3, 5}

12. Find a minimum cut set in Fig. 495 and verify that its capacity equals the maximum flow $f = 14$.

13. Find examples of flow augmenting paths and the maximum flow in the network in Fig. 498.

14–16 CAPACITY

In Fig. 498 find T and cap (S, T) if S equals

14. {1, 2, 4}

15. {1, 2, 4, 6}

16. {1, 2, 3, 4, 5}

17. In Fig. 498 find a minimum cut set and its capacity.

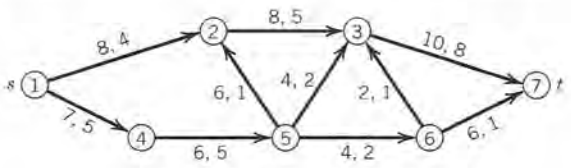


Fig. 498. Problems 13–17

18. Why are backward edges not considered in the definition of the capacity of a cut set?

19. In which case can an edge (i, j) be used as a forward as well as a backward edge of a path in a network with a given flow?

20. **(Incremental network)** Sketch the network in Fig. 498, and on each edge (i, j) write $c_{ij} - f_{ij}$ and f_{ij}. Do you recognize that from this "incremental network" one can more easily see flow augmenting paths?

23.7 Maximum Flow: Ford–Fulkerson Algorithm

Flow augmenting paths, as discussed in the last section, are used as the basic tool in the Ford–Fulkerson[4] algorithm in Table 23.8 on the next page in which a given flow (for instance, zero flow in all edges) is increased until it is maximum. The algorithm accomplishes the increase by a stepwise construction of flow augmenting paths, one at a time, until no further such paths can be constructed, which happens precisely when the flow is maximum.

In Step 1, an initial flow may be given. In Step 3, a vertex j can be labeled if there is an edge (i, j) with i labeled and

$$c_{ij} > f_{ij} \qquad \textbf{("forward edge")}$$

or if there is an edge (j, i) with i labeled and

$$f_{ji} > 0 \qquad \textbf{("backward edge").}$$

To **scan** a labeled vertex i means to label every unlabeled vertex j adjacent to i that can be labeled. Before scanning a labeled vertex i, scan all the vertices that got labeled before i. This **BFS (Breadth First Search)** strategy was suggested by Edmonds and Karp in 1972 (*Journal of the Association for Computing Machinery* **19,** 248–64). It has the effect that one gets shortest possible augmenting paths.

[4]LESTER RANDOLPH FORD (born 1927) and DELBERT RAY FULKERSON (1924–1976), American mathematicians known for their pioneering work on flow algorithms.

Table 23.8 Ford–Fulkerson Algorithm for Maximum Flow
Canadian Journal of Mathematics **9** (1957), 210–218

ALGORITHM FORD–FULKERSON

[$G = (V, E)$, vertices $1\ (= s), \cdots, n\ (= t)$, edges (i, j), c_{ij}]
This algorithm computes the maximum flow in a network G with source s, sink t, and capacities $c_{ij} > 0$ of the edges (i, j).

INPUT: n, $s = 1$, $t = n$, edges (i, j) of G, c_{ij}
OUTPUT: Maximum flow f in G

1. Assign an initial flow f_{ij} (for instance, $f_{ij} = 0$ for all edges), compute f.

2. Label s by $\varnothing$. Mark the other vertices *"unlabeled."*

3. Find a labeled vertex i that has not yet been scanned. Scan i as follows. For every unlabeled adjacent vertex j, if $c_{ij} > f_{ij}$, compute

$$\Delta_{ij} = c_{ij} - f_{ij} \quad \text{and} \quad \Delta_j = \begin{cases} \Delta_{1j} & \text{if } i = 1 \\ \min\,(\Delta_i, \Delta_{ij}) & \text{if } i > 1 \end{cases}$$

and label j with a *"forward label"* (i^+, Δ_j); or if $f_{ji} > 0$, compute

$$\Delta_j = \min\,(\Delta_i, f_{ji})$$

and label j by a "backward label" (i^-, Δ_j).

If no such j exists then OUTPUT f. Stop

[*f is the maximum flow.*]

Else continue (that is, go to Step 4).

4. Repeat Step 3 until t is reached.

[*This gives a flow augmenting path P: $s \to t$.*]

If it is impossible to reach t then OUTPUT f. Stop

[*f is the maximum flow.*]

Else continue (that is, go to Step 5).

5. Backtrack the path P, using the labels.

6. Using P, augment the existing flow by Δ_t. Set $f = f + \Delta_t$.

7. Remove all labels from vertices $2, \cdots, n$. Go to Step 3.

End FORD–FULKERSON

EXAMPLE 1 **Ford–Fulkerson Algorithm**

Applying the Ford–Fulkerson algorithm, determine the maximum flow for the network in Fig. 499 (which is the same as that in Example 1, Sec. 23.6, so that we can compare).

Solution. The algorithm proceeds as follows.

1. An initial flow $f = 9$ is given.

2. Label $s\ (= 1)$ by $\varnothing$. Mark 2, 3, 4, 5, 6 "unlabeled."

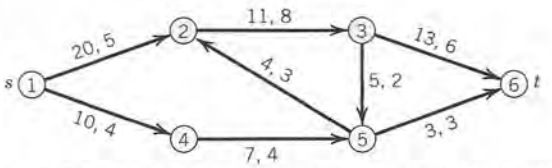

Fig. 499. Network in Example 1 with capacities (first numbers) and given flow

3. Scan 1.

   Compute $\Delta_{12} = 20 - 5 = 15 = \Delta_2$. Label 2 by $(1^+, 15)$.

   Compute $\Delta_{14} = 10 - 4 = 6 = \Delta_4$. Label 4 by $(1^+, 6)$.

4. Scan 2.

   Compute $\Delta_{23} = 11 - 8 = 3$, $\Delta_3 = \min(\Delta_2, 3) = 3$. Label 3 by $(2^+, 3)$.

   Compute $\Delta_5 = \min(\Delta_2, 3) = 3$. Label 5 by $(2^-, 3)$.

   Scan 3.

   Compute $\Delta_{36} = 13 - 6 = 7$, $\Delta_6 = \Delta_t = \min(\Delta_3, 7) = 3$. Label 6 by $(3^+, 3)$.

5. P: $1 - 2 - 3 - 6$ $(= t)$ is a flow augmenting path.

6. $\Delta_t = 3$. Augmentation gives $f_{12} = 8$, $f_{23} = 11$, $f_{36} = 9$, other f_{ij} unchanged. Augmented flow $f = 9 + 3 = 12$.

7. Remove labels on vertices $2, \cdots, 6$. Go to Step 3.

3. Scan 1.

   Compute $\Delta_{12} = 20 - 8 = 12 = \Delta_2$. Label 2 by $(1^+, 12)$.

   Compute $\Delta_{14} = 10 - 4 = 6 = \Delta_4$. Label 4 by $(1^+, 6)$.

4. Scan 2.

   Compute $\Delta_5 = \min(\Delta_2, 3) = 3$. Label 5 by $(2^-, 3)$.

   Scan 4. [*No vertex left for labeling.*]

   Scan 5.

   Compute $\Delta_3 = \min(\Delta_5, 2) = 2$. Label 3 by $(5^-, 2)$.

   Scan 3.

   Compute $\Delta_{36} = 13 - 9 = 4$, $\Delta_6 = \min(\Delta_3, 4) = 2$. Label 6 by $(3^+, 2)$.

5. P: $1 - 2 - 5 - 3 - 6$ $(= t)$ is a flow augmenting path.

6. $\Delta_t = 2$. Augmentation gives $f_{12} = 10$, $f_{52} = 1$, $f_{35} = 0$, $f_{36} = 11$, other f_{ij} unchanged. Augmented flow $f = 12 + 2 = 14$.

7. Remove labels on vertices $2, \cdots, 6$. Go to Step 3.

One can now scan 1 and then scan 2, as before, but in scanning 4 and then 5 one finds that no vertex is left for labeling. Thus one can no longer reach t. Hence the flow obtained (Fig. 500) is maximum, in agreement with our result in the last section. ■

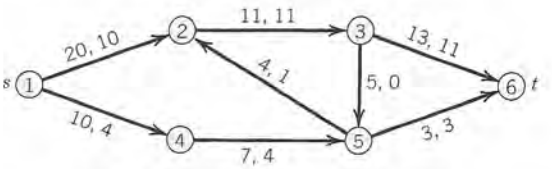

Fig. 500. Maximum flow in Example 1

PROBLEM SET 23.7

1. Do the computations indicated near the end of Example 1 in detail.
2. Solve Example 1 by Ford–Fulkerson with initial flow 0. Is it more work than in Example 1?
3. Which are the "bottleneck" edges by which the flow in Example 1 is actually limited? Hence which capacities could be decreased without decreasing the maximum flow?

4–7 MAXIMUM FLOW

Find the maximum flow by Ford–Fulkerson:

4. In Prob. 2, Sec. 23.6.
5. In Prob. 1, Sec. 23.6.
6. In Prob. 4, Sec. 23.6.
7. In Prob. 3, Sec. 23.6.
8. What is the (simple) reason that Kirchhoff's law is preserved in augmenting a flow by the use of a flow augmenting path?
9. How does Ford–Fulkerson prevent the formation of cycles?
10. How can you see that Ford–Fulkerson follows a BFS technique?
11. Are the consecutive flow augmenting paths produced by Ford–Fulkerson unique?
12. **(Integer flow theorem)** Prove that if the capacities in a network G are integers, then a maximum flow exists and is an integer.
13. **CAS PROBLEM. Ford–Fulkerson.** Write a program and apply it to Probs. 4–7.
14. If the Ford–Fulkerson algorithm stops without reaching t, show that the edges with one end labeled and the other end unlabeled form a cut set (S, T) whose capacity equals the maximum flow.
15. **(Several sources and sinks)** If a network has several sources $s_1, \cdots, s_k$, show that it can be reduced to the case of a single-source network by introducing a new vertex s and connecting s to $s_1, \cdots, s_k$ by k edges of capacity ∞. Similarly if there are several sinks. Illustrate this idea by a network with two sources and two sinks.
16. Find the maximum flow in the network in Fig. 501 with two sources (factories) and two sinks (consumers).
17. Find a minimum cut set in Fig. 499 and its capacity.
18. Show that in a network G with all $c_{ij} = 1$, the maximum flow equals the number of edge-disjoint paths $s \to t$.
19. In Prob. 17, the cut set contains precisely all forward edges used to capacity by the maximum flow (Fig. 500). Is this just by chance?
20. Show that in a network G with capacities all equal to 1, the capacity of a minimum cut set (S, T) equals the minimum number q of edges whose deletion destroys all directed paths $s \to t$. (A **directed path** $v \to w$ is a path in which each edge has the direction in which it is traversed in going from v to w.)

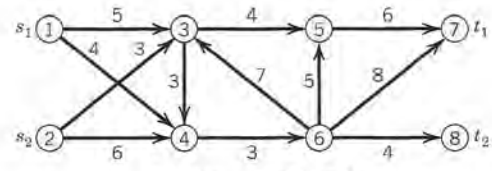

Fig. 501. Problem 16

23.8 Bipartite Graphs. Assignment Problems

From digraphs we return to graphs and discuss another important class of combinatorial optimization problems that arises in **assignment problems** of workers to jobs, jobs to machines, goods to storage, ships to piers, classes to classrooms, exams to time periods, and so on. To explain the problem, we need the following concepts.

A **bipartite graph** $G = (V, E)$ is a graph in which the vertex set V is partitioned into two sets S and T (without common elements, by the definition of a partition) such that every edge of G has one end in S and the other in T. Hence there are no edges in G that have both ends in S or both ends in T. Such a graph $G = (V, E)$ is also written $G = (S, T; E)$.

Figure 502 shows an illustration. V consists of seven elements, three workers a, b, c, making up the set S, and four jobs 1, 2, 3, 4, making up the set T. The edges indicate that worker a can do the jobs 1 and 2, worker b the jobs 1, 2, 3, and worker c the job 4. The problem is to assign one job to each worker so that every worker gets one job to do. This suggests the next concept, as follows.

DEFINITION

Maximum Cardinality Matching

A **matching** in $G = (S, T; E)$ is a set M of edges of G such that no two of them have a vertex in common. If M consists of the greatest possible number of edges, we call it a **maximum cardinality matching** in G.

For instance, a matching in Fig. 502 is $M_1 = \{(a, 2), (b, 1)\}$. Another is $M_2 = \{(a, 1), (b, 3), (c, 4)\}$; obviously, this is of maximum cardinality.

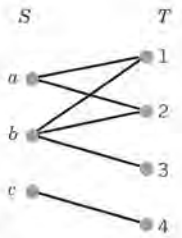

Fig. 502. Bipartite graph in the assignment of a set $S = \{a, b, c\}$ of workers to a set $T = \{1, 2, 3, 4\}$ of jobs

A vertex v is **exposed** (or *not covered*) by a matching M if v is not an endpoint of an edge of M. This concept, which always refers to some matching, will be of interest when we begin to augment given matchings (below). If a matching leaves no vertex exposed, we call it a **complete matching.** Obviously, a complete matching can exist only if S and T consist of the same number of vertices.

We now want to show how one can stepwise increase the cardinality of a matching M until it becomes maximum. Central in this task is the concept of an augmenting path.

An **alternating path** is a path that consists alternately of edges in M and not in M (Fig. 503A). An **augmenting path** is an alternating path both of whose endpoints (a and b in Fig. 503B) are exposed. By dropping from the matching M the edges that are on an augmenting path P (two edges in Fig. 503B) and adding to M the other edges of P (three in the figure), we get a new matching, with one more edge than M. This is how we use an augmenting path in ***augmenting a given matching*** by one edge. We assert that this will always lead, after a number of steps, to a maximum cardinality matching. Indeed, the basic role of augmenting paths is expressed in the following theorem.

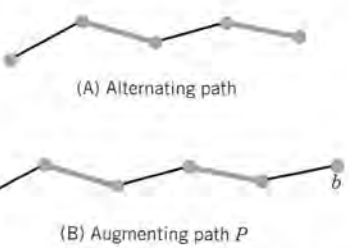

Fig. 503. Alternating and augmenting paths. Heavy edges are those belonging to a matching M.

THEOREM 1

Augmenting Path Theorem for Bipartite Matching

A matching M in a bipartite graph $G = (S, T; E)$ is of maximum cardinality if and only if there does not exist an augmenting path P with respect to M.

PROOF **(a)** We show that if such a path P exists, then M is not of maximum cardinality. Let P have q edges belonging to M. Then P has $q + 1$ edges not belonging to M. (In Fig. 503B we have $q = 2$.) The endpoints a and b of P are exposed, and all the other vertices on P are endpoints of edges in M, by the definition of an alternating path. Hence if an edge of M is not an edge of P, it cannot have an endpoint on P since then M would not be a matching. Consequently, the edges of M not on P, together with the $q + 1$ edges of P not belonging to M form a matching of cardinality one more than the cardinality of M because we omitted q edges from M and added $q + 1$ instead. Hence M cannot be of maximum cardinality.

(b) We now show that if there is no augmenting path for M, then M is of maximum cardinality. Let M^* be a maximum cardinality matching and consider the graph H consisting of all edges that belong either to M or to M^*, but not to both. Then it is possible that two edges of H have a vertex in common, but three edges cannot have a vertex in common since then two of the three would have to belong to M (or to M^*), violating that M and M^* are matchings. So every v in V can be in common with two edges of H or with one or none. Hence we can characterize each "component" (= maximal *connected* subset) of H as follows.

(A) A component of H can be a closed path with an *even* number of edges (in the case of an *odd* number, two edges from M or two from M^* would meet, violating the matching property). See (A) in Fig. 504.

(B) A component of H can be an open path P with the same number of edges from M and edges from M^*, for the following reason. P must be alternating, that is, an edge of M is followed by an edge of M^*, etc. (since M and M^* are matchings). Now if P had an edge more from M^*, then P would be augmenting for M [see (B2) in Fig. 504], contradicting our assumption that there is no augmenting path for M. If P had an edge more from M, it would be augmenting for M^* [see (B3) in Fig. 504], violating the maximum cardinality of M^*, by part (a) of this proof. Hence in each component of H, the two matchings have the same number of edges. Adding to this the number of edges that belong to both M and M^* (which we left aside when we made up H), we conclude that M and M^* must have the same number of edges. Since M^* is of maximum cardinality, this shows that the same holds for M, as we wanted to prove. ■

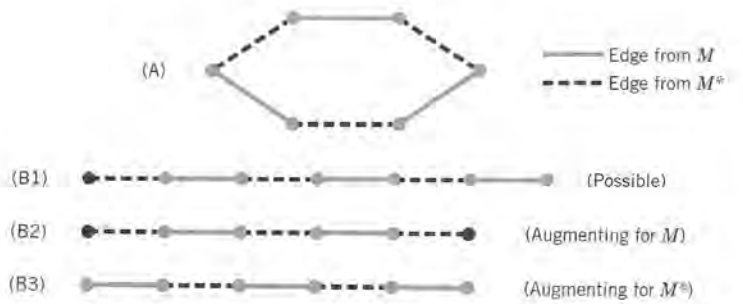

Fig. 504 Proof of the augmenting path theorem for bipartite matching

This theorem suggests the algorithm in Table 23.9 for obtaining augmenting paths, in which vertices are labeled for the purpose of backtracking paths. Such a label is *in addition* to the number of the vertex, which is also retained. Clearly, to get an augmenting path, one must start from an *exposed* vertex, and then trace an alternating path until one arrives at another *exposed* vertex. After Step 3 all vertices in S are labeled. In Step 4, the set T contains at least one exposed vertex, since otherwise we would have stopped at Step 1.

Table 23.9 Bipartite Maximum Cardinality Matching

ALGORITHM MATCHING $[G = (S, T; E), M, n]$

This algorithm determines a maximum cardinality matching M in a bipartite graph G by augmenting a given matching in G.

INPUT: Bipartite graph $G = (S, T; E)$ with vertices $1, \cdots, n$, matching M in G (for instance, $M = \emptyset$)

OUTPUT: Maximum cardinality matching M in G

1. If there is no exposed vertex in S then

OUTPUT M. Stop

[*M is of maximum cardinality in G.*]

Else label all *exposed* vertices *in* S with $\emptyset$.

2. For each i in S and edge (i, j) *not* in M, label j with i, unless already labeled.

3. For each *nonexposed* j in T, label i with j, where i is the other end of the unique edge (i, j) in M.

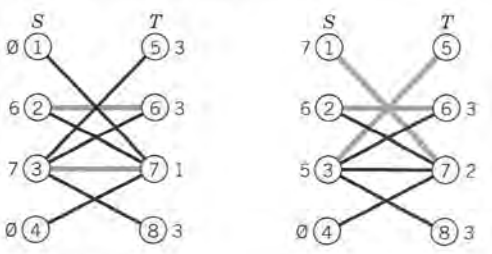
4. Backtrack the alternating paths P ending on an exposed vertex in T by using the labels on the vertices.

5. If no P in Step 4 is augmenting then

OUTPUT M. Stop

[*M is of maximum cardinality in G.*]

Else augment M by using an augmenting path P.



Remove all labels.

Go to Step 1.

End MATCHING

EXAMPLE 1 Maximum Cardinality Matching

Is the matching M_1 in Fig. 505a of maximum cardinality? If not, augment it until maximum cardinality is reached.

(a) Given graph and matching M_1 (b) Matching M_2 and new labels

Fig. 505. Example 1

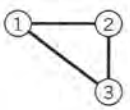
Solution. We apply the algorithm.

1. Label 1 and 4 with ∅.
2. Label 7 with 1. Label 5, 6, 8 with 3.
3. Label 2 with 6, and 3 with 7.

   [*All vertices are now labeled as shown in Fig.* 474a.]
4. P_1: 1 — 7 — 3 — 5. [*By backtracking,* P_1 *is augmenting.*]

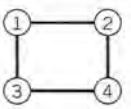
   P_2: 1 — 7 — 3 — 8. [P_2 *is augmenting.*]
5. Augment M_1 by using P_1, dropping (3, 7) from M_1 and including (1, 7) and (3, 5). Remove all labels. Go to Step 1.

   Figure 474b *shows the resulting matching* $M_2 = \{(1, 7), (2, 6), (3, 5)\}$.



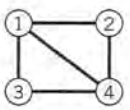
1. Label 4 with ∅.
2. Label 7 with 2. Label 6 and 8 with 3.
3. Label 1 with 7, and 2 with 6, and 3 with 5.
4. P_3: 5 — 3 — 8. [P_3 *is alternating but not augmenting.*]
5. Stop. M_2 *is of maximum cardinality (namely,* 3).

PROBLEM SET 23.8

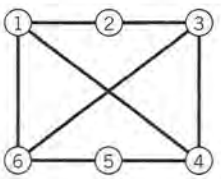


1–6 BIPARTITE OR NOT?

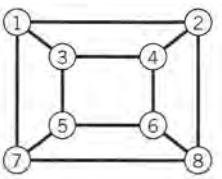
Are the following graphs bipartite? If you answer is yes, find S and T.



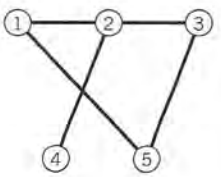
1.



2.



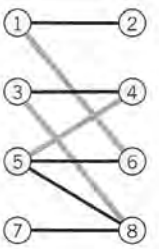
3.



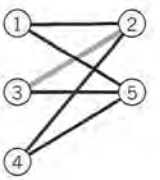
4.

5.

6.

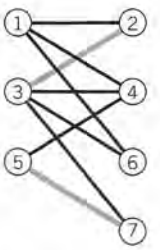


7. Can you obtain the answer to Prob. 3 from that to Prob. 1?



8–10 AUGMENTING PATHS

Find an augmenting path:



8.

9.

10.

11–13 MAXIMUM CARDINALITY MATCHING

Augmenting the given matching, find a maximum cardinality matching:

11. In Prob. 9.

12. In Prob. 8.

13. In Prob. 10.

14. (Scheduling and matching) Three teachers x_1, x_2, x_3 teach four classes y_1, y_2, y_3, y_4 for these numbers of periods:

	y_1	y_2	y_3	y_4
x_1	1	0	1	1
x_2	1	1	1	1
x_3	0	1	1	1

Show that this arrangement can be represented by a bipartite graph G and that a teaching schedule for one period corresponds to a matching in G. Set up a teaching schedule with the smallest possible number of periods.

15. (Vertex coloring and exam scheduling) What is the smallest number of exam periods for six subjects a, b, c, d, e, f if some of the students simultaneously take a, b, f, some c, d, e, some a, c, e, and some c, e? Solve this as follows. Sketch a graph with six vertices $a, \cdots, f$ and join vertices if they represent subjects simultaneously taken by some students. Color the vertices so that adjacent vertices receive different colors. (Use numbers $1, 2, \cdots$ instead of actual colors if you want.) What is the minimum number of colors you need? For any graph G, this minimum number is called the (vertex) **chromatic number** $\chi_v(G)$. Why is this the answer to the problem? Write down a possible schedule.

16. How many colors do you need in vertex coloring the graph in Prob. 5?

17. Show that all trees can be vertex colored with two colors.

18. (Harbor management) How many piers does a harbor master need for accommodating six cruise ships $S_1, \cdots, S_6$ with expected dates of arrival A and departure D in July, $(A, D) = (10, 13), (13, 15), (14, 17), (12, 15), (16, 18), (14, 17)$, respectively, if each pier can accommodate only one ship, arrival being at 6 a:m and departures at 11 p:m? *Hint.* Join S_i and S_j by an edge if their intervals overlap. Then color vertices.

19. What would be the answer to Prob. 18 if only the five ships $S_1, \cdots, S_5$ had to be accommodated?

20. (Complete bipartite graphs) A bipartite graph $G = (S, T; E)$ is called *complete* if every vertex in S is joined to every vertex in T by an edge, and is denoted by K_{n_1,n_2}, where n_1 and n_2 are the numbers of vertices in S and T, respectively. How many edges does this graph have?

21. (Planar graph) A *planar graph* is a graph that can be drawn on a sheet of paper so that no two edges cross. Show that the complete graph K_4 with four vertices is planar. The complete graph K_5 with five vertices is not planar. Make this plausible by attempting to draw K_5 so that no edges cross. Interpret the result in terms of a net of roads between five cities.

22. (Bipartite graph $K_{3,3}$ not planar) Three factories 1, 2, 3 are each supplied underground by water, gas, and electricity, from points A, B, C, respectively. Show that this can be represented by $K_{3,3}$ (the complete bipartite graph $G = (S, T; E)$ with S and T consisting of three vertices each) and that eight of the nine supply lines (edges) can be laid out without crossing. Make it plausible that $K_{3,3}$ is not planar by attempting to draw the ninth line without crossing the others.

23. (Four- (vertex) color theorem) The famous *four-color theorem* states that one can color the vertices of any *planar* graph (so that adjacent vertices get different colors) with at most four colors. It had been conjectured for a long time and was eventually proved in 1976 by Appel and Haken [Illinois J. Math **21** (1977), 429–567]. Can you color the complete graph K_5 with four colors? Does the result contradict the four-color theorem? (For more details, see Ref. [F8] in App. 1.)

24. (Edge coloring) The *edge chromatic number* $\chi_e(G)$ of a graph G is the minimum number of colors needed for coloring the edges of G so that incident edges get different colors. Clearly, $\chi_e(G) \geqq \max d(u)$, where $d(u)$ is the degree of vertex u. If $G = (S, T; E)$ is bipartite, the equality sign holds. Prove this for $K_{n,n}$.

25. Vizing's theorem states that for any graph G (without multiple edges!), $\max d(u) \leqq \chi_e(G) \leqq \max d(u) + 1$. Give an example of a graph for which $\chi_e(G)$ does exceed $\max d(u)$.

CHAPTER 23 REVIEW QUESTIONS AND PROBLEMS

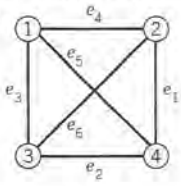
1. What is a graph? A digraph? A tree? A cycle? A path?

2. State from memory how you can handle graphs and digraphs on computers.

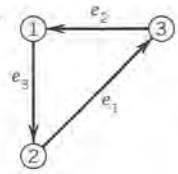
3. Describe situations and problems that can be modeled using graphs or digraphs.

4. What is a shortest path problem? Give applications.

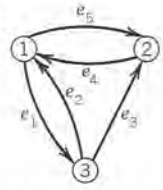
5. What is BFS? DFS? In what connection did these concepts occur?



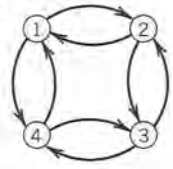
6. Give some applications in which spanning trees play a role.



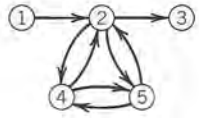
7. What are bipartite graphs? What applications motivate this concept?



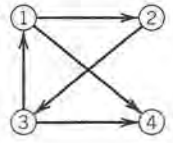
8. What is the traveling salesman problem?
9. What is a network? What optimization problems are connected with it?
10. Can a forward edge in one path be a backward edge in another path? In a cut set? Explain.
11. There is a famous theorem on cut sets. Can you remember and explain it?



12–17 MATRICES FOR GRAPHS OR DIGRAPHS



Find the adjacency matrix of:



12. 

13. 

14. 

15. 

16. 

17. 

18–20 GIVEN ADJACENCY MATRIX

Sketch the graph whose adjacency matrix is:

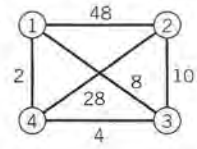
18. $\begin{bmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}$

19. $\begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}$

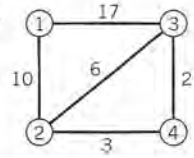
20. $\begin{bmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix}$

21. Make a vertex incidence list of the digraph in Prob. 13.
22. Make a vertex incidence list of the digraph in Prob. 14.

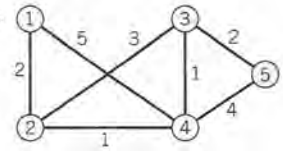
23–28 SHORTEST PATHS



Find a shortest path and its length by Moore's BFS algorithm, assuming that all the edges have length 1:



23. 

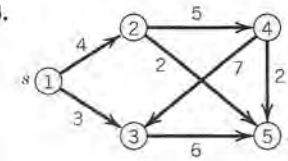


24. 

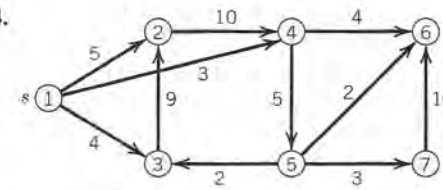
25. 

Find shortest paths by Dijkstra's algorithm:

26. 

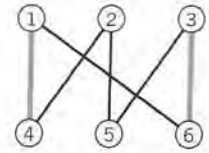


27. 



28. 

29. **(Shortest spanning tree)** Find a shortest spanning tree for the graph in Prob. 26.
30. Find a shortest spanning tree in Prob. 27.
31. **Cayley's theorem** states that the number of spanning trees in a complete graph with n vertices is n^{n-2}. Verify this for $n = 2, 3, 4$.
32. Show that $O(m^3) + O(m^2) = O(m^3)$.



33–34 MAXIMUM FLOW.

Find the maximum flow, where the given numbers are capacities:

33. 

34. 

35. Company A has offices in Chicago, Los Angeles, and New York, Company B in Boston and New York, Company C in Chicago, Dallas, and Los Angeles. Represent this by a bipartite graph.
36. **(Maximum cardinality matching).** Augmenting the given matching, find a maximum cardinality matching:

SUMMARY OF CHAPTER 23
Graphs and Combinatorial Optimization

Combinatorial optimization concerns optimization problems of a discrete or combinatorial structure. It uses graphs and digraphs (Sec. 23.1) as basic tools.

A **graph** $G = (V, E)$ consists of a set V of **vertices** $v_1, v_2, \cdots, v_n$, (often simply denoted by $1, 2, \cdots, n$) and a set E of **edges** $e_1, e_2, \cdots, e_m$, each of which connects two vertices. We also write (i, j) for an edge with vertices i and j as endpoints. A **digraph** (= directed graph) is a graph in which each edge has a direction (indicated by an arrow). For handling graphs and digraphs in computers, one can use *matrices* or *lists* (Sec. 23.1).

This chapter is devoted to important classes of optimization problems for graphs and digraphs that all arise from practical applications, and corresponding algorithms, as follows.

In a **shortest path problem** (Sec. 23.2) we determine a path of minimum length (consisting of edges) from a vertex s to a vertex t in a graph whose edges (i, j) have a "length" $l_{ij} > 0$, which may be an actual length or a travel time or cost or an electrical resistance [if (i, j) is a wire in a net], and so on. **Dijkstra's algorithm** (Sec. 23.3) or, when all $l_{ij} = 1$, **Moore's algorithm** (Sec. 23.2) are suitable for these problems.

A **tree** is a graph that is connected and has no **cycles** (no closed paths). Trees are very important in practice. A *spanning tree* in a graph G is a tree containing *all* the vertices of G. If the edges of G have lengths, we can determine a **shortest spanning tree**, for which the sum of the lengths of all its edges is minimum, by **Kruskal's algorithm** or **Prim's algorithm** (Secs. 23.4, 23.5).

A **network** (Sec. 23.6) is a digraph in which each edge (i, j) has a *capacity* $c_{ij} > 0$ [= maximum possible flow along (i, j)] and at one vertex, the *source* s, a flow is produced that flows along the edges to a vertex t, the *sink* or *target*, where the flow disappears. The problem is to maximize the flow, for instance, by applying the **Ford–Fulkerson algorithm** (Sec. 23.7), which uses **flow augmenting paths** (Sec. 23.6). Another related concept is that of a **cut set**, as defined in Sec. 23.6.

A **bipartite graph** $G = (V, E)$ (Sec. 23.8) is a graph whose vertex set V consists of two parts S and T such that every edge of G has one end in S and the other in T, so that there are no edges connecting vertices in S or vertices in T. A **matching** in G is a set of edges, no two of which have an endpoint in common. The problem then is to find a **maximum cardinality matching** in G, that is, a matching M that has a maximum number of edges. For an algorithm, see Sec. 23.8.

PART G

Probability, Statistics

CHAPTER 24 Data Analysis. Probability Theory

CHAPTER 25 Mathematical Statistics

Probability theory (Chap. 24) provides models of probability distributions (theoretical models of the observable reality involving chance effects) to be tested by statistical methods, and it will also supply the mathematical foundation of these methods in Chap. 25.

Modern **mathematical statistics** (Chap. 25) has various engineering applications, for instance, in testing materials, control of production processes, quality control of production outputs, performance tests of systems, robotics, and automatization in general, production planning, marketing analysis, and so on.

To this we could add a long list of fields of applications, for instance, in agriculture, biology, computer science, demography, economics, geography, management of natural resources, medicine, meteorology, politics, psychology, sociology, traffic control, urban planning, etc. Although these applications are very heterogeneous, we shall see that most statistical methods are universal in the sense that each of them can be applied in various fields.

Additional Software for Probability and Statistics

See also the list of software at the beginning of Part E on Numerical Analysis.

CHAPTER 24

Data Analysis. Probability Theory

We first show how to handle data numerically or in terms of graphs, and how to extract information (average size, spread of data, etc.) from them. If these data are influenced by "chance," by factors whose effect we cannot predict exactly (e.g., weather data, stock prices, lifespans of tires, etc.), we have to rely on **probability theory.** This theory originated in games of chance, such as flipping coins, rolling dice, or playing cards. Nowadays it gives mathematical models of chance processes called *random experiments* or, briefly, **experiments**. In such an experiment we observe a **random variable** X, that is, a function whose values in a **trial** (a performance of an experiment) occur "by chance" (Sec. 24.3) according to a **probability distribution** that gives the individual probabilities with which possible values of X may occur in the long run. (Example: Each of the six faces of a die should occur with the same probability, 1/6.) Or we may simultaneously observe more than one random variable, for instance, height *and* weight of persons or hardness *and* tensile strength of steel. This is discussed in Sec. 24.9, which will also give the basis for the mathematical justification of the statistical methods in Chap. 25.

Prerequisite: Calculus.
References and Answers to Problems: App. 1, Part G, App. 2.

24.1 Data Representation. Average. Spread

Data can be represented numerically or graphically in various ways. For instance, your daily newspaper may contain tables of stock prices and money exchange rates, curves or bar charts illustrating economical or political developments, or pie charts showing how your tax dollar is spent. And there are numerous other representations of data for special purposes.

In this section we discuss the use of standard representations of data in statistics. (For these, software packages, such as DATA DESK and MINITAB, are available, and Maple or Mathematica may also be helpful; see pp. 778 and 991) We explain corresponding concepts and methods in terms of typical examples, beginning with

(1) 89 84 87 81 89 86 91 90 78 89 87 99 83 89.

These are $n = 14$ measurements of the tensile strength of sheet steel in kg/mm^2, recorded in the order obtained and rounded to integer values. To see what is going on, we **sort** these data, that is, we order them by size,

(2) 78 81 83 84 86 87 87 89 89 89 89 90 91 99.

Sorting is a standard process on the computer; see Ref. [E25], listed in App. 1.

Graphic Representation of Data

We shall now discuss standard graphic representations used in statistics for obtaining information on properties of data.

Stem-and-Leaf Plot

This is one of the simplest but most useful representations of data. For (1) it is shown in Fig. 506. The numbers in (1) range from 78 to 99; see (2). We divide these numbers into 5 groups, 75–79, 80–84, 85–89, 90–94, 95–99. The integers in the tens position of the groups are 7, 8, 8, 9, 9. These form the *stem* in Fig. 506. The first *leaf* is 8 (representing 78). The second leaf is 134 (representing 81, 83, 84), and so on.

The number of times a value occurs is called its **absolute frequency.** Thus 78 has absolute frequency 1, the value 89 has absolute frequency 4, etc. The column to the extreme left in Fig. 506 shows the **cumulative absolute frequencies,** that is, the sum of the absolute frequencies of the values up to the line of the leaf. Thus, the number 4 in the second line on the left shows that (1) has 4 values up to and including 84. The number 11 in the next line shows that there are 11 values not exceeding 89, etc. Dividing the cumulative absolute frequencies by n (= 14 in Fig. 506) gives the **cumulative relative frequencies.**

Histogram

For large sets of data, histograms are better in displaying the distribution of data than stem-and-leaf plots. The principle is explained in Fig. 507. (An application to a larger data set is shown in Sec. 25.7). The bases of the rectangles in Fig. 507 are the x-intervals (known as **class intervals**) 74.5–79.5, 79.5–84.5, 84.5–89.5, 89.5–94.5, 94.5–99.5, whose midpoints (known as **class marks**) are $x = 77, 82, 87, 92, 97$, respectively. The height of a rectangle with class mark x is the **relative class frequency** $f_{\text{rel}}(x)$, defined as the number of data values in that class interval, divided by n (= 14 in our case). Hence the areas of the rectangles are proportional to these relative frequencies, so that histograms give a good impression of the distribution of data.

Center and Spread of Data: Median, Quartiles

As a center of the location of data values we can simply take the **median,** the data value that falls in the middle when the values are ordered. In (2) we have 14 values. The seventh of them is 87, the eighth is 89, and we split the difference, obtaining the median 88. (In general, we would get a fraction.)

The spread (variability) of the data values can be measured by the **range** $R = x_{\max} - x_{\min}$, the largest minus the smallest data values, $R = 99 - 78 = 21$ in (2).

Leaf unit = 1.0

1	7	8
4	8	134
11	8	6779999
13	9	01
14	9	9

Fig. 506. Stem-and-leaf plot of the data in (1) and (2)

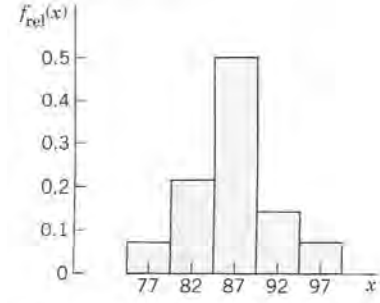

Fig. 507. Histogram of the data in (1) and (2) (grouped as in Fig. 506)

Better information gives the **interquartile range** IQR $= q_U - q_L$. Here the **upper quartile** q_U is the middle value among the data values *above* the median. The **lower quartile** q_L is the middle value among the data values *below* the median. Thus in (2) we have $q_U = 89$ (the fourth value from the end), $q_L = 84$ (the fourth value from the beginning), and IQR $= 89 - 84 = 5$. The median is also called the **middle quartile** and is denoted by q_M. The rule of "splitting the difference" (just applied to the middle quartile) is equally well used for the other quartiles if necessary.

Boxplot

The **boxplot** of (1) in Fig. 508 is obtained from the five numbers $x_{\min}$, q_L, q_M, q_U, $x_{\max}$ just determined. The box extends from q_L to q_U. Hence it has the height IQR. The position of the median in the box shows that the data distribution is not symmetric. The two lines extend from the box to $x_{\min}$ below and to $x_{\max}$ above. Hence they mark the range R.

Boxplots are particularly suitable for making comparisons. For example, Fig. 508 shows boxplots of the data sets (1) and

(3) 91 89 93 91 87 94 92 85 91 90 96 93 89

(consisting of $n = 13$ values). Ordering gives

(4) 85 87 89 89 90 91 91 91 92 93 93 94 96

(tensile strength, as before). From the plot we immediately see that the box of (3) is shorter than the box of (1) (indicating the higher quality of the steel sheets!) and that q_M is located in the middle of the box (showing the more symmetric form of the distribution). Finally, $x_{\max}$ is closer to q_U for (3) than it is for (1), a fact that we shall discuss later.

For plotting the box of (3) we took from (4) the values $x_{\min} = 85$, $q_L = 89$, $q_M = 91$, $q_U = 93$, $x_{\max} = 96$.

Outliers

An **outlier** is a value that appears to be uniquely different from the rest of the data set. It might indicate that something went wrong with the data collection process. In connection with quartiles an outlier is conventionally defined as a value more than a distance of 1.5 IQR from either end of the box.

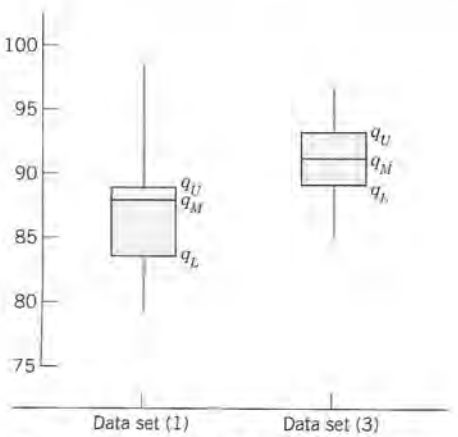

Fig. 508. Boxplots of data sets (1) and (3)

For the data in (1) we have IQR = 5, $q_L = 84$, $q_U = 89$. Hence outliers are smaller than 84 − 7.5 or larger than 89 + 7.5, so that 99 is an outlier [see (2)]. The data (3) have no outliers, as you can readily verify.

Mean. Standard Deviation. Variance

Medians and quartiles are easily obtained by ordering and counting, practically without calculation. But they do not give full information on data: you can change data values to some extent without changing the median. Similarly for the quartiles.

The average size of the data values can be measured in a more refined way by the **mean**

$$\bar{x} = \frac{1}{n}\sum_{j=1}^{n} x_j = \frac{1}{n}(x_1 + x_2 + \cdots + x_n). \tag{5}$$

This is the arithmetic mean of the data values, obtained by taking their sum and dividing by the data *size* n. Thus in (1),

$$\bar{x} = \tfrac{1}{14}(89 + 84 + \cdots + 89) = \tfrac{611}{7} \approx 87.3.$$

Every data value contributes, and changing one of them will change the mean.

Similarly, the spread (variability) of the data values can be measured in a more refined way by the **standard deviation** s or by its square, the **variance**

$$s^2 = \frac{1}{n-1}\sum_{j=1}^{n} (x_j - \bar{x})^2 = \frac{1}{n-1}\left[(x_1 - \bar{x})^2 + \cdots + (x_n - \bar{x})^2\right]. \tag{6}$$

Thus, to obtain the variance of the data, take the difference $x_j - \bar{x}$ of each data value from the mean, square it, take the sum of these n squares, and divide it by $n - 1$ (not n, as we motivate in Sec. 25.2). To get the standard deviation s, take the square root of s^2.

For example, using $\bar{x} = 611/7$, we get for the data (1) the variance

$$s^2 = \tfrac{1}{13}\left[(89 - \tfrac{611}{7})^2 + (84 - \tfrac{611}{7})^2 + \cdots + (89 - \tfrac{611}{7})^2\right] = \tfrac{176}{7} \approx 25.14.$$

Hence the standard deviation is $s = \sqrt{176/7} \approx 5.014$. Note that the standard deviation has the same dimension as the data values (kg/mm^2, see at the beginning), which is an advantage. On the other hand, the variance is preferable to the standard deviation in developing statistical methods, as we shall see in Chap. 25.

CAUTION! Your CAS (Maple, for instance) may use $1/n$ instead of $1/(n-1)$ in (6), but the latter is better when n is small (see Sec. 25.2).

PROBLEM SET 24.1

1–10 DATA REPRESENTATIONS

Represent the data by a stem-and-leaf plot, a histogram, and a boxplot:

1. 20 21 20 19 20 19 21 19

2. 7 6 4 0 7 1 2 4 6 6

3. 56 58 54 33 41 30 44 37 51 46 56 38 38 49 39

4. 12.1 10 12.4 10.5 9.2 17.2 11.4 11.8 14.7 9.9

5. 70.6 70.9 69.1 71.3 70.5 69.7 71.5 69.8 71.1 68.9 70.3 69.2 71.2 70.4 72.8

6. −0.52 0.11 −0.48 0.94 0.24 −0.19 −0.55

7. Reaction time [sec] of an automatic switch
2.3 2.2 2.4 2.5 2.3 2.3 2.4 2.1 2.5 2.4
2.6 2.3 2.5 2.1 2.4 2.2 2.3 2.5 2.4 2.4

8. Carbon content [%] of coal
89 90 89 84 80 88 90 89 88 90 85
87 86 82 85 76 89 87 86 86

9. Weight of filled bottles [g] in an automatic filling process
403 399 398 401 400 401 401

10. Gasoline consumption [gallons per mile] of six cars of the same model
14.0 14.5 13.5 14.0 14.5 14.0

11–16 AVERAGE AND SPREAD

Find the mean and compare it with the median. Find the standard deviation and compare it with the interquartile range.

11. The data in Prob. 1.

12. The data in Prob. 2.

13. The data in Prob. 5.

14. The data in Prob. 6.

15. The data in Prob. 9.

16. 5 22 7 23 6. Why is $|\bar{x} - q_M|$ so large?

17. Construct the simplest possible data with $\bar{x} = 100$ but $q_M = 0$.

18. (Mean) Prove that $\bar{x}$ must always lie between the smallest and the largest data values.

19. (Outlier, reduced data) Calculate s for the data 4 1 3 10 2. Then reduce the data by deleting the outlier and calculate s. Comment.

20. WRITING PROJECT. Average and Spread. Compare Q_M, IQR and $\bar{x}$, s, illustrating the advantages and disadvantages with examples of your own.

24.2 Experiments, Outcomes, Events

We now turn to **probability theory.** This theory has the purpose of providing mathematical models of situations affected or even governed by "chance effects," for instance, in weather forecasting, life insurance, quality of technical products (computers, batteries, steel sheets, etc.), traffic problems, and, of course, games of chance with cards or dice. And the accuracy of these models can be tested by suitable observations or experiments—this is a main purpose of **statistics** to be explained in Chap. 25.

We begin by defining some standard terms. An **experiment** is a process of measurement or observation, in a laboratory, in a factory, on the street, in nature, or wherever; so "experiment" is used in a rather general sense. Our interest is in experiments that involve **randomness,** chance effects, so that we cannot predict a result exactly. A **trial** is a single performance of an experiment. Its result is called an **outcome** or a **sample point.** n trials then give a **sample** of **size** n consisting of n sample points. The **sample space** S of an experiment is the set of all possible outcomes.

EXAMPLES 1–6 Random Experiments. Sample Spaces

(1) Inspecting a lightbulb. S = {Defective, Nondefective}.

(2) Rolling a die. $S = \{1, 2, 3, 4, 5, 6\}$.

(3) Measuring tensile strength of wire. S the numbers in some interval.

(4) Measuring copper content of brass. S: 50% to 90%, say.

(5) Counting daily traffic accidents in New York. S the integers in some interval.

(6) Asking for opinion about a new car model. S = {Like, Dislike, Undecided}. ■

The subsets of S are called **events** and the outcomes **simple events.**

EXAMPLE 7 Events

In (2), events are $A = \{1, 3, 5\}$ (*"Odd number"*), $B = \{2, 4, 6\}$ (*"Even number"*), $C = \{5, 6\}$, etc. Simple events are $\{1\}, \{2\}, \cdots, \{6\}$. ■

If in a trial an outcome a happens and $a \in A$ (a *is an element of* A), we say that A happens. For instance, if a die turns up a 3, the event A: *Odd number* happens. Similarly, if C in Example 1 happens (meaning 5 or 6 turns up), then $D = \{4, 5, 6\}$ happens. Also note that S happens in each trial, meaning that *some* event of S always happens. All this is quite natural.

Unions, Intersections, Complements of Events

In connection with basic probability laws we shall need the following concepts and facts about events (subsets) $A, B, C, \cdots$ of a given sample space S.

The **union** $A \cup B$ of A and B consists of all points in A or B or both.

The **intersection** $A \cap B$ of A and B consists of all points that are in both A and B.

If A and B have no points in common, we write

$$A \cap B = \varnothing$$

where $\varnothing$ is the *empty set* (set with no elements) and we call A and B **mutually exclusive** (or **disjoint**) because in a trial the occurrence of A *excludes* that of B (and conversely)—if your die turns up an odd number, it cannot turn up an even number in the same trial. Similarly, a coin cannot turn up *Head* and *Tail* at the same time.

Complement A^c of A. This is the set of all the points of S ***not*** in A. Thus,

$$A \cap A^c = \varnothing, \qquad A \cup A^c = S.$$

In Example 7 we have $A^c = B$, hence $A \cup A^c = \{1, 2, 3, 4, 5, 6\} = S$.

Another notation for the complement of A is $\overline{A}$ (instead of A^c), but we shall not use this because in set theory $\overline{A}$ is used to denote the *closure* of A (not needed in our work).

Unions and intersections of more events are defined similarly. The **union**

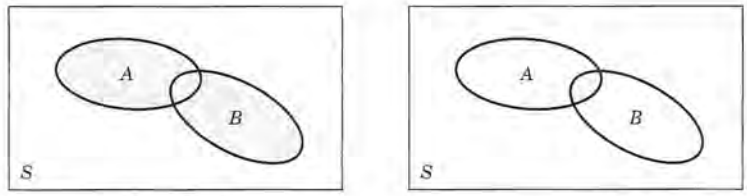
$$\bigcup_{j=1}^{m} A_j = A_1 \cup A_2 \cup \cdots \cup A_m$$

of events $A_1, \cdots, A_m$ consists of all points that are in at least one A_j. Similarly for the union $A_1 \cup A_2 \cup \cdots$ of infinitely many subsets $A_1, A_2, \cdots$ of an *infinite* sample space S (that is, S consists of infinitely many points). The **intersection**

$$\bigcap_{j=1}^{m} A_j = A_1 \cap A_2 \cap \cdots \cap A_m$$

of $A_1, \cdots, A_m$ consists of the points of S that are in each of these events. Similarly for the intersection $A_1 \cap A_2 \cap \cdots$ of infinitely many subsets of S.

Working with events can be illustrated and facilitated by **Venn diagrams**[1] for showing unions, intersections, and complements, as in Figs. 509 and 510, which are typical examples that give the idea.



EXAMPLE 8 Unions and Intersections of 3 Events

In rolling a die, consider the events

A: *Number greater than* 3, B: *Number less than* 6, C: *Even number.*

Then $A \cap B = \{4, 5\}$, $B \cap C = \{2, 4\}$, $C \cap A = \{4, 6\}$, $A \cap B \cap C = \{4\}$. Can you sketch a Venn diagram of this? Furthermore, $A \cup B = S$, hence $A \cup B \cup C = S$ (why?). ■

[1]JOHN VENN (1834–1923), English mathematician.

Union $A \cup B$ Intersection $A \cap B$

Fig. 509. Venn diagrams showing two events A and B in a sample space S and their union $A \cup B$ (colored) and intersection $A \cap B$ (colored)

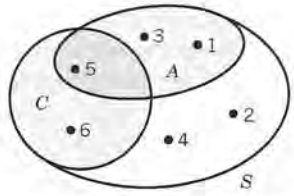


Fig. 510. Venn diagram for the experiment of rolling a die, showing S, $A = \{1, 3, 5\}$, $C = \{5, 6\}$, $A \cup C = \{1, 3, 5, 6\}$, $A \cap C = \{5\}$

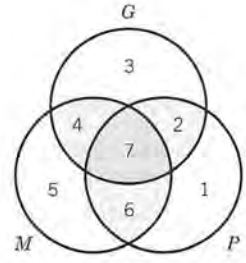
PROBLEM SET 24.2



1–9 SAMPLE SPACES, EVENTS

Graph a sample space for the experiment:

1. Tossing 2 coins
2. Drawing 4 screws from a lot of right-handed and left-handed screws
3. Rolling 2 dice
4. Tossing a coin until the first *Head* appears
5. Rolling a die until the first *"Six"* appears
6. Drawing bolts from a lot of 20, containing one defective D, until D is drawn, one at a time and assuming **sampling without replacement,** that is, bolts drawn are not returned to the lot
7. Recording the lifetime of each of 3 lightbulbs
8. Choosing a committee of 3 from a group of 5 people
9. Recording the daily maximum temperature X and the maximum air pressure Y at some point in a city
10. In Prob. 3, circle and mark the events *A: Equal faces*, *B: Sum exceeds* 9, *C: Sum equals* 7.
11. In rolling 2 dice, are the events *A: Sum divisible by* 3 and *B: Sum divisible by* 5 mutually exclusive?
12. Answer the question in Prob. 11 for rolling 3 dice.
13. In Prob. 5 list the outcomes that make up the event *E:* First *"Six"* in rolling at most 3 times. Describe E^c.
14. List all 8 subsets of the sample space $S = \{a, b, c\}$.

15–20 VENN DIAGRAMS

15. In connection with a trip to Europe by some students, consider the events P that they see Paris, G that they have a good time, and M that they run out of money, and describe in words the events $1, \cdots, 7$ in the diagram.

Problem 15

16. Using Venn diagrams, graph and check the rules

$$A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$$

$$A \cap (B \cup C) = (A \cap B) \cup (A \cap C).$$

17. **(De Morgan's laws)** Using Venn diagrams, graph and check *De Morgan's laws*

$$(A \cup B)^c = A^c \cap B^c$$

$$(A \cap B)^c = A^c \cup B^c.$$

18. Using a Venn diagram, show that $A \subseteq B$ if and only if $A \cap B = A$.

19. Show that, by the definition of complement, for any subset A of a sample space S,

$$(A^c)^c = A, \qquad S^c = \varnothing, \qquad \varnothing^c = S,$$
$$A \cup A^c = S, \qquad A \cap A^c = \varnothing.$$

20. Using a Venn diagram, show that $A \subseteq B$ if and only if $A \cup B = B$.

24.3 Probability

The "probability" of an event A in an experiment is supposed to measure how frequently A is *about* to occur if we make many trials. If we flip a coin, then heads H and tails T will appear *about* equally often—we say that H and T are **"equally likely."** Similarly, for a regularly shaped die of homogeneous material (**"fair die"**) each of the six outcomes $1, \cdots, 6$ will be equally likely. These are examples of experiments in which the sample space S consists of finitely many outcomes (points) that for reasons of some symmetry can be regarded as equally likely. This suggests the following definition.

DEFINITION 1

First Definition of Probability

If the sample space S of an experiment consists of finitely many outcomes (points) that are equally likely, then the probability $P(A)$ of an event A is

$$P(A) = \frac{\text{Number of points in } A}{\text{Number of points in } S}. \tag{1}$$

From this definition it follows immediately that, in particular,

$$P(S) = 1. \tag{2}$$

EXAMPLE 1 **Fair Die**

In rolling a fair die once, what is the probability $P(A)$ of A of obtaining a 5 or a 6? The probability of B: *"Even number"?*

Solution. The six outcomes are equally likely, so that each has probability 1/6. Thus $P(A) = 2/6 = 1/3$ because $A = \{5, 6\}$ has 2 points, and $P(B) = 3/6 = 1/2$. ■

Definition 1 takes care of many games as well as some practical applications, as we shall see, but certainly not of all experiments, simply because in many problems we do not have finitely many equally likely outcomes. To arrive at a more general definition of probability, we regard ***probability as the counterpart of relative frequency.*** Recall from Sec. 24.1 that the **absolute frequency** $f(A)$ of an event A in n trials is the number of times A occurs, and the **relative frequency** of A in these trials is $f(A)/n$; thus

$$f_{\text{rel}}(A) = \frac{f(A)}{n} = \frac{\text{Number of times } A \text{ occurs}}{\text{Number of trials}}. \tag{3}$$

Now if A did not occur, then $f(A) = 0$. If A always occurred, then $f(A) = n$. These are the extreme cases. Division by n gives

$$0 \leqq f_{\text{rel}}(A) \leqq 1. \tag{4*}$$

In particular, for $A = S$ we have $f(S) = n$ because S always occurs (meaning that some event always occurs; if necessary, see Sec. 24.2, after Example 7). Division by n gives

$$f_{\text{rel}}(S) = 1. \tag{5*}$$

Finally, if A and B are mutually exclusive, they cannot occur together. Hence the absolute frequency of their union $A \cup B$ must equal the sum of the absolute frequencies of A and B. Division by n gives the same relation for the relative frequencies,

$$f_{\text{rel}}(A \cup B) = f_{\text{rel}}(A) + f_{\text{rel}}(B) \qquad (A \cap B = \varnothing). \tag{6*}$$

We are now ready to extend the definition of probability to experiments in which equally likely outcomes are not available. Of course, the extended definition should include Definition 1. Since probabilities are supposed to be the theoretical counterpart of relative frequencies, we choose the properties in (4*), (5*), (6*) as axioms. (Historically, such a choice is the result of a long process of gaining experience on what might be best and most practical.)

DEFINITION 2

General Definition of Probability

Given a sample space S, with each event A of S (subset of S) there is associated a number $P(A)$, called the **probability** of A, such that the following **axioms of probability** are satisfied.

1. For every A in S,

$$0 \leqq P(A) \leqq 1. \tag{4}$$

2. The entire sample space S has the probability

$$P(S) = 1. \tag{5}$$

3. For mutually exclusive events A and B ($A \cap B = \varnothing$; see Sec. 24.2),

$$P(A \cup B) = P(A) + P(B) \qquad (A \cap B = \varnothing). \tag{6}$$

If S is infinite (has infinitely many points), Axiom 3 has to be replaced by

3′. For mutually exclusive events $A_1, A_2, \cdots$,

$$P(A_1 \cup A_2 \cup \cdots) = P(A_1) + P(A_2) + \cdots. \tag{6′}$$

In the infinite case the subsets of S on which $P(A)$ is defined are restricted to form a so-called *σ-algebra*, as explained in Ref. [GR6] (not [G6]!) in App. 1. This is of no practical consequence to us.

Basic Theorems of Probability

We shall see that the axioms of probability will enable us to build up probability theory and its application to statistics. We begin with three basic theorems. The first of them is useful if we can get the probability of the complement A^c more easily than $P(A)$ itself.

THEOREM 1

Complementation Rule

For an event A and its complement A^c in a sample space S,

$$P(A^c) = 1 - P(A). \tag{7}$$

PROOF By the definition of complement (Sec. 24.2), we have $S = A \cup A^c$ and $A \cap A^c = \varnothing$. Hence by Axioms 2 and 3,

$$1 = P(S) = P(A) + P(A^c), \qquad \text{thus} \qquad P(A^c) = 1 - P(A). \qquad \blacksquare$$

EXAMPLE 2 **Coin Tossing**

Five coins are tossed simultaneously. Find the probability of the event *A: At least one head turns up.* Assume that the coins are fair.

Solution. Since each coin can turn up heads or tails, the sample space consists of $2^5 = 32$ outcomes. Since the coins are fair, we may assign the same probability (1/32) to each outcome. Then the event A^c (*No heads turn up*) consists of only 1 outcome. Hence $P(A^c) = 1/32$, and the answer is $P(A) = 1 - P(A^c) = 31/32$. ■

The next theorem is a simple extension of Axiom 3, which you can readily prove by induction.

THEOREM 2

Addition Rule for Mutually Exclusive Events

For mutually exclusive events $A_1, \cdots, A_m$ in a sample space S,

$$P(A_1 \cup A_2 \cup \cdots A_m) = P(A_1) + P(A_2) + \cdots + P(A_m). \tag{8}$$

EXAMPLE 3 **Mutually Exclusive Events**

If the probability that on any workday a garage will get 10–20, 21–30, 31–40, over 40 cars to service is 0.20, 0.35, 0.25, 0.12, respectively, what is the probability that on a given workday the garage gets at least 21 cars to service?

Solution. Since these are mutually exclusive events, Theorem 2 gives the answer $0.35 + 0.25 + 0.12 = 0.72$. Check this by the complementation rule. ■

In many cases, events will not be mutually exclusive. Then we have

THEOREM 3

Addition Rule for Arbitrary Events

For events A and B in a sample space,

$$P(A \cup B) = P(A) + P(B) - P(A \cap B). \tag{9}$$

PROOF C, D, E in Fig. 511 make up $A \cup B$ and are mutually exclusive (disjoint). Hence by Theorem 2,

$$P(A \cup B) = P(C) + P(D) + P(E).$$

This gives (9) because on the right $P(C) + P(D) = P(A)$ by Axiom 3 and disjointness; and $P(E) = P(B) - P(D) = P(B) - P(A \cap B)$, also by Axiom 3 and disjointness. ∎

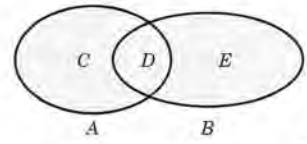


Fig. 511. Proof of Theorem 3

Note that for mutually exclusive events A and B we have $A \cap B = \varnothing$ by definition and, by comparing (9) and (6),

(10) $$P(\varnothing) = 0.$$

(Can you also prove this by (5) and (7)?)

EXAMPLE 4 **Union of Arbitrary Events**

In tossing a fair die, what is the probability of getting an odd number or a number less than 4?

Solution. Let A be the event *"Odd number"* and B the event *"Number less than* 4." Then Theorem 3 gives the answer

$$P(A \cup B) = \tfrac{3}{6} + \tfrac{3}{6} - \tfrac{2}{6} = \tfrac{2}{3}$$

because $A \cap B =$ *"Odd number less than* 4" $= \{1, 3\}$. ∎

Conditional Probability. Independent Events

Often it is required to find the probability of an event B under the condition that an event A occurs. This probability is called the **conditional probability** *of B given A* and is denoted by $P(B|A)$. In this case A serves as a new (reduced) sample space, and that probability is the fraction of $P(A)$ which corresponds to $A \cap B$. Thus

(11) $$P(B|A) = \frac{P(A \cap B)}{P(A)} \qquad [P(A) \neq 0].$$

Similarly, the *conditional probability of A given B* is

(12) $$P(A|B) = \frac{P(A \cap B)}{P(B)} \qquad [P(B) \neq 0].$$

Solving (11) and (12) for $P(A \cap B)$, we obtain

THEOREM 4 **Multiplication Rule**

If A and B are events in a sample space S and $P(A) \neq 0$, $P(B) \neq 0$, then

(13) $$P(A \cap B) = P(A)P(B|A) = P(B)P(A|B).$$

EXAMPLE 5 Multiplication Rule

In producing screws, let A mean "screw too slim" and B "screw too short." Let $P(A) = 0.1$ and let the conditional probability that a slim screw is also too short be $P(B|A) = 0.2$. What is the probability that a screw that we pick randomly from the lot produced will be both too slim and too short?

Solution. $P(A \cap B) = P(A)P(B|A) = 0.1 \cdot 0.2 = 0.02 = 2\%$, by Theorem 4. ■

Independent Events. If events A and B are such that

$$P(A \cap B) = P(A)P(B), \tag{14}$$

they are called **independent events.** Assuming $P(A) \neq 0$, $P(B) \neq 0$, we see from (11)–(13) that in this case

$$P(A|B) = P(A), \qquad P(B|A) = P(B).$$

This means that the probability of A does not depend on the occurrence or nonoccurrence of B, and conversely. This justifies the term "independent."

Independence of m Events. Similarly, m events $A_1, \cdots, A_m$ are called **independent** if

$$P(A_1 \cap \cdots \cap A_m) = P(A_1) \cdots P(A_m) \tag{15a}$$

as well as for every k different events $A_{j_1}, A_{j_2}, \cdots, A_{j_k}$,

$$P(A_{j_1} \cap A_{j_2} \cap \cdots \cap A_{j_k}) = P(A_{j_1})P(A_{j_2}) \cdots P(A_{j_k}) \tag{15b}$$

where $k = 2, 3, \cdots, m - 1$.

Accordingly, three events A, B, C are independent if and only if

$$\begin{aligned} P(A \cap B) &= P(A)P(B), \\ P(B \cap C) &= P(B)P(C), \\ P(C \cap A) &= P(C)P(A), \\ P(A \cap B \cap C) &= P(A)P(B)P(C). \end{aligned} \tag{16}$$

Sampling. Our next example has to do with randomly drawing objects, *one at a time,* from a given set of objects. This is called **sampling from a population,** and there are two ways of sampling, as follows.

1. In **sampling with replacement,** the object that was drawn at random is placed back to the given set and the set is mixed thoroughly. Then we draw the next object at random.
2. In **sampling without replacement** the object that was drawn is put aside.

EXAMPLE 6 Sampling With and Without Replacement

A box contains 10 screws, three of which are defective. Two screws are drawn at random. Find the probability that none of the two screws is defective.

Solution. We consider the events

A: First drawn screw nondefective.

B: Second drawn screw nondefective.

Clearly, $P(A) = \frac{7}{10}$ because 7 of the 10 screws are nondefective and we sample at random, so that each screw has the same probability ($\frac{1}{10}$) of being picked. If we sample with replacement, the situation before the second drawing is the same as at the beginning, and $P(B) = \frac{7}{10}$. The events are independent, and the answer is

$$P(A \cap B) = P(A)P(B) = 0.7 \cdot 0.7 = 0.49 = 49\%.$$

If we sample without replacement, then $P(A) = \frac{7}{10}$, as before. If A has occurred, then there are 9 screws left in the box, 3 of which are defective. Thus $P(B|A) = \frac{6}{9} = \frac{2}{3}$, and Theorem 4 yields the answer

$$P(A \cap B) = \frac{7}{10} \cdot \frac{2}{3} \approx 47\%.$$

Is it intuitively clear that this value must be smaller than the preceding one? ■

PROBLEM SET 24.3

1. Three screws are drawn at random from a lot of 100 screws, 10 of which are defective. Find the probability that the screws drawn will be nondefective in drawing (a) with replacement, (b) without replacement.
2. In Prob. 1 find the probability of *E: At least* 1 *defective* (i) directly, (ii) by using complements; in both cases (a) and (b).
3. If we inspect paper by drawing 5 sheets without replacement from every batch of 500, what is the probability of getting 5 clean sheets although 2% of the sheets contain spots? First guess.
4. Under what conditions will it make *practically* no difference whether we sample with or without replacement? Give numeric examples.
5. If you need a right-handed screw from a box containing 20 right-handed and 5 left-handed screws, what is the probability that you get at least one right-handed screw in drawing 2 screws with replacement?
6. If in Prob. 5 you draw without replacement, does the probability decrease or increase? First think, then calculate.
7. What gives the greater probability of hitting some target at least once: (a) hitting in a shot with probability 1/2 and firing 1 shot, or (b) hitting in a shot with probability 1/4 and firing 2 shots? First guess. Then calculate.
8. Suppose that we draw cards repeatedly and with replacement from a file of 100 cards, 50 of which refer to male and 50 to female persons. What is the probability of obtaining the second "female" card before the third "male" card?
9. What is the complementary event of the event considered in Prob. 8? Calculate its probability and use it to check your result in Prob. 8.
10. In rolling two fair dice, what is the probability of obtaining a sum greater than 4 but not exceeding 7?
11. In rolling two fair dice, what is the probability of obtaining equal numbers or numbers with an even product?
12. Solve Prob. 11 by considering complements.
13. A motor drives an electric generator. During a 30-day period, the motor needs repair with probability 8% and the generator needs repair with probability 4%. What is the probability that during a given period, the entire apparatus (consisting of a motor and a generator) will need repair?
14. If a circuit contains 3 automatic switches and we want that, with a probability of 95%, during a given time interval they are all working, what probability of failure per time interval can we admit for a single switch?
15. If a certain kind of tire has a life exceeding 25 000 miles with probability 0.95, what is the probability that a set of 4 of these tires on a car will last longer than 25 000 miles?
16. In Prob. 15, what is the probability that at least one of the tires will not last for 25 000 miles?
17. A pressure control apparatus contains 4 valves. The apparatus will not work unless all valves are operative. If the probability of failure of each valve during some interval of time is 0.03, what is the corresponding probability of failure of the apparatus?
18. Show that if B is a subset of A, then $P(B) \leqq P(A)$.
19. Extending Theorem 4, show that $P(A \cap B \cap C) = P(A)P(B|A)P(C|A \cap B)$.
20. You may wonder whether in (16) the last relation follows from the others, but the answer is no. To see this, imagine that a chip is drawn from a box containing 4 chips numbered 000, 011, 101, 110, and let A, B, C be the events that the first, second, and third digit, respectively, on the drawn chip is 1. Show that then the first three formulas in (16) hold but the last one does not hold.

24.4 Permutations and Combinations

Permutations and combinations help in finding probabilities $P(A) = a/k$ by ***systematically counting*** the number a of points of which an event A consists; here, k is the number of points of the sample space S. The practical difficulty is that a may often be surprisingly large, so that actual counting becomes hopeless. For example, if in assembling some instrument you need 10 different screws in a certain order and you want to draw them randomly from a box (which contains nothing else) the probability of obtaining them in the required order is only 1/3 628 800 because there are

$$10! = 1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8 \cdot 9 \cdot 10 = 3\,628\,800$$

orders in which they can be drawn. Similarly, in many other situations the numbers of orders, arrangements, etc. are often incredibly large. (If you are unimpressed, take 20 screws—how much bigger will the number be?)

Permutations

A **permutation** of given things (*elements* or *objects*) is an arrangement of these things in a row in some order. For example, for three letters a, b, c there are $3! = 1 \cdot 2 \cdot 3 = 6$ permutations: *abc*, *acb*, *bac*, *bca*, *cab*, *cba*. This illustrates (a) in the following theorem.

THEOREM 1

Permutations

(a) ***Different things.*** *The number of permutations of n different things taken all at a time is*

(1) $$n! = 1 \cdot 2 \cdot 3 \cdots n$$ (read *"n factorial"*).

(b) ***Classes of equal things.*** *If n given things can be divided into c classes of alike things differing from class to class, then the number of permutations of these things taken all at a time is*

(2) $$\frac{n!}{n_1!n_2! \cdots n_c!} \qquad (n_1 + n_2 + \cdots + n_c = n)$$

where n_j is the number of things in the jth class.

PROOF **(a)** There are n choices for filling the first place in the row. Then $n - 1$ things are still available for filling the second place, etc.

(b) n_1 alike things in class 1 make $n_1!$ permutations collapse into a single permutation (those in which class 1 things occupy the same n_1 positions), etc., so that (2) follows from (1). ∎

EXAMPLE 1 **Illustration of Theorem 1(b)**

If a box contains 6 red and 4 blue balls, the probability of drawing first the red and then the blue balls is

$$P = 6!4!/10! = 1/210 \approx 0.5\%.$$

■

A **permutation of n things taken k at a time** is a permutation containing only k of the n given things. Two such permutations consisting of the same k elements, in a different order, are different, by definition. For example, there are 6 different permutations of the three letters a, b, c, taken two letters at a time, ab, ac, bc, ba, ca, cb.

A **permutation of n things taken k at a time with repetitions** is an arrangement obtained by putting any given thing in the first position, any given thing, including a repetition of the one just used, in the second, and continuing until k positions are filled. For example, there are $3^2 = 9$ different such permutations of a, b, c taken 2 letters at a time, namely, the preceding 6 permutations and aa, bb, cc. You may prove (see Team Project 18):

THEOREM 2 **Permutations**

The number of different permutations of n different things taken k at a time without repetitions is

(3a)
$$n(n-1)(n-2)\cdots(n-k+1) = \frac{n!}{(n-k)!}$$

and with repetitions is

(3b)
$$n^k.$$

EXAMPLE 2 **Illustration of Theorem 2**

In a coded telegram the letters are arranged in groups of five letters, called *words*. From (3b) we see that the number of different such words is

$$26^5 = 11\,881\,376.$$

From (3a) it follows that the number of different such words containing each letter no more than once is

$$26!/(26-5)! = 26 \cdot 25 \cdot 24 \cdot 23 \cdot 22 = 7\,893\,600.$$

■

Combinations

In a permutation, the order of the selected things is essential. In contrast, a **combination** of given things means any selection of one or more things *without regard to order*. There are two kinds of combinations, as follows.

The number of **combinations of n different things, taken k at a time, without repetitions** is the number of sets that can be made up from the n given things, each set containing k different things and no two sets containing exactly the same k things.

The number of **combinations of n different things, taken k at a time, with repetitions** is the number of sets that can be made up of k things chosen from the given n things, each being used as often as desired.

For example, there are three combinations of the three letters a, b, c, taken two letters at a time, without repetitions, namely, ab, ac, bc, and six such combinations with repetitions, namely, ab, ac, bc, aa, bb, cc.

THEOREM 3

Combinations

The number of different combinations of n different things taken, k at a time, without repetitions, is

(4a) $$\binom{n}{k} = \frac{n!}{k!(n-k)!} = \frac{n(n-1)\cdots(n-k+1)}{1\cdot 2\cdots k},$$

and the number of those combinations with repetitions is

(4b) $$\binom{n+k-1}{k}.$$

PROOF The statement involving (4a) follows from the first part of Theorem 2 by noting that there are $k!$ *permutations* of k things from the given n things that differ by the order of the elements (see Theorem 1), but there is only a single *combination* of those k things of the type characterized in the first statement of Theorem 3. The last statement of Theorem 3 can be proved by induction (see Team Project 18). ■

EXAMPLE 3 **Illustration of Theorem 3**

The number of samples of five lightbulbs that can be selected from a lot of 500 bulbs is [see (4a)]

$$\binom{500}{5} = \frac{500!}{5!495!} = \frac{500\cdot 499\cdot 498\cdot 497\cdot 496}{1\cdot 2\cdot 3\cdot 4\cdot 5} = 255\,244\,687\,600.$$ ■

Factorial Function

In (1)–(4) the **factorial function** is basic. By definition,

(5) $$0! = 1.$$

Values may be computed recursively from given values by

(6) $$(n+1)! = (n+1)n!.$$

For large n the function is very large (see Table A3 in App. 5). A convenient approximation for large n is the **Stirling formula**[2]

(7) $$n! \sim \sqrt{2\pi n}\left(\frac{n}{e}\right)^n \qquad (e = 2.718\cdots)$$

[2]JAMES STIRLING (1692–1770), Scots mathematician.

where $\sim$ is read **"asymptotically equal"** and means that the ratio of the two sides of (7) approaches 1 as n approaches infinity.

EXAMPLE 4 **Stirling Formula**

$n!$	By (7)	Exact Value	Relative Error
4!	23.5	24	2.1%
10!	3 598 696	3 628 800	0.8%
20!	$2.422\,79 \cdot 10^{18}$	2 432 902 008 176 640 000	0.4%

Binomial Coefficients

The **binomial coefficients** are defined by the formula

$$\binom{a}{k} = \frac{a(a-1)(a-2)\cdots(a-k+1)}{k!} \qquad (k \geqq 0, \text{ integer}). \tag{8}$$

The numerator has k factors. Furthermore, we define

$$\binom{a}{0} = 1, \qquad \text{in particular,} \qquad \binom{0}{0} = 1. \tag{9}$$

For integer $a = n$ we obtain from (8)

$$\binom{n}{k} = \binom{n}{n-k} \qquad (n \geqq 0,\ 0 \leqq k \leqq n). \tag{10}$$

Binomial coefficients may be computed recursively, because

$$\binom{a}{k} + \binom{a}{k+1} = \binom{a+1}{k+1} \qquad (k \geqq 0, \text{ integer}). \tag{11}$$

Formula (8) also yields

$$\binom{-m}{k} = (-1)^k \binom{m+k-1}{k} \qquad \begin{matrix}(k \geqq 0, \text{ integer}) \\ (m > 0).\end{matrix} \tag{12}$$

There are numerous further relations; we mention two important ones,

$$\sum_{s=0}^{n-1} \binom{k+s}{k} = \binom{n+k}{k+1} \qquad \begin{matrix}(k \geqq 0,\ n \geqq 1, \\ \text{both integer})\end{matrix} \tag{13}$$

and

$$\sum_{k=0}^{r} \binom{p}{k} \binom{q}{r-k} = \binom{p+q}{r} \qquad (r \geqq 0, \text{ integer}). \tag{14}$$

PROBLEM SET 24.4

1. List all permutations of four digits 1, 2, 3, 4, taken all at a time.
2. List (a) all permutations, (b) all combinations without repetitions, (c) all combinations with repetitions, of 5 letters a, e, i, o, u taken 2 at a time.
3. In how many ways can we assign 8 workers to 8 jobs (one worker to each job and conversely)?
4. How many samples of 4 objects can be drawn from a lot of 80 objects?
5. In how many different ways can we choose a committee of 3 from 20 persons? First guess.
6. In how many different ways can we select a committee consisting of 3 engineers, 2 biologists, and 2 chemists from 10 engineers, 5 biologists, and 6 chemists? First guess.
7. Of a lot of 10 items, 2 are defective. (a) Find the number of different samples of 4. Find the number of samples of 4 containing (b) no defectives, (c) 1 defective, (d) 2 defectives.
8. If a cage contains 100 mice, two of which are male, what is the probability that the two male mice will be included if 12 mice are randomly selected?
9. An urn contains 2 blue, 3 green, and 4 red balls. We draw 1 ball at random and put it aside. Then we draw the next ball, and so on. Find the probability of drawing at first the 2 blue balls, then the 3 green ones, and finally the red ones.
10. By what factor is the probability in Prob. 9 decreased if the number of balls is doubled (4 blue, etc.)?
11. Determine the number of different bridge hands. (A bridge hand consists of 13 cards selected from a full deck of 52 cards.)
12. In how many different ways can 5 people be seated at a round table?
13. If 3 suspects who committed a burglary and 6 innocent persons are lined up, what is the probability that a witness who is not sure and has to pick three persons will pick the three suspects by chance? That the witness picks 3 innocent persons by chance?
14. **(Birthday problem)** What is the probability that in a group of 20 people (that includes no twins) at least two have the same birthday, if we assume that the probability of having birthday on a given day is 1/365 for every day. First guess.
15. How many different license plates showing 5 symbols, namely, 2 letters followed by 3 digits, could be made?
16. How many automobile registrations may the police have to check in a hit-and-run accident if a witness reports KDP5 and cannot remember the last two digits on the license plate but is certain that all three digits were different?
17. **CAS PROJECT. Stirling formula. (a)** Using (7), compute approximate values of $n!$ for $n = 1, \cdots, 20$.

    (b) Determine the relative error in (a). Find an empirical formula for that relative error.

    (c) An upper bound for that relative error is $e^{1/12n} - 1$. Try to relate your empirical formula to this.

    (d) Search through the literature for further information on Stirling's formula. Write a short report about your findings, arranged in logical order and illustrated with numeric examples.
18. **TEAM PROJECT. Permutations, Combinations.**

    (a) Prove Theorem 2.

    (b) Prove the last statement of Theorem 3.

    (c) Derive (11) from (8).

    (d) By the **binomial theorem,**

$$(a + b)^n = \sum_{k=0}^{n} \binom{n}{k} a^k b^{n-k},$$

    so that $a^k b^{n-k}$ has the coefficient $\binom{n}{k}$. Can you conclude this from Theorem 3 or is this a mere coincidence?

    (e) Prove (14) by using the binomial theorem.

    (f) Collect further formulas for binomial coefficients from the literature and illustrate them numerically.

24.5 Random Variables. Probability Distributions

In Sec. 24.1 we considered frequency distributions of data. These distributions show the absolute or relative frequency of the data values. Similarly, a **probability distribution** or, briefly, a **distribution,** shows the probabilities of events in an experiment. The quantity that we observe in an experiment will be denoted by X and called a **random variable** (or

stochastic variable) because the value it will assume in the next trial depends on chance, on **randomness**—if you roll a dice, you get one of the numbers from 1 to 6, but you don't know which one will show up next. Thus X = *Number a die turns up* is a random variable. So is X = *Elasticity of rubber* (elongation at break). ("Stochastic" means related to chance.)

If we ***count*** (cars on a road, defective screws in a production, tosses until a die shows the first Six), we have a **discrete random variable and distribution.** If we ***measure*** (electric voltage, rainfall, hardness of steel), we have a **continuous random variable and distribution.** Precise definitions follow. In both cases the distribution of X is determined by the **distribution function**

$$F(x) = P(X \leqq x); \tag{1}$$

this is the probability that in a trial, X will assume any value not exceeding x.

CAUTION! The terminology is not uniform. $F(x)$ is sometimes also called the **cumulative distribution function.**

For (1) to make sense in both the discrete and the continuous case we formulate conditions as follows.

DEFINITION

Random Variable

A **random variable** X is a function defined on the sample space S of an experiment. Its values are real numbers. For every number a the probability

$$P(X = a)$$

with which X assumes a is defined. Similarly, for any interval I the probability

$$P(X \in I)$$

with which X assumes any value in I is defined.

Although this definition is very general, practically only a very small number of distributions will occur over and over again in applications.

From (1) we obtain the fundamental formula for the probability corresponding to an interval $a < x \leqq b$,

$$P(a < X \leqq b) = F(b) - F(a). \tag{2}$$

This follows because $X \leqq a$ ("*X assumes any value not exceeding a*") and $a < X \leqq b$ ("*X assumes any value in the interval* $a < x \leqq b$") are mutually exclusive events, so that by (1) and Axiom 3 of Definition 2 in Sec. 24.3

$$\begin{aligned} F(b) = P(X \leqq b) &= P(X \leqq a) + P(a < X \leqq b) \\ &= F(a) + P(a < X \leqq b) \end{aligned}$$

and subtraction of $F(a)$ on both sides gives (2).

Discrete Random Variables and Distributions

By definition, a random variable X and its distribution are **discrete** if X assumes only finitely many or at most countably many values $x_1, x_2, x_3, \cdots$, called the **possible values** of X, with positive probabilities $p_1 = P(X = x_1)$, $p_2 = P(X = x_2)$, $p_3 = P(X = x_3)$, $\cdots$, whereas the probability $P(X \in I)$ is zero for any interval I containing no possible value.

Clearly, the discrete distribution of X is also determined by the **probability function** $f(x)$ of X, defined by

$$f(x) = \begin{cases} p_j & \text{if } x = x_j \\ 0 & \text{otherwise} \end{cases} \qquad (j = 1, 2, \cdots), \tag{3}$$

From this we get the values of the **distribution function** $F(x)$ by taking sums,

$$F(x) = \sum_{x_j \leqq x} f(x_j) = \sum_{x_j \leqq x} p_j \tag{4}$$

where for any given x we sum all the probabilities p_j for which x_j is smaller than or equal to that of x. This is a **step function** with upward jumps of size p_j at the possible values x_j of X and constant in between.

EXAMPLE 1 **Probability Function and Distribution Function**

Figure 512 shows the probability function $f(x)$ and the distribution function $F(x)$ of the discrete random variable

$$X = \textit{Number a fair die turns up.}$$

X has the possible values $x = 1, 2, 3, 4, 5, 6$ with probability 1/6 each. At these x the distribution function has upward jumps of magnitude 1/6. Hence from the graph of $f(x)$ we can construct the graph of $F(x)$, and conversely.

In Figure 512 (and the next one) at each jump the ***fat dot*** indicates the ***function value at the jump!*** ■

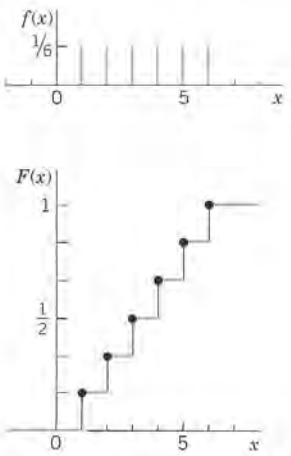

Fig. 512. Probability function $f(x)$ and distribution function $F(x)$ of the random variable X = *Number obtained in tossing a fair die once*

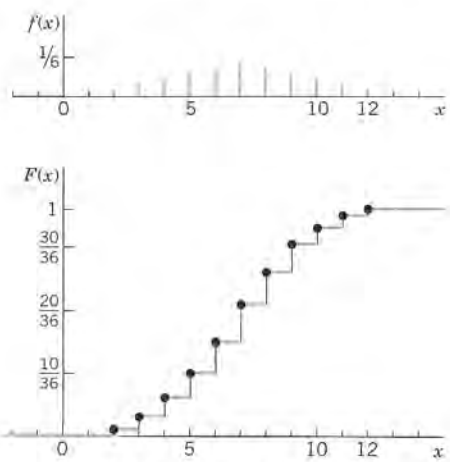

Fig. 513. Probability function $f(x)$ and distribution function $F(x)$ of the random variable X = *Sum of the two numbers obtained in tossing two fair dice once*

EXAMPLE 2 Probability Function and Distribution Function

The random variable X = *Sum of the two numbers two fair dice turn up* is discrete and has the possible values 2 (= 1 + 1), 3, 4, · · · , 12 (= 6 + 6). There are $6 \cdot 6 = 36$ equally likely outcomes (1, 1) (1, 2), · · · , (6, 6), where the first number is that shown on the first die and the second number that on the other die. Each such outcome has probability 1/36. Now $X = 2$ occurs in the case of the outcome (1, 1); $X = 3$ in the case of the two outcomes (1, 2) and (2, 1); $X = 4$ in the case of the three outcomes (1, 3), (2, 2), (3, 1); and so on. Hence $f(x) = P(X = x)$ and $F(x) = P(X \leqq x)$ have the values

x	2	3	4	5	6	7	8	9	10	11	12
$f(x)$	1/36	2/36	3/36	4/36	5/36	6/36	5/36	4/36	3/36	2/36	1/36
$F(x)$	1/36	3/36	6/36	10/36	15/36	21/36	26/36	30/36	33/36	35/36	36/36

Figure 513 shows a bar chart of this function and the graph of the distribution function, which is again a step function, with jumps (of different height!) at the possible values of X. ■

Two useful formulas for discrete distributions are readily obtained as follows. For the probability corresponding to intervals we have from (2) and (4)

$$\textbf{(5)} \qquad P(a < X \leqq b) = F(b) - F(a) = \sum_{a<x_j \leqq b} p_j \qquad (X \text{ discrete}).$$

This is the sum of all probabilities p_j for which x_j satisfies $a < x_j \leqq b$. (Be careful about $<$ and $\leqq$!) From this and $P(S) = 1$ (Sec. 24.3) we obtain the following formula.

$$\textbf{(6)} \qquad \sum_j p_j = 1 \qquad \text{(sum of all probabilities)}.$$

EXAMPLE 3 Illustration of Formula (5)

In Example 2, compute the probability of a sum of at least 4 and at most 8.

Solution. $P(3 < X \leqq 8) = F(8) - F(3) = \frac{26}{36} - \frac{3}{36} = \frac{23}{36}$. ■

EXAMPLE 4 Waiting Time Problem. Countably Infinite Sample Space

In tossing a fair coin, let X = *Number of trials until the first head appears.* Then, by independence of events (Sec. 24.3),

$$\begin{aligned} P(X = 1) &= P(H) = \tfrac{1}{2} && (H = \text{Head}) \\ P(X = 2) &= P(TH) = \tfrac{1}{2} \cdot \tfrac{1}{2} = \tfrac{1}{4} && (T = \text{Tail}) \\ P(X = 3) &= P(TTH) = \tfrac{1}{2} \cdot \tfrac{1}{2} \cdot \tfrac{1}{2} = \tfrac{1}{8}, \quad \text{etc.} \end{aligned}$$

and in general $P(X = n) = (\frac{1}{2})^n$, $n = 1, 2, \cdots$. Also, (6) can be confirmed by the sum formula for the geometric series,

$$\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \cdots = -1 + \frac{1}{1 - \frac{1}{2}}$$

$$= -1 + 2 = 1. \qquad ■$$

Continuous Random Variables and Distributions

Discrete random variables appear in experiments in which we ***count*** (defectives in a production, days of sunshine in Chicago, customers standing in a line, etc.). Continuous random variables appear in experiments in which we ***measure*** (lengths of screws, voltage in a power line, Brinell hardness of steel, etc.). By definition, a random variable X and its distribution are *of continuous type* or, briefly, **continuous,** if its distribution function $F(x)$ [defined in (1)] can be given by an integral

$$F(x) = \int_{-\infty}^{x} f(v)\, dv \tag{7}$$

(we write v because x is needed as the upper limit of the integral) whose integrand $f(x)$, called the **density** of the distribution, is nonnegative, and is continuous, perhaps except for finitely many x-values. Differentiation gives the relation of f to F as

$$f(x) = F'(x) \tag{8}$$

for every x at which $f(x)$ is continuous.

From (2) and (7) we obtain the very important formula for the probability corresponding to an interval:

$$P(a < X \leqq b) = F(b) - F(a) = \int_{a}^{b} f(v)\, dv. \tag{9}$$

This is the analog of (5).

From (7) and $P(S) = 1$ (Sec. 24.3) we also have the analog of (6):

$$\int_{-\infty}^{\infty} f(v)\, dv = 1. \tag{10}$$

Continuous random variables are ***simpler than discrete ones*** with respect to intervals. Indeed, in the continuous case the four probabilities corresponding to $a < X \leqq b$, $a < X < b$, $a \leqq X < b$, and $a \leqq X \leqq b$ with any fixed a and b $(> a)$ are all the same. Can you see why? (*Answer.* This probability is the area under the density curve, as in Fig. 514, and does not change by adding or subtracting a single point in the interval of integration.) This is different from the discrete case! (Explain.)

The next example illustrates notations and typical applications of our present formulas.

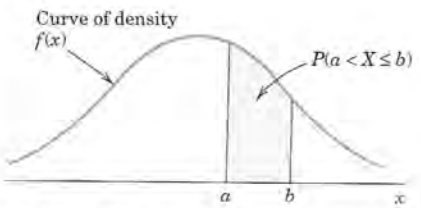

Fig. 514. Example illustrating formula (9)

EXAMPLE 5 **Continuous Distribution**

Let X have the density function $f(x) = 0.75(1 - x^2)$ if $-1 \leqq x \leqq 1$ and zero otherwise. Find the distribution function. Find the probabilities $P(-\frac{1}{2} \leqq X \leqq \frac{1}{2})$ and $P(\frac{1}{4} \leqq X \leqq 2)$. Find x such that $P(X \leqq x) = 0.95$.

Solution. From (7) we obtain $F(x) = 0$ if $x \leqq -1$,

$$F(x) = 0.75 \int_{-1}^{x} (1 - v^2)\, dv = 0.5 + 0.75x - 0.25x^3 \qquad \text{if } -1 < x \leqq 1,$$

and $F(x) = 1$ if $x > 1$. From this and (9) we get

$$P(-\tfrac{1}{2} \leqq X \leqq \tfrac{1}{2}) = F(\tfrac{1}{2}) - F(-\tfrac{1}{2}) = 0.75 \int_{-1/2}^{1/2} (1 - v^2)\, dv = 68.75\%$$

(because $P(-\frac{1}{2} \leqq X \leqq \frac{1}{2}) = P(-\frac{1}{2} < X \leqq \frac{1}{2})$ for a continuous distribution) and

$$P(\tfrac{1}{4} \leqq X \leqq 2) = F(2) - F(\tfrac{1}{4}) = 0.75 \int_{1/4}^{1} (1 - v^2)\, dv = 31.64\%.$$

(Note that the upper limit of integration is 1, not 2. Why?) Finally,

$$P(X \leqq x) = F(x) = 0.5 + 0.75x - 0.25x^3 = 0.95.$$

Algebraic simplification gives $3x - x^3 = 1.8$. A solution is $x = 0.73$, approximately.

Sketch $f(x)$ and mark $x = -\frac{1}{2}, \frac{1}{2}, \frac{1}{4}$, and 0.73, so that you can see the results (the probabilities) as areas under the curve. Sketch also $F(x)$. ■

Further examples of continuous distributions are included in the next problem set and in later sections.

PROBLEM SET 24.5

1. Graph the probability function $f(x) = kx^2$ ($x = 1, 2, 3, 4, 5$; k suitable) and the distribution function.
2. Graph the density function $f(x) = kx^2$ ($0 \leqq x \leqq 5$; k suitable) and the distribution function.
3. **(Uniform distribution)** Graph f and F when the density is $f(x) = k = const$ if $-4 \leqq x \leqq 4$ and 0 elsewhere.
4. In Prob. 3 find $P(0 \leqq x \leqq 4)$ and c such that $P(-c < X < c) = 95\%$.
5. Graph f and F when $f(-2) = f(2) = 1/8$, $f(-1) = f(1) = 3/8$. Can f have further positive values?
6. Graph the distribution function $F(x) = 1 - e^{-3x}$ if $x > 0$, $F(x) = 0$ if $x \leqq 0$, and the density $f(x)$. Find x such that $F(x) = 0.9$.
7. Let X be the number of years before a particular type of machine will need replacement. Assume that X has the probability function $f(1) = 0.1$, $f(2) = 0.2$, $f(3) = 0.2$, $f(4) = 0.2$, $f(5) = 0.3$. Graph f and F. Find the probability that the machine needs no replacement during the first 3 years.
8. If X has the probability function $f(x) = k/2^x$ ($x = 0, 1, 2, \cdots$), what are k and $P(X \geqq 4)$?
9. Find the probability that none of the three bulbs in a traffic signal must be replaced during the first 1200 hours of operation if the probability that a bulb must be replaced is a random variable X with density $f(x) = 6[0.25 - (x - 1.5)^2]$ when $1 \leqq x \leqq 2$ and $f(x) = 0$ otherwise, where x is time measured in multiples of 1000 hours.
10. Suppose that certain bolts have length $L = 200 + X$ mm, where X is a random variable with density $f(x) = \frac{3}{4}(1 - x^2)$ if $-1 \leqq x \leqq 1$ and 0 otherwise. Determine c so that with a probability of 95% a bolt will have any length between $200 - c$ and $200 + c$. *Hint:* See also Example 5.
11. Let X [millimeters] be the thickness of washers a machine turns out. Assume that X has the density $f(x) = kx$ if $1.9 < x < 2.1$ and 0 otherwise. Find k. What is the probability that a washer will have thickness between 1.95 mm and 2.05 mm?

12. Suppose that in an automatic process of filling oil into cans, the content of a can (in gallons) is $Y = 50 + X$, where X is a random variable with density $f(x) = 1 - |x|$ when $|x| \leqq 1$ and 0 when $|x| > 1$. Graph $f(x)$ and $F(x)$. In a lot of 100 cans, about how many will contain 50 gallons or more? What is the probability that a can will contain less than 49.5 gallons? Less than 49 gallons?

13. Let the random variable X with density $f(x) = ke^{-x}$ if $0 \leqq x \leqq 2$ and 0 otherwise (x = time measured in years) be the time after which certain ball bearings are worn out. Find k and the probability that a bearing will last at least 1 year.

14. Let X be the ratio of sales to profits of some firm. Assume that X has the distribution function $F(x) = 0$ if $x < 2$, $F(x) = (x^2 - 4)/5$ if $2 \leqq x < 3$, $F(x) = 1$ if $x \geqq 3$. Find and graph the density. What is the probability that X is between 2.5 (40% profit) and 5 (20% profit)?

15. Show that $b < c$ implies $P(X \leqq b) \leqq P(X \leqq c)$.

16. If the diameter X of axles has the density $f(x) = k$ if $119.9 \leqq x \leqq 120.1$ and 0 otherwise, how many defectives will a lot of 500 axles approximately contain if defectives are axles slimmer than 119.92 or thicker than 120.08?

17. Let X be a random variable that can assume every real value. What are the complements of the events $X \leqq b$, $X < b$, $X \geqq c$, $X > c$, $b \leqq X \leqq c$, $b < X \leqq c$?

18. A box contains 4 right-handed and 6 left-handed screws. Two screws are drawn at random without replacement. Let X be the number of left-handed screws drawn. Find the probabilities $P(X = 0)$, $P(X = 1)$, $P(X = 2)$, $P(1 < X < 2)$, $P(X \leqq 1)$, $P(X \geqq 1)$, $P(X > 1)$, and $P(0.5 < X < 10)$.

24.6 Mean and Variance of a Distribution

The mean μ and variance σ^2 of a random variable X and of its distribution are the theoretical counterparts of the mean $\bar{x}$ and variance s^2 of a frequency distribution in Sec. 24.1 and serve a similar purpose. Indeed, the mean characterizes the central location and the variance the spread (the variability) of the distribution. The **mean** μ (mu) is defined by

$$\text{(1)} \qquad \text{(a)} \quad \mu = \sum_j x_j f(x_j) \qquad \text{(Discrete distribution)}$$

$$\text{(b)} \quad \mu = \int_{-\infty}^{\infty} x f(x)\, dx \qquad \text{(Continuous distribution)}$$

and the **variance** σ^2 (sigma square) by

$$\text{(2)} \qquad \text{(a)} \quad \sigma^2 = \sum_j (x_j - \mu)^2 f(x_j) \qquad \text{(Discrete distribution)}$$

$$\text{(b)} \quad \sigma^2 = \int_{-\infty}^{\infty} (x - \mu)^2 f(x)\, dx \qquad \text{(Continuous distribution).}$$

σ (the positive square root of σ^2) is called the **standard deviation** of X and its distribution. f is the probability function or the density, respectively, in (a) and (b).

The mean μ is also denoted by $E(X)$ and is called the **expectation** *of* X because it gives the average value of X to be expected in many trials. Quantities such as μ and σ^2 that measure certain properties of a distribution are called **parameters.** μ and σ^2 are the two most important ones. From (2) we see that

$$\text{(3)} \qquad \sigma^2 > 0$$

(except for a discrete "distribution" with only one possible value, so that $\sigma^2 = 0$). We assume that μ and σ^2 exist (are finite), as is the case for practically all distributions that are useful in applications.

EXAMPLE 1 **Mean and Variance**

The random variable X = *Number of heads in a single toss of a fair coin* has the possible values $X = 0$ and $X = 1$ with probabilities $P(X = 0) = \frac{1}{2}$ and $P(X = 1) = \frac{1}{2}$. From (1a) we thus obtain the mean $\mu = 0 \cdot \frac{1}{2} + 1 \cdot \frac{1}{2} = \frac{1}{2}$, and (2a) yields the variance

$$\sigma^2 = (0 - \tfrac{1}{2})^2 \cdot \tfrac{1}{2} + (1 - \tfrac{1}{2})^2 \cdot \tfrac{1}{2} = \tfrac{1}{4}.$$

EXAMPLE 2 **Uniform Distribution. Variance Measures Spread**

The distribution with the density

$$f(x) = \frac{1}{b - a} \qquad \text{if} \qquad a < x < b$$

and $f = 0$ otherwise is called the **uniform distribution** on the interval $a < x < b$. From (1b) (or from Theorem 1, below) we find that $\mu = (a + b)/2$, and (2b) yields the variance

$$\sigma^2 = \int_a^b \left(x - \frac{a + b}{2}\right)^2 \frac{1}{b - a}\, dx = \frac{(b - a)^2}{12}.$$

Figure 515 illustrates that the spread is large if and only if σ^2 is large.

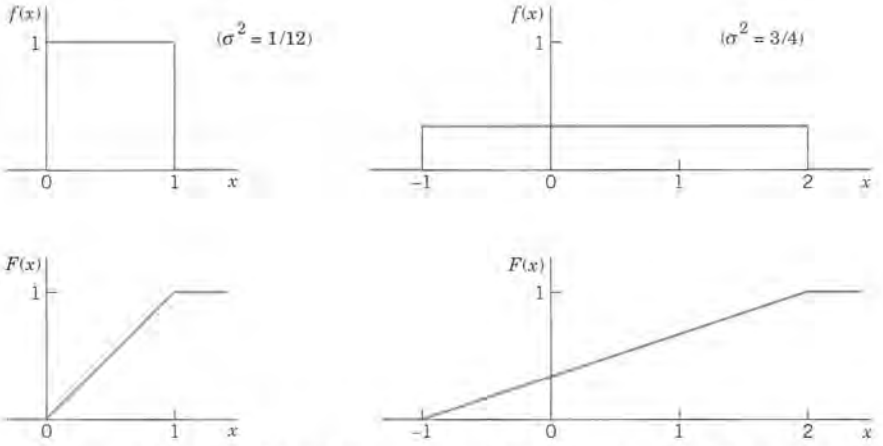

Fig. 515. Uniform distributions having the same mean (0.5) but different variances σ^2

Symmetry. We can obtain the mean μ without calculation if a distribution is symmetric. Indeed, you may prove

THEOREM 1 **Mean of a Symmetric Distribution**

If a distribution is **symmetric** *with respect to $x = c$, that is, $f(c - x) = f(c + x)$, then $\mu = c$.* (Examples 1 and 2 illustrate this.)

Transformation of Mean and Variance

Given a random variable X with mean μ and variance σ^2, we want to calculate the mean and variance of $X^* = a_1 + a_2X$, where a_1 and a_2 are given constants. This problem is important in statistics, where it appears often.

THEOREM 2

Transformation of Mean and Variance

(a) *If a random variable X has mean μ and variance σ^2, then the random variable*

$$X^* = a_1 + a_2X \qquad (a_2 > 0) \tag{4}$$

has the mean μ^* and variance σ^{*2}, where

$$\mu^* = a_1 + a_2\mu \qquad \text{and} \qquad \sigma^{*2} = a_2{}^2\sigma^2. \tag{5}$$

(b) *In particular, the* **standardized random variable** *Z corresponding to X, given by*

$$Z = \frac{X - \mu}{\sigma} \tag{6}$$

has the mean 0 and the variance 1.

PROOF We prove (5) for a continuous distribution. To a small interval I of length Δx on the x-axis there corresponds the probability $f(x)\Delta x$ [approximately; the area of a rectangle of base Δx and height $f(x)$]. Then the probability $f(x)\Delta x$ must equal that for the corresponding interval on the x^*-axis, that is, $f^*(x^*)\Delta x^*$, where f^* is the density of X^* and Δx^* is the length of the interval on the x^*-axis corresponding to I. Hence for differentials we have $f^*(x^*)\,dx^* = f(x)\,dx$. Also, $x^* = a_1 + a_2x$ by (4), so that (1b) applied to X^* gives

$$\begin{aligned}\mu^* &= \int_{-\infty}^{\infty} x^* f^*(x^*)\,dx^* \\ &= \int_{-\infty}^{\infty} (a_1 + a_2x) f(x)\,dx \\ &= a_1 \int_{-\infty}^{\infty} f(x)\,dx + a_2 \int_{-\infty}^{\infty} xf(x)\,dx.\end{aligned}$$

On the right the first integral equals 1, by (10) in Sec. 24.5. The second integral is μ. This proves (5) for μ^*. It implies

$$x^* - \mu^* = (a_1 + a_2x) - (a_1 + a_2\mu) = a_2(x - \mu).$$

From this and (2) applied to X^*, again using $f^*(x^*)\,dx^* = f(x)\,dx$, we obtain the second formula in (5),

$$\sigma^{*2} = \int_{-\infty}^{\infty} (x^* - \mu^*)^2 f^*(x^*)\,dx^* = a_2{}^2 \int_{-\infty}^{\infty} (x - \mu)^2 f(x)\,dx = a_2{}^2\sigma^2.$$

For a discrete distribution the proof of (5) is similar.

Choosing $a_1 = -\mu/\sigma$ and $a_2 = 1/\sigma$ we obtain (6) from (4), writing $X^* = Z$. For these a_1, a_2 formula (5) gives $\mu^* = 0$ and $\sigma^{*2} = 1$, as claimed in (b). ∎

Expectation, Moments

Recall that (1) defines the expectation (the mean) of X, the value of X to be expected on the average, written $\mu = E(X)$. More generally, if $g(x)$ is nonconstant and continuous for all x, then $g(X)$ is a random variable. Hence its *mathematical expectation* or, briefly, its **expectation** $E(g(X))$ is the value of $g(X)$ to be expected on the average, defined [similarly to (1)] by

$$\textbf{(7)} \qquad E(g(X)) = \sum_j g(x_j)f(x_j) \qquad \text{or} \qquad E(g(X)) = \int_{-\infty}^{\infty} g(x)f(x)\,dx.$$

In the first formula, f is the probability function of the discrete random variable X. In the second formula, f is the density of the continuous random variable X. Important special cases are the ***k*th moment** of X (where $k = 1, 2, \cdots$)

$$\textbf{(8)} \qquad E(X^k) = \sum_j x_j^k f(x_j) \qquad \text{or} \qquad \int_{-\infty}^{\infty} x^k f(x)\,dx$$

and the ***k*th central moment** of X ($k = 1, 2, \cdots$)

$$\textbf{(9)} \qquad E([X - \mu]^k) = \sum_j (x_j - \mu)^k f(x_j) \qquad \text{or} \qquad \int_{-\infty}^{\infty} (x - \mu)^k f(x)\,dx.$$

This includes the first moment, the **mean** of X

$$\textbf{(10)} \qquad \mu = E(X) \qquad [(8) \text{ with } k = 1].$$

It also includes the second central moment, the **variance** of X

$$\textbf{(11)} \qquad \sigma^2 = E([X - \mu]^2) \qquad [(9) \text{ with } k = 2].$$

For later use you may prove

$$(12) \qquad E(1) = 1.$$

PROBLEM SET 24.6

1–6 MEAN, VARIANCE

Find the mean and the variance of the random variable X with probability function or density $f(x)$.

1. $f(x) = 2x \quad (0 \leqq x \leqq 1)$
2. $f(0) = 0.512, \quad f(1) = 0.384, \quad f(2) = 0.096, \quad f(3) = 0.008$
3. $X =$ *Number a fair die turns up*
4. $Y = -4X + 5$ with X as in Prob. 1
5. Uniform distribution on $[0, 8]$
6. $f(x) = 2e^{-2x} \quad (x \geqq 0)$
7. What is the expected daily profit if a store sells X air conditioners per day with probability $f(10) = 0.1$, $f(11) = 0.3$, $f(12) = 0.4$, $f(13) = 0.2$ and the profit per conditioner is \$55?
8. What is the mean life of a light bulb whose life X [hours] has the density $f(x) = 0.001e^{-0.001x}$ $(x \geqq 0)$?
9. If the mileage (in multiples of 1000 mi) after which a tire must be replaced is given by the random variable X with density $f(x) = \theta e^{-\theta x}$ $(x > 0)$, what mileage can you expect to get on one of these tires? Let $\theta = 0.04$ and find the probability that a tire will last at least 40000 mi.

10. What sum can you expect in rolling a fair die 10 times? Do it. Repeat this experiment 20 times and record how the sum varies.

11. A small filling station is supplied with gasoline every Saturday afternoon. Assume that its volume X of sales in ten thousands of gallons has the probability density $f(x) = 6x(1 - x)$ if $0 \leqq x \leqq 1$ and 0 otherwise. Determine the mean, the variance, and the standardized variable.

12. What capacity must the tank in Prob. 11 have in order that the probability that the tank will be emptied in a given week be 5%?

13. Let X [cm] be the diameter of bolts in a production. Assume that X has the density $f(x) = k(x - 0.9)(1.1 - x)$ if $0.9 < x < 1.1$ and 0 otherwise. Determine k, sketch $f(x)$, and find μ and σ^2.

14. Suppose that in Prob. 13, a bolt is regarded as being defective if its diameter deviates from 1.00 cm by more than 0.09 cm. What percentage of defective bolts should we then expect?

15. For what choice of the maximum possible deviation c from 1.00 cm shall we obtain 3% defectives in Probs. 13 and 14?

16. TEAM PROJECT. Means, Variances, Expectations.
(a) Show that $E(X - \mu) = 0$, $\sigma^2 = E(X^2) - \mu^2$.

(b) Prove (10)–(12).

(c) Find all the moments of the uniform distribution on an interval $a \leqq x \leqq b$.

(d) The **skewness** γ of a random variable X is defined by

$$\gamma = \frac{1}{\sigma^3} E([X - \mu]^3). \tag{13}$$

Show that for a symmetric distribution (whose third central moment exists) the skewness is zero.

(e) Find the skewness of the distribution with density $f(x) = xe^{-x}$ when $x > 0$ and $f(x) = 0$ otherwise. Sketch $f(x)$.

(f) Calculate the skewness of a few simple discrete distributions of your own choice.

(g) Find a nonsymmetric discrete distribution with 3 possible values, mean 0, and skewness 0.

24.7 Binomial, Poisson, and Hypergeometric Distributions

These are the three most important ***discrete*** distributions, with numerous applications.

Binomial Distribution

The **binomial distribution** occurs in games of chance (rolling a die, see below, etc.), quality inspection (e.g., counting of the number of defectives), opinion polls (counting number of employees favoring certain schedule changes, etc.), medicine (e.g., recording the number of patients recovered by a new medication), and so on. The conditions of its occurrence are as follows.

We are interested in the number of times an event A occurs in n independent trials. In each trial the event A has the same probability $P(A) = p$. Then in a trial, A will not occur with probability $q = 1 - p$. In n trials the random variable that interests us is

$$X = \textit{Number of times the event } A \textit{ occurs in } n \textit{ trials.}$$

X can assume the values $0, 1, \cdots, n$, and we want to determine the corresponding probabilities. Now $X = x$ means that A occurs in x trials and in $n - x$ trials it does not occur. This may look as follows.

$$(1) \qquad \underbrace{A \quad A \cdots A}_{x \text{ times}} \qquad \underbrace{B \quad B \cdots B}_{n-x \text{ times}}.$$

Here $B = A^c$ is the complement of A, meaning that A does not occur (Sec. 24.2). We now use the assumption that the trials are independent, that is, they do not influence each other. Hence (1) has the probability (see Sec. 24.3 on independent events)

$$(1^*) \qquad \underbrace{pp \cdots p}_{x \text{ times}} \cdot \underbrace{qq \cdots q}_{n-x \text{ times}} = p^x q^{n-x}.$$

Now (1) is just one order of arranging x A's and $n - x$ B's. We now use Theorem 1(b) in Sec. 24.4, which gives the number of permutations of n things (the n outcomes of the n trials) consisting of 2 classes, class 1 containing the $n_1 = x$ A's and class 2 containing the $n - n_1 = n - x$ B's. This number is

$$\frac{n!}{x!(n-x)!} = \binom{n}{x}.$$

Accordingly, (1*) multiplied by this binomial coefficient gives the probability $P(X = x)$ of $X = x$, that is, of obtaining A precisely x times in n trials. Hence X has the probability function

$$\textbf{(2)} \qquad f(x) = \binom{n}{x} p^x q^{n-x} \qquad (x = 0, 1, \cdots, n)$$

and $f(x) = 0$ otherwise. The distribution of X with probability function (2) is called the **binomial distribution** or *Bernoulli distribution.* The occurrence of A is called *success* (regardless of what it actually is; it may mean that you miss your plane or lose your watch) and the nonoccurrence of A is called *failure.* Figure 516 shows typical examples. Numeric values can be obtained from Table A5 in App. 5 or from your CAS.

The mean of the binomial distribution is (see Team Project 16)

$$\textbf{(3)} \qquad \mu = np$$

and the variance is (see Team Project 16)

$$\textbf{(4)} \qquad \sigma^2 = npq.$$

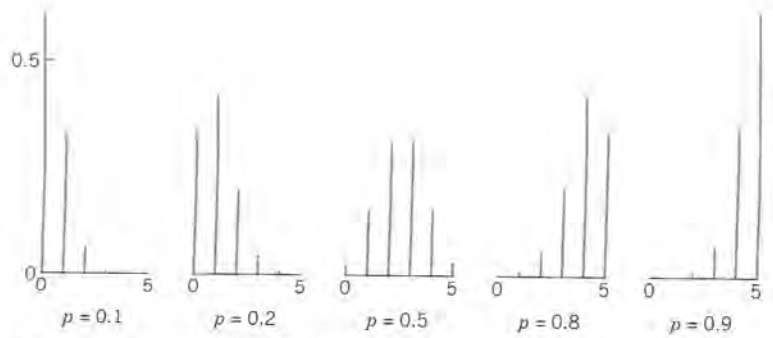

Fig. 516. Probability function (2) of the binomial distribution for $n = 5$ and various values of p

For the ***symmetric case*** of equal chance of success and failure ($p = q = 1/2$) this gives the mean $n/2$, the variance $n/4$, and the probability function

$$\textbf{(2*)} \qquad f(x) = \binom{n}{x}\left(\frac{1}{2}\right)^n \qquad (x = 0, 1, \cdots, n).$$

EXAMPLE 1 **Binomial Distribution**

Compute the probability of obtaining at least two *"Six"* in rolling a fair die 4 times.

Solution. $p = P(A) = P(\text{"}Six\text{"}) = 1/6$, $q = 5/6$, $n = 4$. The event *"At least two 'Six'"* occurs if we obtain 2 or 3 or 4 "Six." Hence the answer is

$$P = f(2) + f(3) + f(4) = \binom{4}{2}\left(\frac{1}{6}\right)^2\left(\frac{5}{6}\right)^2 + \binom{4}{3}\left(\frac{1}{6}\right)^3\left(\frac{5}{6}\right) + \binom{4}{4}\left(\frac{1}{6}\right)^4$$

$$= \frac{1}{6^4}(6 \cdot 25 + 4 \cdot 5 + 1) = \frac{171}{1296} = 13.2\%. \qquad \blacksquare$$

Poisson Distribution

The discrete distribution with infinitely many possible values and probability function

$$\textbf{(5)} \qquad f(x) = \frac{\mu^x}{x!}e^{-\mu} \qquad (x = 0, 1, \cdots)$$

is called the **Poisson distribution,** named after S. D. Poisson (Sec. 18.5). Figure 517 shows (5) for some values of μ. It can be proved that this distribution is obtained as a limiting case of the binomial distribution, if we let $p \to 0$ and $n \to \infty$ so that the mean $\mu = np$ approaches a finite value. (For instance, $\mu = np$ may be kept constant.) The Poisson distribution has the mean μ and the variance (see Team Project 16)

$$\textbf{(6)} \qquad \sigma^2 = \mu.$$

Figure 517 gives the impression that with increasing mean the spread of the distribution increases, thereby illustrating formula (6), and that the distribution becomes more and more (approximately) symmetric.

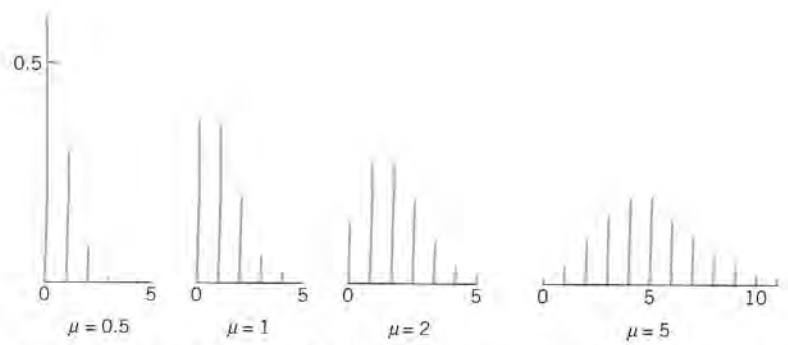

Fig. 517. Probability function (5) of the Poisson distribution for various values of μ

EXAMPLE 2 Poisson Distribution

If the probability of producing a defective screw is $p = 0.01$, what is the probability that a lot of 100 screws will contain more than 2 defectives?

Solution. The complementary event is A^c: *Not more than* 2 *defectives.* For its probability we get from the binomial distribution with mean $\mu = np = 1$ the value [see (2)]

$$P(A^c) = \binom{100}{0} 0.99^{100} + \binom{100}{1} 0.01 \cdot 0.99^{99} + \binom{100}{2} 0.01^2 \cdot 0.99^{98}.$$

Since p is very small, we can approximate this by the much more convenient Poisson distribution with mean $\mu = np = 100 \cdot 0.01 = 1$, obtaining [see (5)]

$$P(A^c) \approx e^{-1}\left(1 + 1 + \frac{1}{2}\right)$$

$$= 91.97\%.$$

Thus $P(A) = 8.03\%$. Show that the binomial distribution gives $P(A) = 7.94\%$, so that the Poisson approximation is quite good. ■

EXAMPLE 3 Parking Problems. Poisson Distribution

If on the average, 2 cars enter a certain parking lot per minute, what is the probability that during any given minute 4 or more cars will enter the lot?

Solution. To understand that the Poisson distribution is a model of the situation, we imagine the minute to be divided into very many short time intervals, let p be the (constant) probability that a car will enter the lot during any such short interval, and assume independence of the events that happen during those intervals. Then we are dealing with a binomial distribution with very large n and very small p, which we can approximate by the Poisson distribution with

$$\mu = np = 2,$$

because 2 cars enter on the average. The complementary event of the event "4 cars or more during a given minute" is "3 *cars or fewer enter the lot*" and has the probability

$$f(0) + f(1) + f(2) + f(3) = e^{-2}\left(\frac{2^0}{0!} + \frac{2^1}{1!} + \frac{2^2}{2!} + \frac{2^3}{3!}\right)$$

$$= 0.857.$$

Answer: 14.3%. (Why did we consider that complement?) ■

Sampling with Replacement

This means that we draw things from a given set one by one, and after each trial we replace the thing drawn (put it back to the given set and mix) before we draw the next thing. This guarantees independence of trials and leads to the **binomial distribution.** Indeed, if a box contains N things, for example, screws, M of which are defective, the probability of drawing a defective screw in a trial is $p = M/N$. Hence the probability of drawing a nondefective screw is $q = 1 - p = 1 - M/N$, and (2) gives the probability of drawing x defectives in n trials in the form

(7) $$f(x) = \binom{n}{x}\left(\frac{M}{N}\right)^x\left(1 - \frac{M}{N}\right)^{n-x} \qquad (x = 0, 1, \cdots, n).$$

Sampling without Replacement. Hypergeometric Distribution

Sampling without replacement means that we return no screw to the box. Then we no longer have independence of trials (why?), and instead of (7) the probability of drawing x defectives in n trials is

$$\textbf{(8)} \qquad f(x) = \frac{\binom{M}{x}\binom{N-M}{n-x}}{\binom{N}{n}} \qquad (x = 0, 1, \cdots, n).$$

The distribution with this probability function is called the **hypergeometric distribution** (because its moment generating function (see Team Project 16) can be expressed by the hypergeometric function defined in Sec. 5.4, a fact that we shall not use).

Derivation of (8). By (4a) in Sec. 24.4 there are

(a) $\binom{N}{n}$ different ways of picking n things from N,

(b) $\binom{M}{x}$ different ways of picking x defectives from M,

(c) $\binom{N-M}{n-x}$ different ways of picking $n - x$ nondefectives from $N - M$,

and each way in (b) combined with each way in (c) gives the total number of mutually exclusive ways of obtaining x defectives in n drawings without replacement. Since (a) is the total number of outcomes and we draw at random, each such way has the probability $1\Big/\binom{N}{n}$. From this, (8) follows. ∎

The hypergeometric distribution has the mean (Team Project 16)

$$\textbf{(9)} \qquad \mu = n\frac{M}{N}$$

and the variance

$$\textbf{(10)} \qquad \sigma^2 = \frac{nM(N-M)(N-n)}{N^2(N-1)}.$$

EXAMPLE 4 **Sampling with and without Replacement**

We want to draw random samples of two gaskets from a box containing 10 gaskets, three of which are defective. Find the probability function of the random variable X = *Number of defectives in the sample.*

Solution. We have $N = 10$, $M = 3$, $N - M = 7$, $n = 2$. For sampling with replacement, (7) yields

$$f(x) = \binom{2}{x}\left(\frac{3}{10}\right)^x\left(\frac{7}{10}\right)^{2-x}, \qquad f(0) = 0.49, \quad f(1) = 0.42, \quad f(2) = 0.09.$$

For sampling without replacement we have to use (8), finding

$$f(x) = \binom{3}{x}\binom{7}{2-x}\Big/\binom{10}{2}. \qquad f(0) = f(1) = \frac{21}{45} \approx 0.47, \quad f(2) = \frac{3}{45} \approx 0.07.$$ ∎

If N, M, and $N - M$ are large compared with n, then it does not matter too much whether we sample with or without replacement, and in this case the hypergeometric distribution may be approximated by the binomial distribution (with $p = M/N$), *which is somewhat simpler.*

Hence in sampling from an indefinitely large population (**"infinite population"**) *we may use the binomial distribution, regardless of whether we sample with or without replacement.*

PROBLEM SET 24.7

1. Four fair coins are tossed simultaneously. Find the probability function of the random variable $X =$ *Number of heads* and compute the probabilities of obtaining no heads, precisely 1 head, at least 1 head, not more than 3 heads.
2. If the probability of hitting a target in a single shot is 10% and 10 shots are fired independently, what is the probability that the target will be hit at least once?
3. In Prob. 2, if the probability of hitting would be 5% and we fired 20 shots, would the probability of hitting at least once be less than, equal to, or greater than in Prob. 2? Guess first, then compute.
4. Suppose that 3% of bolts made by a machine are defective, the defectives occurring at random during production. If the bolts are packaged 50 per box, what is the Poisson approximation of the probability that a given box will contain $x = 0, 1, \cdots, 5$ defectives?
5. Let X be the number of cars per minute passing a certain point of some road between 8 A.M. and 10 A.M. on a Sunday. Assume that X has a Poisson distribution with mean 5. Find the probability of observing 3 or fewer cars during any given minute.
6. Suppose that a telephone switchboard of some company on the average handles 300 calls per hour, and that the board can make at most 10 connections per minute. Using the Poisson distribution, estimate the probability that the board will be overtaxed during a given minute. (Use Table A6 in App. 5 or your CAS.)
7. **(Rutherford–Geiger experiments)** In 1910, E. Rutherford and H. Geiger showed experimentally that the number of alpha particles emitted per second in a radioactive process is a random variable X having a Poisson distribution. If X has mean 0.5, what is the probability of observing two or more particles during any given second?
8. A process of manufacturing screws is checked every hour by inspecting n screws selected at random from that hour's production. If one or more screws are defective, the process is halted and carefully examined. How large should n be if the manufacturer wants the probability to be about 95% that the process will be halted when 10% of the screws being produced are defective? (Assume independence of the quality of any screw of that of the other screws.)
9. Suppose that in the production of 50-Ω resistors, nondefective items are those that have a resistance between 45 Ω and 55 Ω and the probability of a resistor's being defective is 0.2%. The resistors are sold in lots of 100, with the guarantee that all resistors are nondefective. What is the probability that a given lot will violate this guarantee? (Use the Poisson distribution.)
10. Let $p = 1\%$ be the probability that a certain type of lightbulb will fail in a 24-hr test. Find the probability that a sign consisting of 10 such bulbs will burn 24 hours with no bulb failures.
11. Guess how much less the probability in Prob. 10 would be if the sign consisted of 100 bulbs. Then calculate.
12. Suppose that a certain type of magnetic tape contains, on the average, 2 defects per 100 meters. What is the probability that a roll of tape 300 meters long will contain (a) x defects, (b) no defects?
13. Suppose that a test for extrasensory perception consists of naming (in any order) 3 cards randomly drawn from a deck of 13 cards. Find the probability that by chance alone, the person will correctly name (a) no cards, (b) 1 card, (c) 2 cards, (d) 3 cards.
14. A carton contains 20 fuses, 5 of which are defective. Find the probability that, if a sample of 3 fuses is chosen from the carton by random drawing without replacement, x fuses in the sample will be defective.
15. **(Multinomial distribution)** Suppose a trial can result in precisely one of k mutually exclusive events $A_1, \cdots, A_k$ with probabilities $p_1, \cdots, p_k$, respectively, where $p_1 + \cdots + p_k = 1$. Suppose that n independent trials are performed. Show that the probability of getting x_1 A_1's, $\cdots$, x_k A_k's is

$$f(x_1, \cdots, x_k) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k}$$

where $0 \leqq x_j \leqq n$, $j = 1, \cdots, k$, and $x_1 + \cdots + x_k = n$. The distribution having this

probability function is called the *multinomial distribution.*

16. TEAM PROJECT. Moment Generating Function. The moment generating function $G(t)$ is defined by

$$G(t) = E(e^{tX_j}) = \sum_j e^{tx_j} f(x_j)$$

or

$$G(t) = E(e^{tX}) = \int_{-\infty}^{\infty} e^{tx} f(x)\, dx$$

where X is a discrete or continuous random variable, respectively.

(a) Assuming that termwise differentiation and differentiation under the integral sign are permissible, show that $E(X^k) = G^{(k)}(0)$, where $G^{(k)} = d^k G/dt^k$, in particular, $\mu = G'(0)$.

(b) Show that the binomial distribution has the moment generating function

$$G(t) = \sum_{x=0}^{n} e^{tx} \binom{n}{x} p^x q^{n-x} = \sum_{x=0}^{n} \binom{n}{x} (pe^t)^x q^{n-x} = (pe^t + q)^n.$$

(c) Using (b), prove (3).

(d) Prove (4).

(e) Show that the Poisson distribution has the moment generating function $G(t) = e^{-\mu} e^{\mu e^t}$ and prove (6).

(f) Prove $x \binom{M}{x} = M \binom{M-1}{x-1}$.

Using this, prove (9).

24.8 Normal Distribution

Turning from discrete to continuous distributions, in this section we discuss the normal distribution. This is the most important continuous distribution because in applications many random variables are **normal random variables** (that is, they have a normal distribution) or they are approximately normal or can be transformed into normal random variables in a relatively simple fashion. Furthermore, the normal distribution is a useful approximation of more complicated distributions, and it also occurs in the proofs of various statistical tests.

The **normal distribution** or *Gauss distribution* is defined as the distribution with the density

$$\textbf{(1)} \qquad f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \qquad (\sigma > 0)$$

where exp is the exponential function with base $e = 2.718\cdots$. This is simpler than it may at first look. $f(x)$ has these features (see also Fig. 518).

1. μ is the mean and σ the standard deviation.

2. $1/(\sigma\sqrt{2\pi})$ is a constant factor that makes the area under the curve of $f(x)$ from $-\infty$ to ∞ equal to 1, as it must be by (10), Sec. 24.5.

3. The curve of $f(x)$ is symmetric with respect to $x = \mu$ because the exponent is quadratic. Hence for $\mu = 0$ it is symmetric with respect to the y-axis $x = 0$ (Fig. 518, *"bell-shaped curves"*).

4. The exponential function in (1) goes to zero very fast—the faster the smaller the standard deviation σ is, as it should be (Fig. 518).

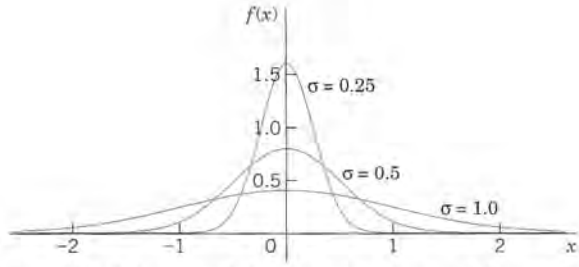

Fig. 518. Density (1) of the normal distribution with $\mu = 0$ for various values of σ

Distribution Function $F(x)$

From (7) in Sec. 24.5 and (1) we see that the normal distribution has the **distribution function**

$$\textbf{(2)} \qquad F(x) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{x} \exp\left[-\frac{1}{2}\left(\frac{v-\mu}{\sigma}\right)^2\right] dv.$$

Here we needed x as the upper limit of integration and wrote v (instead of x) in the integrand.

For the corresponding **standardized normal distribution** with mean 0 and standard deviation 1 we denote $F(x)$ by $\Phi(z)$. Then we simply have from (2)

$$\textbf{(3)} \qquad \Phi(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{z} e^{-u^2/2}\, du.$$

This integral cannot be integrated by one of the methods of calculus. But this is no serious handicap because its values can be obtained from Table A7 in App. 5 or from your CAS. These values are needed in working with the normal distribution. The curve of $\Phi(z)$ is S-shaped. It increases monotone (why?) from 0 to 1 and intersects the vertical axis at 1/2 (why?), as shown in Fig. 519.

Relation Between $F(x)$ and $\Phi(z)$. Although your CAS will give you values of $F(x)$ in (2) with any μ and σ directly, it is important to comprehend that and why any such an $F(x)$ can be expressed in terms of the tabulated standard $\Phi(z)$, as follows.

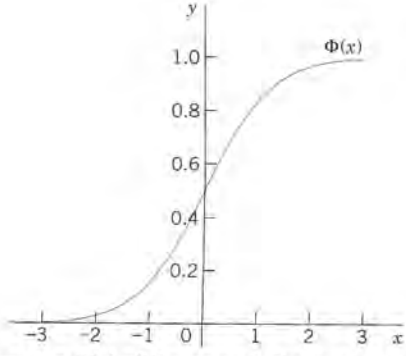

Fig. 519. Distribution function $\Phi(z)$ of the normal distribution with mean 0 and variance 1

THEOREM 1

Use of the Normal Table A7 in App. 5

The distribution function $F(x)$ of the normal distribution with any μ and σ [see (2)] *is related to the standardized distribution function $\Phi(z)$ in* (3) *by the formula*

$$F(x) = \Phi\left(\frac{x - \mu}{\sigma}\right). \tag{4}$$

PROOF Comparing (2) and (3) we see that we should set

$$u = \frac{v - \mu}{\sigma}. \qquad \text{Then } v = x \text{ gives} \qquad u = \frac{x - \mu}{\sigma}$$

as the new upper limit of integration. Also $v - \mu = \sigma u$, thus $dv = \sigma\, du$. Together, since σ drops out,

$$F(x) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{(x-\mu)/\sigma} e^{-u^2/2}\, \sigma\, du = \Phi\left(\frac{x - \mu}{\sigma}\right). \qquad \blacksquare$$

Probabilities corresponding to intervals will be needed quite frequently in statistics in Chap. 25. These are obtained as follows.

THEOREM 2

Normal Probabilities for Intervals

The probability that a normal random variable X with mean μ and standard deviation σ assume any value in an interval $a < x \leqq b$ is

$$P(a < X \leqq b) = F(b) - F(a) = \Phi\left(\frac{b - \mu}{\sigma}\right) - \Phi\left(\frac{a - \mu}{\sigma}\right). \tag{5}$$

PROOF Formula (2) in Sec. 24.5 gives the first equality in (5), and (4) in this section gives the second equality. $\blacksquare$

Numeric Values

In practical work with the normal distribution it is good to remember that about 2/3 of all values of X to be observed will lie between $\mu \pm \sigma$, about 95% between $\mu \pm 2\sigma$, and practically all between the **three-sigma limits** $\mu \pm 3\sigma$. More precisely, by Table A7 in App. 5,

$$\begin{aligned} &\textbf{(a)} \quad P(\mu - \sigma < X \leqq \mu + \sigma) \approx 68\% \\ &\textbf{(b)} \quad P(\mu - 2\sigma < X \leqq \mu + 2\sigma) \approx 95.5\% \\ &\textbf{(c)} \quad P(\mu - 3\sigma < X \leqq \mu + 3\sigma) \approx 99.7\%. \end{aligned} \tag{6}$$

Formulas (6a) and (6b) are illustrated in Fig. 520.

The formulas in (6) show that a value deviating from μ by more than σ, 2σ, or 3σ will occur in one of about 3, 20, and 300 trials, respectively.

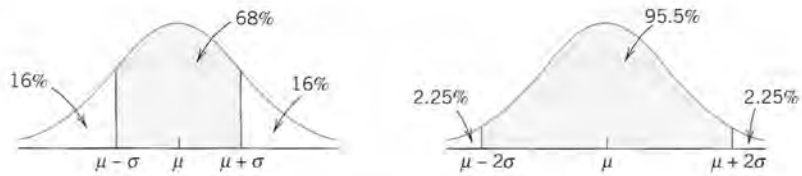

Fig. 520. Illustration of formula (6)

In tests (Chap. 25) we shall ask conversely for the intervals that correspond to certain given probabilities; practically most important are the probabilities of 95%, 99%, and 99.9%. For these, Table A8 in App. 5 gives the answers $\mu \pm 2\sigma$, $\mu \pm 2.5\sigma$, and $\mu \pm 3.3\sigma$, respectively. More precisely,

$$\begin{aligned} &\textbf{(a)} \quad P(\mu - 1.96\sigma < X \leqq \mu + 1.96\sigma) = 95\% \\ (7) \qquad &\textbf{(b)} \quad P(\mu - 2.58\sigma < X \leqq \mu + 2.58\sigma) = 99\% \\ &\textbf{(c)} \quad P(\mu - 3.29\sigma < X \leqq \mu + 3.29\sigma) = 99.9\%. \end{aligned}$$

Working With the Normal Tables A7 and A8 in App. 5

There are two normal tables in App. 5, Tables A7 and A8. If you want probabilities, use Table A7. If probabilities are given and corresponding intervals or x-values are wanted, use Table A8. The following examples are typical. Do them with care, verifying all values, and don't just regard them as dull exercises for your software. Make sketches of the density to see whether the results look reasonable.

EXAMPLE 1 **Reading Entries from Table A7**

If X is standardized normal (so that $\mu = 0$, $\sigma = 1$), then

$$P(X \leqq 2.44) = 0.9927 \approx 99\tfrac{1}{4}\%$$

$$P(X \leqq -1.16) = 1 - \Phi(1.16) = 1 - 0.8770 = 0.1230 = 12.3\%$$

$$P(X \geqq 1) = 1 - P(X \leqq 1) = 1 - 0.8413 = 0.1587 \text{ by (7), Sec. 24.3}$$

$$P(1.0 \leqq X \leqq 1.8) = \Phi(1.8) - \Phi(1.0) = 0.9641 - 0.8413 = 0.1228.$$ ■

EXAMPLE 2 **Probabilities for Given Intervals, Table A7**

Let X be normal with mean 0.8 and variance 4 (so that $\sigma = 2$). Then by (4) and (5)

$$P(X \leqq 2.44) = F(2.44) = \Phi\left(\frac{2.44 - 0.80}{2}\right) = \Phi(0.82) = 0.7939 \approx 80\%$$

or if you like it better (similarly in the other cases)

$$P(X \leqq 2.44) = P\left(\frac{X - 0.80}{2} \leqq \frac{2.44 - 0.80}{2}\right) = P(Z \leqq 0.82) = 0.7939$$

$$P(X \geqq 1) = 1 - P(X \leqq 1) = 1 - \Phi\left(\frac{1 - 0.8}{2}\right) = 1 - 0.5398 = 0.4602$$

$$P(1.0 \leqq X \leqq 1.8) = \Phi(0.5) - \Phi(0.1) = 0.6915 - 0.5398 = 0.1517.$$ ■

EXAMPLE 3 Unknown Values c for Given Probabilities, Table A8

Let X be normal with mean 5 and variance 0.04 (hence standard deviation 0.2). Find c or k corresponding to the given probability

$$P(X \leqq c) = 95\%, \qquad \Phi\left(\frac{c-5}{0.2}\right) = 95\%, \qquad \frac{c-5}{0.2} = 1.645, \qquad c = 5.329$$

$$P(5-k \leqq X \leqq 5+k) = 90\%, \qquad 5+k = 5.329 \qquad \text{(as before; why?)}$$

$$P(X \geqq c) = 1\%, \qquad \text{thus } P(X \leqq c) = 99\%, \qquad \frac{c-5}{0.2} = 2.326, \qquad c = 5.465. \quad \blacksquare$$

EXAMPLE 4 Defectives

In a production of iron rods let the diameter X be normally distributed with mean 2 in. and standard deviation 0.008 in.

(a) What percentage of defectives can we expect if we set the tolerance limits at 2 ± 0.02 in.?

(b) How should we set the tolerance limits to allow for 4% defectives?

Solution. **(a)** $1\frac{1}{4}\%$ because from (5) and Table A7 we obtain for the complementary event the probability

$$\begin{aligned} P(1.98 \leqq X \leqq 2.02) &= \Phi\left(\frac{2.02-2.00}{0.008}\right) - \Phi\left(\frac{1.98-2.00}{0.008}\right) \\ &= \Phi(2.5) - \Phi(-2.5) \\ &= 0.9938 - (1 - 0.9938) \\ &= 0.9876 \\ &\approx 98\tfrac{3}{4}\%. \end{aligned}$$

(b) 2 ± 0.0164 because for the complementary event we have

$$0.96 = P(2-c \leqq X \leqq 2+c)$$

or

$$0.98 = P(X \leqq 2+c)$$

so that Table A8 gives

$$0.98 = \Phi\left(\frac{2+c-2}{0.008}\right),$$

$$\frac{2+c-2}{0.008} = 2.054, \qquad c = 0.0164. \quad \blacksquare$$

Normal Approximation of the Binomial Distribution

The probability function of the binomial distribution is (Sec. 24.7)

$$(8) \qquad f(x) = \binom{n}{x} p^x q^{n-x} \qquad (x = 0, 1, \cdots, n).$$

If n is large, the binomial coefficients and powers become very inconvenient. It is of great practical (and theoretical) importance that in this case the normal distribution provides a good approximation of the binomial distribution, according to the following theorem, one of the most important theorems in all probability theory.

THEOREM 3

Limit Theorem of De Moivre and Laplace

For large n,

$$f(x) \sim f^*(x) \qquad (x = 0, 1, \cdots, n). \tag{9}$$

Here f is given by (8). *The function*

$$f^*(x) = \frac{1}{\sqrt{2\pi}\sqrt{npq}}\, e^{-z^2/2}, \qquad z = \frac{x - np}{\sqrt{npq}} \tag{10}$$

is the density of the normal distribution with mean $\mu = np$ and variance $\sigma^2 = npq$ (the mean and variance of the binomial distribution). The symbol $\sim$ (read **asymptotically equal**) *means that the ratio of both sides approaches* 1 *as n approaches ∞. Furthermore, for any nonnegative integers a and b ($> a$),*

$$P(a \leqq X \leqq b) = \sum_{x=a}^{b} \binom{n}{x} p^x q^{n-x} \sim \Phi(\beta) - \Phi(\alpha), \tag{11}$$

$$\alpha = \frac{a - np - 0.5}{\sqrt{npq}}, \qquad \beta = \frac{b - np + 0.5}{\sqrt{npq}}.$$

A proof of this theorem can be found in [G3] listed in App. 1. The proof shows that the term 0.5 in α and β is a correction caused by the change from a discrete to a continuous distribution.

PROBLEM SET 24.8

1–13 NORMAL DISTRIBUTION

1. Let X be normal with mean 80 and variance 9. Find $P(X > 83)$, $P(X < 81)$, $P(X < 80)$, and $P(78 < X < 82)$.

2. Let X be normal with mean 120 and variance 16. Find $P(X \leqq 126)$, $P(X > 116)$, $P(125 < X < 130)$.

3. Let X be normal with mean 14 and variance 4. Determine c such that $P(X \leqq c) = 95\%$, $P(X \leqq c) = 5\%$, $P(X \leqq c) = 99.5\%$.

4. Let X be normal with mean 4.2 and variance 0.04. Find c such that $P(X \leqq c) = 50\%$, $P(X > c) = 10\%$, $P(-c < X - 4.2 \leqq c) = 99\%$.

5. If the lifetime X of a certain kind of automobile battery is normally distributed with a mean of 4 yr and a standard deviation of 1 yr, and the manufacturer wishes to guarantee the battery for 3 yr, what percentage of the batteries will he have to replace under the guarantee?

6. If the standard deviation in Prob. 5 were smaller, would that percentage be smaller or larger?

7. A manufacturer knows from experience that the resistance of resistors he produces is normal with mean $\mu = 150\ \Omega$ and standard deviation $\sigma = 5\ \Omega$. What percentage of the resistors will have resistance between 148 Ω and 152 Ω? Between 140 Ω and 160 Ω?

8. The breaking strength X [kg] of a certain type of plastic block is normally distributed with a mean of 1250 kg and a standard deviation of 55 kg. What is the maximum load such that we can expect no more than 5% of the blocks to break?

9. A manufacturer produces airmail envelopes whose weight is normal with mean $\mu = 1.950$ grams and standard deviation $\sigma = 0.025$ grams. The envelopes are sold in lots of 1000. How many envelopes in a lot will be heavier than 2 grams?

10. If the resistance X of certain wires in an electrical network is normal with mean 0.01 Ω and standard deviation 0.001 Ω, how many of 1000 wires will meet the specification that they have resistance between 0.009 and 0.011 Ω?

11. If the mathematics scores of the SAT college entrance exams are normal with mean 480 and standard deviation 100 (these are about the actual values over the past years) and if some college sets 500 as the minimum score for new students, what percent of students will not reach that score?

12. If the monthly machine repair and maintenance cost X in a certain factory is known to be normal with mean \$12000 and standard deviation \$2000, what is the probability that the repair cost for the next month will exceed the budgeted amount of \$15000?

13. If sick-leave time X used by employees of a company in one month is (very roughly) normal with mean 1000 hours and standard deviation 100 hours, how much time t should be budgeted for sick leave during the next month if t is to be exceeded with probability of only 20%?

14. TEAM PROJECT. Normal Distribution. **(a)** Derive the formulas in (6) and (7) from the appropriate normal table.

(b) Show that $\Phi(-z) = 1 - \Phi(z)$. Give an example.

(c) Find the points of inflection of the curve of (1).

(d) Considering $\Phi^2(\infty)$ and introducing polar coordinates in the double integral (a standard trick worth remembering), prove

$$\Phi(\infty) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-u^2/2}\, du = 1. \tag{12}$$

(e) Show that σ in (1) is indeed the standard deviation of the normal distribution. [Use (12).]

(f) Bernoulli's law of large numbers. In an experiment let an event A have probability p $(0 < p < 1)$, and let X be the number of times A happens in n independent trials. Show that for any given $\epsilon > 0$,

$$P\left(\left|\frac{X}{n} - p\right| \leqq \epsilon\right) \to 1 \quad \text{as } n \to \infty.$$

(g) Transformation. If X is normal with mean μ and variance σ^2, show that $X^* = c_1X + c_2$ $(c_1 > 0)$ is normal with mean $\mu^* = c_1\mu + c_2$ and variance $\sigma^{*2} = c_1^2\sigma^2$.

15. WRITING PROJECT. Use of Tables. Give a systematic discussion of the use of Tables A7 and A8 for obtaining $P(X < b)$, $P(X > a)$, $P(a < X < b)$, $P(X < c) = k$, $P(X > c) = k$, as well as $P(\mu - c < X < \mu + c) = k$; include simple examples. If you have a CAS, describe to what extent it makes the use of those tables superfluous; give examples.

24.9 Distributions of Several Random Variables

Distributions of two or more random variables are of interest for two reasons:

1. They occur in experiments in which we observe several random variables, for example, carbon content X and hardness Y of steel, amount of fertilizer X and yield of corn Y, height X_1, weight X_2, and blood pressure X_3 of persons, and so on.

2. They will be needed in the mathematical justification of the methods of statistics in Chap. 25.

In this section we consider two random variables X and Y or, as we also say, a **two-dimensional random variable** (X, Y). For (X, Y) the outcome of a trial is a pair of numbers $X = x$, $Y = y$, briefly $(X, Y) = (x, y)$, which we can plot as a point in the XY-plane.

The **two-dimensional probability distribution** of the random variable (X, Y) is given by the **distribution function**

$$F(x, y) = P(X \leqq x, Y \leqq y). \tag{1}$$

This is the probability that in a trial, X will assume any value not greater than x and in the same trial, Y will assume any value not greater than y. This corresponds to the blue region in Fig. 521, which extends to $-\infty$ to the left and below. $F(x, y)$ determines the

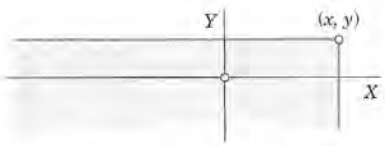

Fig. 521. Formula (1)

probability distribution uniquely, because in analogy to formula (2) in Sec. 24.5, that is, $P(a < X \leqq b) = F(b) - F(a)$, we now have for a rectangle (see Prob. 14)

(2) $P(a_1 < X \leqq b_1, \quad a_2 < Y \leqq b_2) = F(b_1, b_2) - F(a_1, b_2) - F(b_1, a_2) + F(a_1, a_2).$

As before, in the two-dimensional case we shall also have discrete and continuous random variables and distributions.

Discrete Two-Dimensional Distributions

In analogy to the case of a single random variable (Sec. 24.5), we call (X, Y) and its distribution **discrete** if (X, Y) can assume only finitely many or at most countably infinitely many pairs of values (x_1, y_1), (x_2, y_2), $\cdots$ with positive probabilities, whereas the probability for any domain containing none of those values of (X, Y) is zero.

Let (x_i, y_j) be any of those pairs and let $P(X = x_i, Y = y_j) = p_{ij}$ (where we admit that p_{ij} may be 0 for certain pairs of subscripts i, j). Then we define the **probability function** $f(x, y)$ of (X, Y) by

(3) $f(x, y) = p_{ij}$ if $x = x_i, y = y_j$ and $f(x, y) = 0$ otherwise;

here, $i = 1, 2, \cdots$ and $j = 1, 2, \cdots$ independently. In analogy to (4), Sec. 24.5, we now have for the distribution function the formula

(4) $$F(x, y) = \sum_{x_i \leqq x} \sum_{y_j \leqq y} f(x_i, y_j).$$

Instead of (6) in Sec. 24.5 we now have the condition

(5) $$\sum_i \sum_j f(x_i, y_j) = 1.$$

EXAMPLE 1 **Two-Dimensional Discrete Distribution**

If we simultaneously toss a dime and a nickel and consider

X = *Number of heads the dime turns up,*

Y = *Number of heads the nickel turns up,*

then X and Y can have the values 0 or 1, and the probability function is

$$f(0, 0) = f(1, 0) = f(0, 1) = f(1, 1) = \tfrac{1}{4}, \quad f(x, y) = 0 \text{ otherwise.}$$

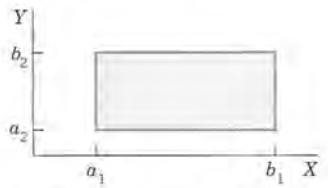

Fig. 522. Notion of a two-dimensional distribution

Continuous Two-Dimensional Distributions

In analogy to the case of a single random variable (Sec. 24.5) we call (X, Y) and its distribution **continuous** if the corresponding distribution function $F(x, y)$ can be given by a double integral

$$F(x, y) = \int_{-\infty}^{y} \int_{-\infty}^{x} f(x^*, y^*)\, dx^*\, dy^* \tag{6}$$

whose integrand f, called the **density** of (X, Y), is nonnegative everywhere, and is continuous, possibly except on finitely many curves.

From (6) we obtain the probability that (X, Y) assume any value in a rectangle (Fig. 522) given by the formula

$$P(a_1 < X \leqq b_1, \quad a_2 < Y \leqq b_2) = \int_{a_2}^{b_2} \int_{a_1}^{b_1} f(x, y)\, dx\, dy. \tag{7}$$

EXAMPLE 2 Two-Dimensional Uniform Distribution in a Rectangle

Let R be the rectangle $\alpha_1 < x \leqq \beta_1$, $\alpha_2 < y \leqq \beta_2$. The density (see Fig. 523)

$$f(x, y) = 1/k \quad \text{if } (x, y) \text{ is in } R, \qquad f(x, y) = 0 \text{ otherwise} \tag{8}$$

defines the so-called **uniform distribution** *in the rectangle R;* here $k = (\beta_1 - \alpha_1)(\beta_2 - \alpha_2)$ is the area of R. The distribution function is shown in Fig. 524. ■

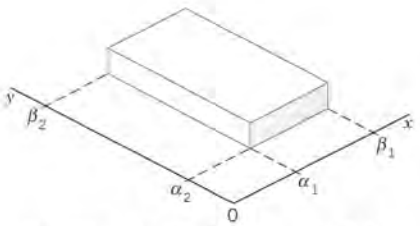

Fig. 523. Density function (8) of the uniform distribution

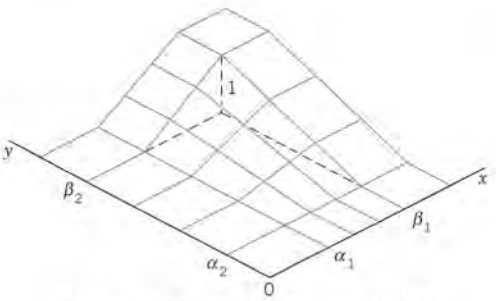

Fig. 524. Distribution function of the uniform distribution defined by (8)

Marginal Distributions of a Discrete Distribution

This is a rather natural idea, without counterpart for a single random variable. It amounts to being interested only in one of the two variables in (X, Y), say, X, and asking for its

distribution, called the **marginal distribution** of X in (X, Y). So we ask for the probability $P(X = x, Y \text{ arbitrary})$. Since (X, Y) is discrete, so is X. We get its probability function, call it $f_1(x)$, from the probability function $f(x, y)$ of (X, Y) by summing over y:

$$\textbf{(9)} \qquad f_1(x) = P(X = x, Y \text{ arbitrary}) = \sum_y f(x, y)$$

where we sum all the values of $f(x, y)$ that are not 0 for that x.

From (9) we see that the distribution function of the marginal distribution of X is

$$\textbf{(10)} \qquad F_1(x) = P(X \leqq x, Y \text{ arbitrary}) = \sum_{x^* \leqq x} f_1(x^*).$$

Similarly, the probability function

$$\textbf{(11)} \qquad f_2(y) = P(X \text{ arbitrary}, Y = y) = \sum_x f(x, y)$$

determines the **marginal distribution** of Y in (X, Y). Here we sum all the values of $f(x, y)$ that are not zero for the corresponding y. The distribution function of this marginal distribution is

$$\textbf{(12)} \qquad F_2(y) = P(X \text{ arbitrary}, Y \leqq y) = \sum_{y^* \leqq y} f_2(y^*).$$

EXAMPLE 3 **Marginal Distributions of a Discrete Two-Dimensional Random Variable**

In drawing 3 cards with replacement from a bridge deck let us consider

$$(X, Y), \qquad X = \textit{Number of queens}, \qquad Y = \textit{Number of kings or aces}.$$

The deck has 52 cards. These include 4 queens, 4 kings, and 4 aces. Hence in a single trial a queen has probability $4/52 = 1/13$ and a king or ace $8/52 = 2/13$. This gives the probability function of (X, Y),

$$f(x, y) = \frac{3!}{x!\, y!\, (3 - x - y)!} \left(\frac{1}{13}\right)^x \left(\frac{2}{13}\right)^y \left(\frac{10}{13}\right)^{3-x-y} \qquad (x + y \leqq 3)$$

and $f(x, y) = 0$ otherwise. Table 24.1 shows in the center the values of $f(x, y)$ and on the right and lower margins the values of the probability functions $f_1(x)$ and $f_2(y)$ of the marginal distributions of X and Y, respectively. ■

Table 24.1 Values of the Probability Functions $f(x, y)$, $f_1(x)$, $f_2(y)$ in Drawing Three Cards with Replacement from a Bridge Deck, where X is the Number of Queens Drawn and Y is the Number of Kings or Aces Drawn

x \ y	0	1	2	3	$f_1(x)$
0	$\frac{1000}{2197}$	$\frac{600}{2197}$	$\frac{120}{2197}$	$\frac{8}{2197}$	$\frac{1728}{2197}$
1	$\frac{300}{2197}$	$\frac{120}{2197}$	$\frac{12}{2197}$	0	$\frac{432}{2197}$
2	$\frac{30}{2197}$	$\frac{6}{2197}$	0	0	$\frac{36}{2197}$
3	$\frac{1}{2197}$	0	0	0	$\frac{1}{2197}$
$f_2(y)$	$\frac{1331}{2197}$	$\frac{726}{2197}$	$\frac{132}{2197}$	$\frac{8}{2197}$	

Marginal Distributions of a Continuous Distribution

This is conceptually the same as for discrete distributions, with probability functions and sums replaced by densities and integrals. For a continuous random variable (X, Y) with density $f(x, y)$ we now have the **marginal distribution** of X in (X, Y), defined by the distribution function

$$\textbf{(13)} \qquad F_1(x) = P(X \leqq x, -\infty < Y < \infty) = \int_{-\infty}^{x} f_1(x^*)\, dx^*$$

with the density f_1 of X obtained from $f(x, y)$ by integration over y,

$$\textbf{(14)} \qquad f_1(x) = \int_{-\infty}^{\infty} f(x, y)\, dy.$$

Interchanging the roles of X and Y, we obtain the **marginal distribution** of Y in (X, Y) with the distribution function

$$\textbf{(15)} \qquad F_2(y) = P(-\infty < X < \infty, Y \leqq y) = \int_{-\infty}^{y} f_2(y^*)\, dy^*$$

and density

$$\textbf{(16)} \qquad f_2(y) = \int_{-\infty}^{\infty} f(x, y)\, dx.$$

Independence of Random Variables

X and Y in a (discrete or continuous) random variable (X, Y) are said to be **independent** if

$$\textbf{(17)} \qquad F(x, y) = F_1(x)F_2(y)$$

holds for all (x, y). Otherwise these random variables are said to be **dependent.** These definitions are suggested by the corresponding definitions for events in Sec. 24.3.

Necessary and sufficient for independence is

$$\textbf{(18)} \qquad f(x, y) = f_1(x)f_2(y)$$

for all x and y. Here the f's are the above probability functions if (X, Y) is discrete or those densities if (X, Y) is continuous. (See Prob. 20.)

EXAMPLE 4 **Independence and Dependence**

In tossing a dime and a nickel, X = *Number of heads on the dime*, Y = *Number of heads on the nickel* may assume the values 0 or 1 and are independent. The random variables in Table 24.1 are dependent. ■

Extension of Independence to n-Dimensional Random Variables. This will be needed throughout Chap. 25. The distribution of such a random variable $\mathbf{X} = (X_1, \cdots, X_n)$ is determined by a **distribution function** of the form

$$F(x_1, \cdots, x_n) = P(X_1 \leqq x_1, \cdots, X_n \leqq x_n).$$

The random variables $X_1, \cdots, X_n$ are said to be **independent** if

$$F(x_1, \cdots, x_n) = F_1(x_1)F_2(x_2) \cdots F_n(x_n) \tag{19}$$

for all $(x_1, \cdots, x_n)$. Here $F_j(x_j)$ is the distribution function of the marginal distribution of X_j in $\mathbf{X}$, that is,

$$F_j(x_j) = P(X_j \leqq x_j, X_k \text{ arbitrary}, k = 1, \cdots, n, k \neq j).$$

Otherwise these random variables are said to be **dependent.**

Functions of Random Variables

When $n = 2$, we write $X_1 = X, X_2 = Y, x_1 = x, x_2 = y$. Taking a nonconstant continuous function $g(x, y)$ defined for all x, y, we obtain a random variable $Z = g(X, Y)$. For example, if we roll two dice and X and Y are the numbers the dice turn up in a trial, then $Z = X + Y$ is the sum of those two numbers (see Fig. 513 in Sec. 24.5).

In the case of a ***discrete*** random variable (X, Y) we may obtain the probability function $f(z)$ of $Z = g(X, Y)$ by summing all $f(x, y)$ for which $g(x, y)$ equals the value of z considered; thus

$$f(z) = P(Z = z) = \sum\sum_{g(x,y)=z} f(x, y). \tag{20}$$

Hence the distribution function of Z is

$$F(z) = P(Z \leqq z) = \sum\sum_{g(x,y)\leqq z} f(x, y) \tag{21}$$

where we sum all values of $f(x, y)$ for which $g(x, y) \leqq z$.

In the case of a ***continuous*** random variable (X, Y) we similarly have

$$F(z) = P(Z \leqq z) = \iint_{g(x,y)\leqq z} f(x, y)\, dx\, dy \tag{22}$$

where for each z we integrate the density $f(x, y)$ of (X, Y) over the region $g(x, y) \leqq z$ in the xy-plane, the boundary curve of this region being $g(x, y) = z$.

Addition of Means

The number

$$E(g(X, Y)) = \begin{cases} \displaystyle\sum_x \sum_y g(x, y)f(x, y) & [(X, Y) \text{ discrete}] \\ \displaystyle\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g(x, y)f(x, y)\, dx\, dy & [(X, Y) \text{ continuous}] \end{cases} \tag{23}$$

is called the *mathematical expectation* or, briefly, the **expectation of** $g(X, Y)$. Here it is assumed that the double series converges absolutely and the integral of $|g(x, y)|f(x, y)$ over the xy-plane exists (is finite). Since summation and integration are linear processes, we have from (23)

$$E(ag(X, Y) + bh(X, Y)) = aE(g(X, Y)) + bE(h(X, Y)). \tag{24}$$

An important special case is

$$E(X + Y) = E(X) + E(Y),$$

and by induction we have the following result.

THEOREM 1

Addition of Means

The mean (expectation) of a sum of random variables equals the sum of the means (expectations), that is,

$$E(X_1 + X_2 + \cdots + X_n) = E(X_1) + E(X_2) + \cdots + E(X_n). \tag{25}$$

Furthermore, we readily obtain

THEOREM 2

Multiplication of Means

The mean (expectation) of the product of ***independent*** *random variables equals the product of the means (expectations), that is,*

$$E(X_1X_2 \cdots X_n) = E(X_1)E(X_2) \cdots E(X_n). \tag{26}$$

PROOF If X and Y are independent random variables (both discrete or both continuous), then $E(XY) = E(X)E(Y)$. In fact, in the discrete case we have

$$E(XY) = \sum_x \sum_y xyf(x, y) = \sum_x xf_1(x) \sum_y yf_2(y) = E(X)E(Y),$$

and in the continuous case the proof of the relation is similar. Extension to n independent random variables gives (26), and Theorem 2 is proved. ■

Addition of Variances

This is another matter of practical importance that we shall need. As before, let $Z = X + Y$ and denote the mean and variance of Z by μ and σ^2. Then we first have (see Team Project 16(a) in Problem Set 24.6)

$$\sigma^2 = E([Z - \mu]^2) = E(Z^2) - [E(Z)]^2.$$

From (24) we see that the first term on the right equals

$$E(Z^2) = E(X^2 + 2XY + Y^2) = E(X^2) + 2E(XY) + E(Y^2).$$

For the second term on the right we obtain from Theorem 1

$$[E(Z)]^2 = [E(X) + E(Y)]^2 = [E(X)]^2 + 2E(X)E(Y) + [E(Y)]^2.$$

By substituting these expressions into the formula for σ^2 we have

$$\begin{aligned}\sigma^2 = {} & E(X^2) - [E(X)]^2 + E(Y^2) - [E(Y)]^2 \\ & + 2[E(XY) - E(X)E(Y)].\end{aligned}$$

From Team Project 16, Sec. 24.6, we see that the expression in the first line on the right is the sum of the variances of X and Y, which we denote by σ_1^2 and σ_2^2, respectively. The quantity in the second line (except for the factor 2) is

(27) $$\sigma_{XY} = E(XY) - E(X)E(Y)$$

and is called the **covariance** of X and Y. Consequently, our result is

(28) $$\sigma^2 = \sigma_1^2 + \sigma_2^2 + 2\sigma_{XY}.$$

If X and Y are independent, then

$$E(XY) = E(X)E(Y);$$

hence $\sigma_{XY} = 0$, and

(29) $$\sigma^2 = \sigma_1^2 + \sigma_2^2.$$

Extension to more than two variables gives the basic

THEOREM 3

Addition of Variances

The variance of the sum of ***independent*** *random variables equals the sum of the variances of these variables.*

CAUTION! In the numerous applications of Theorems 1 and 3 we must always remember that Theorem 3 holds only for ***independent*** variables.

This is the end of Chap. 24 on probability theory. Most of the concepts, methods, and special distributions discussed in this chapter will play a fundamental role in the next chapter, which deals with methods of **statistical inference,** that is, conclusions from samples to populations, whose unknown properties we want to know and try to discover by looking at suitable properties of samples that we have obtained.

PROBLEM SET 24.9

1. Let $f(x, y) = k$ when $8 \leqq x \leqq 12$ and $0 \leqq y \leqq 2$ and zero elsewhere. Find k. Find $P(X \leqq 11, 1 \leqq Y \leqq 1.5)$ and $P(9 \leqq X \leqq 13, Y \leqq 1)$.

2. Find $P(X > 2, Y > 2)$ and $P(X \leqq 1, Y \leqq 1)$ if (X, Y) has the density $f(x, y) = 1/8$ if $x \geqq 0, y \geqq 0, x + y \leqq 4$.

3. Let $f(x, y) = k$ if $x > 0$, $y > 0$, $x + y < 3$ and 0 otherwise. Find k. Sketch $f(x, y)$. Find $P(X + Y \leqq 1)$, $P(Y > X)$.

4. Find the density of the marginal distribution of X in Prob 2.

5. Find the density of the marginal distribution of Y in Fig. 523.

6. If certain sheets of wrapping paper have a mean weight of 10 g each, with a standard deviation of 0.05 g, what are the mean weight and standard deviation of a pack of 10 000 sheets?

7. What are the mean thickness and the standard deviation of transformer cores each consisting of 50 layers of sheet metal and 49 insulating paper layers if the metal sheets have mean thickness 0.5 mm each with a standard deviation of 0.05 mm and the paper layers have mean 0.05 mm each with a standard deviation of 0.02 mm?

8. If the weight of certain (empty) containers has mean 2 lb and standard deviation 0.1 lb, and if the filling of the containers has mean weight 75 lb and standard deviation 0.8 lb, what are the mean weight and standard deviation of filled containers?

9. A 5-gear assembly is put together with spacers between the gears. The mean thickness of the gears is 5.020 cm with a standard deviation of 0.003 cm. The mean thickness of the spacers is 0.040 cm with a standard deviation of 0.002 cm. Find the mean and standard deviation of the assembled units consisting of 5 randomly selected gears and 4 randomly selected spacers.

10. Give an example of two different discrete distributions that have the same marginal distributions.

11. Show that the random variables with the densities

$$f(x, y) = x + y$$

and

$$g(x, y) = (x + \tfrac{1}{2})(y + \tfrac{1}{2})$$

if $0 \leqq x \leqq 1$, $0 \leqq y \leqq 1$ and $f(x, y) = 0$ and $g(x, y) = 0$ elsewhere, have the same marginal distribution.

12. Let X [cm] and Y [cm] be the diameter of a pin and hole, respectively. Suppose that (X, Y) has the density

$$f(x, y) = 2500 \qquad \text{if}$$

$$0.99 < x < 1.01,\ 1.00 < y < 1.02$$

and 0 otherwise. (a) Find the marginal distributions. (b) What is the probability that a pin chosen at random will fit a hole whose diameter is 1.00?

13. An electronic device consists of two components. Let X and Y [months] be the length of time until failure of the first and second component, respectively. Assume that (X, Y) has the probability density

$$f(x, y) = 0.01e^{-0.1(x+y)} \qquad \text{if } x > 0 \text{ and } y > 0$$

and 0 otherwise. (a) Are X and Y dependent or independent? (b) Find the densities of the marginal distributions. (c) What is the probability that the first component has a lifetime of 10 months or longer?

14. Prove (2).

15. Find $P(X > Y)$ when (X, Y) has the density

$$f(x, y) = 0.25e^{-0.5(x+y)} \text{ if } x \geqq 0,\ y \geqq 0$$

and 0 otherwise.

16. Let (X, Y) have the density

$$f(x, y) = k \text{ if } x^2 + y^2 < 1$$

and 0 otherwise. Determine k. Find the densities of the marginal distributions. Find the probability

$$P(X^2 + Y^2 < 1/4).$$

17. Let (X, Y) have the probability function

$$f(0, 0) = f(1, 1) = 1/8,$$
$$f(0, 1) = f(1, 0) = 3/8.$$

Are X and Y independent?

18. Using Theorem 1, obtain the formula for the mean of the hypergeometric distribution. Can you use Theorem 3 to obtain the variance of that distribution?

19. Using Theorems 1 and 3, obtain the formulas for the mean and the variance of the binomial distribution.

20. Prove the statement involving (18).

CHAPTER 24 REVIEW QUESTIONS AND PROBLEMS

1. Why did we begin the chapter with a section on handling data?
2. What are stem-and-leaf plots? Boxplots? Histograms? Compare their advantages.
3. What quantities measure the average size of data? The spread?
4. Why did we consider probability theory? What is its role in statistics?
5. What do we mean by an experiment? By a random variable related with it? What are outcomes? Events?
6. Give examples of experiments in which you have equally likely cases and others in which you don't.
7. State the definition of probability from memory.
8. What is the difference between the concepts of a permutation and a combination?
9. State the main theorems on probability. Illustrate them by simple examples.
10. What is the distribution of a random variable? The distribution function? The probability function? The density?
11. State the definitions of mean and variance of a random variable from memory.
12. If $P(A) = P(B)$ and $A \subseteq B$, can $A \neq B$?
13. If $E \neq S$ (= the sample space), can $P(E) = 1$?
14. What distributions correspond to sampling with replacement and without replacement?
15. When will an experiment involve a binomial distribution? A hypergeometric distribution?
16. When will the Poisson distribution be a good approximation of the binomial distribution?
17. What do you know about the approximation of the binomial distribution by the normal distribution?
18. Explain the use of the tables of the normal distribution. If you have a CAS, how would you proceed without the tables?
19. Can the probability function of a discrete random variable have infinitely many positive values?
20. State the most important facts about distributions of two random variables and their marginal distributions.
21. Make a stem-and-leaf plot, histogram, and boxplot of the data 22.5, 23.2, 22.1, 23.6, 23.3, 23.4, 24.0, 20.6, 23.3.
22. Do the same task as in Prob. 21, for the data 210, 213, 209, 218, 210, 215, 204, 211, 216, 213.
23. Find the mean, standard deviation, and variance in Prob. 21.
24. Find the mean, standard deviation, and variance in Prob. 22.
25. What are the outcomes of the sample space of *X: Tossing a coin until the first Head appears*?
26. What are the outcomes in the sample space of the experiment of simultaneously tossing three coins?
27. A box contains 50 screws, five of which are defective. Find the probability function of the random variable $X =$ *Number of defective screws in drawing two screws without replacement* and compute its values.
28. Find the values of the distribution function in Prob. 27.
29. Using a Venn diagram, show that $A \subseteq B$ if and only if $A \cup B = B$.
30. Using a Venn diagram, show that $A \subseteq B$ if and only if $A \cap B = A$.
31. If X has the density $f(x) = 0.5x$ $(0 \leqq x \leqq 2)$ and 0 otherwise, what are the mean and the variance of $X^* = -2X + 5$?
32. If 6 different inks are available, in how many ways can we select two colors for a printing job? Four colors?
33. Compute 5! by the Stirling formula and find the absolute and relative errors.
34. Two screws are randomly drawn without replacement from a box containing 7 right-handed and 3 left-handed screws. Let X be the number of left-handed screws drawn. Find $P(X = 0)$, $P(X = 1)$, $P(X = 2)$, $P(1 < X < 2)$, $P(0 < X < 5)$.
35. Find the mean and the variance of the distribution having the density $f(x) = \frac{1}{2}e^{-|x|}$.
36. Find the skewness of the distribution with density $f(x) = 2(1 - x)$ if $0 < x < 1$, $f(x) = 0$ otherwise.
37. Sketch the probability function $f(x) = x^2/30$ $(x = 1, 2, 3, 4)$ and the distribution function. Find μ.
38. Sketch $F(x) = 0$ if $x \leqq 0$, $F(x) = 0.2x$ if $0 < x \leqq 5$, $F(x) = 1$ if $x > 5$, and its density $f(x)$.
39. If the life of tires is normal with mean 25 000 km and variance 25 000 000 km^2, what is the probability that a given one of those tires will last at least 30 000 km? At least 35 000 km?
40. If the weight of bags of cement is normal with mean 50 kg and standard deviation 1 kg, what is the probability that 100 bags will be heavier than 5030 kg?

SUMMARY OF CHAPTER 24
Data Analysis. Probability Theory

A *random experiment*, briefly called **experiment,** is a process in which the result (**"outcome"**) depends on "chance" (effects of factors unknown to us). Examples are games of chance with dice or cards, measuring the hardness of steel, observing weather conditions, or recording the number of accidents in a city. (Thus the word "experiment" is used here in a much wider sense than in common language.) The outcomes are regarded as points (elements) of a set S, called the **sample space,** whose subsets are called **events.** For events E we define a **probability** $P(E)$ by the axioms (Sec. 24.3)

$$0 \leqq P(E) \leqq 1$$

(1)
$$P(S) = 1$$

$$P(E_1 \cup E_2 \cup \cdots) = P(E_1) + P(E_2) + \cdots \qquad (E_j \cap E_k = \varnothing).$$

These axioms are motivated by properties of frequency distributions of data (Sec. 24.1).

The complement E^c of E has the probability

(2)
$$P(E^c) = 1 - P(E).$$

The **conditional probability** of an event B under the condition that an event A happens is (Sec. 24.3)

(3)
$$P(B|A) = \frac{P(A \cap B)}{P(A)} \qquad [P(A) > 0].$$

Two events A and B are called **independent** if the probability of their simultaneous appearance in a trial equals the product of their probabilities, that is, if

(4)
$$P(A \cap B) = P(A)P(B).$$

With an experiment we associate a **random variable** X. This is a function defined on S whose values are real numbers; furthermore, X is such that the probability $P(X = a)$ with which X assumes any value a, and the probability $P(a < X \leqq b)$ with which X assumes any value in an interval $a < X \leqq b$ are defined (Sec. 24.5). The **probability distribution** of X is determined by the distribution function

(5)
$$F(x) = P(X \leqq x).$$

In applications there are two important kinds of random variables: those of the **discrete** type, which appear if we count (defective items, customers in a bank, etc.) and those of the **continuous** type, which appear if we measure (length, speed, temperature, weight, etc.).

A discrete random variable has a **probability function**

$$f(x) = P(X = x). \tag{6}$$

Its **mean** μ and **variance** σ^2 are (Sec. 24.6)

$$\mu = \sum_j x_j f(x_j) \quad \text{and} \quad \sigma^2 = \sum_j (x_j - \mu)^2 f(x_j) \tag{7}$$

where the x_j are the values for which X has a positive probability. Important discrete random variables and distributions are the **binomial, Poisson,** and **hypergeometric distributions** discussed in Sec. 24.7.

A continuous random variable has a **density**

$$f(x) = F'(x) \qquad \text{[see (5)]}. \tag{8}$$

Its mean and variance are (Sec. 24.6)

$$\mu = \int_{-\infty}^{\infty} x f(x)\, dx \quad \text{and} \quad \sigma^2 = \int_{-\infty}^{\infty} (x - \mu)^2 f(x)\, dx. \tag{9}$$

Very important is the **normal distribution** (Sec. 24.8), whose density is

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right] \tag{10}$$

and whose distribution function is (Sec. 24.8; Tables A7, A8 in App. 5)

$$F(x) = \Phi\left(\frac{x-\mu}{\sigma}\right). \tag{11}$$

A **two-dimensional random variable** (X, Y) occurs if we simultaneously observe two quantities (for example, height X and weight Y of adults). Its distribution function is (Sec. 24.9)

$$F(x, y) = P(X \leqq x, Y \leqq y). \tag{12}$$

X and Y have the distribution functions (Sec. 24.9)

$$F_1(x) = P(X \leqq x, Y \text{ arbitrary}) \quad \text{and} \quad F_2(y) = P(x \text{ arbitrary}, Y \leqq y) \tag{13}$$

respectively; their distributions are called **marginal distributions.** If both X and Y are discrete, then (X, Y) has a probability function

$$f(x, y) = P(X = x, Y = y).$$

If both X and Y are continuous, then (X, Y) has a density $f(x, y)$.

CHAPTER 25

Mathematical Statistics

In probability theory we set up mathematical models of processes that are affected by "chance". In mathematical statistics or, briefly, **statistics,** we check these models against the observable reality. This is called **statistical inference.** It is done by **sampling,** that is, by drawing random samples, briefly called **samples.** These are sets of values from a much larger set of values that could be studied, called the **population.** An example is 10 diameters of screws drawn from a large lot of screws. Sampling is done in order to see whether a model of the population is accurate enough for practical purposes. If this is the case, the model can be used for predictions, decisions, and actions, for instance, in planning productions, buying equipment, investing in business projects, and so on.

Most important methods of statistical inference are **estimation of parameters** (Secs. 25.2), determination of **confidence intervals** (Sec. 25.3), and **hypothesis testing** (Secs. 25.4, 25.7, 25.8), with application to *quality control* (Sec. 25.5) and *acceptance sampling* (Sec. 25.6).

In the last section (25.9) we give an introduction to **regression** and **correlation analysis,** which concern experiments involving two variables.

Prerequisite: Chap. 24.
Sections that may be omitted in a shorter course: 25.5, 25.6, 25.8.
References, Answers to Problems, and Statistical Tables: App. 1 Part G, App. 2, App. 5.

25.1 Introduction. Random Sampling

Mathematical statistics consists of methods for designing and evaluating random experiments to obtain information about practical problems, such as exploring the relation between iron content and density of iron ore, the quality of raw material or manufactured products, the efficiency of air-conditioning systems, the performance of certain cars, the effect of advertising, the reactions of consumers to a new product, etc.

Random variables occur more frequently in engineering (and elsewhere) than one would think. For example, properties of mass-produced articles (screws, lightbulbs, etc.) always show **random variation,** due to small (uncontrollable!) differences in raw material or manufacturing processes. Thus the diameter of screws is a random variable X and we have *nondefective screws,* with diameter between given tolerance limits, and *defective screws,* with diameter outside those limits. We can ask for the distribution of X, for the percentage of defective screws to be expected, and for necessary improvements of the production process.

Samples are selected from populations—20 screws from a lot of 1000, 100 of 5000 voters, 8 beavers in a wildlife conservation project—because inspecting the entire population would be too expensive, time-consuming, impossible or even senseless (think of destructive testing of lightbulbs or dynamite). To obtain meaningful conclusions, samples must be **random selections.** Each of the 1000 screws must have the same chance of being sampled (of being drawn when we sample), at least approximately. Only then will the sample mean $\bar{x} = (x_1 + \cdots + x_{20})/20$ (Sec. 24.1) of a sample of size $n = 20$ (or any other n) be a good approximation of the population mean μ (Sec. 24.6); and the accuracy of the approximation will generally improve with increasing n, as we shall see. Similarly for other parameters (standard deviation, variance, etc.).

Independent sample values will be obtained in experiments with an infinite sample space S (Sec. 24.2), certainly for the normal distribution. This is also true in sampling with replacement. It is approximately true in drawing *small* samples from a large finite population (for instance, 5 or 10 of 1000 items). However, if we sample without replacement from a small population, the effect of dependence of sample values may be considerable.

Random numbers help in obtaining samples that are in fact random selections. This is sometimes not easy to accomplish because there are many subtle factors that can bias sampling (by personal interviews, by poorly working machines, by the choice of nontypical observation conditions, etc.). Random numbers can be obtained from a **random number generator** in Maple, Mathematica, or other systems listed on p. 991. (The numbers are not truly random, as they would be produced in flipping coins or rolling dice, but are calculated by a tricky formula that produces numbers that do have practically all the essential features of true randomness.)

EXAMPLE 1 **Random Numbers from a Random Number Generator**

To select a sample of size $n = 10$ from 80 given ball bearings, we number the bearings from 1 to 80. We then let the generator randomly produce 10 of the integers from 1 to 80 and include the bearings with the numbers obtained in our sample, for example.

44 55 53 03 52 61 67 78 39 54

or whatever.

Random numbers are also contained in (older) statistical tables. ■

Representing and processing data were considered in Sec. 24.1 in connection with frequency distributions. These are the empirical counterparts of probability distributions and helped motivating axioms and properties in probability theory. The new aspect in this chapter is **randomness:** the data are samples selected **randomly** from a population. Accordingly, we can immediately make the connection to Sec. 24.1, using stem-and-leaf plots, box plots, and histograms for representing samples graphically.

Also, we now call the mean $\bar{x}$ in (5), Sec. 24.1, the **sample mean**

$$\text{(1)} \qquad \bar{x} = \frac{1}{n}\sum_{j=1}^{n} x_j = \frac{1}{n}\,(x_1 + x_2 + \cdots + x_n).$$

We call n the **sample size,** the variance s^2 in (6), Sec. 24.1, the **sample variance**

$$\text{(2)} \qquad s^2 = \frac{1}{n-1}\sum_{j=1}^{n} (x_j - \bar{x})^2 = \frac{1}{n-1}\left[(x_1 - \bar{x})^2 + \cdots + (x_n - \bar{x})^2\right],$$

and its positive square root s the **sample standard deviation.** $\bar{x}$, s^2, and s are called **parameters** *of a sample;* they will be needed throughout this chapter.

25.2 Point Estimation of Parameters

Beginning in this section, we shall discuss the most basic practical tasks in statistics and corresponding statistical methods to accomplish them. The first of them is point estimation of **parameters,** that is, of quantities appearing in distributions, such as p in the binomial distribution and μ and σ in the normal distribution.

A **point estimate** of a parameter is a number (point on the real line), which is computed from a given sample and serves as an approximation of the unknown exact value of the parameter of the population. An **interval estimate** is an interval (*"confidence interval"*) obtained from a sample; such estimates will be considered in the next section. Estimation of parameters is of great practical importance in many applications.

As an approximation of the mean μ of a population we may take the mean $\bar{x}$ of a corresponding sample. This gives the estimate $\hat{\mu} = \bar{x}$ for μ, that is,

$$\hat{\mu} = \bar{x} = \frac{1}{n}(x_1 + \cdots + x_n) \tag{1}$$

where n is the sample size. Similarly, an estimate $\hat{\sigma}^2$ for the variance of a population is the variance s^2 of a corresponding sample, that is,

$$\hat{\sigma}^2 = s^2 = \frac{1}{n-1}\sum_{j=1}^{n}(x_j - \bar{x})^2. \tag{2}$$

Clearly, (1) and (2) are estimates of parameters for distributions in which μ or σ^2 appear explicity as parameters, such as the normal and Poisson distributions. For the binomial distribution, $p = \mu/n$ [see (3) in Sec. 24.7]. From (1) we thus obtain for p the estimate

$$\hat{p} = \frac{\bar{x}}{n}. \tag{3}$$

We mention that (1) is a special case of the so-called **method of moments.** In this method the parameters to be estimated are expressed in terms of the moments of the distribution (see Sec. 24.6). In the resulting formulas those moments of the distribution are replaced by the corresponding moments of the sample. This gives the estimates. Here the ***k*th moment of a sample** $x_1, \cdots, x_n$ is

$$m_k = \frac{1}{n}\sum_{j=1}^{n} x_j^k.$$

Maximum Likelihood Method

Another method for obtaining estimates is the so-called **maximum likelihood method** of R. A. Fisher [*Messenger Math.* **41** (1912), 155–160]. To explain it, we consider a discrete (or continuous) random variable X whose probability function (or density) $f(x)$ depends on a single parameter θ. We take a corresponding sample of n ***independent*** values $x_1, \cdots, x_n$. Then in the discrete case the probability that a sample of size n consists precisely of those n values is

$$l = f(x_1)f(x_2) \cdots f(x_n). \tag{4}$$

In the continuous case the probability that the sample consists of values in the small intervals $x_j \leqq x \leqq x_j + \Delta x$ $(j = 1, 2, \cdots, n)$ is

$$f(x_1)\Delta x\, f(x_2)\Delta x \cdots f(x_n)\Delta x = l(\Delta x)^n. \tag{5}$$

Since $f(x_j)$ depends on θ, the function l in (5) given by (4) depends on $x_1, \cdots, x_n$ and θ. We imagine $x_1, \cdots, x_n$ to be given and fixed. Then l is a function of θ, which is called the **likelihood function.** The basic idea of the maximum likelihood method is quite simple, as follows. We choose *that* approximation for the unknown value of θ for which l is as large as possible. If l is a differentiable function of θ, a necessary condition for l to have a maximum in an interval (not at the boundary) is

$$\frac{\partial l}{\partial \theta} = 0. \tag{6}$$

(We write a *partial* derivative, because l depends also on $x_1, \cdots, x_n$.) A solution of (6) depending on $x_1, \cdots, x_n$ is called a **maximum likelihood estimate** for θ. We may replace (6) by

$$\frac{\partial \ln l}{\partial \theta} = 0, \tag{7}$$

because $f(x_j) > 0$, a maximum of l is in general positive, and $\ln l$ is a monotone increasing function of l. This often simplifies calculations.

Several Parameters. If the distribution of X involves r parameters $\theta_1, \cdots, \theta_r$, then instead of (6) we have the r conditions $\partial l/\partial\theta_1 = 0, \cdots, \partial l/\partial\theta_r = 0$, and instead of (7) we have

$$\frac{\partial \ln l}{\partial \theta_1} = 0, \qquad \cdots, \qquad \frac{\partial \ln l}{\partial \theta_r} = 0. \tag{8}$$

EXAMPLE 1 **Normal Distribution**

Find maximum likelihood estimates for $\theta_1 = \mu$ and $\theta_2 = \sigma$ in the case of the normal distribution.

Solution. From (1), Sec. 24.8, and (4) we obtain the likelihood function

$$l = \left(\frac{1}{\sqrt{2\pi}}\right)^n \left(\frac{1}{\sigma}\right)^n e^{-h} \qquad \text{where} \qquad h = \frac{1}{2\sigma^2} \sum_{j=1}^{n} (x_j - \mu)^2.$$

Taking logarithms, we have

$$\ln l = -n \ln \sqrt{2\pi} - n \ln \sigma - h.$$

The first equation in (8) is $\partial(\ln l)/\partial\mu = 0$, written out

$$\frac{\partial \ln l}{\partial \mu} = -\frac{\partial h}{\partial \mu} = \frac{1}{\sigma^2} \sum_{j=1}^{n} (x_j - \mu) = 0, \qquad \text{hence} \qquad \sum_{j=1}^{n} x_j - n\mu = 0.$$

The solution is the desired estimate $\hat{\mu}$ for μ; we find

$$\hat{\mu} = \frac{1}{n} \sum_{j=1}^{n} x_j = \bar{x}.$$

The second equation in (8) is $\partial(\ln l)/\partial\sigma = 0$, written out

$$\frac{\partial \ln l}{\partial \sigma} = -\frac{n}{\sigma} - \frac{\partial h}{\partial \sigma} = -\frac{n}{\sigma} + \frac{1}{\sigma^3} \sum_{j=1}^{n} (x_j - \mu)^2 = 0.$$

Replacing μ by $\hat{\mu}$ and solving for σ^2, we obtain the estimate

$$\tilde{\sigma}^2 = \frac{1}{n} \sum_{j=1}^{n} (x_j - \bar{x})^2$$

which we shall use in Sec. 25.7. Note that this differs from (2). We cannot discuss criteria for the goodness of estimates but want to mention that for small n, formula (2) is preferable. ■

PROBLEM SET 25.2

1. Find the maximum likelihood estimate for the parameter μ of a normal distribution with known variance $\sigma^2 = \sigma_0^2$.
2. Apply the maximum likelihood method to the normal distribution with $\mu = 0$.
3. **(Binomial distribution)** Derive a maximum likelihood estimate for p.
4. Extend Prob. 3 as follows. Suppose that m times n trials were made and in the first n trials A happened k_1 times, in the second n trials A happened k_2 times, $\cdots$, in the mth n trials A happened k_m times. Find a maximum likelihood estimate of p based on this information.
5. Suppose that in Prob. 4 we made 4 times 5 trials and A happened 2, 1, 4, 4 times, respectively. Estimate p.
6. Consider X = *Number of independent trials until an event A occurs.* Show that X has the probability function $f(x) = pq^{x-1}$, $x = 1, 2, \cdots$, where p is the probability of A in a single trial and $q = 1 - p$. Find the maximum likelihood estimate of p corresponding to a sample $x_1, \cdots, x_n$ of observed values of X.
7. In Prob. 6 find the maximum likelihood estimate of p corresponding to a single observation x of X.
8. In rolling a die, suppose that we get the first Six in the 7th trial and in doing it again we get it in the 6th trial. Estimate the probability p of getting a Six in rolling that die once.
9. **(Poisson distribution)** Apply the maximum likelihood method to the Poisson distribution.
10. **(Uniform distribution)** Show that in the case of the parameters a and b of the uniform distribution (see Sec. 24.6), the maximum likelihood estimate cannot be obtained by equating the first derivative to zero. How can we obtain maximum likelihood estimates in this case?
11. Find the maximum likelihood estimate of θ in the density $f(x) = \theta e^{-\theta x}$ if $x \geqq 0$ and $f(x) = 0$ if $x < 0$.
12. In Prob. 11, find the mean μ, substitute it in $f(x)$, find the maximum likelihood estimate of μ, and show that it is identical with the estimate for μ which can be obtained from that for θ in Prob. 11.
13. Compute $\hat{\theta}$ in Prob. 11 from the sample 1.8, 0.4, 0.8, 0.6, 1.4. Graph the sample distribution function $\hat{F}(x)$ and the distribution function $F(x)$ of the random variable, with $\theta = \hat{\theta}$, on the same axes. Do they agree reasonably well? (We consider goodness of fit systematically in Sec. 25.7.)

14. Do the same task as in Prob. 13 if the given sample is 0.5, 0.7, 0.1, 1.1, 0.1.

15. CAS EXPERIMENT. Maximum Likelihood Estimates. (MLEs). Find experimentally how much MLEs can differ depending on the sample size. *Hint.* Generate many samples of the same size n, e.g., of the standardized normal distribution, and record $\bar{x}$ and s^2. Then increase n.

25.3 Confidence Intervals

Confidence intervals[1] for an unknown parameter θ of some distribution (e.g., $\theta = \mu$) are intervals $\theta_1 \leqq \theta \leqq \theta_2$ that contain θ, not with certainty but with a high probability γ, which we can choose (95% and 99% are popular). Such an interval is calculated from a sample. $\gamma = 95\%$ means probability $1 - \gamma = 5\% = 1/20$ of being wrong—one of about 20 such intervals will not contain θ. Instead of writing $\theta_1 \leqq \theta \leqq \theta_2$, we denote this more distinctly by writing

$$\text{CONF}_\gamma\{\theta_1 \leqq \theta \leqq \theta_2\}. \tag{1}$$

Such a special symbol, CONF, seems worthwhile in order to avoid the misunderstanding that θ *must* lie between θ_1 and θ_2.

γ is called the **confidence level,** and θ_1 and θ_2 are called the **lower** and **upper confidence limits.** They depend on γ. The larger we choose γ, the smaller is the error probability $1 - \gamma$, but the longer is the confidence interval. If $\gamma \to 1$, then its length goes to infinity. The choice of γ depends on the kind of application. In taking no umbrella, a 5% chance of getting wet is not tragic. In a medical decision of life or death, a 5% chance of being wrong may be too large and a 1% chance of being wrong ($\gamma = 99\%$) may be more desirable.

Confidence intervals are more valuable than point estimates (Sec. 25.2). Indeed, we can take the midpoint of (1) as an approximation of θ and half the length of (1) as an "error bound" (not in the strict sense of numerics, but except for an error whose probability we know).

θ_1 and θ_2 in (1) are calculated from a sample $x_1, \cdots, x_n$. These are n observations of a random variable X. Now comes a **standard trick.** *We regard $x_1, \cdots, x_n$ as **single** observations of n random variables $X_1, \cdots, X_n$ (with the same distribution, namely, that of X).* Then $\theta_1 = \theta_1(x_1, \cdots, x_n)$ and $\theta_2 = \theta_2(x_1, \cdots, x_n)$ in (1) are observed values of two random variables $\Theta_1 = \Theta_1(X_1, \cdots, X_n)$ and $\Theta_2 = \Theta_2(X_1, \cdots, X_n)$. The condition (1) involving γ can now be written

$$P(\Theta_1 \leqq \theta \leqq \Theta_2) = \gamma. \tag{2}$$

Let us see what all this means in concrete practical cases.

In each case in this section we shall first state the steps of obtaining a confidence interval in the form of a table, then consider a typical example, and finally justify those steps theoretically.

---

[1] JERZY NEYMAN (1894–1981), American statistician, developed the theory of confidence intervals (*Annals of Mathematical Statistics* **6** (1935), 111–116).

Confidence Interval for μ of the Normal Distribution with Known σ^2

Table 25.1 Determination of a Confidence Interval for the Mean μ of a Normal Distribution with Known Variance σ^2

Step 1. Choose a confidence level γ (95%, 99%, or the like).

Step 2. Determine the corresponding c:

γ	0.90	0.95	0.99	0.999
c	1.645	1.960	2.576	3.291

Step 3. Compute the mean $\bar{x}$ of the sample $x_1, \cdots, x_n$.

Step 4. Compute $k = c\sigma/\sqrt{n}$. The confidence interval for μ is

$$\text{CONF}_\gamma \{\bar{x} - k \leqq \mu \leqq \bar{x} + k\}. \tag{3}$$

EXAMPLE 1 **Confidence Interval for μ of the Normal Distribution with Known σ^2**

Deterimine a 95% confidence interval for the mean of a normal distribution with variance $\sigma^2 = 9$, using a sample of $n = 100$ values with mean $\bar{x} = 5$.

Solution. ***Step 1.*** $\gamma = 0.95$ is required. ***Step 2.*** The corresponding c equals 1.960; see Table 25.1. ***Step 3.*** $\bar{x} = 5$ is given. ***Step 4.*** We need $k = 1.960 \cdot 3/\sqrt{100} = 0.588$. Hence $\bar{x} - k = 4.412$, $\bar{x} + k = 5.588$ and the confidence interval is $\text{CONF}_{0.95}\{4.412 \leqq \mu \leqq 5.588\}$.

This is sometimes written $\mu = 5 \pm 0.588$, but we shall not use this notation, which can be misleading. With your CAS you can determine this interval more directly. Similarly for the other examples in this section. ■

Theory for Table 25.1. The method in Table 25.1 follows from the basic

THEOREM 1 **Sum of Independent Normal Random Variables**

Let $X_1, \cdots, X_n$ be ***independent*** *normal random variables each of which has mean μ and variance σ^2. Then the following holds.*

(a) *The sum $X_1 + \cdots + X_n$ is normal with mean $n\mu$ and variance $n\sigma^2$.*

(b) The following random variable $\overline{X}$ *is normal with mean μ and variance σ^2/n.*

$$\overline{X} = \frac{1}{n}(X_1 + \cdots + X_n) \tag{4}$$

(c) *The following random variable Z is normal with mean 0 and variance 1.*

$$Z = \frac{\overline{X} - \mu}{\sigma/\sqrt{n}} \tag{5}$$

PROOF The statements about the mean and variance in (a) follow from Theorems 1 and 3 in Sec. 24.9. From this and Theorem 2 in Sec. 24.6 we see that $\overline{X}$ has the mean $(1/n)n\mu = \mu$ and the variance $(1/n)^2 n\sigma^2 = \sigma^2/n$. This implies that Z has the mean 0 and variance 1, by Theorem 2(b) in Sec. 24.6. The normality of $X_1 + \cdots + X_n$ is proved in Ref. [G3] listed in App. 1. This implies the normality of (4) and (5). ■

Derivation of (3) in Table 25.1. Sampling from a normal distribution gives independent sample values (see Sec. 25.1), so that Theorem 1 applies. Hence we can choose γ and then determine c such that

$$(6) \qquad P(-c \leqq Z \leqq c) = P\left(-c \leqq \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \leqq c\right) = \Phi(c) - \Phi(-c) = \gamma.$$

For the value $\gamma = 0.95$ we obtain $z(D) = 1.960$ from Table A8 in App. 5, as used in Example 1. For $\gamma = 0.9, 0.99, 0.999$ we get the other values of c listed in Table 25.1. Finally, all we have to do is to convert the inequality in (6) into one for μ and insert observed values obtained from the sample. We multiply $-c \leqq Z \leqq c$ by -1 and then by $\sigma/\sqrt{n}$, writing $c\sigma/\sqrt{n} = k$ (as in Table 25.1),

$$P(-c \leqq Z \leqq c) = P(c \geqq -Z \geqq -c) = P\left(c \geqq \frac{\mu - \bar{X}}{\sigma/\sqrt{n}} \geqq -c\right)$$

$$= P(k \geqq \mu - \bar{X} \geqq -k) = \gamma.$$

Adding $\bar{X}$ gives $P(\bar{X} + k \geqq \mu \geqq \bar{X} - k) = \gamma$ or

$$(7) \qquad P(\bar{X} - k \leqq \mu \leqq \bar{X} + k) = \gamma.$$

Inserting the observed value $\bar{x}$ of $\bar{X}$ gives (3). Here we have regarded $x_1, \cdots, x_n$ as single observations of $X_1, \cdots, X_n$ (the standard trick!), so that $x_1 + \cdots + x_n$ is an observed value of $X_1 + \cdots + X_n$ and $\bar{x}$ is an observed value of $\bar{X}$. Note further that (7) is of the form (2) with $\Theta_1 = \bar{X} - k$ and $\Theta_2 = \bar{X} + k$. ■

EXAMPLE 2 **Sample Size Needed for a Confidence Interval of Prescribed Length**

How large must n be in Example 1 if we want to obtain a 95% confidence interval of length $L = 0.4$?

Solution. The interval (3) has the length $L = 2k = 2c\sigma/\sqrt{n}$. Solving for n, we obtain

$$n = (2c\sigma/L)^2.$$

In the present case the answer is $n = (2 \cdot 1.960 \cdot 3/0.4)^2 \approx 870$.

Figure 525 shows how L decreases as n increases and that for $\gamma = 99\%$ the confidence interval is substantially longer than for $\gamma = 95\%$ (and the same sample size n). ■

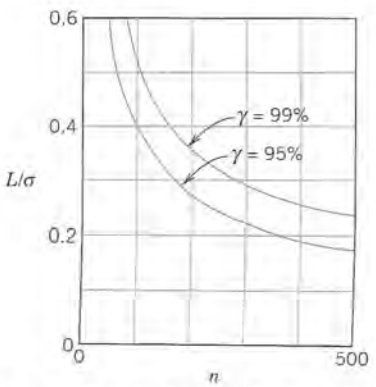

Fig. 525. Length of the confidence interval (3) (measured in multiples of σ) as a function of the sample size n for $\gamma = 95\%$ and $\gamma = 99\%$

Confidence Interval for μ of the Normal Distribution With Unknown σ^2

In practice σ^2 is frequently unknown. Then the method in Table 25.1 does not help and the whole theory changes, although the steps of determining a confidence interval for μ remain quite similar. They are shown in Table 25.2. We see that k differs from that in Table 25.1, namely, the sample standard deviation s has taken the place of the unknown standard deviation σ of the population. And c now depends on the sample size n and must be determined from Table A9 in App. 5 or from your CAS. That table lists values z for given values of the distribution function (Fig. 526)

$$F(z) = K_m \int_{-\infty}^{z} \left(1 + \frac{u^2}{m}\right)^{-(m+1)/2} du \tag{8}$$

of the ***t*-distribution**. Here, m $(= 1, 2, \cdots)$ is a parameter, called the **number of degrees of freedom** of the distribution (***abbreviated* d.f.).** In the present case, $m = n - 1$; see Table 25.2. The constant K_m is such that $F(\infty) = 1$. By integration it turns out that $K_m = \Gamma(\frac{1}{2}m + \frac{1}{2})/\left[\sqrt{m\pi}\,\Gamma(\frac{1}{2}m)\right]$, where Γ is the gamma function (see (24) in App. A3.1).

Table 25.2 Determination of a Confidence Interval for the Mean μ of a Normal Distribution with Unknown Variance σ^2

Step 1. Choose a confidence level γ (95%, 99%, or the like).

Step 2. Determine the solution c of the equation

$$F(c) = \tfrac{1}{2}(1 + \gamma) \tag{9}$$

from the table of the t-distribution with $n - 1$ degrees of freedom (Table A9 in App. 5; or use a CAS; n = sample size).

Step 3. Compute the mean $\bar{x}$ and the variance s^2 of the sample $x_1, \cdots, x_n$.

Step 4. Compute $k = cs/\sqrt{n}$. The confidence interval is

$$\text{CONF}_\gamma\,\{\bar{x} - k \leqq \mu \leqq \bar{x} + k\}. \tag{10}$$

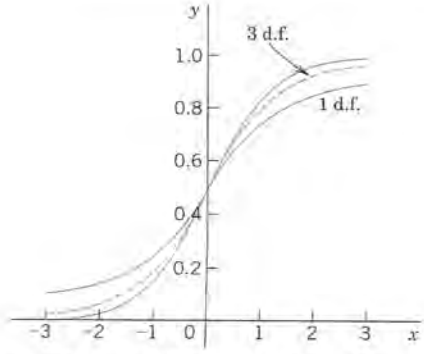

Fig. 526. Distribution functions of the t-distribution with 1 and 3 d.f. and of the standardized normal distribution (steepest curve)

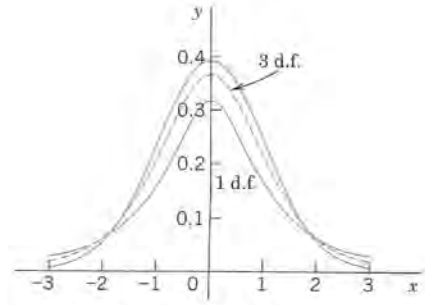

Fig. 527. Densities of the t-distribution with 1 and 3 d.f. and of the standardized normal distribution

Figure 527 compares the curve of the density of the t-distribution with that of the normal distribution. The latter is steeper. This illustrates that Table 25.1 (which uses more information, namely, the known value of σ^2) yields shorter confidence intervals than Table 25.2. This is confirmed in Fig. 528, which also gives an idea of the gain by increasing the sample size.

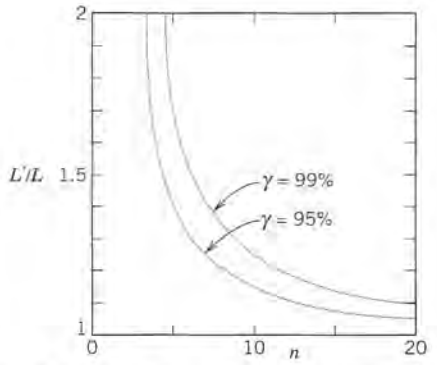

Fig. 528. Ratio of the lengths L' and L of the confidence intervals (10) and (3) with $\gamma = 95\%$ and $\gamma = 99\%$ as a function of the sample size n for equal s and σ

EXAMPLE 3 **Confidence Interval for μ of the Normal Distribution with Unknown σ^2**

Five independent measurements of the point of inflammation (flash point) of Diesel oil (D-2) gave the values (in °F) 144 147 146 142 144. Assuming normality, determine a 99% confidence interval for the mean.

Solution. ***Step 1.*** $\gamma = 0.99$ is required.

Step 2. $F(c) = \frac{1}{2}(1 + \gamma) = 0.995$, and Table A9 in App. 5 with $n - 1 = 4$ d.f. gives $c = 4.60$.

Step 3. $\bar{x} = 144.6$, $s^2 = 3.8$.

Step 4. $k = \sqrt{3.8} \cdot 4.60/\sqrt{5} = 4.01$. The confidence interval is $\text{CONF}_{0.99}\{140.5 \leqq \mu \leqq 148.7\}$.

If the variance σ^2 were known and equal to the sample variance s^2, thus $\sigma^2 = 3.8$, then Table 25.1 would give $k = c\sigma/\sqrt{n} = 2.576\sqrt{3.8}/\sqrt{5} = 2.25$ and $\text{CONF}_{0.99}\{142.35 \leqq \mu \leqq 146.85\}$. We see that the present interval is almost twice as long as that obtained from Table 25.1 (with $\sigma^2 = 3.8$). Hence for small samples the difference is considerable! See also Fig. 528. ■

Theory for Table 25.2. For deriving (10) in Table 25.2 we need from Ref. [G3]

THEOREM 2

Student's t-Distribution

Let $X_1, \cdots, X_n$ be independent normal random variables with the same mean μ and the same variance σ^2. Then the random variable

$$T = \frac{\bar{X} - \mu}{S/\sqrt{n}} \tag{11}$$

has a t-distribution [see (8)] *with $n - 1$ degrees of freedom* (d.f.); *here $\bar{X}$ is given by* (4) *and*

$$S^2 = \frac{1}{n-1} \sum_{j=1}^{n} (X_j - \bar{X})^2. \tag{12}$$

Derivation of (10). This is similar to the derivation of (3). We choose a number γ between 0 and 1 and determine a number c from Table A9 in App. 5 with $n - 1$ d.f. (or from a CAS) such that

$$P(-c \leqq T \leqq c) = F(c) - F(-c) = \gamma. \tag{13}$$

Since the t-distribution is symmetric, we have

$$F(-c) = 1 - F(c),$$

and (13) assumes the form (9). Substituting (11) into (13) and transforming the result as before, we obtain

$$P(\overline{X} - K \leqq \mu \leqq \overline{X} + K) = \gamma \tag{14}$$

where

$$K = cS/\sqrt{n}.$$

By inserting the observed values $\bar{x}$ of $\overline{X}$ and s^2 of S^2 into (14) we finally obtain (10). ■

Confidence Interval for the Variance σ^2 of the Normal Distribution

Table 25.3 shows the steps, which are similar to those in Tables 25.1 and 25.2.

Table 25.3 Determination of a Confidence Interval for the Variance σ^2 of a Normal Distribution, Whose Mean Need Not Be Known

Step 1. Choose a confidence level γ (95%, 99%, or the like).

Step 2. Determine solutions c_1 and c_2 of the equations

$$F(c_1) = \tfrac{1}{2}(1 - \gamma), \qquad F(c_2) = \tfrac{1}{2}(1 + \gamma) \tag{15}$$

from the table of the chi-square distribution with $n - 1$ degrees of freedom (Table A10 in App. 5; or use a CAS; n = sample size).

Step 3. Compute $(n - 1)s^2$, where s^2 is the variance of the sample $x_1, \cdots, x_n$.

Step 4. Compute $k_1 = (n - 1)s^2/c_1$ and $k_2 = (n - 1)s^2/c_2$. The confidence interval is

$$\text{CONF}_\gamma \{k_2 \leqq \sigma^2 \leqq k_1\}. \tag{16}$$

EXAMPLE 4 Confidence Interval for the Variance of the Normal Distribution

Determine a 95% confidence interval (16) for the variance, using Table 25.3 and a sample (tensile strength of sheet steel in kg/mm^2, rounded to integer values)

89 84 87 81 89 86 91 90 78 89 87 99 83 89.

Solution. ***Step 1.*** $\gamma = 0.95$ is required.

Step 2. For $n - 1 = 13$ we find

$$c_1 = 5.01 \quad \text{and} \quad c_2 = 24.74.$$

Step 3. $13s^2 = 326.9$.

Step 4. $13s^2/c_1 = 65.25$, $13s^2/c_2 = 13.21$.

The confidence interval is

$$\text{CONF}_{0.95}\{13.21 \leqq \sigma^2 \leqq 65.25\}.$$

This is rather large, and for obtaining a more precise result, one would need a much larger sample. ■

Theory for Table 25.3. In Table 25.1 we used the normal distribution, in Table 25.2 the t-distribution, and now we shall use the **χ^2-distribution** (*chi-square distribution*), whose distribution function is $F(z) = 0$ if $z < 0$ and

$$F(z) = C_m \int_0^z e^{-u/2} u^{(m-2)/2}\, du \qquad \text{if } z \geqq 0 \qquad \text{(Fig. 529).}$$

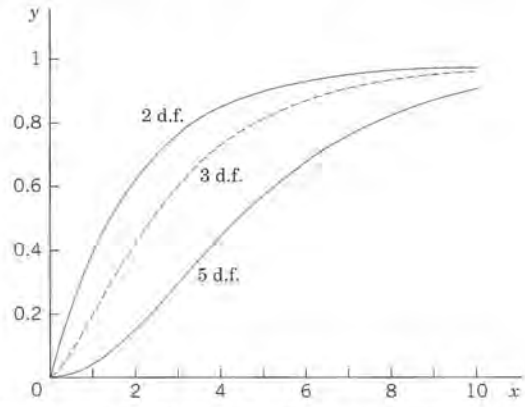

Fig. 529. Distribution function of the chi-square distribution with 2, 3, 5 d.f.

The parameter m $(= 1, 2, \cdots)$ is called the **number of degrees of freedom** (d.f.), and

$$C_m = 1/[2^{m/2}\Gamma(\tfrac{1}{2}m)].$$

Note that the distribution is not symmetric (see also Fig. 530).

For deriving (16) in Table 25.3 we need the following theorem.

THEOREM 3

Chi-Square Distribution

Under the assumptions in Theorem 2 the random variable

(17) $$Y = (n - 1)\frac{S^2}{\sigma^2}$$

with S^2 given by (12) has a chi-square distribution with $n - 1$ degrees of freedom.

Proof in Ref. [G3], listed in App. 1.

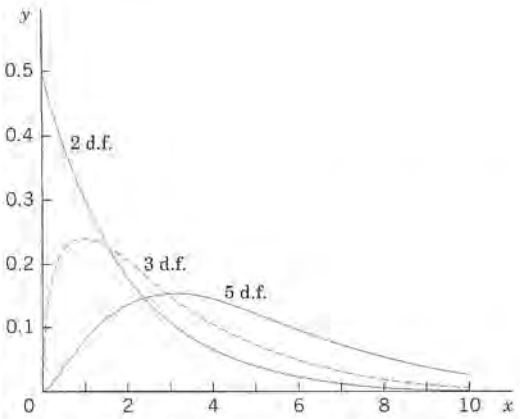

Fig. 530. Density of the chi-square distribution with 2, 3, 5 d.f.

Derivation of (16). This is similar to the derivation of (3) and (10). We choose a number γ between 0 and 1 and determine c_1 and c_2 from Table A10, App. 5, such that [see (15)]

$$P(Y \leqq c_1) = F(c_1) = \tfrac{1}{2}(1 - \gamma), \qquad P(Y \leqq c_2) = F(c_2) = \tfrac{1}{2}(1 + \gamma).$$

Subtraction yields

$$P(c_1 \leqq Y \leqq c_2) = P(Y \leqq c_2) - P(Y \leqq c_1) = F(c_2) - F(c_1) = \gamma.$$

Transforming $c_1 \leqq Y \leqq c_2$ with Y given by (17) into an inequality for σ^2, we obtain

$$\frac{n-1}{c_2} S^2 \leqq \sigma^2 \leqq \frac{n-1}{c_1} S^2.$$

By inserting the observed value s^2 of S^2 we obtain (16). ∎

Confidence Intervals for Parameters of Other Distributions

The methods in Tables 25.1–25.3 for confidence intervals for μ and σ^2 are designed for the normal distribution. We now show that they can also be applied to other distributions if we use large samples.

We know that if $X_1, \cdots, X_n$ are independent random variables with the same mean μ and the same variance σ^2, then their sum $Y_n = X_1 + \cdots + X_n$ has the following properties.

(A) Y_n has the mean $n\mu$ and the variance $n\sigma^2$ (by Theorems 1 and 3 in Sec. 24.9).

(B) If those variables are normal, then Y_n is normal (by Theorem 1).

If those random variables are not normal, then **(B)** is not applicable. However, for large n the random variable Y_n is still *approximately* normal. This follows from the central limit theorem, which is one of the most fundamental results in probability theory.

THEOREM 4

Central Limit Theorem

Let $X_1, \cdots, X_n, \cdots$ be independent random variables that have the same distribution function and therefore the same mean μ and the same variance σ^2. Let $Y_n = X_1 + \cdots + X_n$. Then the random variable

$$Z_n = \frac{Y_n - n\mu}{\sigma\sqrt{n}} \tag{18}$$

is **asymptotically normal** *with mean 0 and variance 1; that is, the distribution function $F_n(x)$ of Z_n satisfies*

$$\lim_{n\to\infty} F_n(x) = \Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-u^2/2}\, du.$$

A proof can be found in Ref. [G3] listed in App. 1.

Hence when applying Tables 25.1–25.3 to a nonnormal distribution, we must use ***sufficiently large samples.*** As a rule of thumb, if the sample indicates that the skewness of the distribution (the asymmetry; see Team Project 16(d), Problem Set 24.6) is small, use at least $n = 20$ for the mean and at least $n = 50$ for the variance.

PROBLEM SET 25.3

1–7 MEAN (VARIANCE KNOWN)

1. Find a 95% confidence interval for the mean μ of a normal population with standard deviation 4.00 from the sample 30, 42, 40, 34, 48, 50.
2. Does the interval in Prob. 1 get longer or shorter if we take $\gamma = 0.99$ instead of 0.95? By what factor?
3. By what factor does the length of the interval in Prob. 1 change if we double the sample size?
4. Find a 90% confidence interval for the mean μ of a normal population with variance 0.25, using a sample of 100 values with mean 212.3.
5. What sample size would be needed for obtaining a 95% confidence interval (3) of length 2σ? Of length σ?
6. **(Use of Fig. 525)** Find a 95% confidence interval for a sample of 200 values with mean 120 from a normal distribution with variance 4, using Fig. 525.
7. What sample size is needed to obtain a 99% confidence interval of length 2.0 for the mean of a normal population with variance 25? Use Fig. 525. Check by calculation.

8–12 MEAN (VARIANCE UNKNOWN)

Find a 99% confidence interval for the mean of a normal population from the sample:

8. 425, 420, 425, 435
9. Length of 20 bolts with sample mean 20.2 cm and sample variance 0.04 cm^2
10. Knoop hardness of diamond 9500, 9800, 9750, 9200, 9400, 9550
11. Copper content (%) of brass 66, 66, 65, 64, 66, 67, 64, 65, 63, 64
12. Melting point (°C) of aluminum 660, 667, 654, 663, 662
13. Find a 95% confidence interval for the percentage of cars on a certain highway that have poorly adjusted brakes, using a random sample of 500 cars stopped at a roadblock on that highway, 87 of which had poorly adjusted brakes.
14. Find a 99% confidence interval for p in the binomial distribution from a classical result by K. Pearson, who in 24000 trials of tossing a coin obtained 12012 Heads. Do you think that the coin was fair?

15–20 VARIANCE

Find a 95% confidence interval for the variance of a normal population from the sample:

15. A sample of 30 values with variance 0.0007

16. The sample in Prob. 9

17. The sample in Prob. 11

18. Carbon monoxide emission (grams per mile) of a certain type of passenger car (cruising at 55 mph): 17.3, 17.8, 18.0, 17.7, 18.2, 17.4, 17.6, 18.1

19. Mean energy (keV) of delayed neutron group (Group 3, half-life 6.2 sec.) for uranium U^{235} fission: 435, 451, 430, 444, 438

20. Ultimate tensile strength (k psi) of alloy steel (Maraging H) at room temperature: 251, 255, 258, 253, 253, 252, 250, 252, 255, 256

21. If X is normal with mean 27 and variance 16, what distributions do $-X$, $3X$, and $5X - 2$ have?

22. If X_1 and X_2 are independent normal random variables with mean 23 and 4 and variance 3 and 1, respectively, what distribution does $4X_1 - X_2$ have? *Hint.* Use Team Project 14(g) in Sec. 24.8.

23. A machine fills boxes weighing Y lb with X lb of salt, where X and Y are normal with mean 100 lb and 5 lb and standard deviation 1 lb and 0.5 lb, respectively. What percent of filled boxes weighing between 104 lb and 106 lb are to be expected?

24. If the weight X of bags of cement is normally distributed with a mean of 40 kg and a standard deviation of 2 kg, how many bags can a delivery truck carry so that the probability of the total load exceeding 2000 kg will be 5%?

25. CAS EXPERIMENT. Confidence Intervals. Obtain 100 samples of size 10 of the standardized normal distribution. Calculate from them and graph the corresponding 95% confidence intervals for the mean and count how many of them do not contain 0. Does the result support the theory? Repeat the whole experiment, compare and comment.

25.4 Testing of Hypotheses. Decisions

The ideas of confidence intervals and of tests[2] are the two most important ideas in modern statistics. In a statistical **test** we make inference from sample to population through testing a **hypothesis,** resulting from experience or observations, from a theory or a quality requirement, and so on. In many cases the result of a test is used as a basis for a **decision,** for instance, to buy (or not to buy) a certain model of car, depending on a test of the fuel efficiency (miles/gal) (and other tests, of course), to apply some medication, depending on a test of its effect; to proceed with a marketing strategy, depending on a test of consumer reactions, etc.

Let us explain such a test in terms of a typical example and introduce the corresponding standard notions of statistical testing.

EXAMPLE 1 **Test of a Hypothesis. Alternative. Significance Level α**

We want to buy 100 coils of a certain kind of wire, provided we can verify the manufacturer's claim that the wire has a breaking limit $\mu = \mu_0 = 200$ lb (or more). This is a test of the **hypothesis** (also called *null hypothesis*) $\mu = \mu_0 = 200$. We shall not buy the wire if the (statistical) test shows that actually $\mu = \mu_1 < \mu_0$, the wire is weaker, the claim does not hold. μ_1 is called the **alternative** (or *alternative hypothesis*) of the test. We shall **accept** the hypothesis if the test suggests that it is true, except for a small error probability α, called the **significance level** of the test. Otherwise we **reject** the hypothesis. Hence α is the probability of rejecting a hypothesis although it is true. The choice of α is up to us. 5% and 1% are popular values.

For the test we need a sample. We randomly select 25 coils of the wire, cut a piece from each coil, and determine the breaking limit experimentally. Suppose that this sample of $n = 25$ values of the breaking limit has the mean $\bar{x} = 197$ lb (somewhat less than the claim!) and the standard deviation $s = 6$ lb.

---

[2]Beginning around 1930, a systematic theory of tests was developed by NEYMAN (see Sec. 25.3) and EGON SHARPE PEARSON (1895–1980), English statistician, the son of Karl Pearson (see the footnote on p. 1066).

At this point we could only speculate whether this difference $197 - 200 = -3$ is due to randomness, is a chance effect, or whether it is **significant,** due to the actually inferior quality of the wire. To continue beyond speculation requires probability theory, as follows.

We assume that the breaking limit is normally distributed. (This assumption could be tested by the method in Sec. 25.7. Or we could remember the central limit theorem (Sec. 25.3) and take a still larger sample.) Then

$$T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$$

in (11), Sec. 25.3, with $\mu = \mu_0$ has a ***t*-distribution** with $n - 1$ degrees of freedom ($n - 1 = 24$ for our sample). Also $\bar{x} = 197$ and $s = 6$ are observed values of $\bar{X}$ and S to be used later. We can now choose a significance level, say, $\alpha = 5\%$. From Table A9 in App. 5 or from a CAS we then obtain a critical value c such that $P(T \leqq c) = \alpha = 5\%$. For $P(T \leqq \tilde{c}) = 1 - \alpha = 95\%$ the table gives $\tilde{c} = 1.71$, so that $c = -\tilde{c} = -1.71$ because of the symmetry of the distribution (Fig. 531).

We now reason as follows—this is the ***crucial idea*** of the test. If the hypothesis is true, we have a chance of only α (= 5%) that we observe a value t of T (calculated from a sample) that will fall between $-\infty$ and -1.71. Hence if we nevertheless do observe such a t, we assert that the hypothesis cannot be true and we reject it. Then we accept the alternative. If, however, $t \geqq c$, we accept the hypothesis.

A simple calculation finally gives $t = (197 - 200)/(6/\sqrt{25}) = -2.5$ as an observed value of T. Since $-2.5 < -1.71$, we reject the hypothesis (the manufacturer's claim) and accept the alternative $\mu = \mu_1 < 200$, the wire seems to be weaker than claimed. ■

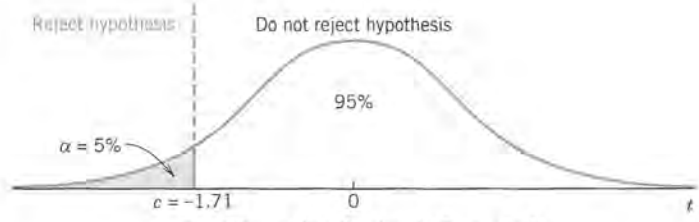

Fig. 531. *t*-distribution in Example 1

This example illustrates the ***steps of a test:***

1. Formulate the **hypothesis** $\theta = \theta_0$ to be tested. ($\theta_0 = \mu_0$ in the example.)
2. Formulate an **alternative** $\theta = \theta_1$. ($\theta_1 = \mu_1$ in the example.)
3. Choose a **significance level** α (5%, 1%, 0.1%).
4. Use a random variable $\hat{\Theta} = g(X_1, \cdots, X_n)$ whose distribution depends on the hypothesis and on the alternative, and this distribution is known in both cases. Determine a critical value c from the distribution of $\hat{\Theta}$, assuming the hypothesis to be true. (In the example, $\hat{\Theta} = T$, and c is, obtained from $P(T \leqq c) = \alpha$.)
5. Use a sample $x_1, \cdots, x_n$ to determine an observed value $\hat{\theta} = g(x_1, \cdots, x_n)$ of $\hat{\Theta}$. (t in the example.)
6. Accept or reject the hypothesis, depending on the size of $\hat{\theta}$ relative to c. ($t < c$ in the example, rejection of the hypothesis.)

Two important facts require further discussion and careful attention. The first is the choice of an alternative. In the example, $\mu_1 < \mu_0$, but other applications may require $\mu_1 > \mu_0$ or $\mu_1 \neq \mu_0$. The second fact has to do with errors. We know that α (the significance level of the test) is the probability of *rejecting* a *true* hypothesis. And we shall discuss the probability β of *accepting* a *false* hypothesis.

One-Sided and Two-Sided Alternatives (Fig. 532)

Let θ be an unknown parameter in a distribution, and suppose that we want to test the hypothesis $\theta = \theta_0$. Then there are three main kinds of alternatives, namely,

(1) $\theta > \theta_0$

(2) $\theta < \theta_0$

(3) $\theta \neq \theta_0$.

(1) and (2) are **one-sided alternatives,** and (3) is a **two-sided alternative.**

We call **rejection region** (or **critical region**) the region such that we reject the hypothesis if the observed value in the test falls in this region. In ① the critical c lies to the right of θ_0 because so does the alternative. Hence the rejection region extends to the right. This is called a **right-sided test.** In ② the critical c lies to the left of θ_0 (as in Example 1), the rejection region extends to the left, and we have a **left-sided test** (Fig. 532, middle part). These are **one-sided tests.** In ③ we have two rejection regions. This is called a **two-sided test** (Fig. 532, lower part).

All three kinds of alternatives occur in practical problems. For example, (1) may arise if θ_0 is the maximum tolerable inaccuracy of a voltmeter or some other instrument. Alternative (2) may occur in testing strength of material, as in Example 1. Finally, θ_0 in (3) may be the diameter of axle-shafts, and shafts that are too thin or too thick are equally undesirable, so that we have to watch for deviations in both directions.

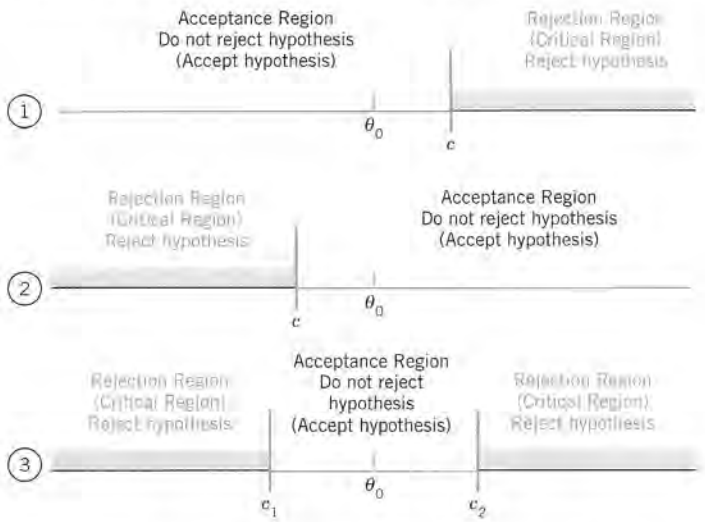

Fig. 532. Test in the case of alternative (1) (upper part of the figure), alternative (2) (middle part), and alternative (3)

Errors in Tests

Tests always involve **risks of making false decisions:**

(I) Rejecting a true hypothesis **(Type I error).**
α = Probability of making a Type I error.

(II) Accepting a false hypothesis **(Type II error).**
β = Probability of making a Type II error.

Clearly, we cannot avoid these errors because no absolutely certain conclusions about populations can be drawn from samples. But we show that there are ways and means of choosing suitable levels of risks, that is, of values α and β. The choice of α depends on the nature of the problem (e.g., a small risk $\alpha = 1\%$ is used if it is a matter of life or death).

Let us discuss this systematically for a test of a hypothesis $\theta = \theta_0$ against an alternative that is a single number θ_1, for simplicity. We let $\theta_1 > \theta_0$, so that we have a right-sided test. For a left-sided or a two-sided test the discussion is quite similar.

We choose a critical $c > \theta_0$ (as in the upper part of Fig. 532, by methods discussed below). From a given sample $x_1, \cdots, x_n$ we then compute a value

$$\hat{\theta} = g(x_1, \cdots, x_n)$$

with a suitable g (whose choice will be a main point of our further discussion; for instance, take $g = (x_1 + \cdots + x_n)/n$ in the case in which θ is the mean). If $\hat{\theta} > c$, we reject the hypothesis. If $\hat{\theta} \leqq c$, we accept it. Here, the value $\hat{\theta}$ can be regarded as an observed value of the random variable

$$\hat{\Theta} = g(X_1, \cdots, X_n) \tag{4}$$

because x_j may be regarded as an observed value of X_j, $j = 1, \cdots, n$. In this test there are two possibilities of making an error, as follows.

Type I Error (see Table 25.4). The hypothesis is true but is rejected (hence the alternative is accepted) because Θ assumes a value $\hat{\theta} > c$. Obviously, the probability of making such an error equals

$$P(\hat{\Theta} > c)_{\theta = \theta_0} = \alpha. \tag{5}$$

α is called the **significance level** of the test, as mentioned before.

Type II Error (see Table 25.4). The hypothesis is false but is accepted because $\hat{\Theta}$ assumes a value $\hat{\theta} \leqq c$. The probability of making such an error is denoted by β; thus

$$P(\hat{\Theta} \leqq c)_{\theta = \theta_1} = \beta. \tag{6}$$

$\eta = 1 - \beta$ is called the **power** of the test. Obviously, the power η is the probability of avoiding a Type II error.

Table 25.4 **Type I and Type II Errors in Testing a Hypothesis $\theta = \theta_0$ Against an Alternative $\theta = \theta_1$**

		Unknown Truth	
		$\theta = \theta_0$	$\theta = \theta_1$
Accepted	$\theta = \theta_0$	True decision $P = 1 - \alpha$	Type II error $P = \beta$
	$\theta = \theta_1$	Type 1 error $P = \alpha$	True decision $P = 1 - \beta$

Formulas (5) and (6) show that both α and β depend on c, and we would like to choose c so that these probabilities of making errors are as small as possible. But the important Figure 533 shows that these are conflicting requirements because to let α decrease we must shift c to the right, but then β increases. In practice we first choose α (5%, sometimes 1%), then determine c, and finally compute β. If β is large so that the power $\eta = 1 - \beta$ is small, we should repeat the test, choosing a larger sample, for reasons that will appear shortly.

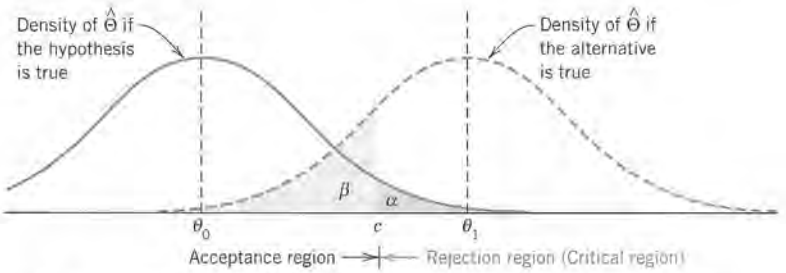

Fig. 533. Illustration of Type I and II errors in testing a hypothesis $\theta = \theta_0$ against an alternative $\theta = \theta_1$ ($> \theta_0$, right-sided test)

If the alternative is not a single number but is of the form (1)–(3), then β becomes a function of θ. This function $\beta(\theta)$ is called the **operating characteristic** (OC) of the test and its curve the **OC curve.** Clearly, in this case $\eta = 1 - \beta$ also depends on θ. This function $\eta(\theta)$ is called the **power function** of the test. (Examples will follow.)

Of course, from a test that leads to the acceptance of a certain hypothesis θ_0, it does ***not*** follow that this is the only possible hypothesis or the best possible hypothesis. Hence the terms **"not reject"** or **"fail to reject"** are perhaps better than the term **"accept."**

Test for μ of the Normal Distribution with Known σ^2

The following example explains the three kinds of hypotheses.

EXAMPLE 2 Test for the Mean of the Normal Distribution with Known Variance

Let X be a normal random variable with variance $\sigma^2 = 9$. Using a sample of size $n = 10$ with mean $\bar{x}$, test the hypothesis $\mu = \mu_0 = 24$ against the three kinds of alternatives, namely,

$$\text{(a)} \quad \mu > \mu_0 \qquad \text{(b)} \quad \mu < \mu_0 \qquad \text{(c)} \quad \mu \neq \mu_0.$$

Solution. We choose the significance level $\alpha = 0.05$. An estimate of the mean will be obtained from

$$\bar{X} = \frac{1}{n}\,(X_1 + \cdots + X_n).$$

If the hypothesis is true, $\bar{X}$ is normal with mean $\mu = 24$ and variance $\sigma^2/n = 0.9$, see Theorem 1, Sec. 25.3. Hence we may obtain the critical value c from Table A8 in App. 5.

Case (a). ***Right-Sided Test.*** We determine c from $P(\bar{X} > c)_{\mu=24} = \alpha = 0.05$, that is,

$$P(\bar{X} \leqq c)_{\mu=24} = \Phi\left(\frac{c - 24}{\sqrt{0.9}}\right) = 1 - \alpha = 0.95.$$

Table A8 in App. 5 gives $(c - 24)/\sqrt{0.9} = 1.645$, and $c = 25.56$, which is greater than μ_0, as in the upper part of Fig. 532. If $\bar{x} \leqq 25.56$, the hypothesis is accepted. If $\bar{x} > 25.56$, it is rejected. The power function of the test is (Fig. 534)

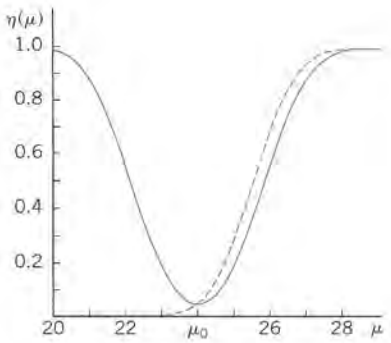

Fig. 534. Power function $\eta(\mu)$ in Example 2, case (a) (dashed) and case (c)

$$\eta(\mu) = P(\bar{X} > 25.56)_\mu = 1 - P(\bar{X} \leqq 25.56)_\mu$$

(7)
$$= 1 - \Phi\left(\frac{25.56 - \mu}{\sqrt{0.9}}\right) = 1 - \Phi(26.94 - 1.05\mu)$$

Case (b). ***Left-Sided Test.*** The critical value c is obtained from the equation

$$P(\bar{X} \leqq c)_{\mu=24} = \Phi\left(\frac{c - 24}{\sqrt{0.9}}\right) = \alpha = 0.05.$$

Table A8 in App. 5 yields $c = 24 - 1.56 = 22.44$. If $\bar{x} \geqq 22.44$, we accept the hypothesis. If $\bar{x} < 22.44$, we reject it. The power function of the test is

(8)
$$\eta(\mu) = P(\bar{X} \leqq 22.44)_\mu = \Phi\left(\frac{22.44 - \mu}{\sqrt{0.9}}\right) = \Phi(23.65 - 1.05\mu).$$

Case (c). ***Two-Sided Test.*** Since the normal distribution is symmetric, we choose c_1 and c_2 equidistant from $\mu = 24$, say, $c_1 = 24 - k$ and $c_2 = 24 + k$, and determine k from

$$P(24 - k \leqq \bar{X} \leqq 24 + k)_{\mu=24} = \Phi\left(\frac{k}{\sqrt{0.9}}\right) - \Phi\left(-\frac{k}{\sqrt{0.9}}\right) = 1 - \alpha = 0.95.$$

Table A8 in App. 5 gives $k/\sqrt{0.9} = 1.960$, hence $k = 1.86$. This gives the values $c_1 = 24 - 1.86 = 22.14$ and $c_2 = 24 + 1.86 = 25.86$. If $\bar{x}$ is not smaller than c_1 and not greater than c_2, we accept the hypothesis. Otherwise we reject it. The power function of the test is (Fig. 534)

$$\eta(\mu) = P(\bar{X} < 22.14)_\mu + P(\bar{X} > 25.86)_\mu = P(\bar{X} < 22.14)_\mu + 1 - P(\bar{X} \leqq 25.86)_\mu$$

(9)
$$= 1 + \Phi\left(\frac{22.14 - \mu}{\sqrt{0.9}}\right) - \Phi\left(\frac{25.86 - \mu}{\sqrt{0.9}}\right)$$

$$= 1 + \Phi(23.34 - 1.05\mu) - \Phi(27.26 - 1.05\mu).$$

Consequently, the operating characteristic $\beta(\mu) = 1 - \eta(\mu)$ (see before) is (Fig. 535)

$$\beta(\mu) = \Phi(27.26 - 1.05\mu) - \Phi(23.34 - 1.05\mu).$$

If we take a larger sample, say, of size $n = 100$ (instead of 10), then $\sigma^2/n = 0.09$ (instead of 0.9) and the critical values are $c_1 = 23.41$ and $c_2 = 24.59$, as can be readily verified. Then the operating characteristic of the test is

$$\beta(\mu) = \Phi\left(\frac{24.59 - \mu}{\sqrt{0.09}}\right) - \Phi\left(\frac{23.41 - \mu}{\sqrt{0.09}}\right)$$

$$= \Phi(81.97 - 3.33\mu) - \Phi(78.03 - 3.33\mu).$$

Figure 535 shows that the corresponding OC curve is steeper than that for $n = 10$. This means that the increase of n has led to an improvement of the test. In any practical case, n is chosen as small as possible but so large that the test brings out deviations between μ and μ_0 that are of practical interest. For instance, if deviations of ± 2 units are of interest, we see from Fig. 535 that $n = 10$ is much too small because when $\mu = 24 - 2 = 22$ or $\mu = 24 + 2 = 26$ β is almost 50%. On the other hand, we see that $n = 100$ is sufficient for that purpose. ■

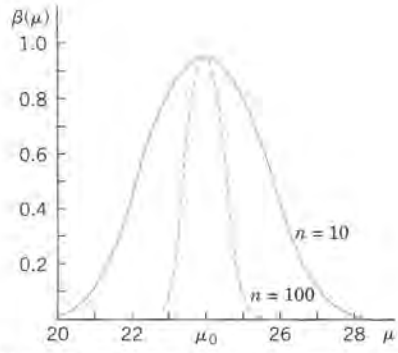

Fig. 535. Curves of the operating characteristic (OC curves) in Example 2, case (*c*), for two different sample sizes n

Test for μ When σ^2 is Unknown, and for σ^2

EXAMPLE 3 **Test for the Mean of the Normal Distribution with Unknown Variance**

The tensile strength of a sample of $n = 16$ manila ropes (diameter 3 in.) was measured. The sample mean was $\bar{x} = 4482$ kg, and the sample standard deviation was $s = 115$ kg (N. C. Wiley, 41st Annual Meeting of the American Society for Testing Materials). Assuming that the tensile strength is a normal random variable, test the hypothesis $\mu_0 = 4500$ kg against the alternative $\mu_1 = 4400$ kg. Here μ_0 may be a value given by the manufacturer, while μ_1 may result from previous experience.

Solution. We choose the significance level $\alpha = 5\%$. If the hypothesis is true, it follows from Theorem 2 in Sec. 25.3, that the random variable

$$T = \frac{\overline{X} - \mu_0}{S/\sqrt{n}} = \frac{\overline{X} - 4500}{S/4}$$

has a t-distribution with $n - 1 = 15$ d.f. The test is left-sided. The critical value c is obtained from $P(T < c)_{\mu_0} = \alpha = 0.05$. Table A9 in App. 5 gives $c = -1.75$. As an observed value of T we obtain from the sample $t = (4482 - 4500)/(115/4) = -0.626$. We see that $t > c$ and accept the hypothesis. For obtaining numeric values of the power of the test, we would need tables called noncentral Student t-tables; we shall not discuss this question here. ■

EXAMPLE 4 **Test for the Variance of the Normal Distribution**

Using a sample of size $n = 15$ and sample variance $s^2 = 13$ from a normal population, test the hypothesis $\sigma^2 = {\sigma_0}^2 = 10$ against the alternative $\sigma^2 = {\sigma_1}^2 = 20$.

Solution. We choose the significance level $\alpha = 5\%$. If the hypothesis is true, then

$$Y = (n - 1)\frac{S^2}{{\sigma_0}^2} = 14\,\frac{S^2}{10} = 1.4S^2$$

has a chi-square distribution with $n - 1 = 14$ d.f. by Theorem 3, Sec. 25.3. From

$$P(Y > c) = \alpha = 0.05, \qquad \text{that is,} \qquad P(Y \leqq c) = 0.95,$$

and Table A10 in App. 5 with 14 degrees of freedom we obtain $c = 23.68$. This is the critical value of Y. Hence

to $S^2 = \sigma_0^2 Y/(n-1) = 0.714Y$ there corresponds the critical value $c^* = 0.714 \cdot 23.68 = 16.91$. Since $s^2 < c^*$, we accept the hypothesis.

If the alternative is true, the random variable $Y_1 = 14S^2/\sigma_1^2 = 0.7S^2$ has a chi-square distribution with 14 d.f. Hence our test has the power

$$\eta = P(S^2 > c^*)_{\sigma^2=20} = P(Y_1 > 0.7c^*)_{\sigma^2=20} = 1 - P(Y_1 \leqq 11.84)_{\sigma^2=20}.$$

From a more extensive table of the chi-square distribution (e.g. in Ref. [G3] or [G8]) or from your CAS, you see that $\eta \approx 62\%$. Hence the Type II risk is very large, namely, 38%. To make this risk smaller, we would have to increase the sample size. ■

Comparison of Means and Variances

EXAMPLE 5 **Comparison of the Means of Two Normal Distributions**

Using a sample $x_1, \cdots, x_{n_1}$ from a normal distribution with unknown mean μ_x and a sample $y_1, \cdots, y_{n_2}$ from another normal distribution with unknown mean μ_y, we want to test the hypothesis that the means are equal, $\mu_x = \mu_y$, against an alternative, say, $\mu_x > \mu_y$. The variances need not be known but are assumed to be equal.[3]

Two cases of comparing means are of practical importance:

Case A. *The samples have the* ***same size.*** *Furthermore, each value of the first sample corresponds to precisely one value of the other,* because corresponding values result from the same person or thing **(paired comparison)**—for example, two measurements of the same thing by two different methods or two measurements from the two eyes of the same person. More generally, they may result from pairs of *similar* individuals or things, for example, identical twins, pairs of used front tires from the same car, etc. Then we should form the differences of corresponding values and test the hypothesis that the population corresponding to the differences has mean 0, using the method in Example 3. If we have a choice, this method is better than the following.

Case B. *The two samples are independent and not necessarily of the same size.* Then we may proceed as follows. Suppose that the alternative is $\mu_x > \mu_y$. We choose a significance level α. Then we compute the sample means $\bar{x}$ and $\bar{y}$ as well as $(n_1 - 1)s_x^2$ and $(n_2 - 1)s_y^2$, where s_x^2 and s_y^2 are the sample variances. Using Table A9 in App. 5 with $n_1 + n_2 - 2$ degrees of freedom, we now determine c from

$$P(T \leqq c) = 1 - \alpha. \tag{10}$$

We finally compute

$$t_0 = \sqrt{\frac{n_1 n_2 (n_1 + n_2 - 2)}{n_1 + n_2}} \, \frac{\bar{x} - \bar{y}}{\sqrt{(n_1 - 1)s_x^2 + (n_2 - 1)s_y^2}}. \tag{11}$$

It can be shown that this is an observed value of a random variable that has a t-distribution with $n_1 + n_2 - 2$ degrees of freedom, provided the hypothesis is true. If $t_0 \leqq c$, the hypothesis is accepted. If $t_0 > c$, it is rejected.

If the alternative is $\mu_x \neq \mu_y$, then (10) must be replaced by

$$P(T \leqq c_1) = 0.5\alpha, \qquad P(T \leqq c_2) = 1 - 0.5\alpha. \tag{10*}$$

Note that for samples of equal size $n_1 = n_2 = n$, formula (11) reduces to

$$t_0 = \sqrt{n} \, \frac{\bar{x} - \bar{y}}{\sqrt{s_x^2 + s_y^2}}. \tag{12}$$

---

[3]This assumption of equality of variances can be tested, as shown in the next example. If the test shows that they differ significantly, choose two samples of the same size $n_1 = n_2 = n$ (not too small, > 30, say), use the test in Example 2 together with the fact that (12) is an observed value of an approximately standardized normal random variable.

To illustrate the computations, let us consider the two samples $(x_1, \cdots, x_{n_1})$ and $(y_1, \cdots, y_{n_2})$ given by

105	108	86	103	103	107	124	105

and

89	92	84	97	103	107	111	97

showing the relative output of tin plate workers under two different working conditions [J. J. B. Worth, *Journal of Industrial Engineering* **9**, 249–253). Assuming that the corresponding populations are normal and have the same variance, let us test the hypothesis $\mu_x = \mu_y$ against the alternative $\mu_x \neq \mu_y$. (Equality of variances will be tested in the next example.)

Solution. We find

$$\bar{x} = 105.125, \qquad \bar{y} = 97.500, \qquad s_x^2 = 106.125, \qquad s_y^2 = 84.000.$$

We choose the significance level $\alpha = 5\%$. From (10*) with $0.5\alpha = 2.5\%$, $1 - 0.5\alpha = 97.5\%$ and Table A9 in App. 5 with 14 degrees of freedom we obtain $c_1 = -2.14$ and $c_2 = 2.14$. Formula (12) with $n = 8$ gives the value

$$t_0 = \sqrt{8} \cdot 7.625/\sqrt{190.125} = 1.56.$$

Since $c_1 \leqq t_0 \leqq c_2$, we ***accept the hypothesis*** $\mu_x = \mu_y$ that under both conditions the mean output is the same.

Case A applies to the example because the two first sample values correspond to a certain type of work, the next two were obtained in another kind of work, etc. So we may use the differences

16	16	2	6	0	0	13	8

of corresponding sample values and the method in Example 3 to test the hypothesis $\mu = 0$, where μ is the mean of the population corresponding to the differences. As a logical alternative we take $\mu \neq 0$. The sample mean is $\bar{d} = 7.625$, and the sample variance is $s^2 = 45.696$. Hence

$$t = \sqrt{8}\,(7.625 - 0)/\sqrt{45.696} = 3.19.$$

From $P(T \leqq c_1) = 2.5\%$, $P(T \leqq c_2) = 97.5\%$ and Table A9 in App. 5 with $n - 1 = 7$ degrees of freedom we obtain $c_1 = -2.36$, $c_2 = 2.36$ and ***reject the hypothesis*** because $t = 3.19$ does not lie between c_1 and c_2. Hence our present test, in which we used more information (but the same samples), shows that the difference in output is significant. ■

EXAMPLE 6 Comparison of the Variance of Two Normal Distributions

Using the two samples in the last example, test the hypothesis $\sigma_x^2 = \sigma_y^2$; assume that the corresponding populations are normal and the nature of the experiment suggests the alternative $\sigma_x^2 > \sigma_y^2$.

Solution. We find $s_x^2 = 106.125$, $s_y^2 = 84.000$. We choose the significance level $\alpha = 5\%$. Using $P(V \leqq c) = 1 - \alpha = 95\%$ and Table A11 in App. 5, with $(n_1 - 1, n_2 - 1) = (7, 7)$ degrees of freedom, we determine $c = 3.79$. We finally compute $v_0 = s_x^2/s_y^2 = 1.26$. Since $v_0 \leqq c$, we accept the hypothesis. If $v_0 > c$, we would reject it.

This test is justified by the fact that v_0 is an observed value of a random variable that has a so-called ***F*-distribution** with $(n_1 - 1, n_2 - 1)$ degrees of freedom, provided the hypothesis is true. (Proof in Ref. [G3] listed in App. 1.) The F-distribution with (m, n) degrees of freedom was introduced by R. A. Fisher[4] and has the distribution function $F(z) = 0$ if $z < 0$ and

$$\textbf{(13)} \qquad F(z) = K_{mn} \int_0^z t^{(m-2)/2}(mt + n)^{-(m+n)/2}\,dt \qquad (z \geqq 0),$$

where $K_{mn} = m^{m/2}n^{n/2}\Gamma(\frac{1}{2}m + \frac{1}{2}n)/\Gamma(\frac{1}{2}m)\Gamma(\frac{1}{2}n)$. (For Γ see App. A3.1.) ■

---

[4]After the pioneering work of the English statistician and biologist, KARL PEARSON (1857–1936), the founder of the English school of statistics, and WILLIAM SEALY GOSSET (1876–1937), who discovered the t-distribution (and published under the name 'Student'), the English statistician Sir RONALD AYLMER FISHER (1890–1962), professor of eugenics in London (1933–1943) and professor of genetics in Cambridge, England (1943–1957) and Adelaide, Australia (1957–1962), had great influence on the further development of modern statistics.

This long section contained the basic ideas and concepts of testing, along with typical applications and you may perhaps want to review it quickly before going on, because the next sections concern an adaption of these ideas to tasks of great practical importance and resulting tests in connection with quality control, acceptance (or rejection) of goods produced, and so on.

PROBLEM SET 25.4

1. Test $\mu = 0$ against $\mu > 0$, assuming normality and using the sample 1, −1, 1, 3, −8, 6, 0 (deviations of the azimuth [multiples of 0.01 radian] in some revolution of a satellite). Choose $\alpha = 5\%$.
2. In one of his classical experiments Buffon obtained 2048 heads in tossing a coin 4040 times. Was the coin fair?
3. Do the same test as in Prob. 2, using a result by K. Pearson, who obtained 6 019 heads in 12 000 trials.
4. Assuming normality and known variance $\sigma^2 = 4$, test the hypothesis $\mu = 30.0$ against the alternative (a) $\mu = 28.5$, (b) $\mu = 30.7$, using a sample of size 10 with mean $\bar{x} = 28.5$ and choosing $\alpha = 5\%$.
5. How does the result in Prob. 4(a) change if we use a smaller sample, say, of size 4, the other data ($\bar{x} = 28.5$, $\alpha = 5\%$, etc.) remaining as before?
6. Detemine the power of the test in Prob. 4(a).
7. What is the rejection region in Prob. 4 in the case of a two-sided test with $\alpha = 5\%$?
8. Using the sample 0.80, 0.81, 0.81, 0.82, 0.81, 0.82, 0.80, 0.82, 0.81, 0.81 (length of nails in inches), test the hypothesis $\mu = 0.80$ in. (the length indicated on the box) against the alternative $\mu \neq 0.80$ in. (Assume normality, choose $\alpha = 5\%$.)
9. A firm sells oil in cans containing 1000 g oil per can and is interested to know whether the mean weight differs significantly from 1000 g at the 5% level, in which case the filling machine has to be adjusted. Set up a hypothesis and an alternative and perform the test, assuming normality and using a sample of 20 fillings with mean 996 g and standard deviation 5 g.
10. If a sample of 50 tires of a certain kind has a mean life of 32 000 mi and a standard deviation of 4000 mi, can the manufacturer claim that the true mean life of such tires is greater than 30 000 mi? Set up and test a corresponding hypothesis at a 5% level, assuming normality.
11. If simultaneous measurements of electric voltage by two different types of voltmeter yield the differences (in volts) 0.8, 0.2, −0.3, 0.1, 0.0, 0.5, 0.7, 0.2, can we assert at the 5% level that there is no significant difference in the calibration of the two types of instruments? (Assume normality.)
12. If a standard medication cures about 70% of patients with a certain disease and a new medication cured 148 of the first 200 patients on whom it was tried, can we conclude that the new medication is better? (Choose $\alpha = 5\%$.)
13. Suppose that in the past the standard deviation of weights of certain 25.0-oz packages filled by a machine was 0.4 oz. Test the hypothesis H_0: $\sigma = 0.4$ against the alternative H_1: $\sigma > 0.4$ (an undesirable increase), using a sample of 10 packages with standard deviation 0.5 oz and assuming normality. (Choose $\alpha = 5\%$.)
14. Suppose that in operating battery-powered electrical equipment, it is less expensive to replace all batteries at fixed intervals than to replace each battery individually when it breaks down, provided the standard deviation of the lifetime is less than a certain limit, say, less than 5 hours. Set up and apply a suitable test, using a sample of 28 values of lifetimes with standard deviation $s = 3.5$ hours and assuming normality; choose $\alpha = 5\%$.
15. Brand A gasoline was used in 9 automobiles of the same model under identical conditions. The corresponding sample of 9 values (miles per gallon) had mean 20.2 and standard deviation 0.5. Under the same conditions, high-power brand B gasoline gave a sample of 10 values with mean 21.8 and standard deviation 0.6. Is the mileage of B significantly better than that of A? (Test at the 5% level; assume normality.)
16. The two samples 70, 80, 30, 70, 60, 80 and 140, 120, 130, 120, 120, 130, 120 are values of the differences of temperatures (°C) of iron at two stages of casting, taken from two different crucibles. Is the variance of the first population larger than that of the second? (Assume normality. Choose $\alpha = 5\%$.)
17. Using samples of sizes 10 and 16 with variances $s_x^2 = 50$ and $s_y^2 = 30$ and assuming normality of the corresponding populations, test the hypothesis H_0: $\sigma_x^2 = \sigma_y^2$ against the alternative $\sigma_x^2 > \sigma_y^2$. Choose $\alpha = 5\%$.
18. Assuming normality and equal variance and using independent samples with $n_1 = 9$, $\bar{x} = 12$, $s_x = 2$, $n_2 = 9$, $\bar{y} = 15$, $s_y = 2$, test H_0: $\mu_x = \mu_y$ against $\mu_x \neq \mu_y$; choose $\alpha = 5\%$.

19. Show that for a normal distribution the two types of errors in a test of a hypothesis H_0: $\mu = \mu_0$ against an alternative H_1: $\mu = \mu_1$ can be made as small as one pleases (not zero) by taking the sample sufficiently large.

20. CAS EXPERIMENT. Tests of Means and Variances. (a) Obtain 100 samples of size 10 each from the normal distribution with mean 100 and variance 25. For each sample test the hypothesis $\mu_0 = 100$ against the alternative $\mu_1 > 100$ at the level of $\alpha = 10\%$. Record the number of rejections of the hypothesis. Do the whole experiment once more and compare.

(b) Set up a similar experiment for the variance of a normal distribution and perform it 100 times.

25.5 Quality Control

The ideas on testing can be adapted and extended in various ways to serve basic practical needs in engineering and other fields. We show this in the remaining sections for some of the most important tasks solvable by statistical methods. As a first such area of problems, we discuss industrial quality control, a highly successful method used in various industries.

No production process is so perfect that all the products are completely alike. There is always a small variation that is caused by a great number of small, uncontrollable factors and must therefore be regarded as a chance variation. It is important to make sure that the products have required values (for example, length, strength, or whatever property may be essential in a particular case). For this purpose one makes a test of the hypothesis that the products have the required property, say, $\mu = \mu_0$, where μ_0 is a required value. If this is done after an entire lot has been produced (for example, a lot of 100 000 screws), the test will tell us how good or how bad the products are, but it it obviously too late to alter undesirable results. It is much better to test during the production run. This is done at regular intervals of time (for example, every hour or half-hour) and is called **quality control.** Each time a sample of the same size is taken, in practice 3 to 10 times. If the hypothesis is rejected, we stop the production and look for the cause of the trouble.

If we stop the production process even though it is progressing properly, we make a Type I error. If we do not stop the process even though something is not in order, we make a Type II error (see Sec. 25.4). The result of each test is marked in graphical form on what is called a **control chart.** This was proposed by W. A. Shewhart in 1924 and makes quality control particularly effective.

Control Chart for the Mean

An illustration and example of a control chart is given in the upper part of Fig. 536. This control chart for the mean shows the **lower control limit** LCL, the **center control line** CL, and the **upper control limit** UCL. The two **control limits** correspond to the critical values c_1 and c_2 in case (c) of Example 2 in Sec. 25.4. As soon as a sample mean falls outside the range between the control limits, we reject the hypothesis and assert that the production process is "out of control"; that is, we assert that there has been a shift in process level. Action is called for whenever a point exceeds the limits.

If we choose control limits that are too loose, we shall not detect process shifts. On the other hand, if we choose control limits that are too tight, we shall be unable to run the process because of frequent searches for nonexistent trouble. The usual significance level

is $\alpha = 1\%$. From Theorem 1 in Sec. 25.3 and Table A8 in App. 5 we see that in the case of the normal distribution the corresponding control limits for the mean are

$$\text{(1)} \qquad \text{LCL} = \mu_0 - 2.58\,\frac{\sigma}{\sqrt{n}}, \qquad \text{UCL} = \mu_0 + 2.58\,\frac{\sigma}{\sqrt{n}}.$$

Here σ is assumed to be known. If σ is unknown, we may compute the standard deviations of the first 20 or 30 samples and take their arithmetic mean as an approximation of σ. The broken line connecting the means in Fig. 536 is merely to display the results.

Additional, more subtle controls are often used in industry. For instance, one observes the motions of the sample means above and below the centerline, which should happen frequently. Accordingly, long runs (conventionally of length 7 or more) of means all above (or all below) the centerline could indicate trouble.

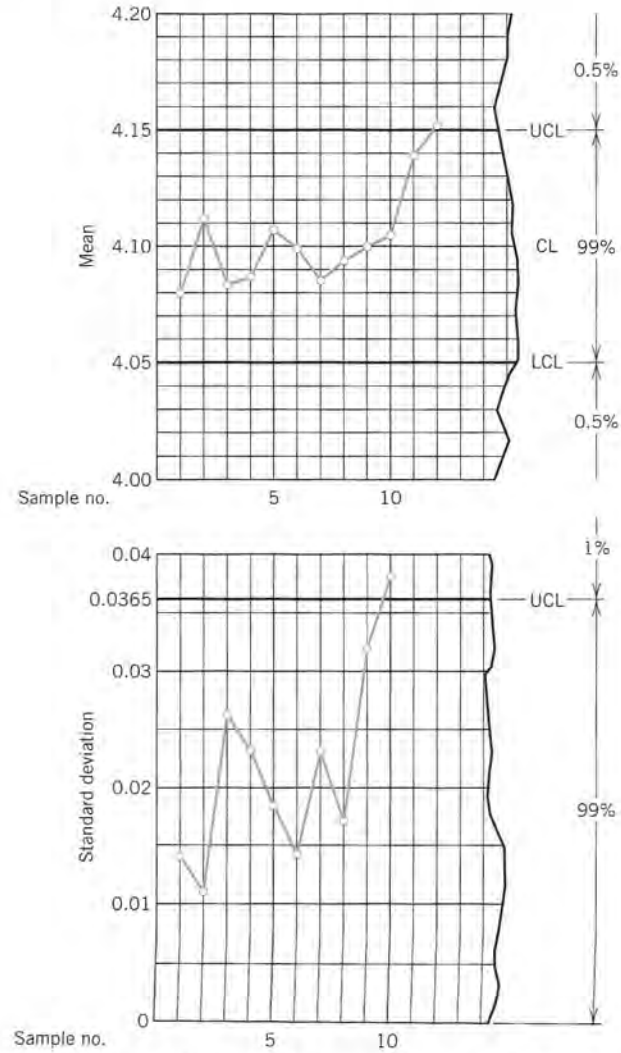

Fig. 536. Control charts for the mean (upper part of figure) and the standard deviation in the case of the samples on p. 1070

Table 25.5 Twelve Samples of Five Values Each (Diameter of Small Cylinders, Measured in Millimeters)

Sample Number	Sample Values					$\bar{x}$	s	R
1	4.06	4.08	4.08	4.08	4.10	4.080	0.014	0.04
2	4.10	4.10	4.12	4.12	4.12	4.112	0.011	0.02
3	4.06	4.06	4.08	4.10	4.12	4.084	0.026	0.06
4	4.06	4.08	4.08	4.10	4.12	4.088	0.023	0.06
5	4.08	4.10	4.12	4.12	4.12	4.108	0.018	0.04
6	4.08	4.10	4.10	4.10	4.12	4.100	0.014	0.04
7	4.06	4.08	4.08	4.10	4.12	4.088	0.023	0.06
8	4.08	4.08	4.10	4.10	4.12	4.096	0.017	0.04
9	4.06	4.08	4.10	4.12	4.14	4.100	0.032	0.08
10	4.06	4.08	4.10	4.12	4.16	4.104	0.038	0.10
11	4.12	4.14	4.14	4.14	4.16	4.140	0.014	0.04
12	4.14	4.14	4.16	4.16	4.16	4.152	0.011	0.02

Control Chart for the Variance

In addition to the mean, one often controls the variance, the standard deviation, or the range. To set up a control chart for the variance in the case of a normal distribution, we may employ the method in Example 4 of Sec. 25.4 for determining control limits. It is customary to use only one control limit, namely, an upper control limit. Now from Example 4 of Sec. 25.4 we have $S^2 = \sigma_0^2 Y/(n-1)$, where because of our normality assumption the random variable Y has a chi-square distribution with $n-1$ degrees of freedom. Hence the desired control limit is

$$\text{UCL} = \frac{\sigma^2 c}{n-1} \tag{2}$$

where c is obtained from the equation

$$P(Y > c) = \alpha, \qquad \text{that is,} \qquad P(Y \leqq c) = 1 - \alpha$$

and the table of the chi-square distribution (Table A10 in App. 5) with $n-1$ degrees of freedom (or from your CAS); here α (5% or 1%, say) is the probability that in a properly running process an observed value s^2 of S^2 is greater than the upper control limit.

If we wanted a control chart for the variance with both an upper control limit UCL and a lower control limit LCL, these limits would be

$$\text{LCL} = \frac{\sigma^2 c_1}{n-1} \qquad \text{and} \qquad \text{UCL} = \frac{\sigma^2 c_2}{n-1}. \tag{3}$$

where c_1 and c_2 are obtained from Table A10 with $n-1$ d.f. and the equations

$$P(Y \leqq c_1) = \frac{\alpha}{2} \qquad \text{and} \qquad P(Y \leqq c_2) = 1 - \frac{\alpha}{2}. \tag{4}$$

Control Chart for the Standard Deviation

To set up a control chart for the standard deviation, we need an upper control limit

$$\text{UCL} = \frac{\sigma\sqrt{c}}{\sqrt{n-1}} \tag{5}$$

obtained from (2). For example, in Table 25.5 we have $n = 5$. Assuming that the corresponding population is normal with standard deviation $\sigma = 0.02$ and choosing $\alpha = 1\ \%$, we obtain from the equation

$$P(Y \leqq c) = 1 - \alpha = 99\%$$

and Table A10 in App. 5 with 4 degrees of freedom the critical value $c = 13.28$ and from (5) the corresponding value

$$\text{UCL} = \frac{0.02\sqrt{13.28}}{\sqrt{4}} = 0.0365,$$

which is shown in the lower part of Fig. 536.

A control chart for the standard deviation with both an upper and a lower control limit is obtained from (3).

Control Chart for the Range

Instead of the variance or standard deviation, one often controls the **range** R (= largest sample value minus smallest sample value). It can be shown that in the case of the normal distribution, the standard deviation σ is proportional to the expectation of the random variable R^* for which R is an observed value, say, $\sigma = \lambda_n E(R^*)$, where the factor of proportionality λ_n depends on the sample size n and has the values

n	2	3	4	5	6	7	8	9	10
$\lambda_n = \sigma/E(R^*)$	0.89	0.59	0.49	0.43	0.40	0.37	0.35	0.34	0.32

n	12	14	16	18	20	30	40	50
$\lambda_n = \sigma/E(R^*)$	0.31	0.29	0.28	0.28	0.27	0.25	0.23	0.22

Since R depends on two sample values only, it gives less information about a sample than s does. Clearly, the larger the sample size n is, the more information we lose in using R instead of s. A practical rule is to use s when n is larger than 10.

PROBLEM SET 25.5

1. Suppose a machine for filling cans with lubricating oil is set so that it will generate fillings which form a normal population with mean 1 gal and standard deviation 0.03 gal. Set up a control chart of the type shown in Fig. 536 for controlling the mean (that is, find LCL and UCL), assuming that the sample size is 6.
2. **(Three-sigma control chart)** Show that in Prob. 1, the requirement of the significance level $\alpha = 0.3\%$ leads to $\text{LCL} = \mu - 3\sigma/\sqrt{n}$ and $\text{UCL} = \mu + 3\sigma/\sqrt{n}$, and find the corresponding numeric values.
3. What sample size should we choose in Prob. 1 if we want LCL and UCL somewhat closer together, say, $\text{UCL} - \text{LCL} = 0.05$, without changing the significance level?

4. How does the meaning of the control limits (1) change if we apply a control chart with these limits in the case of a population that is not normal?

5. How should we change the sample size in controlling the mean of a normal population if we want the difference

$$\text{UCL} - \text{LCL}$$

to decrease to half its original value?

6. What LCL and UCL should we use instead of (1) if instead of $\bar{x}$ we use the sum $x_1 + \cdots + x_n$ of the sample values? Determine these limits in the case of Fig. 536.

7. Ten samples of size 2 were taken from a production lot of bolts. The values (length in mm) are as shown. Assuming that the population is normal with mean 27.5 and variance 0.024 and using (1), set up a control chart for the mean and graph the sample means on the chart.

Sample No.	1	2	3	4	5	6	7	8	9	10
Length	27.4	27.4	27.5	27.3	27.9	27.6	27.6	27.8	27.5	27.3
	27.6	27.4	27.7	27.4	27.5	27.5	27.4	27.3	27.4	27.7

8. Graph the means of the following 10 samples (thickness of washers, coded values) on a control chart for means, assuming that the population is normal with mean 5 and standard deviation 1.55.

Time	8:00	8:30	9:00	9:30	10:00	10:30	11:00	11:30	12:00	12:30
Sample Values	3	3	5	7	7	4	5	6	5	5
	4	6	2	5	3	4	6	4	5	2
	8	6	5	4	6	3	4	6	6	5
	4	8	6	4	5	6	6	4	4	3

9. Graph the ranges of the samples in Prob. 8 on a control chart for ranges.

10. What effect on UCL − LCL does it have if we double the sample size? If we switch from $\alpha = 1\%$ to $\alpha = 5\%$?

11. Since the presence of a point outside control limits for the mean indicates trouble ("the process is out of control"), how often would we be making the mistake of looking for nonexistent trouble if we used (a) 1-sigma limits, (b) 2-sigma limits? (Assume normality.)

12. Graph $\lambda_n = \sigma/E(R^*)$ as a function of n. Why is λ_n a monotone decreasing function of n?

13. **(Number of defectives)** Find formulas for the UCL, CL, and LCL (corresponding to 3σ-limits) in the case of a control chart for the number of defectives, assuming that in a state of statistical control the fraction of defectives is p.

14. How would progressive tool wear in an automatic lathe operation be indicated by a control chart of the mean? Answer the same question for a sudden change in the position of the tool in that operation.

15. **(Number of defects per unit)** A so-called *c-chart* or *defects-per-unit chart* is used for the control of the number X of defects per unit (for instance, the number of defects per 10 meters of paper, the number of missing rivets in an airplane wing, etc.) (a) Set up formulas for CL and LCL, UCL corresponding to

$$\mu \pm 3\sigma,$$

assuming that X has a Poisson distribution. (b) Compute CL, LCL, and UCL in a control process of the number of imperfections in sheet glass; assume that this number is 2.5 per sheet on the average when the process is under control.

16. **(Attribute control charts).** Twenty samples of size 100 were taken from a production of containers. The numbers of defectives (leaking containers) in those samples (in the order observed) were

3 7 6 1 4 5 4 9 7 0 5 6 13 4

9 0 2 1 12 8.

From previous experience it was known that the average fraction defective is $p = 5\%$ provided that the process of production is running properly. Using the binomial distribution, set up a *fraction defective chart* (also called a ***p*-chart**), that is, choose the LCL = 0 and determine the UCL for the fraction defective (in percent) by the use of 3-sigma limits, where σ^2 is the variance of the random variable

$$\bar{X} = \textit{Fraction defective in a sample of size } 100.$$

Is the process under control?

17. **CAS PROJECT. Control Charts. (a)** Obtain 100 samples of 4 values each from the normal distribution with mean 8.0 and variance 0.16 and their means, variances, and ranges.

(b) Use these samples for making up a control chart for the mean.

(c) Use them on a control chart for the standard deviation.

(d) Make up a control chart for the range.

(e) Describe quantitative properties of the samples that you can see from those charts (e.g., whether the corresponding process is under control, whether the quantities observed vary randomly, etc.).

25.6 Acceptance Sampling

Acceptance sampling is usually done when products leave the factory (or in some cases even within the factory). The standard situation in acceptance sampling is that a **producer** supplies to a **consumer** (a buyer or wholesaler) a lot of N items (a carton of screws, for instance). The decision to **accept** or **reject** the lot is made by determining the number x of **defectives** (= defective items) in a sample of size n from the lot. The lot is accepted if $x \leqq c$, where c is called the **acceptance number,** giving the allowable number of defectives. If $x > c$, the consumer rejects the lot. Clearly, producer and consumer must agree on a certain **sampling plan** giving n and c.

From the hypergeometric distribution we see that the event A: *"Accept the lot"* has probability (see Sec. 24.7)

$$P(A) = P(X \leqq c) = \sum_{x=0}^{c} \binom{M}{x} \binom{N-M}{n-x} \Big/ \binom{N}{n} \tag{1}$$

where M is the number of defectives in a lot of N items. In terms of the **fraction defective** $\theta = M/N$ we can write (1) as

$$P(A;\ \theta) = \sum_{x=0}^{c} \binom{N\theta}{x} \binom{N-N\theta}{n-x} \Big/ \binom{N}{n}. \tag{2}$$

$P(A;\ \theta)$ can assume $n + 1$ values corresponding to $\theta = 0,\ 1/N,\ 2/N,\ \cdots,\ N/N$; here, n and c are fixed. A monotone smooth curve through these points is called the **operating characteristic curve (OC curve)** of the sampling plan considered.

EXAMPLE 1 **Sampling Plan**

Suppose that certain tool bits are packaged 20 to a box, and the following sampling plan is used. A sample of two tool bits is drawn, and the corresponding box is accepted if and only if both bits in the sample are good. In this case, $N = 20$, $n = 2$, $c = 0$, and (2) takes the form (a factor 2 drops out)

$$P(A;\ \theta) = \binom{20\theta}{0} \binom{20 - 20\theta}{2} \Big/ \binom{20}{2}$$

$$= \frac{(20 - 20\theta)(19 - 20\theta)}{380}.$$

The values of $P(A,\ \theta)$ for $\theta = 0,\ 1/20,\ 2/20,\ \cdots,\ 20/20$ and the resulting OC curve are shown in Fig. 537 on p. 1074. (Verify!) ■

In most practical cases θ will be small (less than 10%). Then if we take small samples compared to N, we can approximate (2) by the Poisson distribution (Sec. 24.7); thus

$$P(A;\ \theta) \sim e^{-\mu} \sum_{x=0}^{c} \frac{\mu^x}{x!} \qquad (\mu = n\theta). \tag{3}$$

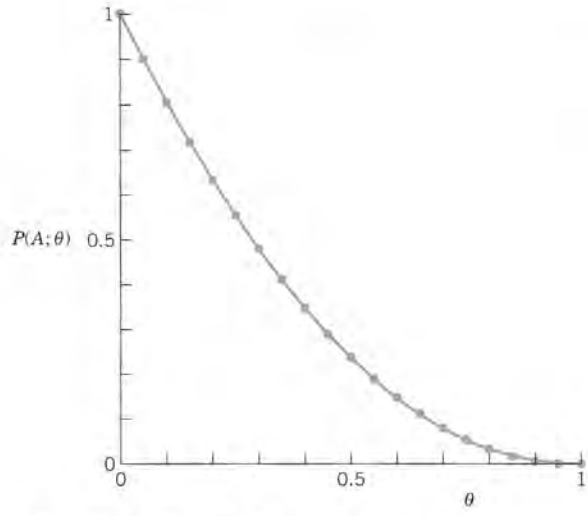

Fig. 537. OC curve of the sampling plan with $n = 2$ and $c = 0$ for lots of size $N = 20$

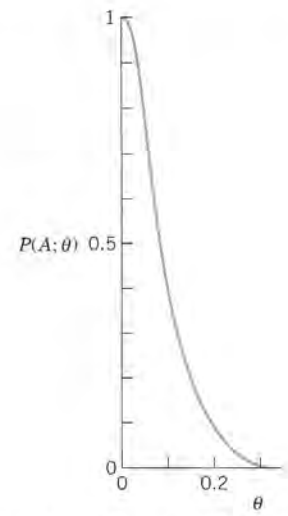

Fig. 538. OC curve in Example 2

EXAMPLE 2 **Sampling Plan. Poisson Distribution**

Suppose that for large lots the following sampling plan is used. A sample of size $n = 20$ is taken. If it contains not more than one defective, the lot is accepted. If the sample contains two or more defectives, the lot is rejected. In this plan, we obtain from (3)

$$P(A;\ \theta) \sim e^{-20\,\theta}(1 + 20\,\theta).$$

The corresponding OC curve is shown in Fig. 538. ■

Errors in Acceptance Sampling

We show how acceptance sampling fits into general test theory (Sec. 25.4) and what this means from a practical point of view. The producer wants the probability α of rejecting an **acceptable lot** (a lot for which θ does not exceed a certain number θ_0 on which the two parties agree) to be small. θ_0 is called the **acceptable quality level** (AQL). Similarly,

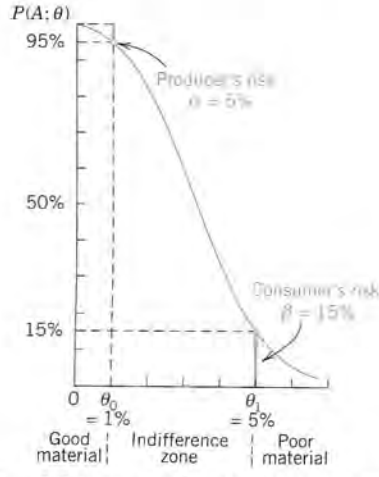

Fig. 539. OC curve, producer's and consumer's risks

the consumer (the buyer) wants the probability β of accepting an **unacceptable lot** (a lot for which θ is greater than or equal to some θ_1) to be small. θ_1 is called the **lot tolerance percent defective** (LTPD) or the **rejectable quality level** (RQL). α is called **producer's risk.** It corresponds to a Type I error in Sec. 25.4. β is called **consumer's risk** and corresponds to a Type II error. Figure 539 shows an example. We see that the points $(\theta_0, 1 - \alpha)$ and (θ_1, β) lie on the OC curve. It can be shown that for large lots we can choose θ_0, θ_1 $(> \theta_0)$, α, β and then determine n and c such that the OC curve runs very close to those prescribed points. Table 25.6 shows the analogy between acceptance sampling and hypothesis testing in Sec. 25.4.

Table 25.6 **Acceptance Sampling and Hypothesis Testing**

Acceptance Sampling	Hypothesis Testing
Acceptable quality level (AQL) $\theta = \theta_0$	Hypothesis $\theta = \theta_0$
Lot tolerance percent defectives (LTPD) $\theta = \theta_1$	Alternative $\theta = \theta_1$
Allowable number of defectives c	Critical value c
Producer's risk α of rejecting a lot with $\theta \leqq \theta_0$	Probability α of making a Type I error (significance level)
Consumer's risk β of accepting a lot with $\theta \geqq \theta_1$	Probability β of making a Type II error

Rectification

Rectification of a *rejected* lot means that the lot is inspected item by item and all defectives are removed and replaced by nondefective items. (This may be too expensive if the lot is cheap; in this case the lot may be sold at a cut-rate price or scrapped.) If a production turns out $100\theta\%$ defectives, then in K lots of size N each, $KN\theta$ of the KN items are defectives. Now $KP(A;\ \theta)$ of these lots are accepted. These contain $KPN\theta$ defectives, whereas the rejected and rectified lots contain no defectives, because of the rectification. Hence after the rectification the fraction defective in all K lots equals $KPN\theta/KN$. This is called the **average outgoing quality** (AOQ); thus

$$\text{AOQ}(\theta) = \theta P(A;\ \theta). \tag{4}$$

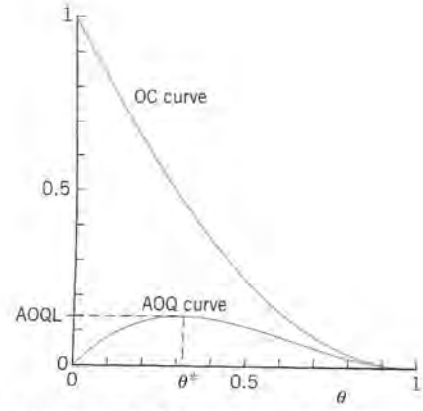

Fig. 540. OC curve and AOQ curve for the sampling plan in Fig. 537

Figure 540 on p. 1075 shows an example. Since AOQ(0) = 0 and $P(A;\ 1) = 0$, the AOQ curve has a maximum at some $\theta = \theta^*$, giving the **average outgoing quality limit** (AOQL). This is the worst average quality that may be expected to be accepted under rectification.

PROBLEM SET 25.6

1. Lots of knives are inspected by a sampling plan that uses a sample of size 20 and the acceptance number $c = 1$. What are probabilities of accepting a lot with 1%, 2%, 10% defectives (dull blades)? Use Table A6 in App. 5. Graph the OC curve.
2. What happens in Prob. 1 if the sample size is increased to 50? First guess. Then calculate. Graph the OC curve and compare.
3. How will the probabilities in Prob. 1 with $n = 20$ change (up or down) if we decrease c to zero? First guess.
4. What are the producer's and consumer's risks in Prob. 1 if the AQL is 1.5% and the RQL is 7.5%?
5. Large lots of batteries are inspected according to the following plan. $n = 30$ batteries are randomly drawn from a lot and tested. If this sample contains at most $c = 1$ defective battery, the lot is accepted. Otherwise it is rejected. Graph the OC curve of the plan, using the Poisson approximation.
6. Graph the AOQ curve in Prob. 5. Determine the AOQL, assuming that rectification is applied.
7. Do the work required in Prob. 5 if $n = 50$ and $c = 0$.
8. Find the binomial approximation of the hypergeometric distribution in Example 1 and compare the approximate and the accurate values.
9. In Example 1, what are the producer's and consumer's risks if the AQL is 0.1 and the RQL is 0.6?
10. Calculate $P(A;\ \theta)$ in Example 1 if the sample size is increased from $n = 2$ to $n = 3$, the other data remaining as before. Compute $P(A;\ 0.10)$ and $P(A;\ 0.20)$ and compare with Example 1.
11. Samples of 5 screws are drawn from a lot with fraction defective θ. The lot is accepted if the sample contains (a) no defective screws, (b) at most 1 defective screw. Using the binomial distribution, find, graph, and compare the OC curves.
12. Find the risks in the single sampling plan with $n = 5$ and $c = 0$, assuming that the AQL is $\theta_0 = 1\%$ and the RQL is $\theta_1 = 15\%$.
13. Why is it impossible for an OC curve to have a vertical portion separating good from poor quality?
14. If in a single sampling plan for large lots of spark plugs, the sample size is 100 and we want the AQL to be 5% and the producer's risk 2%, what acceptance number c should we choose? (Use the normal approximation.)
15. What is the consumer's risk in Prob. 14 if we want the RQL to be 12%?
16. Graph and compare sampling plans with $c = 1$ and increasing values of n, say, $n = 2, 3, 4$. (Use the binomial distribution.)
17. Samples of 3 fuses are drawn from lots and a lot is accepted if in the corresponding sample we find no more than 1 defective fuse. Criticize this sampling plan. In particular, find the probability of accepting a lot that is 50% defective. (Use the binomial distribution.)
18. Graph the OC curve and the AOQ curve for the single sampling plan for large lots with $n = 5$ and $c = 0$, and find the AOQL.

25.7 Goodness of Fit. χ^2-Test

To test for **goodness of fit** means that we wish to test that a certain function $F(x)$ is the distribution function of a distribution from which we have a sample $x_1, \cdots, x_n$. Then we test whether the **sample distribution function** $\tilde{F}(x)$ defined by

$$\tilde{F}(x) = \textit{Sum of the relative frequencies of all sample values } x_j \textit{ not exceeding } x$$

fits $F(x)$ "sufficiently well." If this is so, we shall accept the hypothesis that $F(x)$ is the distribution function of the population; if not, we shall reject the hypothesis.

This test is of considerable practical importance, and it differs in character from the tests for parameters (μ, σ^2, etc.) considered so far.

To test in that fashion, we have to know how much $\tilde{F}(x)$ can differ from $F(x)$ if the hypothesis is true. Hence we must first introduce a quantity that measures the deviation of $\tilde{F}(x)$ from $F(x)$, and we must know the probability distribution of this quantity under the assumption that the hypothesis is true. Then we proceed as follows. We determine a number c such that if the hypothesis is true, a deviation greater than c has a small preassigned probability. If, nevertheless, a deviation greater than c occurs, we have reason to doubt that the hypothesis is true and we reject it. On the other hand, if the deviation does not exceed c, so that $\tilde{F}(x)$ approximates $F(x)$ sufficiently well, we accept the hypothesis. Of course, if we accept the hypothesis, this means that we have insufficient evidence to reject it, and this does not exclude the possibility that there are other functions that would not be rejected in the test. In this respect the situation is quite similar to that in Sec. 25.4.

Table 25.7 shows a test of that type, which was introduced by R. A. Fisher. This test is justified by the fact that if the hypothesis is true, then ${\chi_0}^2$ is an observed value of a random variable whose distribution function approaches that of the chi-square distribution with $K - 1$ degrees of freedom (or $K - r - 1$ degrees of freedom if r parameters are estimated) as n approaches infinity. The requirement that at least five sample values lie in each interval in Table 25.7 results from the fact that for finite n that random variable has only *approximately* a chi-square distribution. A proof can be found in Ref. [G3] listed in App. 1. If the sample is so small that the requirement cannot be satisfied, one may continue with the test, but then use the result with caution.

Table 25.7 Chi-square Test for the Hypothesis That $F(x)$ is the Distribution Function of a Population from Which a Sample $x_1, \cdots, x_n$ is Taken

Step 1. Subdivide the x-axis into K intervals $I_1, I_2, \cdots, I_K$ such that each interval contains at least 5 values of the given sample $x_1, \cdots, x_n$. Determine the number b_j of sample values in the interval I_j, where $j = 1, \cdots, K$. If a sample value lies at a common boundary point of two intervals, add 0.5 to each of the two corresponding b_j.

Step 2. Using $F(x)$, compute the probability p_j that the random variable X under consideration assumes any value in the interval I_j, where $j = 1, \cdots, K$. Compute

$$e_j = np_j.$$

(This is the number of sample values theoretically expected in I_j if the hypothesis is true.)

Step 3. Compute the deviation

$$(1) \qquad {\chi_0}^2 = \sum_{j=1}^{K} \frac{(b_j - e_j)^2}{e_j}.$$

Step 4. Choose a significance level (5%, 1%, or the like).

Step 5. Determine the solution c of the equation

$$P(\chi^2 \leqq c) = 1 - \alpha$$

from the table of the chi-sqare distribution with $K - 1$ degrees of freedom (Table A10 in App. 5). If r parameters of $F(x)$ are unknown and their maximum likelihood estimates (Sec. 25.2) are used, then use $K - r - 1$ degrees of freedom (instead of $K - 1$). If ${\chi_0}^2 \leqq c$, accept the hypothesis. If ${\chi_0}^2 > c$, reject the hypothesis.

D. L. IVEY, Splitting tensile tests on structural lightweight aggregate concrete. Texas Transportation Institute, College Station, Texas.

EXAMPLE 1 **Test of Normality**

Test whether the population from which the sample in Table 25.8 was taken is normal.

Solution. Table 25.8 shows the values (column by column) in the order obtained in the experiment. Table 25.9 gives the frequency distribution and Fig. 541 the histogram. It is hard to guess the outcome of the test—does the histogram resemble a normal density curve sufficiently well or not?

The maximum likelihood estimates for μ and σ^2 are $\hat{\mu} = \bar{x} = 364.7$ and $\hat{\sigma}^2 = 712.9$. The computation in Table 25.10 yields ${\chi_0}^2 = 2.942$. It is very interesting that the interval $375 \cdots 385$ contributes over 50% of ${\chi_0}^2$. From the histogram we see that the corresponding frequency looks much too small. The second largest contribution comes from $395 \cdots 405$, and the histogram shows that the frequency seems somewhat too large, which is perhaps not obvious from inspection.

Table 25.9 Frequency Table of the Sample in Table 25.8

1 Tensile Strength x [lb/in.^{2}]	2 Absolute Frequency	3 Relative Frequency $\tilde{f}(x)$	4 Cumulative Absolute Frequency	5 Cumulative Relative Frequency $\tilde{F}(x)$
300	2	0.02	2	0.02
310	0	0.00	2	0.02
320	4	0.04	6	0.06
330	6	0.06	12	0.12
340	11	0.11	23	0.23
350	14	0.14	37	0.37

430	0	0.00	99	0.99
440	1	0.01	100	1.00

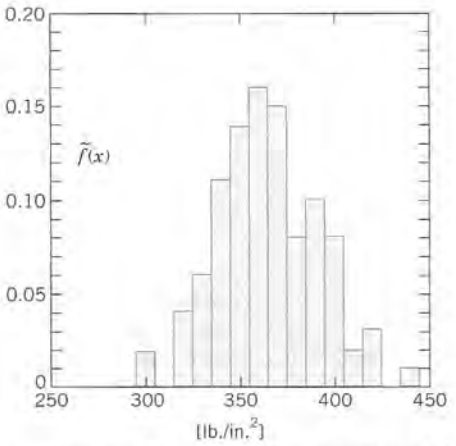

Fig. 541. Frequency histogram of the sample in Table 25.8

We choose $\alpha = 5\%$. Since $K = 10$ and we estimated $r = 2$ parameters we have to use Table A10 in App. 5 with $K - r - 1 = 7$ degrees of freedom. We find $c = 14.07$ as the solution of $P(\chi^2 \leqq c) = 95\%$. Since $\chi_0^2 < c$, we accept the hypothesis that the population is normal. ■

Table 25.10 **Computations in Example 1**

x_j	$\frac{x_j - 364.7}{26.7}$	$\Phi\left(\frac{x_j - 364.7}{26.7}\right)$	e_j	b_j	Term in (1)

$\chi_0^2 = 2.942$

PROBLEM SET 25.7

1. If 100 flips of a coin result in 30 heads and 70 tails, can we assert on the 5% level that the coin is fair?
2. If in 10 flips of a coin we get the same ratio as in Prob. 1 (3 heads and 7 tails), is the conclusion the same as in Prob. 1? First conjecture, then compute.
3. What would be the smallest number of heads in Prob. 1 under which the hypothesis "Fair coin" is still accepted (with $\alpha = 5\%$)?
4. If in rolling a die 180 times we get 39, 22, 41, 26, 20, 32, can we claim on the 5% level that the die is fair?
5. Solve Prob. 4 if the sample is 25, 31, 33, 27, 29, 35.
6. A manufacturer claims that in a process of producing kitchen knives, only 2.5% of the knives are dull. Test the claim against the alternative that more than 2.5% of the knives are dull, using a sample of 400 knives containing 17 dull ones. (Use $\alpha = 5\%$.)
7. Between 1 P.M. and 2 P.M. on five consecutive days (Monday through Friday) a certain service station has 92, 60, 66, 62, and 90 customers, respectively. Test the hypothesis that the expected number of customers during that hour is the same on those days. (Use $\alpha = 5\%$.)

8. Test for normality at the 1% level using a sample of $n = 79$ (rounded) values x (tensile strength [kg/mm^2] of steel sheets of 0.3 mm thickness). $a = a(x)$ = absolute frequency. (Take the first two values together, also the last three, to get $K = 5$.)

x	57	58	59	60	61	62	63	64
a	4	10	17	27	8	9	3	1

9. In a sample of 100 patients having a certain disease 45 are men and 55 women. Does this support the claim that the disease is equally common among men and women? Choose $\alpha = 5\%$.

10. In Prob. 9 find the smallest number (>50) of women that leads to the rejection of the hypothesis on the levels 5%, 1%, 0.5%.

11. Verify the calculations in Example 1 of the text.

12. Does the random variable X = *Number of accidents per week in a certain foundry* have a Poisson distribution if within 50 weeks, 33 were accident-free, 1 accident occurred in 11 of the 50 weeks, 2 in 6 of the weeks and more than 2 accidents in no week? (Choose $\alpha = 5\%$.)

13. Using the given sample, test that the corresponding population has a Poisson distribution. x is the number of alpha particles per 7.5-sec intervals observed by E. Rutherford and H. Geiger in one of their classical experiments in 1910, and $a(x)$ is the absolute frequency (= number of time periods during which exactly x particles were observed). (Use $\alpha = 5\%$.)

x	0	1	2	3	4	5	6
a	57	203	383	525	532	408	273
x	7	8	9	10	11	12	≧13
a	139	45	27	10	4	2	0

14. Can we assert that the traffic on the three lanes of an expressway (in one direction) is about the same on each lane if a count gives 910, 850, 720 cars on the right, middle, and left lanes, respectively, during a particular time interval? (Use $\alpha = 5\%$.)

15. If it is known that 25% of certain steel rods produced by a standard process will break when subjected to a load of 5000 lb, can we claim that a new process yields the same breakage rate if we find that in a sample of 80 rods produced by the new process, 27 rods broke when subjected to that load? (Use $\alpha = 5\%$.)

16. Three samples of 200 rivets each were taken from a large production of each of three machines. The numbers of defective rivets in the samples were 7, 8, and 12. Is this difference significant? (Use $\alpha = 5\%$.)

17. In a table of properly rounded function values, even and odd last decimals should appear about equally often. Test this for the 90 values of $J_1(x)$ in Table A1 in App. 5.

18. Are the 5 tellers in a certain bank equally time-efficient if during the same time interval on a certain day they serve 120, 95, 110, 108, 102 customers? (Use $\alpha = 5\%$.)

19. CAS EXPERIMENT. Random Number Generator. Check your generator experimentally by imitating results of n trials of rolling a fair die, with a convenient n (e.g., 60 or 300 or the like). Do this many times and see whether you can notice any "nonrandomness" features, for example, too few Sixes, too many even numbers, etc., or whether your generator seems to work properly. Design and perform other kinds of checks.

20. TEAM PROJECT. Difficulty with Random Selection. 77 students were asked to choose 3 of the integers 11, 12, 13, · · · , 30 completely arbitrarily. The amazing result was as follows.

Number	11	12	13	14	15	16	17	18	19	20
Frequ.	11	10	20	8	13	9	21	9	16	8
Number	21	22	23	24	25	26	27	28	29	30
Frequ.	12	8	15	10	10	9	12	8	13	9

If the selection were completely random, the following hypotheses should be true.

(a) The 20 numbers are equally likely.

(b) The 10 even numbers together are as likely as the 10 odd numbers together.

(c) The 6 prime numbers together have probability 0.3 and the 14 other numbers together have probability 0.7. Test these hypotheses, using $\alpha = 5\%$. Design further experiments that illustrate the difficulties of random selection.

25.8 Nonparametric Tests

Nonparametric tests, also called **distribution-free tests,** are valid for any distribution. Hence they are used in cases when the kind of distribution is unknown, or is known but such that no tests specifically designed for it are available. In this section we shall explain the basic idea of these tests, which are based on **"order statistics"** and are rather simple.

If there is a choice, then tests designed for a specific distribution generally give better results than do nonparametric tests. For instance, this applies to the tests in Sec. 25.4 for the normal distribution.

We shall discuss two tests in terms of typical examples. In deriving the distributions used in the test, it is essential that the distributions from which we sample are continuous. (Nonparametric tests can also be derived for discrete distributions, but this is slightly more complicated.)

EXAMPLE 1 Sign Test for the Median

A **median** of the population is a solution $x = \tilde{\mu}$ of the equation $F(x) = 0.5$, where F is the distribution function of the population.

Suppose that eight radio operators were tested, first in rooms without air-conditioning and then in air-conditioned rooms over the same period of time, and the difference of errors (unconditioned minus conditioned) were

$$9 \quad 4 \quad 0 \quad 6 \quad 4 \quad 0 \quad 7 \quad 11.$$

Test the hypothesis $\tilde{\mu} = 0$ (that is, air-conditioning has no effect) against the alternative $\tilde{\mu} > 0$ (that is, inferior performance in unconditioned rooms).

Solution. We choose the significance level $\alpha = 5\%$. If the hypothesis is true, the probability p of a positive difference is the same as that of a negative difference. Hence in this case, $p = 0.5$, and the random variable

$$X = \textit{Number of positive values among } n \textit{ values}$$

has a binomial distribution with $p = 0.5$. Our sample has eight values. We omit the values 0, which do not contribute to the decision. Then six values are left, all of which are positive. Since

$$\begin{aligned} P(X = 6) &= \binom{6}{6} (0.5)^6 (0.5)^0 \\ &= 0.0156 \\ &= 1.56\% \end{aligned}$$

we do have observed an event whose probability is very small if the hypothesis is true: in fact $1.56\% < \alpha = 5\%$. Hence we assert that the alternative $\tilde{\mu} > 0$ is true. That is, the number of errors made in unconditioned rooms is significantly higher, so that installation of air conditioning should be considered. ■

EXAMPLE 2 Test for Arbitrary Trend

A certain machine is used for cutting lengths of wire. Five successive pieces had the lengths

$$29 \quad 31 \quad 28 \quad 30 \quad 32.$$

Using this sample, test the hypothesis that there is **no trend,** that is, the machine does not have the tendency to produce longer and longer pieces or shorter and shorter pieces. Assume that the type of machine suggests the alternative that there is *positive trend,* that is, there is the tendency of successive pieces to get longer.

Solution. We count the number of **transpositions** in the sample, that is, the number of times a larger value precedes a smaller value:

29 precedes 28 (1 transposition),

31 precedes 28 and 30 (2 transpositions).

The remaining three sample values follow in ascending order. Hence in the sample there are $1 + 2 = 3$ transpositions. We now consider the random variable

$$T = \textit{Number of transpositions.}$$

If the hypothesis is true (no trend), then each of the $5! = 120$ permutations of five elements 1 2 3 4 5 has the same probability (1/120). We arrange these permutations according to their number of transpositions:

$T = 0$	$T = 1$	$T = 2$	$T = 3$
1 2 3 4 5	1 2 3 5 4	1 2 4 5 3	1 2 5 4 3
	1 2 4 3 5	1 2 5 3 4	1 3 4 5 2
	1 3 2 4 5	1 3 2 5 4	1 3 5 2 4
	2 1 3 4 5	1 3 4 2 5	1 4 2 5 3
		1 4 2 3 5	1 4 3 2 5
		2 1 3 5 4	1 5 2 3 4
		2 1 4 3 5	2 1 4 5 3
		2 3 1 4 5	2 1 5 3 4 etc.
		3 1 2 4 5	2 3 1 5 4
			2 3 4 1 5
			2 4 1 3 5
			3 1 2 5 4
			3 1 4 2 5
			3 2 1 4 5
			4 1 2 3 5

From this we obtain

$$P(T \leqq 3) = \tfrac{1}{120} + \tfrac{4}{120} + \tfrac{9}{120} + \tfrac{15}{120} = \tfrac{29}{120} = 24\%.$$

We accept the hypothesis because we have observed an event that has a relatively large probability (certainly much more than 5%) if the hypothesis is true.

Values of the distribution function of T in the case of no trend are shown in Table A12, App. 5. For instance, if $n = 3$, then $F(0) = 0.167$, $F(1) = 0.500$, $F(2) = 1 - 0.167$. If $n = 4$, then $F(0) = 0.042$, $F(1) = 0.167$, $F(2) = 0.375$, $F(3) = 1 - 0.375$, $F(4) = 1 - 0.167$, and so on.

Our method and those values refer to *continuous* distributions. Theoretically, we may then expect that all the values of a sample are different. Practically, some sample values may still be equal, because of rounding: If m values are equal, add $m(m - 1)/4$ (= mean value of the transpositions in the case of the permutations of m elements), that is, $\frac{1}{2}$ for each pair of equal values, $\frac{3}{2}$ for each triple, etc. ■

PROBLEM SET 25.8

1. What would change in Example 1, had we observed only 5 positive values? Only 4?

2. Does a process of producing plastic pipes of length $\mu = 2$ meters need adjustment if in a sample, 4 pipes have the exact length and 15 are shorter and 3 longer than 2 meters? (Use the normal approximation of the binomial distribution.)

3. Do the computations in Prob. 2 without the use of the DeMoivre–Laplace limit theorem (in Sec. 24.8).

4. Test whether a thermostatic switch is properly set to 20°C against the alternative that its setting is too low. Use a sample of 9 values, 8 of which are less than 20°C and 1 is greater than 20°C.

5. Are air filters of type A better than type B filters if in 10 trials, A gave cleaner air than B in 7 cases, B gave cleaner air than A in 1 case, whereas in 2 of the trials the results for A and B were practically the same?

6. In a clinical experiment, each of 10 patients were given two different sedatives A and B. The following table shows the effect (increase of sleeping time, measured in hours). Using the sign test, find out whether the difference is significant.

A	1.9	0.8	1.1	0.1	−0.1	4.4	5.5	1.6	4.6	3.4
B	0.7	−1.6	−0.2	−1.2	−0.1	3.4	3.7	0.8	0.0	2.0
Difference	1.2	2.4	1.3	1.3	0.0	1.0	1.8	0.8	4.6	1.4

7. Assuming that the populations corresponding to the samples in Prob. 6 are normal, apply a suitable test for the normal distribution.

8. Thirty new employees were grouped into 15 pairs of similar intelligence and experience and were then instructed in data processing by an old method (A) applied to one (randomly selected) person of each pair, and by a new presumably better method (B) applied to

the other person of each pair. Test for equality of methods against the alternative that (B) is better than (A), using the following scores obtained after the end of the training period.

A	60	70	80	85	75	40	70	45	95	80	90	60	80	75	65
B	65	85	85	80	95	65	100	60	90	85	100	75	90	60	80

9. Assuming normality, solve Prob. 8 by a suitable test from Sec. 25.4.

10. Set up a sign test for the lower quartile q_{25} (defined by the condition $F(q_{25}) = 0.25$).

11. How would you proceed in the sign test if the hypothesis is $\tilde{\mu} = \tilde{\mu}_0$ (any number) instead of $\tilde{\mu} = 0$?

12. Check the table in Example 2 of the text.

13. Apply the test in Example 2 to the following data (x = disulfide content of a certain type of wool, measured in percent of the content in unreduced fibers; y = saturation water content of the wool, measured in percent). Test for no trend against negative trend.

x	10	15	30	40	50	55	80	100
y	50	46	43	42	36	39	37	33

14. Test the hypothesis that for a certain type of voltmeter, readings are independent of temperature T [°C] against the alternative that they tend to increase with T. Use a sample of values obtained by applying a constant voltage:

Temperature T [°C]	10	20	30	40	50
Reading V [volts]	99.5	101.1	100.4	100.8	101.6

15. In a swine-feeding experiment, the following gains in weight [kg] of 10 animals (ordered according to increasing amounts of food given per day) were recorded:

20 17 19 18 23 16 25 28 24 22.

Test for no trend against positive trend.

16. Apply the test explained in Example 2 to the following data (x = diastolic blood pressure [mm Hg], y = weight of heart [in grams] of 10 patients who died of cerebral hemorrhage).

x	121	120	95	123	140	112	92	100	102	91
y	521	465	352	455	490	388	301	395	375	418

17. Does an increase in temperature cause an increase of the yield of a chemical reaction from which the following sample was taken?

Temperature [°C]	10	20	30	40	60	80
Yield [kg/min]	0.6	1.1	0.9	1.6	1.2	2.0

18. Does the amount of fertilizer increase the yield of wheat X [kg/plot]? Use a sample of values ordered according to increasing amounts of fertilizer:

41.4 43.3 39.6 43.0 44.1 45.6 44.5 46.7.

25.9 Regression. Fitting Straight Lines. Correlation

So far we were concerned with random experiments in which we observed a single quantity (random variable) and got samples whose values were single numbers. In this section we discuss experiments in which we observe or measure two quantities simultaneously, so that we get samples of *pairs* of values (x_1, y_1), (x_2, y_2), $\cdots$, (x_n, y_n). Most applications involve one of two kinds of experiments, as follows.

1. In **regression analysis** one of the two variables, call it x, can be regarded as an ordinary variable because we can measure it without substantial error or we can even give it values we want. x is called the **independent variable,** or sometimes the **controlled variable** because we can control it (set it at values we choose). The other variable, Y, is a random variable, and we are interested in the dependence of Y on x. Typical examples are the dependence of the blood pressure Y on the age x of a person or, as we shall now say, the regression of Y on x, the regression of the gain of weight Y of certain animals on the daily ration of food x, the regression of the heat conductivity Y of cork on the specific weight x of the cork, etc.

2. In **correlation analysis** both quantities are random variables and we are interested in relations between them. Examples are the relation (one says "correlation") between wear X and wear Y of the front tires of cars, between grades X and Y of students in mathematics and in physics, respectively, between the hardness X of steel plates in the center and the hardness Y near the edges of the plates, etc.

Regression Analysis

In regression analysis the dependence of Y on x is a dependence of the mean μ of Y on x, so that $\mu = \mu(x)$ is a function in the ordinary sense. The curve of $\mu(x)$ is called the **regression curve** of Y on x.

In this section we discuss the simplest case, namely, that of a straight **regression line**

$$\mu(x) = \kappa_0 + \kappa_1 x. \tag{1}$$

Then we may want to graph the sample values as n points in the xY-plane, fit a straight line through them, and use it for estimating $\mu(x)$ at values of x that interest us, so that we know what values of Y we can expect for those x. Fitting that line by eye would not be good because it would be subjective; that is, different persons' results would come out differently, particularly if the points are scattered. So we need a mathematical method that gives a unique result depending only on the n points. A widely used procedure is the method of least squares by Gauss and Legendre. For our task we may formulate it as follows.

Least Squares Principle

The straight line should be fitted through the given points so that the sum of the squares of the distances of those points from the straight line is minimum, where the distance is measured in the vertical direction (the y-direction). (Formulas below.)

To get uniqueness of the straight line, we need some extra condition. To see this, take the sample $(0, 1)$, $(0, -1)$. Then all the lines $y = k_1 x$ with any k_1 satisfy the principle. (Can you see it?) The following assumption will imply uniqueness, as we shall find out.

General Assumption (A1)

The x-values $x_1, \cdots, x_n$ in our sample $(x_1, y_1), \cdots, (x_n, y_n)$ are not all equal.

From a given sample $(x_1, y_1), \cdots, (x_n, y_n)$ we shall now determine a straight line by least squares. We write the line as

$$y = k_0 + k_1 x \tag{2}$$

and call it the **sample regression line** because it will be the counterpart of the population regression line (1).

Now a sample point (x_j, y_j) has the vertical distance (distance measured in the y-direction) from (2) given by

$$|y_j - (k_0 + k_1 x_j)| \qquad \text{(see Fig. 542).}$$

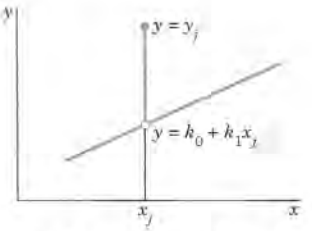

Fig. 542. Vertical distance of a point (x_j, y_j) from a straight line $y = k_0 + k_1 x$

Hence the sum of the squares of these distances is

$$q = \sum_{j=1}^{n} (y_j - k_0 - k_1 x_j)^2. \tag{3}$$

In the method of least squares we now have to determine k_0 and k_1 such that q is minimum. From calculus we know that a necessary condition for this is

$$\frac{\partial q}{\partial k_0} = 0 \quad \text{and} \quad \frac{\partial q}{\partial k_1} = 0. \tag{4}$$

We shall see that from this condition we obtain for the sample regression line the formula

$$y - \bar{y} = k_1(x - \bar{x}). \tag{5}$$

Here $\bar{x}$ and $\bar{y}$ are the means of the x- and the y-values in our sample, that is,

$$\text{(a)} \quad \bar{x} = \frac{1}{n}(x_1 + \cdots + x_n)$$
$$\text{(b)} \quad \bar{y} = \frac{1}{n}(y_1 + \cdots + y_n). \tag{6}$$

The slope k_1 in (5) is called the **regression coefficient** of the sample and is given by

$$k_1 = \frac{s_{xy}}{s_x^2}. \tag{7}$$

Here the **"sample covariance"** s_{xy} is

$$s_{xy} = \frac{1}{n-1} \sum_{j=1}^{n} (x_j - \bar{x})(y_j - \bar{y}) = \frac{1}{n-1} \left[\sum_{j=1}^{n} x_j y_j - \frac{1}{n} \left(\sum_{i=1}^{n} x_i \right) \left(\sum_{j=1}^{n} y_j \right) \right] \tag{8}$$

and s_x^2 is given by

$$s_x^2 = \frac{1}{n-1} \sum_{j=1}^{n} (x_j - \bar{x})^2 = \frac{1}{n-1} \left[\sum_{j=1}^{n} x_j^2 - \frac{1}{n} \left(\sum_{j=1}^{n} x_j \right)^2 \right]. \tag{9a}$$

From (5) we see that the sample regression line passes through the point $(\bar{x}, \bar{y})$, by which it is determined, together with the regression coefficient (7). We may call s_x^2 the *variance* of the x-values, but we should keep in mind that x is an ordinary variable, not a random variable.

We shall soon also need

$$\textbf{(9b)} \qquad s_y^2 = \frac{1}{n-1}\sum_{j=1}^{n}(y_j - \bar{y})^2 = \frac{1}{n-1}\left[\sum_{j=1}^{n} y_j^2 - \frac{1}{n}\left(\sum_{j=1}^{n} y_j\right)^2\right].$$

Derivation of (5) and (7). Differentiating (3) and using (4), we first obtain

$$\frac{\partial q}{\partial k_0} = -2\sum (y_j - k_0 - k_1 x_j) = 0,$$

$$\frac{\partial q}{\partial k_1} = -2\sum x_j(y_j - k_0 - k_1 x_j) = 0$$

where we sum over j from 1 to n. We now divide by 2, write each of the two sums as three sums, and take the sums containing y_j and $x_j y_j$ over to the right. Then we get the **"normal equations"**

$$\textbf{(10)} \qquad \begin{aligned} k_0 n + k_1 \sum x_j &= \sum y_j \\ k_0 \sum x_j + k_1 \sum x_j^2 &= \sum x_j y_j. \end{aligned}$$

This is a linear system of two equations in the two unknowns k_0 and k_1. Its coefficient determinant is [see (9)]

$$\begin{vmatrix} n & \sum x_j \\ \sum x_j & \sum x_j^2 \end{vmatrix} = n\sum x_j^2 - \left(\sum x_j\right)^2 = n(n-1)s_x^2 = n\sum (x_j - \bar{x})^2$$

and is not zero because of Assumption (A1). Hence the system has a unique solution. Dividing the first equation of (10) by n and using (6), we get $k_0 = \bar{y} - k_1\bar{x}$. Together with $y = k_0 + k_1 x$ in (2) this gives (5). To get (7), we solve the system (10) by Cramer's rule (Sec. 7.6) or elimination, finding

$$(11) \qquad k_1 = \frac{n\sum x_j y_j - \sum x_i \sum y_j}{n(n-1)s_x^2}.$$

This gives (7)–(9) and completes the derivation. [The equality of the two expressions in (8) and in (9) may be shown by the student; see Prob. 14]. ■

EXAMPLE 1 **Regression Line**

The decrease of volume y [%] of leather for certain fixed values of high pressure x [atmospheres] was measured. The results are shown in the first two columns of Table 25.11. Find the regression line of y on x.

Solution. We see that $n = 4$ and obtain the values $\bar{x} = 28\,000/4 = 7000$, $\bar{y} = 19.0/4 = 4.75$, and from (9) and (8)

Table 25.11 Regression of the Decrease of Volume y [%] of Leather on the Pressure x [Atmospheres]

Given Values		Auxiliary Values	
x_j	y_j	x_j^2	$x_j y_j$
4 000	2.3	16 000 000	9 200
6 000	4.1	36 000 000	24 600
8 000	5.7	64 000 000	45 600
10 000	6.9	100 000 000	69 000
28 000	19.0	216 000 000	148 400

$$s_x^2 = \frac{1}{3}\left(216\,000\,000 - \frac{28\,000^2}{4}\right) = \frac{20\,000\,000}{3}$$

$$s_{xy} = \frac{1}{3}\left(148\,400 - \frac{28\,000 \cdot 19}{4}\right) = \frac{15\,400}{3}.$$

Hence $k_1 = 15\,400/20\,000\,000 = 0.000\,77$ from (7), and the regression line is

$$y - 4.75 = 0.000\,77(x - 7000) \qquad \text{or} \qquad y = 0.000\,77x - 0.64.$$

Note that $y(0) = -0.64$, which is physically meaningless, but typically indicates that a linear relation is merely an approximation valid on some restricted interval. ■

Confidence Intervals in Regression Analysis

If we want to get confidence intervals, we have to make assumptions about the distribution of Y (which we have not made so far; least squares is a "geometric principle," nowhere involving probabilities!). We assume normality and independence in sampling:

Assumption (A2)

For each fixed x the random variable Y is normal with mean (1), *that is,*

$$\mu(x) = \kappa_0 + \kappa_1 x \tag{12}$$

and variance σ^2 independent of x.

Assumption (A3)

The n performances of the experiment by which we obtain a sample

$$(x_1, y_1), \qquad (x_2, y_2), \qquad \cdots, \qquad (x_n, y_n)$$

are independent.

κ_1 in (12) is called the **regression coefficient** of the population because it can be shown that under Assumptions (A1)–(A3) the maximum likelihood estimate of κ_1 is the sample regression coefficient k_1 given by (11).

Under Assumptions (A1)–(A3) we may now obtain a confidence interval for κ_1, as shown in Table 25.12.

Table 25.12 Determination of a Confidence Interval for κ_1 in (1) under Assumptions (A1)–(A3)

Step 1. Choose a confidence level γ (95%, 99%, or the like).

Step 2. Determine the solution c of the equation

$$F(c) = \tfrac{1}{2}(1 + \gamma) \tag{13}$$

from the table of the t-distribution with $n - 2$ degrees of freedom (Table A9 in App. 5; n = sample size).

Step 3. Using a sample $(x_1, y_1), \cdots, (x_n, y_n)$, compute $(n-1)s_x^2$ from (9a), $(n-1)s_{xy}$ from (8), k_1 from (7),

$$(n-1)s_y^2 = \sum_{j=1}^{n} y_j^2 - \frac{1}{n}\left(\sum_{j=1}^{n} y_j\right)^2 \tag{14}$$

[as in (9b)], and

$$q_0 = (n-1)(s_y^2 - k_1^2 s_x^2). \tag{15}$$

Step 4. Compute

$$K = c\sqrt{\frac{q_0}{(n-2)(n-1)s_x^2}}.$$

The confidence interval is

$$\mathrm{CONF}_\gamma\{k_1 - K \leqq \kappa_1 \leqq k_1 + K\}. \tag{16}$$

EXAMPLE 2 Confidence Interval for the Regression Coefficient

Using the sample in Table 25.11, determine a confidence interval for κ_1 by the method in Table 25.12.

Solution. ***Step 1.*** We choose $\gamma = 0.95$.

Step 2. Equation (13) takes the form $F(c) = 0.975$, and Table A9 in App. 5 with $n - 2 = 2$ degrees of freedom gives $c = 4.30$.

Step 3. From Example 1 we have $3s_x^2 = 20\,000\,000$ and $k_1 = 0.00077$. From Table 25.11 we compute

$$\begin{aligned} 3s_y^2 &= 102.2 - \frac{19^2}{4} \\ &= 11.95, \\ q_0 &= 11.95 - 20\,000\,000 \cdot 0.00077^2 \\ &= 0.092. \end{aligned}$$

Step 4. We thus obtain

$$K = 4.30\sqrt{0.092/(2 \cdot 20\,000\,000)}$$

$$= 0.000\,206$$

and

$$\mathrm{CONF}_{0.95}\{0.00056 \leqq \kappa_1 \leqq 0.00098\}.$$

Correlation Analysis

We shall now give an introduction to the basic facts in correlation analysis; for proofs see Ref. [G2] or [G8] in App. 1.

Correlation analysis is concerned with the relation between X and Y in a two-dimensional random variable (X, Y) (Sec. 24.9). A sample consists of n ordered pairs of values $(x_1, y_1), \cdots, (x_n, y_n)$, as before. The interrelation between the x and y values in the sample is measured by the sample covariance s_{xy} in (8) or by the sample **correlation coefficient**

$$r = \frac{s_{xy}}{s_x s_y} \tag{17}$$

with s_x and s_y given in (9). Here r has the advantage that it does not change under a multiplication of the x and y values by a factor (in going from feet to inches, etc.).

THEOREM 1

Sample Correlation Coefficient

The sample correlation coefficient r satisfies $-1 \leqq r \leqq 1$. In particular, $r = \pm 1$ if and only if the sample values lie on a straight line. (See Fig. 543.)

The theoretical counterpart of r is the **correlation coefficient** ρ of X and Y,

$$\rho = \frac{\sigma_{XY}}{\sigma_X \sigma_Y} \tag{18}$$

where $\mu_X = E(X)$, $\mu_Y = E(Y)$, $\sigma_X^2 = E([X - \mu_X]^2)$, $\sigma_Y^2 = E([Y - \mu_Y]^2)$ (the means and variances of the marginal distributions of X and Y; see Sec. 24.9), and σ_{XY} is the

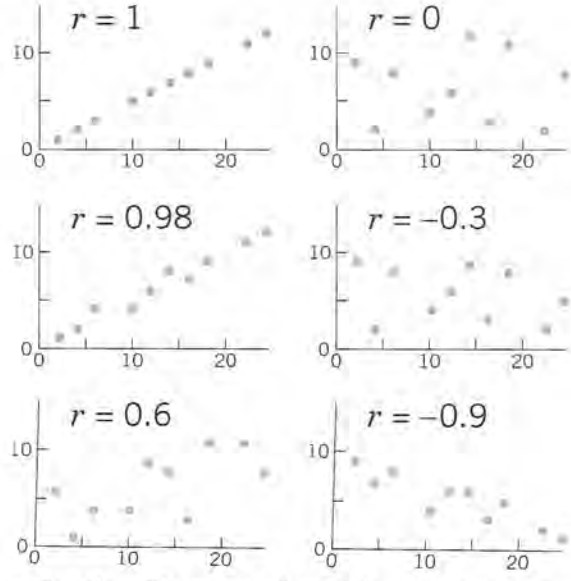

Fig. 543. Samples with various values of the correlation coefficient r

covariance of X and Y given by (see Sec. 24.9)

$$\sigma_{XY} = E([X - \mu_X][Y - \mu_Y]) = E(XY) - E(X)E(Y). \tag{19}$$

The analog of Theorem 1 is

THEOREM 2

Correlation Coefficient

The correlation coefficient ρ satisfies $-1 \leqq \rho \leqq 1$. In particular, $\rho = \pm 1$ if and only if X and Y are **linearly related,** *that is, $Y = \gamma X + \delta$, $X = \gamma^* Y + \delta^*$.*

X and Y are called **uncorrelated** if $\rho = 0$.

THEOREM 3

Independence. Normal Distribution

(a) *Independent X and Y* (see Sec. 24.9) *are uncorrelated.*

(b) *If (X, Y) is normal* (see below), *then uncorrelated X and Y are independent.*

Here the two-dimensional normal distribution can be introduced by taking two independent standardized normal random variables X^*, Y^*, whose joint distribution thus has the density

$$f^*(x^*, y^*) = \frac{1}{2\pi} e^{-(x^{*2}+y^{*2})/2} \tag{20}$$

(representing a surface of revolution over the x^*y^*-plane with a bell-shaped curve as cross section) and setting

$$X = \mu_X + \sigma_X X^*$$
$$Y = \mu_Y + \rho\sigma_Y X^* + \sqrt{1 - \rho^2}\, \sigma_Y Y^*.$$

This gives the general **two-dimensional normal distribution** with the density

$$f(x, y) = \frac{1}{2\pi\sigma_X\sigma_Y\sqrt{1 - \rho^2}} e^{-h(x,y)/2} \tag{21a}$$

where

$$h(x, y) = \frac{1}{1 - \rho^2}\left[\left(\frac{x - \mu_X}{\sigma_X}\right)^2 - 2\rho\left(\frac{x - \mu_X}{\sigma_X}\right)\left(\frac{y - \mu_Y}{\sigma_Y}\right) + \left(\frac{y - \mu_Y}{\sigma_Y}\right)^2\right]. \tag{21b}$$

In Theorem 3(b), normality is important, as we can see from the following example.

EXAMPLE 3 **Uncorrelated but Dependent Random Variables**

If X assumes -1, 0, 1 with probability 1/3 and $Y = X^2$, then $E(X) = 0$ and in (3)

$$\sigma_{XY} = E(XY) = E(X^3) = (-1)^3 \cdot \frac{1}{3} + 0^3 \cdot \frac{1}{3} + 1^3 \cdot \frac{1}{3} = 0,$$

so that $\rho = 0$ and X and Y are uncorrelated. But they are certainly not independent since they are even functionally related. ■

Test for the Correlation Coefficient ρ

Table 25.13 shows a test for ρ in the case of the two-dimensional normal distribution. t is an observed value of a random variable that has a t-distribution with $n - 2$ degrees of freedom. This was shown by R. A. Fisher (*Biometrika* **10** (1915), 507–521).

Table 25.13 Test of the Hypothesis $\rho = 0$ Against the Alternative $\rho > 0$ in the Case of the Two-Dimensional Normal Distribution

Step 1. Choose a significance level α (5%, 1%, or the like).

Step 2. Determine the solution c of the equation

$$P(T \leqq c) = 1 - \alpha$$

from the t-distribution (Table A9 in App. 5) with $n - 2$ degrees of freedom.

Step 3. Compute r from (17), using a sample $(x_1, y_1), \cdots, (x_n, y_n)$.

Step 4. Compute

$$t = r\left(\sqrt{\frac{n-2}{1-r^2}}\right).$$

If $t \leqq c$, accept the hypothesis. If $t > c$, reject the hypothesis.

EXAMPLE 4 Test for the Correlation Coefficient ρ

Test the hypothesis $\rho = 0$ (independence of X and Y, because of Theorem 3) against the alternative $\rho > 0$, using the data in the lower left corner of Fig. 543, where $r = 0.6$ (manual soldering errors on 10 two-sided circuit boards done by 10 workers; x = front, y = back of the boards).

Solution. We choose $\alpha = 5\%$; thus $1 - \alpha = 95\%$. Since $n = 10$, $n - 2 = 8$, the table gives $c = 1.86$. Also, $t = 0.6\sqrt{8/0.64} = 2.12 > c$. We reject the hypothesis and assert that there is a **positive correlation.** A worker making few (many) errors on the front side also tends to make few (many) errors on the reverse side of the board. ■

PROBLEM SET 25.9

1–10 SAMPLE REGRESSION LINE

Find and sketch or graph the sample regression line of y and x and the given data as points on the same axes.

1. $(-1, 1), (0, 1.7), (1, 3)$
2. $(3, 3.5), (5, 2), (7, 4.5), (9, 3)$
3. $(2, 12), (5, 24), (9, 33), (14, 50)$
4. $(11, 22), (15, 18), (17, 16), (20, 9), (22, 10)$
5.

Speed x [mph] of a car	30	40	50	60
Stopping distance y [ft]	150	195	240	295

Also find the stopping distance at 35 mph.

6. x = Deformation of a certain steel [mm], y = Brinell hardness [kg/mm^2]

x	6	9	11	13	22	26	28	33	35
y	68	67	65	53	44	40	37	34	32

7. x = Revolutions per minute, y = Power of a Diesel engine [hp]

x	400	500	600	700	750
y	580	1030	1420	1880	2100

8.

Humidity of air x [%]	10	20	30	40
Expansion of gelatin y [%]	0.8	1.6	2.3	2.8

9.

Voltage x [V]	40	40	80	80	110	110
Current y [A]	5.1	4.8	10.0	10.3	13.0	12.7

Also find the resistance R [Ω] by **Ohms' law** (Sec. 2.9].

10.

Force x [lb]	2	4	6	8
Extension y [in] of a spring	4.1	7.8	12.3	15.8

Also find the spring modulus by **Hooke's law** (Sec. 2.4).

11–13 CONFIDENCE INTERVALS

Find a 95% confidence interval for the regression coefficient κ_1, assuming that (A2) and (A3) hold and using the sample:

11. In Prob. 6

12. In Prob. 7

13. In Prob. 8

14. Derive the second expression for s_x^2 in (9a) from the first one.

15. CAS EXPERIMENT. Moving Data. Take a sample, for instance, that in Prob. 6, and investigate and graph the effect of changing y-values (a) for small x, (b) for large x, (c) in the middle of the sample.

CHAPTER 25 REVIEW QUESTIONS AND PROBLEMS

1. What is a sample? Why do we take samples?

2. What is the role of probability theory in statistics?

3. Will you get better results by taking larger samples? Explain.

4. Do several samples from a certain population have the same mean? The same variance?

5. What is a parameter? How can we estimate it? Give an example.

6. What is a statistical test? What errors occur in testing?

7. How do we test in quality control?

8. What is the χ^2-test? Give a simple example from memory.

9. What are nonparametric tests? When would you apply them?

10. In what tests did we use the t-distribution? The χ^2-distribution?

11. What are one-sided and two-sided tests? Give typical examples.

12. List some areas of application of statistical tests.

13. What do we mean by "goodness of fit"?

14. Acceptance sampling uses principles of testing. Explain.

15. What is the power of a test? What can you do if the power is low?

16. Explain the idea of a maximum likelihood estimate from memory.

17. How does the length of a confidence interval depend on the sample size? On the confidence level?

18. Couldn't we make the error in interval estimation zero simply by choosing the confidence level 1?

19. What is the least squares principle? Give applications.

20. What is the difference between regression and correlation analysis?

21. Find the maximum likelihood estimates of mean and variance of a normal distribution using the sample 5, 4, 6, 5, 3, 5, 7, 4, 6, 5, 8, 6.

22. Determine a 95% confidence interval for the mean μ of a normal population with variance $\sigma^2 = 16$, using a sample of size 400 with mean 53.

23. What will happen to the length of the interval in Prob. 22 if we reduce the sample size to 100?

24. Determine a 99% confidence interval for the mean of a normal population with standard deviation 2.2, using the sample 28, 24, 31, 27, 22.

25. What confidence interval do we obtain in Prob. 24 if we assume the variance to be unknown?

26. Assuming normality, find a 95% confidence interval for the variance from the sample 145.3, 145.1, 145.4, 146.2.

27–29 Find a 95% confidence interval for the mean μ, assuming normality and using the sample:

27. Nitrogen content [%] of steel 0.74, 0.75, 0.73, 0.75, 0.74, 0.72

28. Diameters of 10 gaskets with mean 4.37 cm and standard deviation 0.157 cm

29. Density [g/cm^3] of coke 1.40, 1.45, 1.39, 1.44, 1.38

30. What sample size should we use in Prob. 28 if we want to obtain a confidence interval of length 0.1, assuming that the standard deviation of the samples is (about) the same?

31–32 Find a 99% confidence interval for the variance σ^2, assuning normality and using the sample:

31. Rockwell hardness of tool bits 64.9, 64.1, 63.8, 64.0

32. A sample of size $n = 128$ with variance $s^2 = 1.921$

33. Using a sample of 10 values with mean 14.5 from a normal population with variance $\sigma^2 = 0.25$, test the hypothesis $\mu_0 = 15.0$ against the alternative $\mu_1 = 14.4$ on the 5% level.

34. In Prob. 33, change the alternative to $\mu \neq 15.0$ and test as before.

35. Find the power in Prob. 33.

36. Using a sample of 15 values with mean 36.2 and variance 0.9, test the hypothesis $\mu_0 = 35.0$ against the alternative $\mu_1 = 37.0$, assuming normality and taking $\alpha = 1\%$.

37. Using a sample of 20 values with variance 8.25 from a normal population, test the hyothesis ${\sigma_0}^2 = 5.0$ against the alternative ${\sigma_1}^2 = 8.1$, choosing $\alpha = 5\%$.

38. A firm sells paint in cans containing 1 kg of paint per can and is interested to know whether the mean weight differs significantly from 1 kg, in which case the filling machine must be adjusted. Set up a hypothesis and an alternative and perform the test, assuming normality and using a sample of 20 fillings having a mean of 991 g and a standard deviation of 8 g. (Choose $\alpha = 5\%$.)

39. Using samples of sizes 10 and 5 with variances ${s_x}^2 = 50$ and ${s_y}^2 = 20$ and assuming normality of the corresponding populations, test the hypothesis H_0: ${\sigma_x}^2 = {\sigma_y}^2$ against the alternative ${\sigma_x}^2 > {\sigma_y}^2$. Choose $\alpha = 5\%$.

40. Assume the thickness X of washers to be normal with mean 2.75 mm and variance 0.00024 mm^2. Set up a control chart for μ, choosing $\alpha = 1\%$, and graph the means of the five samples (2.74, 2.76), (2.74, 2.74), (2.79, 2.81), (2.78, 2.76), (2.71, 2.75) on the chart.

41. What effect on UCL − LCL in a control chart for the mean does it have if we double the sample size? If we switch from $\alpha = 1\%$ to $\alpha = 5\%$?

42. The following samples of screws (length in inches) were taken from an ongoing production. Assuming that the population is normal with mean 3.500 and variance 0.0004, set up a control chart for the mean, choosing $\alpha = 1\%$, and graph the sample means on the chart.

Sample No.	1	2	3	4	5	6	7	8
Length	3.49	3.48	3.52	3.50	3.51	3.49	3.52	3.53
	3.50	3.47	3.49	3.51	3.48	3.50	3.50	3.49

43. A purchaser checks gaskets by a single sampling plan that uses a sample size of 40 and an acceptance number of 1. Use Table A6 in App. 5 to compute the probability of acceptance of lots containing the following percentages of defective gaskets $\frac{1}{4}\%$, $\frac{1}{2}\%$, 1%, 2%, 5%, 10%. Graph the OC curve. (Use the Poisson approximation.)

44. Does an automatic cutter have the tendency of cutting longer and longer pieces of wire if the lengths of subsequent pieces [in.] were 10.1, 9.8, 9.9, 10.2, 10.6, 10.5?

45. Find the least squares regression line to the data (−2, 1), (0, 1), (2, 3), (4, 4), (6, 5).

SUMMARY OF CHAPTER 25
Mathematical Statistics

We recall from Chap. 24 that with an experiment in which we observe some quantity (number of defectives, height of persons, etc.) there is associated a random variable X whose probability distribution is given by a distribution function

(1) $$F(x) = P(X \leqq x)$$ (Sec. 24.5)

which for each x gives the probability that X assumes any value not exceeding x.

In statistics we take random samples $x_1, \cdots, x_n$ of size n by performing that experiment n times (Sec. 25.1) and draw conclusions from properties of samples about properties of the distribution of the corresponding X. We do this by calculating *point estimates* or *confidence intervals* or by performing a *test* for **parameters** (μ and σ^2 in the normal distribution, p in the binomial distribution, etc.) or by a test for distribution functions.

A **point estimate** (Sec. 25.2) is an approximate value for a parameter in the distribution of X obtained from a sample. Notably, the **sample mean** (Sec. 25.1)

$$\bar{x} = \frac{1}{n}\sum_{j=1}^{n} x_j = \frac{1}{n}(x_1 + \cdots + x_n) \tag{2}$$

is an estimate of the mean μ of X, and the **sample variance** (Sec. 25.1)

$$s^2 = \frac{1}{n-1}\sum_{j=1}^{n}(x_j - \bar{x})^2 = \frac{1}{n-1}[(x_1 - \bar{x})^2 + \cdots + (x_n - \bar{x})^2] \tag{3}$$

is an estimate of the variance σ^2 of X. Point estimation can be done by the basic **maximum likelihood method** (Sec. 25.2).

Confidence intervals (Sec. 25.3) are intervals $\theta_1 \leqq \theta \leqq \theta_2$ with endpoints calculated from a sample such that with a high probability γ we obtain an interval that contains the unknown true value of the parameter θ in the distribution of X. Here, γ is chosen at the beginning, usually 95% or 99%. We denote such an interval by $\text{CONF}_\gamma\{\theta_1 \leqq \theta \leqq \theta_2\}$.

In a **test** for a parameter we test a *hypothesis* $\theta = \theta_0$ against an *alternative* $\theta = \theta_1$ and then, on the basis of a sample, accept the hypothesis, or we reject it in favor of the alternative (Sec. 25.4). Like any conclusion about X from samples, this may involve errors leading to a false decision. There is a small probability α (which we can choose, 5% or 1%, for instance) that we reject a true hypothesis, and there is a probability β (which we can compute and decrease by taking larger samples) that we accept a false hypothesis. α is called the **significance level** and $1 - \beta$ the **power** of the test. Among many other engineering applications, testing is used in **quality control** (Sec. 25.5) and **acceptance sampling** (Sec. 25.6).

If not merely a parameter but the kind of distribution of X is unknown, we can use the **chi-square test** (Sec. 25.7) for testing the hypothesis that some function $F(x)$ is the unknown distribution function of X. This is done by determining the discrepancy between $F(x)$ and the distribution function $\tilde{F}(x)$ of a given sample.

"Distribution-free" or **nonparametric tests** are tests that apply to any distribution, since they are based on combinatorial ideas. These tests are usually very simple. Two of them are discussed in Sec. 25.8.

The last section deals with samples of **pairs of values,** which arise in an experiment when we simultaneously observe two quantities. In **regression analysis,** one of the quantities, x, is an ordinary variable and the other, Y, is a random variable whose mean μ depends on x, say, $\mu(x) = \kappa_0 + \kappa_1 x$. In **correlation analysis** the relation between X and Y in a two-dimensional random variable (X, Y) is investigated, notably in terms of the **correlation coefficient** ρ.

APPENDIX 2

Answers to Odd-Numbered Problems

Problem Set 1.1, page 8

1. $(\cos \pi x)/\pi + c$ **3.** $e^{x^2/2} + c$ **5.** First order
7. Second order **9.** Third order
11. $y = \frac{1}{2} \tan (2x + n\pi)$, $n = 0, \pm 1, \pm 2, \cdots$
13. $y = e^{-x^2}$ **15.** (A) No. (B) No. Only $y = 0$.
17. $y'' = g$, $y' = gt$, $y = gt^2/2$
19. $y'' = k$, $y' = kt + 6$, $y = \frac{1}{2}kt^2 + 6t$, $y(60) = 1800k + 360 = 3000$, $k = 1.47$, $y'(60) = 1.47 \cdot 60 + 6 = 94$ [m/sec] $= 210$ [mph]
21. $e^{kH} = \frac{1}{2}$, $H = (\ln \frac{1}{2})/k = (10^{11} \ln 2)/1.4 = 1570$ [years]

Problem Set 1.2, page 11

11. $y = -(2/\pi) \cos \frac{1}{2}\pi x + c$ **15.** $y = x(1 - \ln x) + c$
17. Verify the general solution $y^2 + t^2 = c$. Circle of radius $3\sqrt{2}$
19. $mv' = mg - bv^2$, $v' = 9.8 - v^2$, $v(0) = 10$. $v' = 0$ gives the limit $\sqrt{9.8} = 3.1$ [meter/sec].

Problem Set 1.3, page 18

3. $\cos 2y \, dy = 2 \, dx$, $y = \frac{1}{2} \arcsin (4x + c)$ **5.** $y^2 + 36x^2 = c$, ellipses
7. $dy/y = \cot \pi x \, dx$, $y = c(\sin \pi x)^{1/\pi}$ **9.** $y = \tan (c - e^{-\pi x}/\pi)$
11. $r = r_0 e^{-t^2}$ **13.** $I = I_0 e^{-Rt/L}$
15. $y = e^x/\sqrt{2x + 5}$ **17.** $y = 4 \ln x$
19. $y = \sqrt{\ln (x^2 - 2x + e)}$
21. $y' = (y - b)/(x - a)$, $y - b = c(x - a)$
23. $y_0 e^k = 2y_0$, $e^k = 2$ (1 week), $e^{2k} = 2^2$ (2 weeks), $e^{4k} = 2^4$
25. $y = y_0 e^{kt} = y_0 e^{-0.0001213t} = y_0 e^{-0.0001213 \cdot 4000} = 0.62y_0$; 62%; cf. Example 2.
27. $y' = -ky$, $y = y_0 e^{-kt}$, $e^{-5k} = 0.5$, $k = -(\ln 0.5)/5 = 0.139$, $t = -(\ln 0.05)/0.139 = 22$ [min]
29. $T(0) = 10$, $T = 23 - 13e^{kt}$, $T(2) = 23 - 13e^{2k} = 18$, $k = -0.478$, $T = 22.8$ gives $t = [\ln (-0.2/-13)]/(-0.478) = 8.73$ [min].
31. $h = gt^2/2$, $t = \sqrt{2h/g}$, $v = gt = g\sqrt{2h/g} = \sqrt{2gh}$
33. $y' = 0 - (2/800)y$, $y = 200e^{-0.0025t}$, $t = 300$ [min], $y(300) = 94.5$ [lb]
35. (A) is related to the error function and (C) concerns the Fresnel integral $C(x)$; see App. 3.1. (D) $y' = 2xy + 1$, $y(0) = 0$

Problem Set 1.4, page 25

1. Exact. $x^4 + y^4 = c$

3. Exact. $u = \cos \pi x \sinh y + k(y)$, $u_y = \cos \pi x \cosh y + k'$, $k' = 0$.
Ans. $\cos \pi x \sinh y = c$

5. Exact. $9x^2 + 4y^2 = c$

7. Exact, $M_\theta = N_r = -2e^{-2\theta}$, $u = re^{-2\theta} + k(\theta)$, $u_\theta = -2re^{-2\theta} + k'$, $k' = 0$.
Ans. $re^{-2\theta} = c$, $r = ce^{2\theta}$

9. Exact. $u = y/x + \sin 2x + k(y)$, $u_y = 1/x + k' = 1/x - 2 \sin 2y$.
Ans. $y/x + \sin 2x + \cos 2y = c$

11. Not exact. $F = 1/x^2$ by Theorem 1. $-y/x^2\, dx + 1/x\, dy = d(y/x) = 0$. *Ans.* $y = cx$

13. $-3y^2/x^4\, dx + 2y/x^3\, dy = d(y^2/x^3) = 0$. $y = cx^{3/2}$ (semicubical parabolas)

15. Exact, $u = e^{2x} \cos y + k(y)$, $u_y = -e^{2x} \sin y + k'$, $k' = 0$. *Ans.* $e^{2x} \cos y = c$, $c = 1$

17. Not exact. Try R. $F = e^{-x}$, $e^{-x}(\cos \omega x + \omega \sin \omega x)\, dx + dy = 0$, $u = y + l(x)$, $u_x = l' = e^{-x}(\cos \omega x + \omega \sin \omega x)$, $u = y + l = y - e^{-x} \cos \omega x = c$, $c = 0$

19. $u = e^x + k(y)$, $u_y = k' = -1 + e^y$, $k = -y + e^y$. *Ans.* $e^x - y + e^y = c$

21. $B = C$, $\frac{1}{2}Ax^2 + Cxy + \frac{1}{2}Dy^2 = c$

Problem Set 1.5, page 32

3. $y = ce^{-3.5x} + 0.8$

5. $y = 2.6e^{-1.25x} + 4$

7. $y = x + c$ (if $k = 0$). $y = ce^{-kx} + e^{2kx}/3k$ if $k \neq 0$

9. Separate. $y - 2.5 = c \cosh^4 1.5x$

11. $y = 2xe^{\cos 2x}$

13. $y = \sin 2x + c/\sin^2 2x$, $c = 1$

15. $y = e^{1/x}(x^2 + c)$, $c = 4.1$

17. $y = (c + \frac{1}{2} \cosh 10x)/x^3$. Note $(x^3y)' = 5 \sinh 10x$.

19. $y = 1/u$, $u = ce^{-5.7x} - \dfrac{6.5}{5.7}$

21. $u = y^{-2} = e^{x^2}(1 + ce^{2x})$, $c = 3$, $u(0) = 4$

23. Separate variables. $y^2 = 1 - ce^{\cos x}$, $c = -1/e$

25. $y' = Ry + k$, $y = ce^{Rt} - k/R$, $c = y_0 + k/R$. $y_0 = 1000$, $R = 0.06$, $t = 65 - 25 = 40$, $k = 1000$, $y = \$178\,076.12$. Start at 45 gives $y_0[(1 + 1/0.06)e^{0.06 \cdot 20} - 1/0.06] = 41.988732y_0 = 178\,076.12$, $y_0 = k = \$4241.05$.

27. $y' = 175(0.0001 - y/450)$, $y(0) = 450 \cdot 0.0004 = 0.18$, $y = 0.135e^{-0.3889t} + 0.045 = 0.18/2$, $e^{-0.3889t} = (0.09 - 0.045)/0.135 = 1/3$, $t = (\ln 3)/0.3889 = 2.82$. *Ans.* About 3 years

29. $y' = A - ky$, $y(0) = 0$, $y = A(1 - e^{-kt})/k$

31. $y' = By^2 - Ay = By(y - A/B)$, $A > 0$, $B > 0$. Constant solutions $y = 0$, $y = A/B$. $y' > 0$ if $y > A/B$ (unlimited growth), $y' < 0$ if $0 < y < A/B$ (extinction). $y = A/(ce^{At} + B)$, $y(0) > A/B$ if $c < 0$, $y(0) < A/B$ if $c > 0$.

33. $y' = y - y^2 - 0.2y$, $y = 1/(1.25 - 0.75e^{-0.8t})$, limit 0.8, limit 1

35. $y' = y - 0.25y^2 - 0.1y = 0.25y(3.6 - y)$. Equilibrium harvest 3.6, $y = 18/(5 + ce^{-0.9t})$

37. $(y_1 + y_2)' + p(y_1 + y_2) = (y_1' + py_1) + (y_2' + py_2) = 0 + 0 = 0$

39. $(y_1 + y_2)' + p(y_1 + y_2) = (y_1' + py_1) + (y_2' + py_2) = r + 0 = r$

41. Solution of $cy_1' + pcy_1 = c(y_1' + py_1) = cr$

43. CAS Experiment (a) $y = x \sin(1/x) + cx$. $c = 0$ if $y(2/\pi) = 2/\pi$. y is undefined at $x = 0$, the point at which the "waves" of $\sin(1/x)$ accumulate; the factor x makes them smaller and smaller. Experiment with various x-intervals.
(b) $y = x^n[\sin(1/x) + c]$. $y(2/\pi) = (2/\pi)^n$. n need not be an integer. Try $n = \frac{1}{2}$. Try $n = -1$ and see how the "waves" near 0 become larger and larger.

45. $y = uy^*$, $y' + py = u'y^* + uy^{*\prime} + puy^* = u'y^* + u(y^{*\prime} + py^*) = u'y^* + u \cdot 0 = r$, $u' = r/y^* = re^{\int p\,dx}$, $u = \int e^{\int p\,dx} r\,dx + c$. Thus, $y = uy_h$ gives (4). We shall see that this method extends to higher-order ODEs (Secs. 2.10 and 3.3).

Problem Set 1.6, page 36

1. $y' = 4$, $\tilde{y}' = -1/4$, $\tilde{y} = -x/4 + c^*$

3. $y/x = c$, $y'/x = y/x^2$, $y' = y/x$, $\tilde{y}' = -x/\tilde{y}$, $\tilde{y}^2 + x^2 = c^*$, circles

5. $2xy + x^2y' = 0$, $y' = -2y/x$, $\tilde{y}' = x/(2\tilde{y})$, $\tilde{y}^2 - x^2/2 = c^*$, hyperbolas

7. $ye^{-x^2/2} = c$, $y' = xy$, $\tilde{y}' = -1/(x\tilde{y})$, $\tilde{y}\tilde{y}' = -1/x$, $\tilde{y}^2/2 = -\ln|x| + c^{**}$, $x = c^*e^{-\tilde{y}^2/2}$, bell-shaped curves (with x and $\tilde{y}$ interchanged)

9. $y' = -4x/y$, $\tilde{y}' = \tilde{y}/4x$, $4\ln|\tilde{y}| = \ln|x| + c^{**}$, $x = c^*\tilde{y}^4$, parabolas

11. $xe^{-y/4} = c$, $y' = 4/x$, $\tilde{y}' = -x/4$, $\tilde{y} = -x^2/8 + c^*$

13. Use $dy/dx = 1/(dx/dy)$. $(y - 2x)e^x = c$, $(y' - 2 + y - 2x)e^x = 0$, $y' = 2 - y + 2x$, $dx/d\tilde{y} = -2 + \tilde{y} - 2x$ is linear, $dx/d\tilde{y} + 2x = \tilde{y} - 2$, $x = c^*e^{-2y} + y/2 - 5/4$

15. $u = c$, $u_x dx + u_y dy = 0$, $y' = -u_x/u_y$. Trajectories $\tilde{y}' = u_{\tilde{y}}/u_x$. Now $v = c^*$, $v_x dx + v_y dy = 0$, $y' = -v_x/v_y$. This agrees with the trajectory ODE in u if $u_x = v_y$ (equal denominators) and $u_y = -v_x$ (equal numerators). But these are just the Cauchy-Riemann equations.

17. $2x + 2yy' = 0$, $y' = -x/y$. Trajectories $\tilde{y}' = \tilde{y}/x$, $\ln|\tilde{y}| = \ln|x| + c^{**}$, $\tilde{y} = c^*x$.

19. $y' = -4x/9y$. Trajectories $\tilde{y}' = 9\tilde{y}/4x$, $\tilde{y} = c^*x^{9/4}$ ($c^* > 0$). Sketch or graph these curves.

Problem Set 1.7, page 41

1. In $|x - x_0| < a$; just take b in $\alpha = b/K$ large, namely, $b = aK$.

3. No. At a common point (x_1, y_1) they would both satisfy the "initial condition" $y(x_1) = y_1$, violating uniqueness.

5. $y' = f(x, y) = r(x) - p(x)y$; hence $\partial f/\partial y = -p(x)$ is continuous and is thus bounded in the closed interval $|x - x_0| \leqq a$.

7. R has sides $2a$ and $2b$ and center $(1, 1)$ since $y(1) = 1$. In R, $f = 2y^2 \leqq 2(b + 1)^2 = K$, $\alpha = b/K = b/(2(b + 1)^2)$. $d\alpha/db = 0$ gives $b = 1$, and $\alpha_{opt} = b/K = 1/8$. Solution by $dy/y^2 = 2\,dx$, etc., $y = 1/(3 - 2x)$.

9. $|1 + y^2| \leqq K = 1 + b^2$, $\alpha = b/K$, $d\alpha/db = 0$, $b = 1$, $\alpha = 1/2$.

Chapter 1 Review Questions and Problems, page 42

11. $dy/(y^2 + \frac{1}{4}) = 4\,dx$, $2\arctan 2y = 4x + c^*$, $y = \frac{1}{2}\tan(2x + c)$

13. Logistic ODE. $y = 1/u$, $y' = -u'/u^2 = 4/u - 1/u^2$, $u = c^*e^{-4x} + \frac{1}{4}$

15. $dy/(y^2 + 1) = x^2\,dx$, $\arctan y = x^3/3 + c$, $y = \tan(x^3/3 + c)$

17. Bernoulli. $y' + xy = x/y$, $u = y^2$, $u' = 2yy' = 2x - 2xu$ linear, $u = e^{-x^2}(\int e^{x^2} 2x\,dx + c) = 1 + ce^{-x^2}$, $y = \sqrt{u}$. Or write $yy' = -x(y^2 - 1)$ and separate.

19. Linear, $y = e^{\cos x}(\int e^{-\cos x} \sin x\, dx + c) = ce^{\cos x} + 1$. Or by separation.

21. Not exact. Use Theorem 1, Sec. 1.4; $R = 2/x$, $F = x^2$; the resulting exact ODE is $3x^2 \sin 2y\, dx + 2x^3 \cos 2y\, dy = d(x^3 \sin 2y)$, $x^3 \sin 2y = c$. Or by separation, $\cot 2y\, dy = -3/(2x)\, dx$, etc., $\sin 2y = cx^{-3}$.

23. Exact. $u = \int M\, dx = \sin xy - x^2 + k$, $u_y = x \cos xy + k' = N$, $k = y^2$, $\sin xy - x^2 + y^2 = c$.

25. Not exact. $R^* = 1$ in Theorem 2, Sec. 1.4, $F^* = e^y$. Exact is $e^y \sin(y - x)\, dx + e^y[\cos(y - x) - \sin(y - x)]\, dy = 0$. $u = \int M\, dx = e^y \cos(y - x) + k$, $u_y = e^y(\cos(y - x) - \sin(y - x)) + k' = N$, $e^y \cos(y - x) = c$.

27. Separation. $y^2 + x^2 = 25$

29. Separation. $y = \tan(x + c)$, $c = -\frac{1}{4}\pi$

31. Exact. $u = x^2y^2 + \cos x + 2y = c$, $c = u(0, 1) = 3$

33. $y' = x/y$. Trajectories $\tilde{y}' = -\tilde{y}/x$, $\tilde{y} = c^*/x$ by separation. Hyperbolas.

35. $y = y_0e^{kt}$, $e^{4k} = 0.9$, $k = \frac{1}{4} \ln 0.9$, $e^{kt} = 0.5$, $t = (\ln 0.5)/k = (\ln 0.5)/[(\ln 0.9)/4] = 26.3$ [days]

37. $e^{kt} = 0.01$, $t = (\ln 0.01)/k = 175$ [days]

39. $y' = -4x/y$. Trajectories $\tilde{y} = c_1x^{1/4}$ or $x = c_2\tilde{y}^4$

41. Logistic ODE $y' = Ay - By^2$, $y = 1/u$, $u' + Au = +B$, $u = ce^{-At} + B/A$

43. A = amount of incident light. A thin layer of thickness Δx absorbs $\Delta A = -kA\Delta x$ ($-k$ = constant of proportionality). Thus $\Delta A/\Delta x = -kA$. Let $\Delta x \to 0$. Then $A' = -kA$, $A = A_0e^{-kx}$ = amount of light in a thick layer at depth x from the surface of incidence.

Problem Set 2.1, page 52

1. $y = 2.5e^{4x} + 0.5e^{-4x}$

3. $y = e^{-x} \cos x$

5. $y = 4x^2 + 7/x^2$

7. Yes

9. Yes if $a \neq 0$

11. No

13. No

15. $F(x, z, z') = 0$

17. $y = c_1e^{kx} + c_2$

19. $y\, dz/dy = 4z$, $y = (c_1x + c_2)^{-1/3}$

21. $(dz/dy)z = -z^3 \sin y$, $-1/z = -dx/dy = \cos y + \tilde{c}_1$, $x = -\sin y + c_1y + c_2$

23. $y''y' = 2$, $y = \frac{4}{3}(t + 1)^{3/2} - \frac{1}{3}$, $y(3) = \frac{31}{3}$, $y'(3) = 4$

25. $y'' = ky'$, $z' = kz$, $z = c_1e^{kx} = y'$, $c_1 = 1$, $y = (e^{kx} - 1)/k$

Problem Set 2.2, page 59

1. $y = c_1e^{7x} + c_2e^{-x}$

3. $y = (c_1 + c_2x)e^{2.5x}$

5. $y = c_1e^{0.9x} + c_2e^{-1.1x}$

7. $y = e^{0.5x}(A \cos 1.5x + B \sin 1.5x)$

9. $y = c_1e^{3.5x} + c_2e^{-1.5x}$

11. $y = A \cos 3\pi x + B \sin 3\pi x$

13. $y = c_1e^{12x} + c_2e^{-12x}$

15. $y'' - 3y' + 2y = 0$

17. $y'' - 2\sqrt{3}\, y' + 3y = 0$

19. $y'' - 16y = 0$

21. $y = 4e^{3x} - 2e^{-x}$

23. $y = e^{-2x}(2 \cos x - \sin x)$

25. $y = 2 + e^{-\pi x}$

27. $y = (2 - 4x)e^{-0.25x}$

29. $y = e^{-0.1x}(3.2 \cos 0.2x + 1.6 \sin 0.2x)$

31. $y = 4e^{5x} - 4e^{-5x}$

33. $y_1 = e^{-x}$, $y_2 = 0.001e^x + e^{-x}$

35. Write $E = e^{-ax/2}$, $c = \cos \omega x$, $s = \sin \omega x$. Note that $E' = -\frac{1}{2}aE$, $c' = -\omega s$, $s' = \omega c$. Substitute, drop E, collect c-terms, then s-terms, and use $\omega^2 = b - \frac{1}{4}a^2$, to get $c(b - \frac{1}{2}a^2 + \frac{1}{4}a^2 - \omega^2) + s(-a\omega + \frac{1}{2}a\omega + \frac{1}{2}a\omega) = 0 + 0 = 0$.

Problem Set 2.3, page 61

1. 0, 0, $-2 \cos x$ **3.** $-0.8x^3 + 6x^2 + 0.4$, 0, $e^{0.4x}$
5. $-12x^3 + 9x^2 + 8x - 2$, $-28 \sin 4x - 4 \cos 4x$, 0
7. $y = (c_1 + c_2x)e^{-2x}$ **9.** $y = e^{-3x}(A \cos 2x + B \sin 2x)$
11. $y = c_1e^{-3.1x} + c_2e^{-x}$ **13.** $y = A \cos 4.2\omega x + B \sin 4.2\omega x$

Problem Set 2.4, page 68

1. $y = y_0 \cos \omega_0 t + (v_0/\omega_0) \sin \omega_0 t$. At integer t (if $\omega_0 = \pi$), because of periodicity.
3. $mL\theta'' = -mg \sin \theta \approx -mg\theta$ (tangential component of $W = mg$), $\theta'' + \omega_0{}^2\theta = 0$, $\omega_0/(2\pi) = \sqrt{g/L}/(2\pi)$.
5. No, because the frequency depends only on k/m.
7. (i) Greater by a factor $\sqrt{3}$. (ii) Lower
9. $\omega^* = [\omega_0{}^2 - c^2/(4m^2)]^{1/2} = \omega_0[1 - c^2/(4mk)]^{1/2} \approx \omega_0(1 - c^2/8mk) = 2.9583$
11. $2\pi/\omega^*$ since Eq. (10) and $y' = 0$ give $\tan(\omega^* t - \delta) = -\alpha/\omega^*$; tan is periodic with period π/ω^*.
13. Case (II) of (5) with $c = \sqrt{4mk} = \sqrt{4 \cdot 500 \cdot 4500} = 3000$ [kg/sec], where 500 kg is the mass per wheel.
15. $y = [y_0 + (v_0 + \alpha y_0)t]e^{-\alpha t}$, $y = [1 + (v_0 + 1)t]e^{-t}$; (ii) $v_0 = -2, -3/2, -4/3, -5/4, -6/5$
17. $y = 0$ gives $c_1 = -c_2e^{-2\beta t}$, which has one or no positive zero, depending on the initial conditions.

Problem Set 2.5, page 72

1. $c_1x^3 + c_2x^{-2}$ **3.** $(c_1 + c_2 \ln |x|)x^4$
5. $x[A \cos(\ln |x|) + B \sin(\ln |x|)]$ **7.** $c_1x^{1.4} + c_2x^{1.6}$
9. $c_1x^{0.1} + c_2x^{0.9}$ **11.** $3x^2 - 2x^3$
13. $x^{-0.5}[2 \cos(10 \ln |x|) - \sin(10 \ln |x|)]$ **15.** $2x^{-3} + 10$

Problem Set 2.6, page 77

1. $y'' - 0.25y = 0$, $W = -1$ **3.** $y'' - 2ky' + k^2y = 0$, $W = e^{2kx}$
5. $x^2y'' + 0.5xy' + 0.0625y = 0$, $W = x^{-0.5}$ **7.** $x^2y'' + xy' + 4y = 0$, $W = 2/x$
9. $x^2y'' - 0.75y = 0$, $W = -2$ **11.** $y'' - 6.25y = 0$, $W = 2.5$
13. $y'' + 2y' + 1.64y = 0$, $W = 0.8e^{-2x}$ **15.** $y'' + 5y' + 6.34y = 0$, $W = 0.3e^{-5x}$
17. $y'' + 7.6\pi y' + 14.44\pi^2 y = 0$, $W = e^{-7.6\pi x}$

Problem Set 2.7, page 83

1. $c_1e^{-x} + c_2e^{-2x} + 2.5e^{2x}$ **3.** $c_1e^{4x} + c_2e^{-4x} + 2.4xe^{4x} - 4e^{x}$
5. $c_1e^{2x} + c_2e^{-3x} - x^3 - 3x - 0.5$
7. $e^{-3x}(A \cos 8x + B \sin 8x) + e^{x}(\cos 4x + \frac{1}{2} \sin 4x)$

Problem Set 5.5, page 197

1. Use (7b) in Sec. 5.2.
3. 0.77958 (exact 0.76520), 0.19674 (0.22389), −0.27651 (−0.26005), −0.39788 (−0.39715), −0.17038 (−0.17760), 0.15680 (0.15065), 0.30086 (0.30008), 0.16833 (0.17165)
5. $y = c_1J_\nu(\lambda x) + c_2J_{-\nu}(\lambda x)$, $\nu \neq 0, \pm 1, \cdots$
7. $y = c_1J_\nu(\sqrt{x}) + c_2J_{-\nu}(\sqrt{x})$, $\nu \neq 0, \pm 1, \cdots$
9. $y = c_1xJ_1(2x)$, J_1, J_{-1} linearly dependent
11. $y = x^{-\nu}[c_1J_\nu(x) + c_2J_{-\nu}(x)]$, $\nu \neq 0, \pm 1, \cdots$
13. $y = c_1J_\nu(x^3) + c_2J_{-\nu}(x^3)$, $\nu \neq 0, \pm 1, \cdots$
15. $y = c_1\sqrt{x}J_1(2\sqrt{x})$, J_1, J_{-1} linearly dependent
17. $y = x^{1/4}J_1(\frac{2}{3}x^{1/4})$, J_1, J_{-1} linearly dependent
19. $y = x^{2/5}(c_1J_{8/5}(4x^{1/4}) + c_2J_{-8/5}(4x^{1/4}))$
21. Use (24b) with $\nu = 0$, (24a) with $\nu = 1$, (24d) with $\nu = 2$, respectively.
23. $J_n(x_1) = J_n(x_2) = 0$ implies ${x_1}^{-n}J_n(x_1) = {x_2}^{-n}J_n(x_2) = 0$ and $[x^{-n}J_n(x)]' = 0$ somewhere between x_1 and x_2 by Rolle's theorem. Now use (24b) to get $J_{n+1}(x) = 0$ there. Conversely, $J_{n+1}(x_3) = J_{n+1}(x_4) = 0$, thus ${x_3}^{n+1}J_{n+1}(x_3) = {x_4}^{n+1}J_{n-1}(x_4) = 0$ implies $J_n(x) = 0$ in between by Rolle's theorem and (24a) with $\nu = n + 1$.
25. Integrate the formulas in (24).
27. Use (24a) with $\nu = 1$, partial integration, (24b) with $\nu = 0$, partial integration.
33. CAS Experiment. (b) $x_0 = 1$, $x_1 = 2.5$, $x_2 = 20$, approximately. It increases with n. (c) (14) is exact. (d) It oscillates. (e) Formula (24b) with $\nu = 0$

Problem Set 5.6, page 202

1. $y = c_1J_5(x) + c_2Y_5(x)$
3. $y = c_1J_0(\sqrt{x}) + c_2Y_0(\sqrt{x})$
5. $y = c_1J_2(x^2) + c_2Y_2(x^2)$
7. $y = x^{-5}(c_1J_5(x) + c_2Y_5(x))$
9. $y = x^3(c_1J_3(x^3) + c_2Y_3(x^3))$
11. Set $H^{(1)} = kH^{(2)}$, use (10).
13. Set $x = is$ in (1), Sec. 5.5, to get the present ODE (12) in terms of s. Use (20), Sec. 5.5.

Problem Set 5.7, page 209

3. Set $x = ct + k$.
5. $x = \cos\theta$, $dx = -\sin\theta\, d\theta$, etc.
7. $\lambda_m = (m\pi/5)^2$, $m = 1, 2, \cdots$; $y_m = \sin(m\pi x/5)$
9. $\lambda_m = [(2m + 1)\pi/2L]^2$, $m = 0, 1, \cdots$; $y_m(x) = \sin[(2m + 1)\pi x/2L]$
11. $\lambda_m = m^2$, $m = 0, 1, \cdots$; $y_0 = 1$, $y_m = \cos mx, \sin mx$, $m = 1, 2, \cdots$
13. $k = k_m$ from $\tan k = -k$. $\lambda_m = {k_m}^2$, $m = 1, 2, \cdots$; $y_m = \sin k_m x$
15. $\lambda_m = m^2$, $m = 1, 2, \cdots$; $y_m = x\sin(m \ln |x|)$
17. $p = e^{8x}$, $q = 0$, $r = e^{8x}$, $\lambda_m = m^2$; $y_m = e^{-4x}\sin mx$, $m = 1, 2, \cdots$
19. $\lambda_m = (m\pi)^2$, $y_m = x\cos m\pi x, x\sin m\pi x$, $m = 0, 1, \cdots$

Problem Set 5.8, page 216

1. $1.6P_4(x) - 0.6P_0(x)$ **3.** $\frac{2}{5}P_3(x) - \frac{2}{3}P_2(x) + \frac{8}{5}P_1(x) - \frac{4}{3}P_0(x)$

7. $-0.4775P_1(x) - 0.6908P_3(x) + 1.844P_5(x) - 0.8234P_7(x) + 0.1544P_9(x) + \cdots$, $m_0 = 9$. Rounding seems to have considerable influence in Probs. 6–15.

9. $0.3799P_2(x) + 1.673P_4(x) - 1.397P_6(x) + 0.3968P_8(x) + \cdots$, $m_0 = 8$

(b) $\frac{6}{\pi}\left(\sin\frac{\pi x}{2} - \frac{1}{3}\sin\pi x + \frac{1}{3}\sin\frac{3\pi x}{2} + \frac{1}{5}\sin\frac{5\pi x}{2} - \frac{1}{9}\sin 3\pi x + \cdots\right)$

23. (a) $\frac{L}{2} - \frac{4L}{\pi^2}\left(\cos\frac{\pi x}{L} + \frac{1}{9}\cos\frac{3\pi x}{L} + \frac{1}{25}\cos\frac{5\pi x}{L} + \cdots\right)$

(b) $\frac{2L}{\pi}\left(\sin\frac{\pi x}{L} - \frac{1}{2}\sin\frac{2\pi x}{L} + \frac{1}{3}\sin\frac{3\pi x}{L} - + \cdots\right)$

25. (a) $\frac{\pi}{2} + \frac{4}{\pi}\left(\cos x + \frac{1}{9}\cos 3x + \frac{1}{25}\cos 5x + \cdots\right)$

(b) $2\left(\sin x + \frac{1}{2}\sin 2x + \frac{1}{3}\sin 3x + \cdots\right)$

Problem Set 11.4, page 499

3. Use (5).

7. $-\frac{2i}{\pi}\sum_{n=-\infty}^{\infty}\frac{1}{2n+1}e^{(2n+1)ix}$

9. $i\sum_{\substack{n=-\infty\\ n\neq 0}}^{\infty}\frac{(-1)^n}{n}e^{inx}$

11. $\frac{\pi^2}{3} + 2\sum_{\substack{n=-\infty\\ n\neq 0}}^{\infty}\frac{(-1)^n}{n^2}e^{inx}$

13. $\pi + i\sum_{\substack{n=-\infty\\ n\neq 0}}^{\infty}\frac{1}{n}e^{inx}$

Problem Set 11.5, page 501

3. $(0.05n)^2$ in D_n changes to $(0.02n)^2$, which gives $C_5 = 0.5100$, leaving the other coefficients almost unaffected.

5. $y = c_1 \cos \omega t + c_2 \sin \omega t + A(\omega) \cos t$, $A(\omega) = 1/(\omega^2 - 1) < 0$ if $\omega^2 < 1$ (phase shift!) and > 0 if $\omega^2 > 1$

7. $y = c_1 \cos \omega t + c_2 \sin \omega t + \sum_{n=1}^{N} \dfrac{a_n}{\omega^2 - n^2} \cos nt$

9. $y = c_1 \cos \omega t + c_2 \sin \omega t + \dfrac{\pi}{2\omega^2} + \dfrac{4}{\pi}\left(\dfrac{1}{\omega^2 - 1} \cos t + \dfrac{1/9}{\omega^2 - 9} \cos 3t + \cdots\right)$

11. $y = c_1 \cos \omega t + c_2 \sin \omega t + \dfrac{1}{2\omega^2} - \dfrac{1}{1 \cdot 3(\omega^2 - 4)} \cos 2t - \dfrac{1}{3 \cdot 5(\omega^2 - 16)} \cos 4t - \cdots$

13. The situation is the same as in Fig. 53 in Sec. 2.8.

15. $y = -\dfrac{3c}{64 + 9c^2} \cos 3t - \dfrac{8}{64 + 9c^2} \sin 3t$

17. $y = \sum_{n=1}^{N} \left(-\dfrac{ncb_n}{D_n} \cos nt + \dfrac{(1 - n^2)b_n}{D_n} \sin nt\right)$, $D_n = (1 - n^2)^2 + n^2c^2$

19. $I(t) = \sum_{n=1}^{\infty} (A_n \cos nt + B_n \sin nt)$, $A_n = (-1)^{n+1} \dfrac{240(10 - n^2)}{n^2 D_n}$,

$B_n = (-1)^{n+1} \dfrac{2400}{nD_n}$, $D_n = (10 - n^2)^2 + 100n^2$

Problem Set 11.6, page 505

1. $F = 2\left(\sin x - \dfrac{1}{2} \sin 2x + \cdots + \dfrac{(-1)^{N+1}}{N} \sin Nx\right)$, $E^* = 8.1, 5.0, 3.6, 2.8, 2.3$

3. $F = \dfrac{\pi}{2} - \dfrac{4}{\pi}\left(\cos x + \dfrac{1}{9} \cos 3x + \dfrac{1}{25} \cos 5x + \cdots\right)$, $E^* = 0.0748, 0.0748, 0.0119, 0.0119, 0.0037$

5. $F = \dfrac{2}{\pi} - \dfrac{4}{\pi}\left(\dfrac{1}{1 \cdot 3} \cos 2x + \dfrac{1}{3 \cdot 5} \cos 4x + \dfrac{1}{5 \cdot 7} \cos 6x + \cdots\right)$, $E^* = 0.5951, 0.0292, 0.0292, 0.0066, 0.0066$

7. $F = \dfrac{4}{\pi}\left(\sin x + \dfrac{1}{3} \sin 3x + \dfrac{1}{5} \sin 5x + \cdots\right)$, $E^* = 1.1902, 1.1902, 0.6243, 0.6243, 0.4206$ (0.1272 when $N = 20$)

9. $\dfrac{8}{\pi}\left(\sin x + \dfrac{1}{27} \sin 3x + \dfrac{1}{125} \sin 5x + \cdots\right)$, $E^* = 0.0295, 0.0295, 0.0015, 0.0015, 0.00023$

Problem Set 11.7, page 512

1. $f(x) = \pi e^{-x}$ $(x > 0)$ gives $A = \displaystyle\int_0^\infty e^{-v} \cos wv \, dv = \frac{1}{1 + w^2}$, $B = \dfrac{w}{1 + w^2}$ (see Example 3), etc.

3. $f(x) = \frac{1}{2}\pi e^{-x}$ gives $A = 1/(1 + w^2)$.

5. Use $f = (\pi/2) \cos v$ and (11) in App. 3.1 to get $A = (\cos(\pi w/2))/(1 - w^2)$.

7. $\dfrac{2}{\pi} \displaystyle\int_0^\infty \frac{\sin aw \cos xw}{w} \, dw$

9. $\dfrac{2}{\pi} \displaystyle\int_0^\infty \frac{\cos w + w \sin w - 1}{w^2} \cos xw \, dw$

11. $\dfrac{2}{\pi} \displaystyle\int_0^\infty \frac{\cos \pi w + 1}{1 - w^2} \cos xw \, dw$

15. $\dfrac{2}{\pi} \displaystyle\int_0^\infty \frac{\sin \pi w}{1 - w^2} \sin xw \, dw$

17. $\dfrac{2}{\pi} \displaystyle\int_0^\infty \frac{\pi w - \sin \pi w}{w^2} \sin xw \, dw$

19. $\dfrac{2}{\pi} \displaystyle\int_0^\infty \frac{wa - \sin wa}{w^2} \sin xw \, dw$

Problem Set 11.8, page 517

1. $\sqrt{\dfrac{2}{\pi}} \left(\dfrac{\sin 2w - 2 \sin w}{w} \right)$

5. $\sqrt{\pi/2}\, e^{-x}$ $(x > 0)$

7. $\sqrt{\pi/2} \cos w$ if $0 < w < \pi/2$ and 0 if $w > \pi/2$

9. Yes, no

11. $\sqrt{(2/\pi)}\, w/(w^2 + \pi^2)$

13. $\mathcal{F}_s(xe^{-x^2/2}) = \mathcal{F}_s(-(e^{-x^2/2})') = w\mathcal{F}_c(e^{-x^2/2}) = we^{-w^2/2}$

17. $\mathcal{F}_c(f') = \mathcal{F}_c(-af) = -a\mathcal{F}_c(f) = -\sqrt{\dfrac{2}{\pi}} \dfrac{a^2}{a^2 + w^2} = w\mathcal{F}_s(f) - \sqrt{\dfrac{2}{\pi}} \cdot 1.$

$$\mathcal{F}_s(f) = \sqrt{\frac{2}{\pi}} \frac{w}{a^2 + w^2}$$

19. In (5) for $f(ax)$ set $ax = v$.

Problem Set 11.9, page 528

3. $ik(e^{-ibw} - 1)/(\sqrt{2\pi}w)$

5. $\sqrt{(2/\pi)}k\,(\sin w)/w$

7. $[(1 + iw)e^{-iw} - 1]/(\sqrt{2\pi}w^2)$

9. $\sqrt{(2/\pi)}i(\cos w - 1)/w$

11. $\frac{1}{2}e^{-w^2/2}$

13. $(e^{ibw} - e^{-ibw})/(iw\sqrt{2\pi}) = \sqrt{2/\pi}(\sin bw)/w$

Chapter 11 Review Questions and Problems, page 532

1. $20x + 200, 20z + 200$ **3.** $110 - 50xy, 110 + 25iz^2$
5. $F = (110/\ln 2)\operatorname{Ln} z$ **7.** $F = 200 - (100/\ln 2)\operatorname{Ln} z$
13. Use Fig. 388 in Sec. 17.4 with the z- and w-planes interchanged, and $\cos z = \sin(z + \frac{1}{2}\pi)$.
15. $\Phi = 220 - 110xy$

Problem Set 18.2, page 757

1. $u^2 - v^2 = e^{2x}(\cos^2 y - \sin^2 y)$, $\Phi_{xx} = 4e^{2x}(\cos^2 y - \sin^2 y) = -\Phi_{yy}$, $\nabla^2\Phi = 0$
3. Straightforward calculation, involving the chain rule and the Cauchy-Riemann equations
5. See Fig. 389 in Sec. 17.4. $\Phi = \sin^2 x \cosh^2 y - \cos^2 x \sinh^2 y$.
9. (i) $\Phi = U_1(1 - xy)$. (ii) $w = iz^2$ maps R onto $-2 \leqq u \leqq 0$, thus $\Phi^* = U_1(1 + \frac{1}{2}u) = U_1(1 + \frac{1}{2}(-2xy))$.
11. By Theorem 1 in Sec. 17.2
13. $\Phi = 10[1 - (1/\pi)\operatorname{Arg}(z - 4)]$, $F = 10[1 + (i/\pi)\operatorname{Ln}(z - 4)]$
15. Corresponding rays in the w-plane make equal angles, and the mapping is conformal.

Problem Set 18.3, page 760

3. $(100/d)y$. Rotate through $\pi/2$. **5.** $100 - 240\theta/\pi$
7. $\operatorname{Re} F(z) = 100 + (200/\pi)\operatorname{Re}(\arcsin z)$ **9.** $(240/\pi)\operatorname{Arg} z$
11. $T_0 + (2/\pi)(T_1 - T_0)\operatorname{Arg} z$ **13.** $50 + (400/\pi)\operatorname{Arg} z$

Problem Set 18.4, page 766

1. $V = iV_2 = iK$, $\Psi = -Kx = const$, $\Phi = Ky = const$
3. $F(z) = Kz$ (K positive real)
5. $V = (1 + 2i)K$, $F = (1 - 2i)Kz$
7. $F(z) = z^3$
9. Hyperbolas $(x + 1)y = const$. Flow around a corner formed by $x = -1$ and the x-axis.
11. $y/(x^2 + y^2) = c$ or $x^2 + (y - k)^2 = k^2$
13. $F(z) = z/r_0 + r_0/z$

15. Use that $w = \arccos z$ is $w = \cos z$ with the roles of the z- and w-planes interchanged.

Problem Set 18.5, page 771

5. $1 - r^2 \cos 2\theta$

7. $2(r \sin \theta - \frac{1}{2}r^2 \sin 2\theta + \frac{1}{3}r^3 \sin 3\theta - + \cdots)$

9. $\frac{3}{4}r^2 \sin 2\theta - \frac{1}{4}r^6 \sin 6\theta$

11. $\frac{1}{3}\pi^2 - 4(r \cos \theta - \frac{1}{4}r^2 \cos 2\theta + \frac{1}{9}r^3 \cos 3\theta - + \cdots)$

13. $\dfrac{4}{\pi}\left(r \sin \theta - \dfrac{1}{9}\, r^3 \sin 3\theta + \dfrac{1}{25}\, r^5 \sin 5\theta - + \cdots\right)$

Problem Set 18.6, page 774

1. No; $|z|^2$ is not analytic. **3.** Use (2). $F(\frac{1}{3}) = \frac{25}{9}$ **5.** $\Phi(4, -4) = -12$

7. Use (3). $\Phi(1, 1) = -2$ **11.** $|F(e^{i\theta})|^2 = 2 - 2 \cos 2\theta$, $\theta = \pi/2$, Max $= 2$

13. $|F(z)| = [\cos^2 2x + \sinh^2 2y]^{1/2}$, $z = \pm i$, Max $= [1 + \sinh^2 2]^{1/2} = \cosh 2 = 3.7622$

15. No

Chapter 18 Review Questions and Problems, page 775

11. $\Phi = 10(1 - x + y)$, $F = 10 - 10(1 + i)z$

13. $(20/\ln 10)$ Ln z **15.** $(10/\ln 10)(\ln 100 - \ln r)$

17. Arg $z = const$ **19.** $(-i/\pi)$ Ln z

23. $T(x, y) = x(2y + 1) = const$ **25.** Circles $(x - c)^2 + y^2 = c^2$

27. $F(z) = \dfrac{c}{2\pi}$ Ln $(z - 5)$, Arg $(z - 5) = c$

29. $20 + \dfrac{80}{\pi}\left(r \sin \theta + \dfrac{1}{3}\, r^3 \sin 3\theta + \dfrac{1}{5}\, r^5 \sin 5\theta + \cdots\right)$

Problem Set 19.1, page 786

1. $0.9817 \cdot 10^2$, $-0.1010 \cdot 10^3$, $0.5787 \cdot 10^{-2}$, $-0.1360 \cdot 10^5$

3. $0.36443/(17.862 - 17.798) = 0.36443/0.064 = 5.6942$, $0.3644/(17.86 - 17.80) = 0.3644/0.06 = 6.073$, $0.364/(17.9 - 17.8) = 3.64$, impossible

5. $\dfrac{0.36443(17.862 + 17.798)}{17.862^2 - 17.798^2} = \dfrac{0.36443 \cdot 35.660}{319.05 - 316.77} = \dfrac{12.996}{2.28} = 5.7000,$

$\dfrac{13.00}{2.28} = 5.702,\ \dfrac{13.0}{2.28} = 5.70,\ \dfrac{13}{2.3} = 5.7,\ \dfrac{10}{2} = 5$

7. 19.95, 0.049, 0.05013; 20, 0, 0.05

9. In the present calculation, (b) is more accurate than (a).

11. $-0.126 \cdot 10^{-2}$, $-0.402 \cdot 10^{-3}$; $-0.267 \cdot 10^{-6}$, $-0.847 \cdot 10^{-7}$

13. Add first, then round.

15. $\dfrac{a_1}{a_2} = \dfrac{\tilde{a}_1 + \epsilon_1}{\tilde{a}_2 + \epsilon_2} = \dfrac{\tilde{a}_1 + \epsilon_1}{\tilde{a}_2}\left(1 - \dfrac{\epsilon_2}{\tilde{a}_2} + \dfrac{{\epsilon_2}^2}{{\tilde{a}_2}^2} - + \cdots\right) \approx \dfrac{\tilde{a}_1}{\tilde{a}_2} + \dfrac{\epsilon_1}{\tilde{a}_2} - \dfrac{\epsilon_2}{\tilde{a}_2} \cdot \dfrac{\tilde{a}_1}{\tilde{a}_2},$

hence $\left|\left(\frac{a_1}{a_2} - \frac{\tilde{a}_1}{\tilde{a}_2}\right) \Big/ \left|\frac{a_1}{a_2}\right|\right| \approx \left|\frac{\epsilon_1}{a_1} - \frac{\epsilon_2}{a_2}\right| \leqq |\epsilon_{r1}| + |\epsilon_{r2}| \leqq \beta_{r1} + \beta_{r2}$

19. (a) 19/21 = 0.90476 1905, $\epsilon_{\text{chop}} = \epsilon_{\text{round}} = 0.1905 \cdot 10^{-5}$, $\epsilon_{r,\text{chop}} = \epsilon_{r,\text{round}} = 0.2106 \cdot 10^{-5}$, etc.

Problem Set 19.2, page 796

1. $g = 1.4 \sin x$, 1.37263 ($= x_5$)
5. $g = x^4 + 0.2$, 0.20165 ($= x_3$)
7. 2.403 ($= x_5$, exact to 3S)
9. 0.904557 ($= x_3$)
11. 1.834243 ($= x_4$)
13. $x_0 = 4.5$, $x_4 = 4.73004$ (6S exact)
15. (a) 0.5, 0.375, 0.377968, 0.377964; (b) $1/\sqrt{7} = 0.377964\,473$
17. $x_{n-1} = (2x_n + 7/x_n^2)/3$, 1.912931 ($= x_3$)
19. (a) **Algorithm Bisect** (f, a_0, b_0, N) **Bisection Method**

This algorithm computes an interval $[a_n, b_n]$ containing a solution of $f(x) = 0$ (f continuous) or it computes a solution c_n, given an initial interval $[a_0, b_0]$ such that $f(a_0)f(b_0) < 0$. Here N is determined by $(b - a)/2^N \leqq \beta$, β the required accuracy.

INPUT: Initial interval $[a_0, b_0]$, maximum number of iterations N.
OUTPUT: Interval $[a_N, b_N]$ containing a solution, or a solution c_n.
For $n = 0, 1, \cdots, N - 1$ do:
  Compute $c_n = \frac{1}{2}(a_n + b_n)$.
  If $f(c_n) = 0$ then OUTPUT c_n. Stop. [*Procedure completed*]
  Else continue.
  If $f(a_n)f(c_n) < 0$ then $a_{n+1} = a_n$ and $b_{n+1} = c_n$.
  Else set $a_{n+1} = c_n$ and $b_{n+1} = b_n$.
End
OUTPUT $[a_N, b_N]$. Stop.
[*Procedure completed*]
End BISECT

Note that $[a_N, b_N]$ gives $(a_N + b_N)/2$ as an approximation of the zero and $(b_N - a_N)/2$ as a corresponding error bound.

Problem Set 21.1, page 897

1. $y = e^x$, 0.0382, 0.1245 (error of x_5, x_{10})
3. $y = x - \tanh x$ (set $y - x = u$), 0.009292, 0.0188465 (error of x_5, x_{10})
5. $y = e^x$, 0.001275, 0.004200 (error of x_5, x_{10})
7. $y = 1/(1 - x^2/2)$, 0.00029, 0.01187 (error of x_5, x_{10})
9. $y = 1/(1 - x^2/2)$, 0.03547, 0.28715 (error of x_5, x_{10})
11. $y = 1/(1 - x^2/2)$; error -10^{-8}, $-4 \cdot 10^{-8}$, $\cdots$, $-6 \cdot 10^{-7}$, $+10^{-5}$; about $1.3 \cdot 10^{-5}$ by (10)
13. $y = xe^x$; error $\cdot 10^5$ (for $x = 1, \cdots, 3$) 19, 46, 85, 139, 213, 315, 454, 640, 889, 1219
15. $y = 3 \cos x - 2 \cos^2 x$; error $\cdot 10^7$: 0.18, 0.74, 1.73, 3.28, 5.59, 9.04, 14.33, 22.77, 36.80, 61.42
17. $y = 1/(x^5 + 1)$, 0.000307, -0.000259 (error of x_5, x_{10})
19. The errors are for E.-C. 0.02000, 0.06287, 0.05076, for Improved E.-C. -0.000455, 0.012086, 0.009601, for RK 0.0000012, 0.000016, 0.000536.

Problem Set 21.2, page 901

3. $y = e^{-0.1x^2}$; errors 10^{-6} to $6 \cdot 10^{-6}$
5. $y = \tan x$; $y_4, \cdots, y_{10}$ (error $\cdot 10^5$): 0.422798 (-0.48), 0.546315 (-1.2), 0.684161 (-2.4), 0.842332 (-4.4), 1.029714 (-7.5), 1.260288 (-13), 1.557626 (-22)
7. RK-error smaller, error $\cdot 10^5 = 0.4, 0.3, 0.2, 5.6$ (for $x = 0.4, 0.6, 0.8, 1.0$)
9. $y_4 = 4.229\,690$, $y_5 = 4.556\,859$, $y_6 = 5.360\,657$, $y_7 = 8.082\,563$
11. Errors between $-6 \cdot 10^{-7}$ and $+3 \cdot 10^{-7}$. Solution $e^x - x - 1$
13. Errors $\cdot 10^5$ from $x = 0.3$ to 0.7: -5, -11, -19, -31, -47
15. (a) 0, 0.02, 0.0884, 0.215 848, $y_4 = 0.417\,818$, $y_5 = 0.708\,887$ (poor).
(b) By 30–50%

Problem Set 21.3, page 908

3. $y_1 = e^x$, $y_2 = -e^x$, errors range from ± 0.02 to ± 0.23, monotone.
5. $y_1' = y_2$, $y_2' = -4y_1$, $y = y_1 = 1, 0.84, 0.52, 0.0656, -0.4720$; $y = \cos 2x$
7. $y_1 = 4e^{-x} \sin x$, $y_2 = 4e^{-x} \cos x$; errors from 0 to about ± 0.1
9. Errors smaller by about a factor 10^4
11. $y = 0.198669, 0.389494, 0.565220, 0.719632, 0.847790$;
$y' = 0.980132, 0.922062, 0.830020, 0.709991, 0.568572$
13. $y_1 = e^{-3x} - e^{-5x}$, $y_2 = e^{-3x} + e^{-5x}$; $y_1 = 0.1341, 0.1807, 0.1832, 0.1657, 0.1409$; $y_2 = 1.348, 0.9170, 0.6300, 0.4368, 0.3054$
17. You get the exact solution, except for a roundoff error [e.g., $y_1 = 2.761\,608$, $y(0.2) = 2.7616$ (exact), etc.]. Why?
19. $y = 0.198669, 0.389494, 0.565220, 0.719631, 0.847789$;
$y' = 0.980132, 0.922061, 0.830019, 0.709988, 0.568568$

Problem Set 21.4, page 916

3. 105, 155, 105, 115; Step 5: 104.94, 154.97, 104.97, 114.98
5. 0.108253, 0.108253, 0.324760, 0.324760; Step 10: 0.108538, 0.108396, 0.324902, 0.324831

7. 0, 0, 0, 0. All equipotential lines meet at the corners (why?). Step 5: 0.29298, 0.14649, 0.14649, 0.073245

9. $-3u_{11} + u_{12} = -200$, $u_{11} - 3u_{12} = -100$

11. $u_{12} = u_{32} = 31.25$, $u_{21} = u_{23} = 18.75$, $u_{jk} = 25$ at the others

13. $u_{21} = u_{23} = 0.25$, $u_{12} = u_{32} = -0.25$, $u_{jk} = 0$ else

15. (a) $u_{11} = -u_{12} = -66$. (b) Reduce to 4 equations by symmetry.
$u_{11} = u_{31} = -u_{15} = -u_{35} = -92.92$, $u_{21} = -u_{25} = -87.45$,
$u_{12} = u_{32} = -u_{14} = -u_{34} = -64.22$, $u_{22} = -u_{24} = -53.98$,
$u_{13} = u_{23} = u_{33} = 0$

17. $\sqrt{3}$, $u_{11} = u_{21} = 0.0849$, $u_{12} = u_{22} = 0.3170$. (0.1083, 0.3248 are 4S-values of the solution of the linear system of the problem.)

Problem Set 21.5, page 921

5. $u_{11} = 0.766$, $u_{21} = 1.109$, $u_{12} = 1.957$, $u_{22} = 3.293$

7. **A** as in Example 1, right sides -2, -2, -2, -2. Solution $u_{11} = u_{21} = 1.14286$, $u_{12} = u_{22} = 1.42857$

11. $-4u_{11} + u_{21} + u_{12} = -3$, $u_{11} - 4u_{21} + u_{22} = -12$, $u_{11} - 4u_{12} + u_{22} = 0$, $2u_{21} + 2u_{12} - 12u_{22} = -14$, $u_{11} = u_{22} = 2$, $u_{21} = 4$, $u_{12} = 1$. Here $-14/3 = -\frac{4}{3}(1 + 2.5)$ with 4/3 from the stencil.

13. $\mathbf{b} = [-380 \quad -190, \quad -190, \quad 0]^T$; $u_{11} = 140$, $u_{21} = u_{12} = 90$, $u_{22} = 30$

Problem Set 21.6, page 927

5. 0.1636, 0.2545 ($t = 0.04$, $x = 0.2$, 0.4), 0.1074, 0.1752 ($t = 0.08$), 0.0735, 0.1187 ($t = 0.12$), 0.0498, 0.0807 ($t = 0.16$), 0.0339, 0.0548 ($t = 0.2$; exact 0.0331, 0.0535)

7. Substantially less accurate, 0.15, 0.25 ($t = 0.04$), 0.100, 0.163 ($t = 0.08$)

9. Step 5 gives 0, 0.06279, 0.09336, 0.08364, 0.04707, 0.

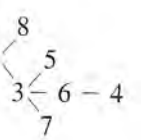
1.



$L = 12$

3.

$L = 10$

5.

$L = 28$

9. 1 − 3 − 4 < 2, 5 — 6, $L = 38$ **11.** Yes

15. G is connected. If G were not a tree, it would have a cycle, but this cycle would provide two paths between any pair of its vertices, contradicting the uniqueness.

19. If we add an edge (u, v) to T, then since T is connected, there is a path $u \to v$ in T which, together with (u, v), forms a cycle.

Problem Set 23.5, page 972

1. (1, 2), (1, 4), (3, 4), (4, 5), $L = 12$

3. (1, 2), (2, 8), (8, 7), (8, 6), (6, 5), (2, 4), (4, 3), $L = 40$

5. (1, 4), (3, 4), (2, 4), (3, 5), $L = 20$

7. (1, 2), (1, 3), (1, 4), (2, 6), (3, 5), $L = 32$

11. If G is a tree

13. A shortest spanning tree of the largest connected graph that contains vertex 1

Problem Set 23.6, page 978

1. 1 − 2 − 5, $\Delta f = 2$; 1 − 4 − 2 − 5, $\Delta f = 2$, etc.

3. 1 − 2 − 4 − 6, $\Delta f = 2$; 1 − 2 − 3 − 5 − 6, $\Delta f = 1$, etc.

5. $f_{12} = 4$, $f_{13} = 1$, $f_{14} = 4$, $f_{42} = 4$, $f_{43} = 0$, $f_{25} = 8$, $f_{35} = 1$, $f = 9$

7. $f_{12} = 4$, $f_{13} = 3$, $f_{24} = 4$, $f_{35} = 3$, $f_{54} = 2$, $f_{46} = 6$, $f_{56} = 1$, $f = 7$

9. {4, 5, 6}, 28 **11.** {2, 4, 6}, 50

13. 1 − 2 − 3 − 7, $\Delta f = 2$; 1 − 4 − 5 − 6 − 7, $\Delta f = 1$; 1 − 2 − 3 − 6 − 7, $\Delta f = 1$; $f_{\max} = 14$

15. {3, 5, 7}, 22 **17.** $S = \{1, 4\}$, cap $(S, T) = 6 + 8 = 14$

19. If $f_{ij} < c_{ij}$ as well as $f_{ij} > 0$

Problem Set 23.7, page 982

3. (2, 3) and (5, 6)

5. 1 − 2 − 5, $\Delta_t = 2$; 1 − 4 − 2 − 5, $\Delta_t = 1$; $f = 6 + 2 + 1 = 9$

7. 1 − 2 − 4 − 6, $\Delta_t = 2$; 1 − 3 − 5 − 6, $\Delta_t = 1$; $f = 4 + 2 + 1 = 7$

9. By considering only edges with one labeled end and one unlabeled end

17. $S = \{1, 2, 4, 5\}$, $T = \{3, 6\}$, cap $(S, T) = 14$

Problem Set 23.8, page 986

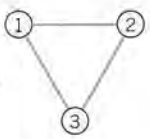
1. No **3.** No **5.** Yes, $S = \{1, 4, 5, 8\}$

7. Yes; a graph is not bipartite if it has a nonbipartite subgraph.

9. 1 − 2 − 3 − 5

11. (1, 5), (2, 3) by inspection. The augmenting path 1 − 2 − 3 − 5 gives 1 − 2 − 3 − 5, that is, (1, 2), (3, 5).

13. (1, 4), (2, 3), (5, 7) by inspection. Or (1, 2), (3, 4), (5, 7) by the use of the path 1 − 2 − 3 − 4.



15. 3 **19.** 3 **23.** No; K_5 is not planar.

25. K_3

11. $\bar{x} = 19.875, s = 0.835$, IQR $= 1.5$

13. $\bar{x} = 70.49, s = 1.047$, IQR $= 1.5$

15. $\bar{x} = 400.4, s = 1.618$, IQR $= 2$

17. 0 0 300

19. 3.54, 1.29

Problem Set 24.2, page 999

1. 4 outcomes: HH, HT, TH, TT (H = Head, T = Tail)

3. $6^2 = 36$ outcomes (1, 1), (1, 2), $\cdots$, (6, 6)

5. Infinitely many outcomes $S, S^cS, S^cS^cS, \cdots$ (S = "Six")

7. The space of ordered triples of nonnegative numbers

9. The space of ordered pairs of numbers

11. Yes

13. $E = \{S, S^cS, S^cS^cS\}, E^c = \{S^cS^cS^cS, S^cS^cS^cS^cS, \cdots\}$ (S = "Six")

Problem Set 24.3, page 1005

1. (a) $0.9^3 = 72.9\%$, (b) $\frac{90}{100} \cdot \frac{89}{99} \cdot \frac{88}{98} = 72.65\%$

3. $\frac{490}{500} \cdot \frac{489}{499} \cdot \frac{488}{498} \cdot \frac{487}{497} \cdot \frac{486}{496} = 90.35\%$

5. $1 - \frac{1}{25} = 0.96$

7. $1 - 0.75^2 = 0.4375 < 0.5$

9. $P(MMM) + P(MMFM) + P(MFMM) + P(FMMM) = \frac{1}{8} + 3 \cdot \frac{1}{16} = \frac{5}{16}$

11. $\frac{6}{36} + \frac{27}{36} - \frac{3}{36} = \frac{30}{36}$ by Theorem 3, or by counting outcomes
13. $0.08 + 0.04 - 0.08 \cdot 0.04 = 11.68\%$
15. $0.95^4 = 81.5\%$ **17.** $1 - 0.97^4 = 11.5\%$

Problem Set 24.4, page 1010

3. In 40 320 ways
5. $\binom{20}{3} = 1140$
7. 210, 70, 112, 28
9. $9!/(2!3!4!) = 1260$. *Ans.* 1/1260
11. $\binom{52}{13} = 635\,013\,559\,600$
13. 1/84, 5/21
15. 676 000

Problem Set 24.5, page 1015

1. $k = 1/55$ by (6)
3. $k = 1/8$ by (10)
5. No because of (6)
7. $1 - P(X \leqq 3) = 0.5$
9. $P(X > 1200) = \int_{1.2}^{2} 6[0.25 - (x - 1.5)^2]\,dx = 0.896$. *Ans.* $0.896^3 = 72\%$
11. $k = 2.5$; 50%
13. $k = 1.1565$; 26.9%
17. $X > b$, $X \geqq b$, $X < c$, $X \leqq c$, etc.

5. 16%
7. 31.1%, 95.5%
9. About 23
11. About 58%
13. $t = 1084$ hours

Problem Set 24.9, page 1040

1. 1/8, 3/16, 3/8
3. 2/9, 2/9, 1/2
5. $f_2(y) = 1/(\beta_2 - \alpha_2)$ if $\alpha_2 < y < \beta_2$ and 0 elsewhere
7. 27.45 mm, 0.38 mm
9. 25.26 cm, 0.0078 cm

13. Independent, $f_1(x) = 0.1e^{-0.1x}$ if $x > 0$, $f_2(y) = 0.1e^{-0.1y}$ if $y > 0$, 36.8%
15. 50% **17.** No

Chapter 24 Review Questions and Problems, page 1041

21. $Q_L = 22.3$, $Q_M = 23.3$, $Q_U = 23.5$ **23.** $\bar{x} = 22.89$, $s = 1.028$, $s^2 = 1.056$
25. *H*, *TH*, *TTH*, etc.
27. $f(0) = 0.80816$, $f(1) = 0.18367$, $f(2) = 0.00816$
29. Always $B \subseteq A \cup B$. If also $A \subseteq B$, then $B = A \cup B$, etc.
31. 7/3, 8/9 **33.** 118.019, 1.98, 1.65%
35. 0, 2 **37.** $\mu = 100/30$
39. 16%, 2.3% (see Fig. 520 in Sec. 24.8)

Problem Set 25.2, page 1048

3. $l = p^k(1 - p)^{n-k}$, $\hat{p} = k/n$, k = number of successes in n trials
5. 11/20
7. $l = f(x)$, $\partial(\ln l)/\partial p = 1/p - (x - 1)/(1 - p) = 0$, $\hat{p} = 1/x$
9. $\hat{\mu} = \bar{x}$ **11.** $\hat{\theta} = n/\Sigma x_j = 1/\bar{x}$
13. $\hat{\theta} = 1$ **15.** Variability larger than perhaps expected

Problem Set 25.3, page 1057

1. $\text{CONF}_{0.95}\{37.47 \leqq \mu \leqq 43.87\}$ **3.** Shorter by a factor $\sqrt{2}$
5. 4, 16 **7.** Cf. Example 2. $n = 166$
9. $\text{CONF}_{0.99}\{20.07 \leqq \mu \leqq 20.33\}$ **11.** $\text{CONF}_{0.99}\{63.71 \leqq \mu \leqq 66.29\}$
13. $c = 1.96$, $\bar{x} = 87$, $s^2 = 87 \cdot 413/500 = 71.86$, $k \approx cs/\sqrt{n} = 0.743$, $\text{CONF}_{0.95}\{86 \leqq \mu \leqq 88\}$, $\text{CONF}_{0.95}\{0.17 \leqq p \leqq 0.18\}$
15. $\text{CONF}_{0.95}\{0.00045 \leqq \sigma^2 \leqq 0.00131\}$ **17.** $\text{CONF}_{0.95}\{0.73 \leqq \sigma^2 \leqq 5.19\}$
19. $\text{CONF}_{0.95}\{23 \leqq \sigma^2 \leqq 548\}$. Hence a larger sample would be desirable.
21. Normal distributions, means −27, 81, 133, variances 16, 144, 400
23. $Z = X + Y$ is normal with mean 105 and variance 1.25.
Ans. $P(104 \leqq Z \leqq 106) = 63\%$

Problem Set 25.4, page 1067

1. $t = \sqrt{7}(0.286 - 0)/4.31 = 0.18 < c = 1.94$; do not reject the hypothesis.
3. $c = 6090 > 6019$; do not reject the hypothesis.
5. $\sigma^2/n = 1$, $c = 28.36$; do not reject the hypothesis.
7. $\mu < 28.76$ or $\mu > 31.24$
9. Alternative $\mu \neq 1000$, $t = \sqrt{20}(996 - 1000)/5 = -3.58 < c = -2.09$ (Table A9, 19 degrees of freedom). Reject the hypothesis $\mu = 1000$ g.
11. Test $\mu = 0$ against $\mu \neq 0$. $t = 2.11 < c = 2.36$ (7 degrees of freedom). Do not reject the hypothesis.
13. $\alpha = 5\%$, $c = 16.92 > 9 \cdot 0.5^2/0.4^2 = 14.06$; do not reject hypothesis.
15. $t_0 = \sqrt{10 \cdot 9 \cdot 17/19}\,(21.8 - 20.2)/\sqrt{9 \cdot 0.6^2 + 8 \cdot 0.5^2} = 6.3 > c = 1.74$ (17 degrees of freedom). Reject the hypothesis and assert that B is better.

17. $v_0 = 50/30 = 1.67 < c = 2.59$ [(9, 15) degrees of freedom]; do not reject the hypothesis.

Problem Set 25.5, page 1071

1. LCL $= 1 - 2.58 \cdot 0.03/\sqrt{6} = 0.968$, UCL $= 1.032$
3. $n = 10$
5. Choose 4 times the original sample size (why?).
7. $2.58\sqrt{0.024}/\sqrt{2} = 0.283$, UCL $= 27.783$, LCL $= 27.217$
11. In 30% (5%) of the cases, approximately
13. UCL $= np + 3\sqrt{np(1-p)}$, CL $= np$, LCL $= np - 3\sqrt{np(1-p)}$
15. CL $= \mu = 2.5$, UCL $= \mu + 3\sqrt{\mu} = 7.2$, LCL $= \mu - 3\sqrt{\mu}$ is negative in (b) and we set LCL $= 0$.

Problem Set 25.6, page 1076

1. 0.9825, 0.9384, 0.4060
3. 0.8187, 0.6703, 0.1353
5. $P(A;\theta) \approx e^{-30\theta}(1 + 30\theta)$
7. $P(A;\theta) \approx e^{-50\theta}$
9. 19.5%, 14.7%
11. $(1-\theta)^5$, $(1-\theta)^5 + 5\theta(1-\theta)^4$
13. Because n is finite
15. $\Phi((9 - 12 + \frac{1}{2})/\sqrt{12(1-0.12)}) = 0.22$ (if $c = 9$)
17. $(1 - \frac{1}{2})^3 + 3 \cdot \frac{1}{2}(1 - \frac{1}{2})^2 = \frac{1}{2}$

Problem Set 25.7, page 1079

1. ${\chi_0}^2 = (30 - 50)^2/50 + (70 - 50)^2/50 = 16 > c = 3.84$; no
3. 41
5. ${\chi_0}^2 = 2.33 < c = 11.07$. Yes
7. $e_j = np_j = 370/5 = 74$, ${\chi_0}^2 = 984/74 = 13.3$, $c = 9.49$. Reject the hypothesis.
9. ${\chi_0}^2 = 1 < 3.84$; yes
13. Combining the results for $x = 10, 11, 12$, we have $K - r - 1 = 9$ ($r = 1$ since we estimated the mean, $\frac{10094}{2608} \approx 3.87$). ${\chi_0}^2 = 12.98 < c = 16.92$. Do not reject.
15. ${\chi_0}^2 = 49/20 + 49/60 = 3.27 < c = 3.84$ (1 degree of freedom, $\alpha = 5\%$), which supports the claim.
17. 42 even digits, accept.

Problem Set 25.8, page 1082

3. $(\frac{1}{2})^{18}(1 + 18 + 153 + 816) = 0.0038$
5. Hypothesis: A and B are equally good. Then the probability of at least 7 trials favorable to A is $\frac{1}{2}^{18} + 8 \cdot \frac{1}{2}^{18} = 3.5\%$. Reject the hypothesis.
7. Hypothesis $\mu = 0$. Alternative $\mu > 0$, $\bar{x} = 1.58$,
$t = \sqrt{10} \cdot 1.58/1.23 = 4.06 > c = 1.83$ ($\alpha = 5\%$). Hypothesis rejected.
9. $\bar{x} = 9.67$, $s = 11.87$, $t_0 = 9.67/(11.87/\sqrt{15}) = 3.15 > c = 1.76$ ($\alpha = 5\%$). Hypothesis rejected.
11. Consider $y_j = x_j - \tilde{\mu}_0$.
13. $P(T \leqq 2) = 0.1\%$ from Table A12. Reject.

15. $P(T \leqq 15) = 10.8\%$. Do not reject.
17. $P(T \leqq 2) = 2.8\%$. Reject.

37. $30.14/3.8 = 7.93 < 8.25$. Reject.
39. $v_0 = 2.5 < 6.0$ [(9, 4) degrees of freedom]; accept the hypothesis.
41. Decrease by a factor $\sqrt{2}$. By a factor $2.58/1.96 = 1.32$.
43. 0.9953, 0.9825, 0.9384, etc. **45.** $y = 1.70 + 0.55x$

APPENDIX 3

Auxiliary Material

A3.1 Formulas for Special Functions

For tables of numeric values, see Appendix 5.

Exponential function e^x (Fig. 544)

$$e = 2.71828\ 18284\ 59045\ 23536\ 02874\ 71353$$

(1) $$e^x e^y = e^{x+y}, \qquad e^x/e^y = e^{x-y}, \qquad (e^x)^y = e^{xy}$$

Natural logarithm (Fig. 545)

(2) $$\ln(xy) = \ln x + \ln y, \qquad \ln(x/y) = \ln x - \ln y, \qquad \ln(x^a) = a \ln x$$

$\ln x$ is the inverse of e^x, and $e^{\ln x} = x$, $e^{-\ln x} = e^{\ln(1/x)} = 1/x$.

Logarithm of base ten $\log_{10} x$ or simply $\log x$

(3) $$\log x = M \ln x, \qquad M = \log e = 0.43429\ 44819\ 03251\ 82765\ 11289\ 18917$$

(4) $$\ln x = \frac{1}{M} \log x, \qquad \frac{1}{M} = \ln 10 = 2.30258\ 50929\ 94045\ 68401\ 79914\ 54684$$

$\log x$ is the inverse of 10^x, and $10^{\log x} = x$, $10^{-\log x} = 1/x$.

Sine and cosine functions (Figs. 546, 547). In calculus, angles are measured in radians, so that $\sin x$ and $\cos x$ have period 2π.

$\sin x$ is odd, $\sin(-x) = -\sin x$, and $\cos x$ is even, $\cos(-x) = \cos x$.

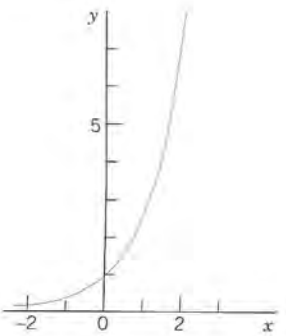

Fig. 544. Exponential function e^x

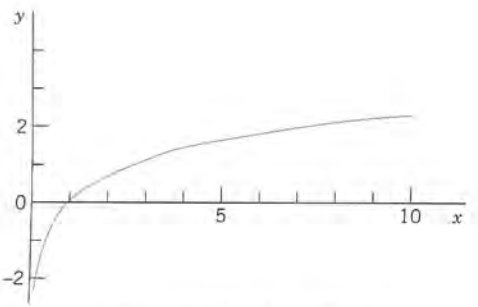

Fig. 545. Natural logarithm $\ln x$

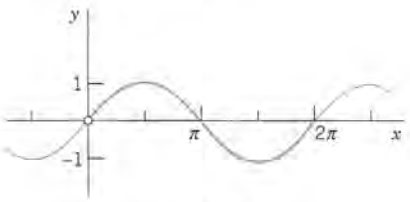

Fig. 546. sin x

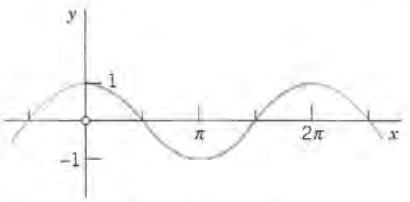

Fig. 547. cos x

$$1^\circ = 0.01745\ 32925\ 19943 \text{ radian}$$

$$1 \text{ radian} = 57^\circ\ 17'\ 44.80625''$$

$$= 57.29577\ 95131^\circ$$

(5) $$\sin^2 x + \cos^2 x = 1$$

(6)
$$\begin{cases} \sin (x + y) = \sin x \cos y + \cos x \sin y \\ \sin (x - y) = \sin x \cos y - \cos x \sin y \\ \cos (x + y) = \cos x \cos y - \sin x \sin y \\ \cos (x - y) = \cos x \cos y + \sin x \sin y \end{cases}$$

(7) $$\sin 2x = 2 \sin x \cos x, \qquad \cos 2x = \cos^2 x - \sin^2 x$$

(8)
$$\begin{cases} \sin x = \cos\left(x - \dfrac{\pi}{2}\right) = \cos\left(\dfrac{\pi}{2} - x\right) \\ \cos x = \sin\left(x + \dfrac{\pi}{2}\right) = \sin\left(\dfrac{\pi}{2} - x\right) \end{cases}$$

(9) $$\sin (\pi - x) = \sin x, \qquad \cos (\pi - x) = -\cos x$$

(10) $$\cos^2 x = \tfrac{1}{2}(1 + \cos 2x), \qquad \sin^2 x = \tfrac{1}{2}(1 - \cos 2x)$$

(11)
$$\begin{cases} \sin x \sin y = \tfrac{1}{2}[-\cos (x + y) + \cos (x - y)] \\ \cos x \cos y = \tfrac{1}{2}[\cos (x + y) + \cos (x - y)] \\ \sin x \cos y = \tfrac{1}{2}[\sin (x + y) + \sin (x - y)] \end{cases}$$

(12)
$$\begin{cases} \sin u + \sin v = 2 \sin \dfrac{u + v}{2} \cos \dfrac{u - v}{2} \\ \cos u + \cos v = 2 \cos \dfrac{u + v}{2} \cos \dfrac{u - v}{2} \\ \cos v - \cos u = 2 \sin \dfrac{u + v}{2} \sin \dfrac{u - v}{2} \end{cases}$$

(13) $$A \cos x + B \sin x = \sqrt{A^2 + B^2} \cos (x \pm \delta), \qquad \tan \delta = \frac{\sin \delta}{\cos \delta} = \mp \frac{B}{A}$$

(14) $$A \cos x + B \sin x = \sqrt{A^2 + B^2} \sin (x \pm \delta), \qquad \tan \delta = \frac{\sin \delta}{\cos \delta} = \pm \frac{A}{B}$$

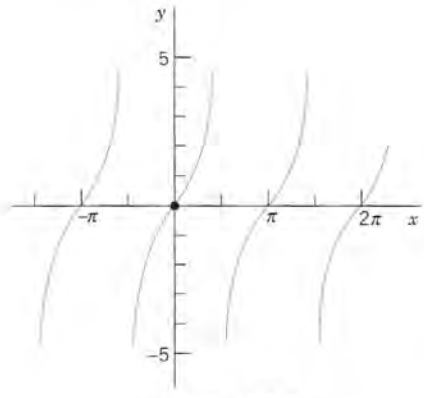

Fig. 548. tan x

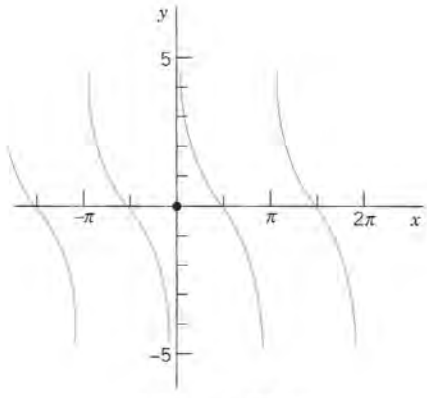

Fig. 549. cot x

Tangent, cotangent, secant, cosecant (Figs. 548, 549)

$$(15)\quad \tan x = \frac{\sin x}{\cos x}, \qquad \cot x = \frac{\cos x}{\sin x}, \qquad \sec x = \frac{1}{\cos x}, \qquad \csc x = \frac{1}{\sin x}$$

$$(16)\quad \tan (x + y) = \frac{\tan x + \tan y}{1 - \tan x \tan y}, \qquad \tan (x - y) = \frac{\tan x - \tan y}{1 + \tan x \tan y}$$

Hyperbolic functions (hyperbolic sine $\sinh x$, etc.; Figs. 550, 551)

$$(17)\quad \sinh x = \tfrac{1}{2}(e^x - e^{-x}), \qquad \cosh x = \tfrac{1}{2}(e^x + e^{-x})$$

$$(18)\quad \tanh x = \frac{\sinh x}{\cosh x}, \qquad \coth x = \frac{\cosh x}{\sinh x}$$

$$(19)\quad \cosh x + \sinh x = e^x, \qquad \cosh x - \sinh x = e^{-x}$$

$$(20)\quad \cosh^2 x - \sinh^2 x = 1$$

$$(21)\quad \sinh^2 x = \tfrac{1}{2}(\cosh 2x - 1), \qquad \cosh^2 x = \tfrac{1}{2}(\cosh 2x + 1)$$

(22)
$$\begin{cases} \sinh(x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y \\ \cosh(x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y \end{cases}$$

(23)
$$\tanh(x \pm y) = \frac{\tanh x \pm \tanh y}{1 \pm \tanh x \tanh y}$$

Gamma function (Fig. 552 and Table A2 in App. 5). The gamma function $\Gamma(\alpha)$ is defined by the integral

(24)
$$\Gamma(\alpha) = \int_0^\infty e^{-t} t^{\alpha-1}\, dt \qquad (\alpha > 0)$$

which is meaningful only if $\alpha > 0$ (or, if we consider complex α, for those α whose real part is positive). Integration by parts gives the important *functional relation of the gamma function,*

(25)
$$\Gamma(\alpha + 1) = \alpha\Gamma(\alpha).$$

From (24) we readily have $\Gamma(1) = 1$; hence if α is a positive integer, say k, then by repeated application of (25) we obtain

(26)
$$\Gamma(k + 1) = k! \qquad (k = 0, 1, \cdots).$$

This shows that *the gamma function can be regarded as a generalization of the elementary factorial function.* [Sometimes the notation $(\alpha - 1)!$ is used for $\Gamma(\alpha)$, even for noninteger values of α, and the gamma function is also known as the **factorial function.**]

By repeated application of (25) we obtain

$$\Gamma(\alpha) = \frac{\Gamma(\alpha + 1)}{\alpha} = \frac{\Gamma(\alpha + 2)}{\alpha(\alpha + 1)} = \cdots = \frac{\Gamma(\alpha + k + 1)}{\alpha(\alpha + 1)(\alpha + 2) \cdots (\alpha + k)}$$

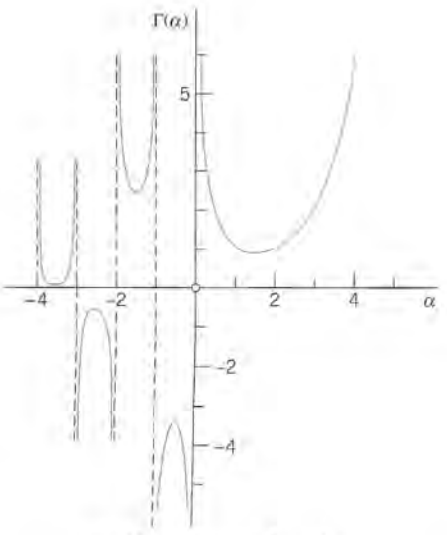

Fig. 552. Gamma function

and we may use this relation

$$\Gamma(\alpha) = \frac{\Gamma(\alpha + k + 1)}{\alpha(\alpha + 1) \cdots (\alpha + k)} \qquad (\alpha \neq 0, -1, -2, \cdots) \tag{27}$$

for defining the gamma function for negative α ($\neq -1, -2, \cdots$), choosing for k the smallest integer such that $\alpha + k + 1 > 0$. *Together with* (24), *this then gives a definition of* $\Gamma(\alpha)$ *for all* α *not equal to zero or a negative integer* (Fig. 552).

It can be shown that the gamma function may also be represented as the limit of a product, namely, by the formula

$$\Gamma(\alpha) = \lim_{n \to \infty} \frac{n!\, n^\alpha}{\alpha(\alpha + 1)(\alpha + 2) \cdots (\alpha + n)} \qquad (\alpha \neq 0, -1, \cdots). \tag{28}$$

From (27) or (28) we see that, for complex α, the gamma function $\Gamma(\alpha)$ is a meromorphic function with simple poles at $\alpha = 0, -1, -2, \cdots$.

An approximation of the gamma function for large positive α is given by the **Stirling formula**

$$\Gamma(\alpha + 1) \approx \sqrt{2\pi\alpha} \left(\frac{\alpha}{e}\right)^\alpha \tag{29}$$

where e is the base of the natural logarithm. We finally mention the special value

$$\Gamma(\tfrac{1}{2}) = \sqrt{\pi}. \tag{30}$$

Incomplete gamma functions

$$P(\alpha, x) = \int_0^x e^{-t} t^{\alpha-1}\, dt, \qquad Q(\alpha, x) = \int_x^\infty e^{-t} t^{\alpha-1}\, dt \qquad (\alpha > 0) \tag{31}$$

$$\Gamma(\alpha) = P(\alpha, x) + Q(\alpha, x) \tag{32}$$

Beta function

$$B(x, y) = \int_0^1 t^{x-1}(1 - t)^{y-1}\, dt \qquad (x > 0, y > 0) \tag{33}$$

Representation in terms of gamma functions:

$$B(x, y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x + y)} \tag{34}$$

Error function (Fig. 553 and Table A4 in App. 5)

$$\operatorname{erf} x = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2}\, dt \tag{35}$$

$$\operatorname{erf} x = \frac{2}{\sqrt{\pi}} \left(x - \frac{x^3}{1!3} + \frac{x^5}{2!5} - \frac{x^7}{3!7} + - \cdots\right) \tag{36}$$

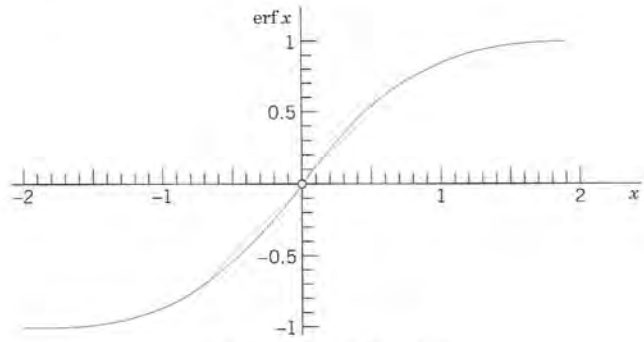

Fig. 553. Error function

$$\mathrm{Ei}(x) = \int_x^\infty \frac{e^{-t}}{t}\, dt \qquad (x > 0) \tag{43}$$

Logarithmic integral

$$\mathrm{li}(x) = \int_0^x \frac{dt}{\ln t} \tag{44}$$

A3.2 Partial Derivatives

For differentiation formulas, see inside of front cover.

Let $z = f(x, y)$ be a real function of two independent real variables, x and y. If we keep y constant, say, $y = y_1$, and think of x as a variable, then $f(x, y_1)$ depends on x alone. If the derivative of $f(x, y_1)$ with respect to x for a value $x = x_1$ exists, then the value of this derivative is called the **partial derivative** of $f(x, y)$ *with respect to* x *at the point* (x_1, y_1) and is denoted by

$$\left.\frac{\partial f}{\partial x}\right|_{(x_1, y_1)} \qquad \text{or by} \qquad \left.\frac{\partial z}{\partial x}\right|_{(x_1, y_1)}$$

Other notations are

$$f_x(x_1, y_1) \qquad \text{and} \qquad z_x(x_1, y_1);$$

these may be used when subscripts are not used for another purpose and there is no danger of confusion.

We thus have, by the definition of the derivative,

$$(1) \qquad \left.\frac{\partial f}{\partial x}\right|_{(x_1,y_1)} = \lim_{\Delta x \to 0} \frac{f(x_1 + \Delta x, y_1) - f(x_1, y_1)}{\Delta x}.$$

The partial derivative of $z = f(x, y)$ with respect to y is defined similarly; we now keep x constant, say, equal to x_1, and differentiate $f(x_1, y)$ with respect to y. Thus

$$(2) \qquad \left.\frac{\partial f}{\partial y}\right|_{(x_1,y_1)} = \left.\frac{\partial z}{\partial y}\right|_{(x_1,y_1)} = \lim_{\Delta y \to 0} \frac{f(x_1, y_1 + \Delta y) - f(x_1, y_1)}{\Delta y}.$$

Other notations are $f_y(x_1, y_1)$ and $z_y(x_1, y_1)$.

It is clear that the values of those two partial derivatives will in general depend on the point (x_1, y_1). Hence the partial derivatives $\partial z/\partial x$ and $\partial z/\partial y$ at a variable point (x, y) are functions of x and y. The function $\partial z/\partial x$ is obtained as in ordinary calculus by differentiating $z = f(x, y)$ with respect to x, ***treating y as a constant,*** and $\partial z/\partial y$ is obtained by differentiating z with respect to y, ***treating x as a constant.***

EXAMPLE 1 Let $z = f(x, y) = x^2y + x \sin y$. Then

$$\frac{\partial f}{\partial x} = 2xy + \sin y, \qquad \frac{\partial f}{\partial y} = x^2 + x \cos y. \quad \blacksquare$$

The partial derivatives $\partial z/\partial x$ and $\partial z/\partial y$ of a function $z = f(x, y)$ have a very simple **geometric interpretation.** The function $z = f(x, y)$ can be represented by a surface in space. The equation $y = y_1$ then represents a vertical plane intersecting the surface in a curve, and the partial derivative $\partial z/\partial x$ at a point (x_1, y_1) is the slope of the tangent (that is, $\tan \alpha$ where α is the angle shown in Fig. 556) to the curve. Similarly, the partial derivative $\partial z/\partial y$ at (x_1, y_1) is the slope of the tangent to the curve $x = x_1$ on the surface $z = f(x, y)$ at (x_1, y_1).

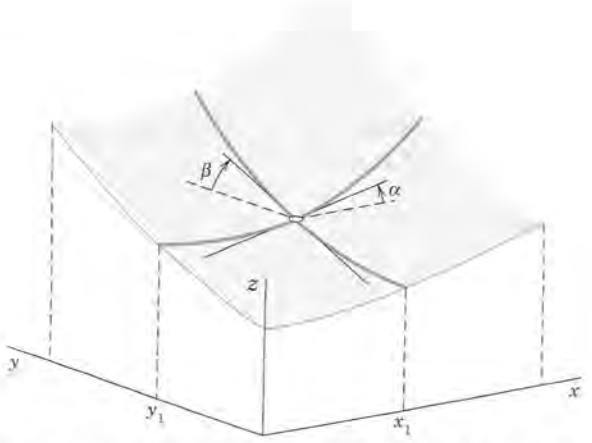

Fig. 556. Geometrical interpretation of first partial derivatives

The partial derivatives $\partial z/\partial x$ and $\partial z/\partial y$ are called *first partial derivatives* or *partial derivatives of first order.* By differentiating these derivatives once more, we obtain the four *second partial derivatives* (or *partial derivatives of second order*)[2]

$$(3) \qquad \begin{aligned} \frac{\partial^2 f}{\partial x^2} &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x}\right) = f_{xx} \\ \frac{\partial^2 f}{\partial x\,\partial y} &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial y}\right) = f_{yx} \\ \frac{\partial^2 f}{\partial y\,\partial x} &= \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x}\right) = f_{xy} \\ \frac{\partial^2 f}{\partial y^2} &= \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial y}\right) = f_{yy}. \end{aligned}$$

It can be shown that if all the derivatives concerned are continuous, then the two mixed partial derivatives are equal, so that the order of differentiation does not matter (see Ref. [GR4] in App. 1), that is,

$$(4) \qquad \frac{\partial^2 z}{\partial x\,\partial y} = \frac{\partial^2 z}{\partial y\,\partial x}.$$

EXAMPLE 2 For the function in Example 1.

$$f_{xx} = 2y, \qquad f_{xy} = 2x + \cos y = f_{yx}, \qquad f_{yy} = -x \sin y.$$

By differentiating the second partial derivatives again with respect to x and y, respectively, we obtain the *third partial derivatives* or *partial derivatives of the third order* of f, etc.

If we consider a function $f(x, y, z)$ of ***three independent variables,*** then we have the three first partial derivatives $f_x(x, y, z)$, $f_y(x, y, z)$, and $f_z(x, y, z)$. Here f_x is obtained by differentiating f with respect to x, ***treating both y and z as constants.*** Thus, analogous to (1), we now have

$$\left.\frac{\partial f}{\partial x}\right|_{(x_1, y_1, z_1)} = \lim_{\Delta x \to 0} \frac{f(x_1 + \Delta x, y_1, z_1) - f(x_1, y_1, z_1)}{\Delta x},$$

etc. By differentiating f_x, f_y, f_z again in this fashion we obtain the second partial derivatives of f, etc.

EXAMPLE 3 Let $f(x, y, z) = x^2 + y^2 + z^2 + xy\,e^z$. Then

$$\begin{aligned} &f_x = 2x + y\,e^z, && f_y = 2y + x\,e^z, && f_z = 2z + xy\,e^z, \\ &f_{xx} = 2, && f_{xy} = f_{yx} = e^z, && f_{xz} = f_{zx} = y\,e^z, \\ &f_{yy} = 2, && f_{yz} = f_{zy} = x\,e^z, && f_{zz} = 2 + xy\,e^z. \end{aligned}$$

[2] CAUTION! In the subscript notation the subscripts are written in the order in which we differentiate, whereas in the "∂" notation the order is opposite.

A3.3 Sequences and Series

See also Chap. 15.

Monotone Real Sequences

We call a real sequence $x_1, x_2, \cdots, x_n, \cdots$ a **monotone sequence** if it is either **monotone increasing,** that is,

$$x_1 \leqq x_2 \leqq x_3 \leqq \cdots$$

or **monotone decreasing,** that is,

$$x_1 \geqq x_2 \geqq x_3 \geqq \cdots.$$

We call $x_1, x_2, \cdots$ a **bounded sequence** if there is a positive constant K such that $|x_n| < K$ for all n.

THEOREM 1 *If a real sequence is bounded and monotone, it converges.*

PROOF Let $x_1, x_2, \cdots$ be a bounded monotone increasing sequence. Then its terms are smaller than some number B and, since $x_1 \leqq x_n$ for all n, they lie in the interval $x_1 \leqq x_n \leqq B$, which will be denoted by I_0. We bisect I_0; that is, we subdivide it into two parts of equal length. If the right half (together with its endpoints) contains terms of the sequence, we denote it by I_1. If it does not contain terms of the sequence, then the left half of I_0 (together with its endpoints) is called I_1. This is the first step.

In the second step we bisect I_1, select one half by the same rule, and call it I_2, and so on (see Fig. 557 on p. A70).

In this way we obtain shorter and shorter intervals $I_0, I_1, I_2, \cdots$ with the following properties. Each I_m contains all I_n for $n > m$. No term of the sequence lies to the right of I_m, and, since the sequence is monotone increasing, all x_n with n greater than some number N lie in I_m; of course, N will depend on m, in general. The lengths of the I_m approach zero as m approaches infinity. Hence there is precisely one number, call it L, that lies in all those intervals,[3] and we may now easily prove that the sequence is convergent with the limit L.

In fact, given an $\epsilon > 0$, we choose an m such that the length of I_m is less than ϵ. Then L and all the x_n with $n > N(m)$ lie in I_m, and, therefore, $|x_n - L| < \epsilon$ for all those n. This completes the proof for an increasing sequence. For a decreasing sequence the proof is the same, except for a suitable interchange of "left" and "right" in the construction of those intervals. ■

[3]This statement seems to be obvious, but actually it is not; it may be regarded as an axiom of the real number system in the following form. Let $J_1, J_2, \cdots$ be closed intervals such that each J_m contains all J_n with $n > m$, and the lengths of the J_m approach zero as m approaches infinity. Then there is precisely one real number that is contained in all those intervals. This is the so-called **Cantor–Dedekind axiom,** named after the German mathematicians GEORG CANTOR (1845–1918), the creator of set theory, and RICHARD DEDEKIND (1831–1916), known for his fundamental work in number theory. For further details see Ref. [GR2] in App. 1. (An interval I is said to be **closed** if its two endpoints are regarded as points belonging to I. It is said to be **open** if the endpoints are not regarded as points of I.)

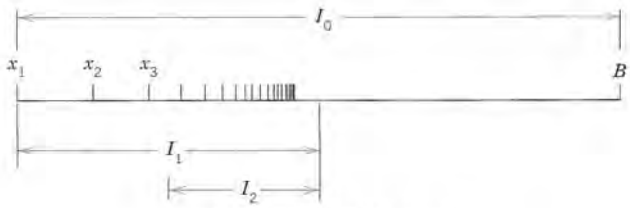

Fig. 557. Proof of Theorem 1

Real Series

THEOREM 2

Leibniz Test for Real Series

Let $x_1, x_2, \cdots$ be real and monotone decreasing to zero, that is,

(1) (a) $x_1 \geqq x_2 \geqq x_3 \geqq \cdots$, (b) $\lim_{m\to\infty} x_m = 0.$

Then the series with terms of alternating signs

$$x_1 - x_2 + x_3 - x_4 + - \cdots$$

converges, and for the remainder R_n after the nth term we have the estimate

(2) $$|R_n| \leqq x_{n+1}.$$

PROOF Let s_n be the nth partial sum of the series. Then, because of (1a),

$$s_1 = x_1, \qquad s_2 = x_1 - x_2 \leqq s_1,$$

$$s_3 = s_2 + x_3 \geqq s_2, \qquad s_3 = s_1 - (x_2 - x_3) \leqq s_1,$$

so that $s_2 \leqq s_3 \leqq s_1$. Proceeding in this fashion, we conclude that (Fig. 558)

(3) $$s_1 \geqq s_3 \geqq s_5 \geqq \cdots \geqq s_6 \geqq s_4 \geqq s_2$$

which shows that the odd partial sums form a bounded monotone sequence, and so do the even partial sums. Hence, by Theorem 1, both sequences converge, say,

$$\lim_{n\to\infty} s_{2n+1} = s, \qquad \lim_{n\to\infty} s_{2n} = s^*.$$

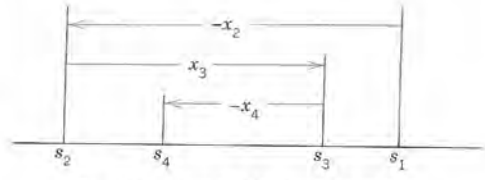

Fig. 558. Proof of the Leibniz test

Now, since $s_{2n+1} - s_{2n} = x_{2n+1}$, we readily see that (1b) implies

$$s - s^* = \lim_{n\to\infty} s_{2n+1} - \lim_{n\to\infty} s_{2n} = \lim_{n\to\infty} (s_{2n+1} - s_{2n}) = \lim_{n\to\infty} x_{2n+1} = 0.$$

Hence $s^* = s$, and the series converges with the sum s.

We prove the estimate (2) for the remainder. Since $s_n \to s$, it follows from (3) that

$$s_{2n+1} \geqq s \geqq s_{2n} \qquad \text{and also} \qquad s_{2n-1} \geqq s \geqq s_{2n}.$$

By subtracting s_{2n} and s_{2n-1}, respectively, we obtain

$$s_{2n+1} - s_{2n} \geqq s - s_{2n} \geqq 0, \qquad 0 \geqq s - s_{2n-1} \geqq s_{2n} - s_{2n-1}.$$

In these inequalities, the first expression is equal to x_{2n+1}, the last is equal to $-x_{2n}$, and the expressions between the inequality signs are the remainders R_{2n} and R_{2n-1}. Thus the inequalities may be written

$$x_{2n+1} \geqq R_{2n} \geqq 0, \qquad 0 \geqq R_{2n-1} \geqq -x_{2n}$$

and we see that they imply (2). This completes the proof. ■

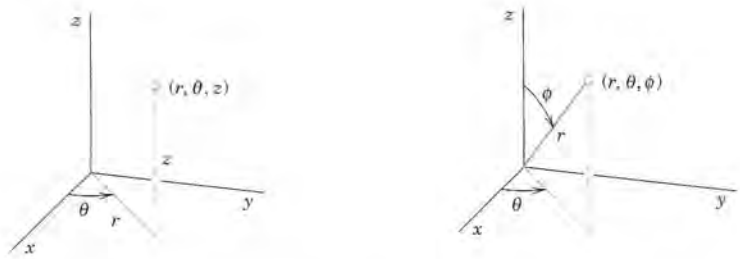
A3.4 Grad, Div, Curl, ∇^2 in Curvilinear Coordinates

To simplify formulas we write Cartesian coordinates $x = x_1$, $y = x_2$, $z = x_3$. We denote curvilinear coordinates by q_1, q_2, q_3. Through each point P there pass three coordinate surfaces $q_1 = const$, $q_2 = const$, $q_3 = const$. They intersect along coordinate curves. We assume the three coordinate curves through P to be **orthogonal** (perpendicular to each other). We write coordinate transformations as

$$(1) \qquad x_1 = x_1(q_1, q_2, q_3), \qquad x_2 = x_2(q_1, q_2, q_3), \qquad x_3 = x_3(q_1, q_2, q_3).$$

Corresponding transformations of grad, div, curl, and ∇^2 can all be written by using

$$(2) \qquad h_j^2 = \sum_{k=1}^{3} \left(\frac{\partial x_k}{\partial q_j}\right)^2.$$



Next to Cartesian coordinates, most important are **cylindrical coordinates** $q_1 = r$, $q_2 = \theta$, $q_3 = z$ (Fig. 559a on p. A72) defined by

$$(3) \quad x_1 = q_1 \cos q_2 = r \cos \theta, \qquad x_2 = q_1 \sin q_2 = r \sin \theta, \qquad x_3 = q_3 = z$$

and **spherical coordinates** $q_1 = r$, $q_2 = \theta$, $q_3 = \phi$ (Fig. 559b) defined by[4]

$$(4) \quad x_1 = q_1 \cos q_2 \sin q_3 = r \cos \theta \sin \phi, \qquad x_2 = q_1 \sin q_2 \sin q_3 = r \sin \theta \sin \phi$$
$$x_3 = q_1 \cos q_3 = r \cos \phi.$$

[4]This is the notation used in calculus and in many other books. It is logical since in it, θ plays the same role as in polar coordinates. CAUTION! Some books interchange the roles of θ and ϕ.

(a) Cylindrical coordinates (b) Spherical coordinates

Fig. 559. Special curvilinear coordinates

In addition to the general formulas for any orthogonal coordinates q_1, q_2, q_3, we shall give additional formulas for these important special cases.

Linear Element *ds*. In Cartesian coordinates,

$$ds^2 = dx_1^2 + dx_2^2 + dx_3^2 \qquad \text{(Sec. 9.5).}$$

For the q-coordinates,

$$(5) \qquad ds^2 = h_1^2\, dq_1^2 + h_2^2\, dq_2^2 + h_3^2\, dq_3^2.$$

$$(5') \qquad ds^2 = dr^2 + r^2\, d\theta^2 + dz^2 \qquad \text{(Cylindrical coordinates).}$$

For polar coordinates set $dz^2 = 0$.

$$(5'') \qquad ds^2 = dr^2 + r^2 \sin^2\phi\, d\theta^2 + r^2\, d\phi^2 \qquad \text{(Spherical coordinates).}$$

Gradient. grad $f = \nabla f = [f_{x_1},\ f_{x_2},\ f_{x_3}]$ (partial derivatives; Sec. 9.7). In the q-system, with **u, v, w** denoting unit vectors in the positive directions of the q_1, q_2, q_3 coordinate curves, respectively,

$$(6) \qquad \operatorname{grad} f = \nabla f = \frac{1}{h_1}\frac{\partial f}{\partial q_1}\mathbf{u} + \frac{1}{h_2}\frac{\partial f}{\partial q_2}\mathbf{v} + \frac{1}{h_3}\frac{\partial f}{\partial q_3}\mathbf{w}$$

$$(6') \qquad \operatorname{grad} f = \nabla f = \frac{\partial f}{\partial r}\mathbf{u} + \frac{1}{r}\frac{\partial f}{\partial \theta}\mathbf{v} + \frac{\partial f}{\partial z}\mathbf{w} \qquad \text{(Cylindrical coordinates)}$$

$$(6'') \qquad \operatorname{grad} f = \nabla f = \frac{\partial f}{\partial r}\mathbf{u} + \frac{1}{r\sin\phi}\frac{\partial f}{\partial \theta}\mathbf{v} + \frac{1}{r}\frac{\partial f}{\partial \phi}\mathbf{w} \qquad \text{(Spherical coordinates).}$$

Divergence div $\mathbf{F} = \nabla\cdot\mathbf{F} = (F_1)_{x_1} + (F_2)_{x_2} + (F_3)_{x_3}$ ($\mathbf{F} = [F_1, F_2, F_3]$, Sec. 9.8);

$$(7) \qquad \operatorname{div}\mathbf{F} = \nabla\cdot\mathbf{F} = \frac{1}{h_1h_2h_3}\left[\frac{\partial}{\partial q_1}(h_2h_3F_1) + \frac{\partial}{\partial q_2}(h_3h_1F_2) + \frac{\partial}{\partial q_3}(h_1h_2F_3)\right]$$

$$(7') \qquad \operatorname{div}\mathbf{F} = \nabla\cdot\mathbf{F} = \frac{1}{r}\frac{\partial}{\partial r}(rF_1) + \frac{1}{r}\frac{\partial F_2}{\partial \theta} + \frac{\partial F_3}{\partial z} \qquad \text{(Cylindrical coordinates)}$$

$$(7'') \quad \operatorname{div} \mathbf{F} = \nabla \cdot \mathbf{F} = \frac{1}{r^2}\frac{\partial}{\partial r}(r^2 F_1) + \frac{1}{r\sin\phi}\frac{\partial F_2}{\partial \theta} + \frac{1}{r\sin\phi}\frac{\partial}{\partial \phi}(\sin\phi\, F_3) \qquad \text{(Spherical coordinates).}$$

Laplacian $\nabla^2 f = \nabla \cdot \nabla f = \operatorname{div}(\operatorname{grad} f) = f_{x_1x_1} + f_{x_2x_2} + f_{x_3x_3}$ (Sec. 9.8):

$$(8) \quad \nabla^2 f = \frac{1}{h_1h_2h_3}\left[\frac{\partial}{\partial q_1}\left(\frac{h_2h_3}{h_1}\frac{\partial f}{\partial q_1}\right) + \frac{\partial}{\partial q_2}\left(\frac{h_3h_1}{h_2}\frac{\partial f}{\partial q_2}\right) + \frac{\partial}{\partial q_3}\left(\frac{h_1h_2}{h_3}\frac{\partial f}{\partial q_3}\right)\right]$$

$$(8') \quad \nabla^2 f = \frac{\partial^2 f}{\partial r^2} + \frac{1}{r}\frac{\partial f}{\partial r} + \frac{1}{r^2}\frac{\partial^2 f}{\partial \theta^2} + \frac{\partial^2 f}{\partial z^2} \qquad \text{(Cylindrical coordinates)}$$

$$(8'') \quad \nabla^2 f = \frac{\partial^2 f}{\partial r^2} + \frac{2}{r}\frac{\partial f}{\partial r} + \frac{1}{r^2\sin^2\phi}\frac{\partial^2 f}{\partial \theta^2} + \frac{1}{r^2}\frac{\partial^2 f}{\partial \phi^2} + \frac{\cot\phi}{r^2}\frac{\partial f}{\partial \phi} \qquad \text{(Spherical coordinates).}$$

Curl (Sec. 9.9):

$$(9) \quad \operatorname{curl} \mathbf{F} = \nabla \times \mathbf{F} = \frac{1}{h_1h_2h_3}\begin{vmatrix} h_1\mathbf{u} & h_2\mathbf{v} & h_3\mathbf{w} \\ \dfrac{\partial}{\partial q_1} & \dfrac{\partial}{\partial q_2} & \dfrac{\partial}{\partial q_3} \\ h_1F_1 & h_2F_2 & h_3F_3 \end{vmatrix}.$$

For cylindrical coordinates we have in (9) (as in the previous formulas)

$$h_1 = h_r = 1, \qquad h_2 = h_\theta = q_1 = r, \qquad h_3 = h_z = 1$$

and for spherical coordinates we have

$$h_1 = h_r = 1, \qquad h_2 = h_\theta = q_1 \sin q_3 = r\sin\phi, \qquad h_3 = h_\phi = q_1 = r.$$

APPENDIX 4

Additional Proofs

Section 2.6, page 73

PROOF OF THEOREM 1 Uniqueness[1]

Assuming that the problem consisting of the ODE

$$y'' + p(x)y' + q(x)y = 0 \tag{1}$$

and the two initial conditions

$$y(x_0) = K_0, \qquad y'(x_0) = K_1 \tag{3}$$

has two solutions $y_1(x)$ and $y_2(x)$ on the interval I in the theorem, we show that their difference

$$y(x) = y_1(x) - y_2(x)$$

is identically zero on I; then $y_1 \equiv y_2$ on I, which implies uniqueness.

Since (1) is homogeneous and linear, y is a solution of that ODE on I, and since y_1 and y_2 satisfy the same initial conditions, y satisfies the conditions

$$y(x_0) = 0, \qquad y'(x_0) = 0. \tag{10}$$

We consider the function

$$z(x) = y(x)^2 + y'(x)^2$$

and its derivative

$$z' = 2yy' + 2y'y''.$$

From the ODE we have

$$y'' = -py' - qy.$$

By substituting this in the expression for z' we obtain

$$z' = 2yy' - 2py'^2 - 2qyy'. \tag{11}$$

Now, since y and y' are real,

$$(y \pm y')^2 = y^2 \pm 2yy' + y'^2 \geqq 0.$$

[1]This proof was suggested by my colleague, Prof. A. D. Ziebur. In this proof we use formula numbers that have not yet been used in Sec. 2.6.

From this and the definition of z we obtain the two inequalities

(12) (a) $2yy' \leqq y^2 + y'^2 = z$, (b) $-2yy' \leqq y^2 + y'^2 = z$.

From (12b) we have $2yy' \geqq -z$. Together, $|2yy'| \leqq z$. For the last term in (11) we now obtain

$$-2qyy' \leqq |-2qyy'| = |q||2yy'| \leqq |q|z.$$

Using this result as well as $-p \leqq |p|$ and applying (12a) to the term $2yy'$ in (11), we find

$$z' \leqq z + 2|p|y'^2 + |q|z.$$

Since $y'^2 \leqq y^2 + y'^2 = z$, from this we obtain

$$z' \leqq (1 + 2|p| + |q|)z$$

or, denoting the function in parentheses by h,

(13a) $$z' \leqq hz \qquad \text{for all } x \text{ on } I.$$

Similarly, from (11) and (12) it follows that

(13b)
$$\begin{aligned} -z' &= -2yy' + 2py'^2 + 2qyy' \\ &\leqq z + 2|p|z + |q|z = hz. \end{aligned}$$

The inequalities (13a) and (13b) are equivalent to the inequalities

(14) $$z' - hz \leqq 0, \qquad z' + hz \geqq 0.$$

Integrating factors for the two expressions on the left are

$$F_1 = e^{-\int h(x)\,dx} \qquad \text{and} \qquad F_2 = e^{\int h(x)\,dx}.$$

The integrals in the exponents exist because h is continuous. Since F_1 and F_2 are positive, we thus have from (14)

$$F_1(z' - hz) = (F_1 z)' \leqq 0 \qquad \text{and} \qquad F_2(z' + hz) = (F_2 z)' \geqq 0.$$

This means that $F_1 z$ is nonincreasing and $F_2 z$ is nondecreasing on I. Since $z(x_0) = 0$ by (10), when $x \leqq x_0$ we thus obtain

$$F_1 z \geqq (F_1 z)_{x_0} = 0, \qquad F_2 z \leqq (F_2 z)_{x_0} = 0$$

and similarly, when $x \geqq x_0$,

$$F_1 z \leqq 0, \qquad F_2 z \geqq 0.$$

Dividing by F_1 and F_2 and noting that these functions are positive, we altogether have

$$z \leqq 0, \qquad z \geqq 0 \qquad \text{for all } x \text{ on } I.$$

This implies that $z = y^2 + y'^2 \equiv 0$ on I. Hence $y \equiv 0$ or $y_1 \equiv y_2$ on I. ■

Section 5.4, pages 184

PROOF OF THEOREM 2 **Frobenius Method. Basis of Solutions. Three Cases**

The formula numbers in this proof are the same as in the text of Sec. 5.4. An additional formula not appearing in Sec. 5.4 will be called (A) (see below).

The ODE in Theorem 2 is

$$(1) \qquad y'' + \frac{b(x)}{x}\,y' + \frac{c(x)}{x^2}\,y = 0,$$

where $b(x)$ and $c(x)$ are analytic functions. We can write it

$$(1') \qquad x^2y'' + xb(x)y' + c(x)y = 0.$$

The indicial equation of (1) is

$$(4) \qquad r(r-1) + b_0r + c_0 = 0.$$

The roots r_1, r_2 of this quadratic equation determine the general form of a basis of solutions of (1), and there are three possible cases as follows.

Case 1. Distinct Roots not Differing by an Integer. A first solution of (1) is of the form

$$(5) \qquad y_1(x) = x^{r_1}(a_0 + a_1x + a_2x^2 + \cdots)$$

and can be determined as in the power series method. For a proof that in this case, the ODE (1) has a second independent solution of the form

$$(6) \qquad y_2(x) = x^{r_2}(A_0 + A_1x + A_2x^2 + \cdots),$$

see Ref. [A11] listed in App. 1.

Case 2. Double Root. The indicial equation (4) has a double root r if and only if $(b_0 - 1)^2 - 4c_0 = 0$, and then $r = \frac{1}{2}(1 - b_0)$. A first solution

$$(7) \qquad y_1(x) = x^r(a_0 + a_1x + a_2x^2 + \cdots), \qquad r = \tfrac{1}{2}(1 - b_0),$$

can be determined as in Case 1. We show that a second independent solution is of the form

$$(8) \qquad y_2(x) = y_1(x)\ln x + x^r(A_1x + A_2x^2 + \cdots) \qquad (x > 0).$$

We use the method of reduction of order (see Sec. 2.1), that is, we determine $u(x)$ such that $y_2(x) = u(x)y_1(x)$ is a solution of (1). By inserting this and the derivatives

$$y_2' = u'y_1 + uy_1', \qquad y_2'' = u''y_1 + 2u'y_1' + uy_1''$$

into the ODE (1′) we obtain

$$x^2(u''y_1 + 2u'y_1' + uy_1'') + xb(u'y_1 + uy_1') + cuy_1 = 0.$$

Since y_1 is a solution of (1′), the sum of the terms involving u is zero, and this equation reduces to

$$x^2y_1u'' + 2x^2y_1'u' + xby_1u' = 0.$$

By dividing by x^2y_1 and inserting the power series for b we obtain

$$u'' + \left(2\frac{y_1'}{y_1} + \frac{b_0}{x} + \cdots\right)u' = 0.$$

Here and in the following the dots designate terms that are constant or involve positive powers of x. Now from (7) if follows that

$$\frac{y_1'}{y_1} = \frac{x^{r-1}[ra_0 + (r+1)a_1x + \cdots]}{x^r[a_0 + a_1x + \cdots]}$$

$$= \frac{1}{x}\left(\frac{ra_0 + (r+1)a_1x + \cdots}{a_0 + a_1x + \cdots}\right) = \frac{r}{x} + \cdots.$$

Hence the previous equation can be written

$$\text{(A)} \qquad u'' + \left(\frac{2r + b_0}{x} + \cdots\right)u' = 0.$$

Since $r = (1 - b_0)/2$, the term $(2r + b_0)/x$ equals $1/x$, and by dividing by u' we thus have

$$\frac{u''}{u'} = -\frac{1}{x} + \cdots.$$

By integration we obtain $\ln u' = -\ln x + \cdots$, hence $u' = (1/x)e^{(\cdots)}$. Expanding the exponential function in powers of x and integrating once more, we see that u is of the form

$$u = \ln x + k_1x + k_2x^2 + \cdots.$$

Inserting this into $y_2 = uy_1$, we obtain for y_2 a representation of the form (8).

Case 3. Roots Differing by an Integer. We write $r_1 = r$ and $r_2 = r - p$ where p is a ***positive*** integer. A first solution

$$\text{(9)} \qquad y_1(x) = x^{r_1}(a_0 + a_1x + a_2x^2 + \cdots)$$

can be determined as in Cases 1 and 2. We show that a second independent solution is of the form

$$\text{(10)} \qquad y_2(x) = ky_1(x)\ln x + x^{r_2}(A_0 + A_1x + A_2x^2 + \cdots)$$

where we may have $k \neq 0$ or $k = 0$. As in Case 2 we set $y_2 = uy_1$. The first steps are literally as in Case 2 and give Eq. (A),

$$u'' + \left(\frac{2r + b_0}{x} + \cdots\right)u' = 0.$$

Now by elementary algebra, the coefficient $b_0 - 1$ of r in (4) equals minus the sum of the roots,

$$b_0 - 1 = -(r_1 + r_2) = -(r + r - p) = -2r + p.$$

Hence $2r + b_0 = p + 1$, and division by u' gives

$$\frac{u''}{u'} = -\left(\frac{p+1}{x} + \cdots\right).$$

The further steps are as in Case 2. Integrating, we find

$$\ln u' = -(p+1)\ln x + \cdots, \qquad \text{thus} \qquad u' = x^{-(p+1)}e^{(\cdots)}$$

where dots stand for some series of nonnegative integer powers of x. By expanding the exponential function as before we obtain a series of the form

$$u' = \frac{1}{x^{p+1}} + \frac{k_1}{x^p} + \cdots + \frac{k_{p-1}}{x^2} + \frac{k_p}{x} + k_{p+1} + k_{p+2}x + \cdots.$$

We integrate once more. Writing the resulting logarithmic term first, we get

$$u = k_p \ln x + \left(-\frac{1}{px^p} - \cdots - \frac{k_{p-1}}{x} + k_{p+1}x + \cdots\right).$$

Hence, by (9) we get for $y_2 = uy_1$ the formula

$$y_2 = k_p y_1 \ln x + x^{r_1 - p}\left(-\frac{1}{p} - \cdots - k_{p-1}x^{p-1} + \cdots\right)(a_0 + a_1 x + \cdots).$$

But this is of the form (10) with $k = k_p$ since $r_1 - p = r_2$ and the product of the two series involves nonnegative integer powers of x only. ∎

Section 5.7, page 205

THEOREM

Reality of Eigenvalues

If p, q, r, and p' in the Sturm–Liouville equation (1) of Sec. 5.7 are real-valued and continuous on the interval $a \leqq x \leqq b$ and $r(x) > 0$ throughout that interval (or $r(x) < 0$ throughout that interval), then all the eigenvalues of the Sturm–Liouville problem (1), (2), Sec. 5.7, are real.

PROOF Let $\lambda = \alpha + i\beta$ be an eigenvalue of the problem and let

$$y(x) = u(x) + iv(x)$$

be a corresponding eigenfunction; here α, β, u, and v are real. Substituting this into (1), Sec. 5.7, we have

$$(pu' + ipv')' + (q + \alpha r + i\beta r)(u + iv) = 0.$$

This complex equation is equivalent to the following pair of equations for the real and the imaginary parts:

$$(pu')' + (q + \alpha r)u - \beta rv = 0$$
$$(pv')' + (q + \alpha r)v + \beta ru = 0.$$

Multiplying the first equation by v, the second by $-u$ and adding, we get

$$\begin{aligned} -\beta(u^2 + v^2)r &= u(pv')' - v(pu')' \\ &= [(pv')u - (pu')v]'. \end{aligned}$$

The expression in brackets is continuous on $a \leqq x \leqq b$, for reasons similar to those in the proof of Theorem 1, Sec. 5.7. Integrating over x from a to b, we thus obtain

$$-\beta \int_a^b (u^2 + v^2)r \, dx = \Big[p(uv' - u'v) \Big]_a^b.$$

Because of the boundary conditions the right side is zero; this is as in that proof. Since y is an eigenfunction, $u^2 + v^2 \neq 0$. Since y and r are continuous and $r > 0$ (or $r < 0$) on the interval $a \leqq x \leqq b$, the integral on the left is not zero. Hence, $\beta = 0$, which means that $\lambda = \alpha$ is real. This completes the proof. ∎

Section 7.7, page 308

THEOREM

Determinants

The definition of a determinant

$$D = \det \mathbf{A} = \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix} \tag{7}$$

as given in Sec. 7.7 is unambiguous, that is, it yields the same value of D no matter which rows or columns we choose in developings.

PROOF In this proof we shall use formula numbers not yet used in Sec. 7.7.

We shall prove first that *the same value is obtained no matter which* ***row*** *is chosen.*

The proof is by induction. The statement is true for a second-order determinant, for which the developments by the first row $a_{11}a_{22} + a_{12}(-a_{21})$ and by the second row $a_{21}(-a_{12}) + a_{22}a_{11}$ give the same value $a_{11}a_{22} - a_{12}a_{21}$. Assuming the statement to be true for an $(n - 1)$st-order determinant, we prove that it is true for an nth-order determinant.

For this purpose we expand D in terms of each of two arbitrary rows, say, the ith and the jth, and compare the results. Without loss of generality let us assume $i < j$.

First Expansion. We expand D by the ith row. A typical term in this expansion is

$$a_{ik}C_{ik} = a_{ik} \cdot (-1)^{i+k}M_{ik}. \tag{19}$$

The minor M_{ik} of a_{ik} in D is an $(n-1)$st-order determinant. By the induction hypothesis we may expand it by any row. We expand it by the row corresponding to the jth row of D. This row contains the entries a_{jl} $(l \neq k)$. It is the $(j-1)$st row of M_{ik}, because M_{ik} does not contain entries of the ith row of D, and $i < j$. We have to distinguish between two cases as follows.

Case I. If $l < k$, then the entry a_{jl} belongs to the lth column of M_{ik} (see Fig. 560). Hence the term involving a_{jl} in this expansion is

$$a_{jl} \cdot (\text{cofactor of } a_{jl} \text{ in } M_{ik}) = a_{jl} \cdot (-1)^{(j-1)+l}M_{ikjl} \tag{20}$$

where M_{ikjl} is the minor of a_{jl} in M_{ik}. Since this minor is obtained from M_{ik} by deleting the row and column of a_{jl}, it is obtained from D by deleting the ith and jth rows and the kth and lth columns of D. We insert the expansions of the M_{ik} into that of D. Then it follows from (19) and (20) that the terms of the resulting representation of D are of the form

$$a_{ik}a_{jl} \cdot (-1)^b M_{ikjl} \qquad (l < k) \tag{21a}$$

where

$$b = i + k + j + l - 1.$$

Case II. If $l > k$, the only difference is that then a_{jl} belongs to the $(l-1)$st column of M_{ik}, because M_{ik} does not contain entries of the kth column of D, and $k < l$. This causes an additional minus sign in (20), and, instead of (21a), we therefore obtain

$$-a_{ik}a_{jl} \cdot (-1)^b M_{ikjl} \qquad (l > k) \tag{21b}$$

where b is the same as before.

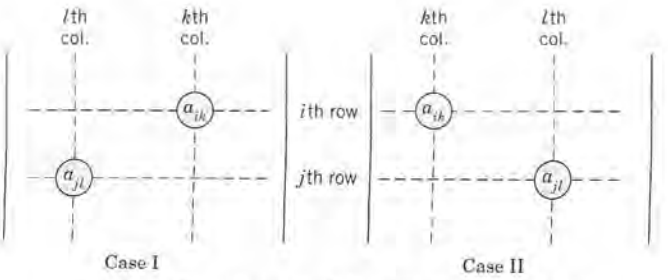


Fig. 560. Cases I and II of the two expansions of D

Second Expansion. We now expand D at first by the jth row. A typical term in this expansion is

$$a_{jl}C_{jl} = a_{jl} \cdot (-1)^{j+l}M_{jl}. \tag{22}$$

By the induction hypothesis we may expand the minor M_{jl} of a_{jl} in D by its ith row, which corresponds to the ith row of D, since $j > i$.

Case I. If $k > l$, the entry a_{ik} in that row belongs to the $(k-1)$st column of M_{jl}, because M_{jl} does not contain entries of the lth column of D, and $l < k$ (see Fig. 560). Hence the term involving a_{ik} in this expansion is

$$a_{ik} \cdot (\text{cofactor of } a_{ik} \text{ in } M_{jl}) = a_{ik} \cdot (-1)^{i+(k-1)}M_{ikjl}, \tag{23}$$

where the minor M_{ikjl} of a_{ik} in M_{jl} is obtained by deleting the ith and jth rows and the kth and lth columns of D [and is, therefore, identical with M_{ikjl} in (20), so that our notation is consistent]. We insert the expansions of the M_{jl} into that of D. It follows from (22) and (23) that this yields a representation whose terms are identical with those given by (21a) when $l < k$.

Case II. If $k < l$, then a_{ik} belongs to the kth column of M_{jl}, we obtain an additional minus sign, and the result agrees with that characterized by (21b).

We have shown that the two expansions of D consist of the same terms, and this proves our statement concerning rows.

The proof of the statement concerning ***columns*** is quite similar; if we expand D in terms of two arbitrary columns, say, the kth and the lth, we find that the general term involving $a_{jl}a_{ik}$ is exactly the same as before. This proves that not only all column expansions of D yield the same value, but also that their common value is equal to the common value of the row expansions of D.

This completes the proof and shows that *our definition of an nth-order determinant is unambiguous.* ■

Section 9.3, page 377

PROOF OF FORMULA (2)

We prove that in right-handed Cartesian coordinates, the vector product

$$\mathbf{v} = \mathbf{a} \times \mathbf{b} = [a_1, \quad a_2, \quad a_3] \times [b_1, \quad b_2, \quad b_3]$$

has the components

$$v_1 = a_2b_3 - a_3b_2, \qquad v_2 = a_3b_1 - a_1b_3, \qquad v_3 = a_1b_2 - a_2b_1. \tag{2}$$

We need only consider the case $\mathbf{v} \neq \mathbf{0}$. Since $\mathbf{v}$ is perpendicular to both $\mathbf{a}$ and $\mathbf{b}$, Theorem 1 in Sec. 9.2 gives $\mathbf{a} \cdot \mathbf{v} = 0$ and $\mathbf{b} \cdot \mathbf{v} = 0$; in components [see (2), Sec. 9.2],

$$\begin{aligned} a_1v_1 + a_2v_2 + a_3v_3 &= 0 \\ b_1v_1 + b_2v_2 + b_3v_3 &= 0. \end{aligned} \tag{3}$$

Multiplying the first equation by b_3, the last by a_3, and subtracting, we obtain

$$(a_3b_1 - a_1b_3)v_1 = (a_2b_3 - a_3b_2)v_2.$$

Multiplying the first equation by b_1, the last by a_1, and subtracting, we obtain

$$(a_1b_2 - a_2b_1)v_2 = (a_3b_1 - a_1b_3)v_3.$$

We can easily verify that these two equations are satisfied by

$$(4) \qquad v_1 = c(a_2b_3 - a_3b_2), \qquad v_2 = c(a_3b_1 - a_1b_3), \qquad v_3 = c(a_1b_2 - a_2b_1)$$

where c is a constant. The reader may verify by inserting that (4) also satisfies (3). Now each of the equations in (3) represents a plane through the origin in $v_1v_2v_3$-space. The vectors $\mathbf{a}$ and $\mathbf{b}$ are normal vectors of these planes (see Example 6 in Sec. 9.2). Since $\mathbf{v} \neq \mathbf{0}$, these vectors are not parallel and the two planes do not coincide. Hence their intersection is a straight line L through the origin. Since (4) is a solution of (3) and, for varying c, represents a straight line, we conclude that (4) represents L, and every solution of (3) must be of the form (4). In particular, the components of $\mathbf{v}$ must be of this form, where c is to be determined. From (4) we obtain

$$|\mathbf{v}|^2 = {v_1}^2 + {v_2}^2 + {v_3}^2 = c^2\left[(a_2b_3 - a_3b_2)^2 + (a_3b_1 - a_1b_3)^2 + (a_1b_2 - a_2b_1)^2\right].$$

This can be written

$$|\mathbf{v}|^2 = c^2\left[({a_1}^2 + {a_2}^2 + {a_3}^2)({b_1}^2 + {b_2}^2 + {b_3}^2) - (a_1b_1 + a_2b_2 + a_3b_3)^2\right],$$

as can be verified by performing the indicated multiplications in both formulas and comparing. Using (2) in Sec. 9.2, we thus have

$$|\mathbf{v}|^2 = c^2\left[(\mathbf{a} \cdot \mathbf{a})(\mathbf{b} \cdot \mathbf{b}) - (\mathbf{a} \cdot \mathbf{b})^2\right].$$

By comparing this with formula (12) in Team Project 24 of Problem Set 9.3 we conclude that $c = \pm 1$.

We show that $c = +1$. This can be done as follows.

If we change the lengths and directions of $\mathbf{a}$ and $\mathbf{b}$ continuously and so that at the end $\mathbf{a} = \mathbf{i}$ and $\mathbf{b} = \mathbf{j}$ (Fig. 186a in Sec. 9.3), then $\mathbf{v}$ will change its length and direction continuously, and at the end, $\mathbf{v} = \mathbf{i} \times \mathbf{j} = \mathbf{k}$. Obviously we may effect the change so that both $\mathbf{a}$ and $\mathbf{b}$ remain different from the zero vector and are not parallel at any instant. Then $\mathbf{v}$ is never equal to the zero vector, and since the change is continuous and c can only assume the values $+1$ or -1, it follows that at the end c must have the same value as before. Now at the end $\mathbf{a} = \mathbf{i}$, $\mathbf{b} = \mathbf{j}$, $\mathbf{v} = \mathbf{k}$ and, therefore, $a_1 = 1$, $b_2 = 1$, $v_3 = 1$, and the other components in (4) are zero. Hence from (4) we see that $v_3 = c = +1$. This proves Theorem 1.

For a left-handed coordinate system, $\mathbf{i} \times \mathbf{j} = -\mathbf{k}$ (see Fig. 186b in Sec. 9.3), resulting in $c = -1$. This proves the statement right after formula (2). ■

Section 9.9, page 416

PROOF OF THE INVARIANCE OF THE CURL

This proof will follow from two theorems (A and B), which we prove first.

THEOREM A

Transformation Law for Vector Components

For any vector $\mathbf{v}$ *the components* v_1, v_2, v_3 *and* v_1^*, v_2^*, v_3^* *in any two systems of Cartesian coordinates* x_1, x_3, x_3 *and* x_1^*, x_2^*, x_3^*, *respectively, are related by*

$$
\begin{aligned}
v_1^* &= c_{11}v_1 + c_{12}v_2 + c_{13}v_3 \\
v_2^* &= c_{21}v_1 + c_{22}v_2 + c_{23}v_3 \\
v_3^* &= c_{31}v_1 + c_{32}v_2 + c_{33}v_3,
\end{aligned} \tag{1}
$$

and conversely

$$
\begin{aligned}
v_1 &= c_{11}v_1^* + c_{21}v_2^* + c_{31}v_3^* \\
v_2 &= c_{12}v_1^* + c_{22}v_2^* + c_{32}v_3^* \\
v_3 &= c_{13}v_1^* + c_{23}v_2^* + c_{33}v_3^*
\end{aligned} \tag{2}
$$

with coefficients

$$
\begin{aligned}
c_{11} &= \mathbf{i}^* \cdot \mathbf{i} \qquad c_{12} = \mathbf{i}^* \cdot \mathbf{j} \qquad c_{13} = \mathbf{i}^* \cdot \mathbf{k} \\
c_{21} &= \mathbf{j}^* \cdot \mathbf{i} \qquad c_{22} = \mathbf{j}^* \cdot \mathbf{j} \qquad c_{23} = \mathbf{j}^* \cdot \mathbf{k} \\
c_{31} &= \mathbf{k}^* \cdot \mathbf{i} \qquad c_{32} = \mathbf{k}^* \cdot \mathbf{j} \qquad c_{33} = \mathbf{k}^* \cdot \mathbf{k}
\end{aligned} \tag{3}
$$

satisfying

$$
\sum_{j=1}^{3} c_{kj}c_{mj} = \delta_{km} \qquad (k, m = 1, 2, 3), \tag{4}
$$

where the **Kronecker delta**[2] *is given by*

$$
\delta_{km} = \begin{cases} 0 & (k \neq m) \\ 1 & (k = m) \end{cases}
$$

and $\mathbf{i}, \mathbf{j}, \mathbf{k}$ *and* $\mathbf{i}^*, \mathbf{j}^*, \mathbf{k}^*$ *denote the unit vectors in the positive* x_1-, x_2-, x_3- *and* x_1^*-, x_2^*-, x_3^*-*directions, respectively.*

---

[2]LEOPOLD KRONECKER (1823–1891), German mathematician at Berlin, who made important contributions to algebra, group theory, and number theory.

We shall keep our discussion completely independent of Chap. 7, but readers familiar with matrices should recognize that we are dealing with **orthogonal transformations and matrices** and that our present theorem follows from Theorem 2 in Sec. 8.3.

PROOF The representation of $\mathbf{v}$ in the two systems are

$$(5) \qquad \text{(a)} \quad \mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k} \qquad \text{(b)} \quad \mathbf{v} = v_1^*\mathbf{i}^* + v_2^*\mathbf{j}^* + v_3^*\mathbf{k}^*.$$

Since $\mathbf{i}^* \cdot \mathbf{i}^* = 1$, $\mathbf{i}^* \cdot \mathbf{j}^* = 0$, $\mathbf{i}^* \cdot \mathbf{k}^* = 0$, we get from (5b) simply $\mathbf{i}^* \cdot \mathbf{v} = v_1^*$ and from this and (5a)

$$v_1^* = \mathbf{i}^* \cdot \mathbf{v} = \mathbf{i}^* \cdot v_1\mathbf{i} + \mathbf{i}^* \cdot v_2\mathbf{j} + \mathbf{i}^* \cdot v_3\mathbf{k} = v_1\mathbf{i}^* \cdot \mathbf{i} + v_2\mathbf{i}^* \cdot \mathbf{j} + v_3\mathbf{i}^* \cdot \mathbf{k}.$$

Because of (3), this is the first formula in (1), and the other two formulas are obtained similarly, by considering $\mathbf{j}^* \cdot \mathbf{v}$ and then $\mathbf{k}^* \cdot \mathbf{v}$. Formula (2) follows by the same idea, taking $\mathbf{i} \cdot \mathbf{v} = v_1$ from (5a) and then from (5b) and (3)

$$v_1 = \mathbf{i} \cdot \mathbf{v} = v_1^*\mathbf{i} \cdot \mathbf{i}^* + v_2^*\mathbf{i} \cdot \mathbf{j}^* + v_3^*\mathbf{i} \cdot \mathbf{k}^* = c_{11}v_1^* + c_{21}v_2^* + c_{31}v_3^*,$$

and similarly for the other two components.

We prove (4). We can write (1) and (2) briefly as

$$(6) \qquad \text{(a)} \quad v_j = \sum_{m=1}^{3} c_{mj}v_m^*, \qquad \text{(b)} \quad v_k^* = \sum_{j=1}^{3} c_{kj}v_j.$$

Substituting v_j into v_k^*, we get

$$v_k^* = \sum_{j=1}^{3} c_{kj} \sum_{m=1}^{3} c_{mj}v_m^* = \sum_{m=1}^{3} v_m^* \left(\sum_{j=1}^{3} c_{kj}c_{mj} \right),$$

where $k = 1, 2, 3$. Taking $k = 1$, we have

$$v_1^* = v_1^* \left(\sum_{j=1}^{3} c_{1j}c_{1j} \right) + v_2^* \left(\sum_{j=1}^{3} c_{1j}c_{2j} \right) + v_3^* \left(\sum_{j=1}^{3} c_{1j}c_{3j} \right).$$

For this to hold for *every* vector $\mathbf{v}$, the first sum must be 1 and the other two sums 0. This proves (4) with $k = 1$ for $m = 1, 2, 3$. Taking $k = 2$ and then $k = 3$, we obtain (4) with $k = 2$ and 3, for $m = 1, 2, 3$. ∎

THEOREM 8

Transformation Law for Cartesian Coordinates

The transformation of any Cartesian $x_1x_2x_3$-coordinate system into any other Cartesian $x_1^*x_2^*x_3^*$-coordinate system is of the form

$$(7) \qquad x_m^* = \sum_{j=1}^{3} c_{mj}x_j + b_m, \quad m = 1, 2, 3,$$

with coefficients (3) *and constants b_1, b_2, b_3; conversely,*

$$(8) \qquad x_k = \sum_{n=1}^{3} c_{nk}x_n^* + \tilde{b}_k, \qquad k = 1, 2, 3.$$

Theorem B follows from Theorem A by noting that the most general transformation of a Cartesian coordinate system into another such system may be decomposed into a transformation of the type just considered and a translation; and under a translation, corresponding coordinates differ merely by a constant.

PROOF OF THE INVARIANCE OF THE CURL

We write again x_1, x_2, x_3 instead of x, y, z, and similarly x_1^*, x_2^*, x_3^* for other Cartesian coordinates, assuming that both systems are right-handed. Let a_1, a_2, a_3 denote the components of curl $\mathbf{v}$ in the $x_1x_2x_3$-coordinates, as given by (1), Sec. 9.9, with

$$x = x_1, \qquad y = x_2, \qquad z = x_3.$$

Similarly, let a_1^*, a_2^*, a_3^* denote the components of curl $\mathbf{v}$ in the $x_1^*x_2^*x_3^*$-coordinate system. We prove that the length and direction of curl $\mathbf{v}$ are independent of the particular choice of Cartesian coordinates, as asserted. We do this by showing that the components of curl $\mathbf{v}$ satisfy the transformation law (2), which is characteristic of vector components. We consider a_1. We use (6a), and then the chain rule for functions of several variables (Sec. 9.6). This gives

$$a_1 = \frac{\partial v_3}{\partial x_2} - \frac{\partial v_2}{\partial x_3} = \sum_{m=1}^{3} \left(c_{m3} \frac{\partial v_m^*}{\partial x_2} - c_{m2} \frac{\partial v_m^*}{\partial x_3} \right)$$

$$= \sum_{m=1}^{3} \sum_{j=1}^{3} \left(c_{m3} \frac{\partial v_m^*}{\partial x_j^*} \frac{\partial x_j^*}{\partial x_2} - c_{m2} \frac{\partial v_m^*}{\partial x_j^*} \frac{\partial x_j^*}{\partial x_3} \right).$$

From this and (7) we obtain

$$a_1 = \sum_{m=1}^{3} \sum_{j=1}^{3} (c_{m3}c_{j2} - c_{m2}c_{j3}) \frac{\partial v_m^*}{\partial x_j^*}$$

$$= (c_{33}c_{22} - c_{32}c_{23}) \left(\frac{\partial v_3^*}{\partial x_2^*} - \frac{\partial v_2^*}{\partial x_3^*} \right) + \cdots$$

$$= (c_{33}c_{22} - c_{32}c_{23})a_1^* + (c_{13}c_{32} - c_{12}c_{33})a_2^* + (c_{23}c_{12} - c_{22}c_{13})a_3^*.$$

Note what we did. The double sum had $3 \times 3 = 9$ terms, 3 of which were zero (when $m = j$), and the remaining 6 terms we combined in pairs as we needed them in getting a_1^*, a_2^*, a_3^*.

We now use (3), Lagrange's identity (see Team Project 24 in Problem Set 9.3) and $\mathbf{k}^* \times \mathbf{j}^* = -\mathbf{i}^*$ and $\mathbf{k} \times \mathbf{j} = -\mathbf{i}$. Then

$$c_{33}c_{22} - c_{32}c_{23} = (\mathbf{k}^* \cdot \mathbf{k})(\mathbf{j}^* \cdot \mathbf{j}) - (\mathbf{k}^* \cdot \mathbf{j})(\mathbf{j}^* \cdot \mathbf{k})$$

$$= (\mathbf{k}^* \times \mathbf{j}^*) \cdot (\mathbf{k} \times \mathbf{j}) = \mathbf{i}^* \cdot \mathbf{i} = c_{11}, \qquad \text{etc.}$$

Hence $a_1 = c_{11}a_1^* + c_{21}a_2^* + c_{31}a_3^*$. This is of the form of the first formula in (2) in Theorem A, and the other two formulas of the form (2) are obtained similarly. This proves the theorem for right-handed systems. If the $x_1x_2x_3$-coordinates are left-handed, then $\mathbf{k} \times \mathbf{j} = +\mathbf{i}$, but then there is a minus sign in front of the determinant in (1), Sec. 9.9. ■

Section 10.2, pages 426–427

PROOF OF THEOREM 1, PART (b) We prove that if

$$(1) \qquad \int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_C (F_1\,dx + F_2\,dy + F_3\,dz)$$

with continuous F_1, F_2, F_3 in a domain D is independent of path in D, then $F = \operatorname{grad} f$ in D for some f; in components

$$(2') \qquad F_1 = \frac{\partial f}{\partial x}, \qquad F_2 = \frac{\partial f}{\partial y}, \qquad F_3 = \frac{\partial f}{\partial z}.$$

We choose any fixed A: (x_0, y_0, z_0) in D and any B: (x, y, z) in D and define f by

$$(3) \qquad f(x, y, z) = f_0 + \int_A^B (F_1\,dx^* + F_2\,dy^* + F_3\,dz^*)$$

with any constant f_0 and any path from A to B in D. Since A is fixed and we have independence of path, the integral depends only on the coordinates x, y, z, so that (3) defines a function $f(x, y, z)$ in D. We show that $\mathbf{F} = \operatorname{grad} f$ with this f, beginning with the first of the three relations (2′). Because of independence of path we may integrate from A to B_1: (x_1, y, z) and then parallel to the x-axis along the segment B_1B in Fig. 561 with B_1 chosen so that the whole segment lies in D. Then

$$f(x, y, z) = f_0 + \int_A^{B_1} (F_1\,dx^* + F_2\,dy^* + F_3\,dz^*) + \int_{B_1}^{B} (F_1\,dx^* + F_2\,dy^* + F_3\,dz^*).$$

We now take the partial derivative with respect to x on both sides. On the left we get $\partial f/\partial x$. We show that on the right we get F_1. The derivative of the first integral is zero because A: (x_0, y_0, z_0) and B_1: (x_1, y, z) do not depend on x. We consider the second integral. Since on the segment B_1B, both y and z are constant, the terms $F_2\,dy^*$ and

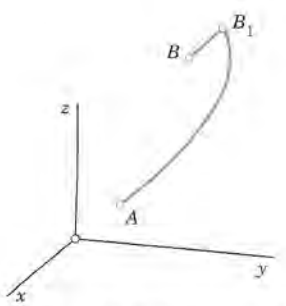

Fig. 561. Proof of Theorem 1

$F_3\,dz^*$ do not contribute to the derivative of the integral. The remaining part can be written as a definite integral,

$$\int_{B_1}^{B} F_1\,dx^* = \int_{x_1}^{x} F_1(x^*, y, z)\,dx^*.$$

Hence its partial derivative with respect to x is $F_1(x, y, z)$, and the first of the relations (2′) is proved. The other two formulas in (2′) follow by the same argument. ■

Section 13.4, page 620

PROOF OF THEOREM 2 **Cauchy–Riemann Equations**

We prove that Cauchy–Riemann equations

$$(1) \qquad u_x = v_y, \qquad u_y = -v_x$$

are sufficient for a complex function $f(z) = u(x, y) + iv(x, y)$ to be analytic; precisely, *if the real part u and the imaginary part v of $f(z)$ satisfy* (1) *in a domain D in the complex plane and if the partial derivatives in* (1) *are* ***continuous*** *in D, then $f(z)$ is analytic in D.*

In this proof we write $\Delta z = \Delta x + i\Delta y$ and $\Delta f = f(z + \Delta z) - f(z)$. The idea of proof is as follows.

(a) We express Δf in terms of first partial derivatives of u and v, by applying the mean value theorem of Sec. 9.6.

(b) We get rid of partial derivatives with respect to y by applying the Cauchy–Riemann equations.

(c) We let Δz approach zero and show that then $\Delta f/\Delta z$ as obtained approaches a limit, which is equal to $u_x + iv_x$, the right side of (4) in Sec. 13.4, regardless of the way of approach to zero.

(a) Let P: (x, y) be any fixed point in D. Since D is a domain, it contains a neighborhood of P. We can choose a point Q: $(x + \Delta x, y + \Delta y)$ in this neighborhood such that the straight-line segment PQ is in D. Because of our continuity assumptions we may apply the mean value theorem in Sec. 9.6. This yields

$$u(x + \Delta x, y + \Delta y) - u(x, y) = (\Delta x)u_x(M_1) + (\Delta y)u_y(M_1)$$
$$v(x + \Delta x, y + \Delta y) - v(x, y) = (\Delta x)v_x(M_2) + (\Delta y)v_y(M_2)$$

where M_1 and M_2 ($\neq M_1$ in general!) are suitable points on that segment. The first line is Re Δf and the second is Im Δf, so that

$$\Delta f = (\Delta x)u_x(M_1) + (\Delta y)u_y(M_1) + i\big[(\Delta x)v_x(M_2) + (\Delta y)v_y(M_2)\big].$$

(b) $u_y = -v_x$ and $v_y = u_x$ by the Cauchy–Riemann equations, so that

$$\Delta f = (\Delta x)u_x(M_1) - (\Delta y)v_x(M_1) + i\big[(\Delta x)v_x(M_2) + (\Delta y)u_x(M_2)\big].$$

Also $\Delta z = \Delta x + i\Delta y$, so that we can write $\Delta x = \Delta z - i\Delta y$ in the first term and $\Delta y = (\Delta z - \Delta x)/i = -i(\Delta z - \Delta x)$ in the second term. This gives

$$\Delta f = (\Delta z - i\Delta y)u_x(M_1) + i(\Delta z - \Delta x)v_x(M_1) + i\big[(\Delta x)v_x(M_2) + (\Delta y)u_x(M_2)\big].$$

By performing the multiplications and reordering we obtain

$$\begin{aligned}\Delta f = {} & (\Delta z)u_x(M_1) - i\Delta y\{u_x(M_1) - u_x(M_2)\} \\ & + i[(\Delta z)v_x(M_1) - \Delta x\{v_x(M_1) - v_x(M_2)\}].\end{aligned}$$

Division by Δz now yields

$$\text{(A)}\quad \frac{\Delta f}{\Delta z} = u_x(M_1) + iv_x(M_1) - \frac{i\Delta y}{\Delta z}\{u_x(M_1) - u_x(M_2)\} - \frac{i\Delta x}{\Delta z}\{v_x(M_1) - v_x(M_2)\}.$$

(c) We finally let Δz approach zero and note that $|\Delta y/\Delta z| \leqq 1$ and $|\Delta x/\Delta z| \leqq 1$ in (A). Then Q: $(x + \Delta x, y + \Delta y)$ approaches P: (x, y), so that M_1 and M_2 must approach P. Also, since the partial derivatives in (A) are assumed to be continuous, they approach their value at P. In particular, the differences in the braces $\{\cdots\}$ in (A) approach zero. Hence the limit of the right side of (A) exists and is independent of the path along which $\Delta z \to 0$. We see that this limit equals the right side of (4) in Sec. 13.4. This means that $f(z)$ is analytic at every point z in D, and the proof is complete. ■

Section 14.2, pages 647–648

GOURSAT'S PROOF OF CAUCHY'S INTEGRAL THEOREM Goursat proved Cauchy's integral theorem without assuming that $f'(z)$ is continuous, as follows.

We start with the case when C is the boundary of a triangle. We orient C counterclockwise. By joining the midpoints of the sides we subdivide the triangle into four congruent triangles (Fig. 562). Let C_{I}, C_{II}, C_{III}, C_{IV} denote their boundaries. We claim that (see Fig. 562).

$$(1)\qquad \oint_C f\,dz = \oint_{C_{\mathrm{I}}} f\,dz + \oint_{C_{\mathrm{II}}} f\,dz + \oint_{C_{\mathrm{III}}} f\,dz + \oint_{C_{\mathrm{IV}}} f\,dz.$$

Indeed, on the right we integrate along each of the three segments of subdivision in both possible directions (Fig. 562), so that the corresponding integrals cancel out in pairs, and the sum of the integrals on the right equals the integral on the left. We now pick an integral on the right that is biggest in absolute value and call its path C_1. Then, by the triangle inequality (Sec. 13.2),

$$\left|\oint_C f\,dz\right| \leqq \left|\oint_{C_{\mathrm{I}}} f\,dz\right| + \left|\oint_{C_{\mathrm{II}}} f\,dz\right| + \left|\oint_{C_{\mathrm{III}}} f\,dz\right| + \left|\oint_{C_{\mathrm{IV}}} f\,dz\right| \leqq 4\left|\oint_{C_1} f\,dz\right|.$$

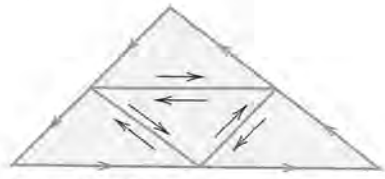

Fig. 562. Proof of Cauchy's integral theorem

We now subdivide the triangle bounded by C_1 as before and select a triangle of subdivision with boundary C_2 for which

$$\left|\oint_{C_1} f\,dz\right| \leqq 4\left|\oint_{C_2} f\,dz\right|. \qquad \text{Then} \qquad \left|\oint_{C} f\,dz\right| \leqq 4^2\left|\oint_{C_2} f\,dz\right|.$$

Continuing in this fashion, we obtain a sequence of triangles $T_1, T_2, \cdots$ with boundaries $C_1, C_2, \cdots$ that are similar and such that T_n lies in T_m when $n > m$, and

$$\left|\oint_{C} f\,dz\right| \leqq 4^n\left|\oint_{C_n} f\,dz\right|, \qquad n = 1, 2, \cdots. \tag{2}$$

Let z_0 be the point that belongs to all these triangles. Since f is differentiable at $z = z_0$, the derivative $f'(z_0)$ exists. Let

$$h(z) = \frac{f(z) - f(z_0)}{z - z_0} - f'(z_0). \tag{3}$$

Solving this algebraically for $f(z)$ we have

$$f(z) = f(z_0) + (z - z_0)f'(z_0) + h(z)(z - z_0).$$

Integrating this over the boundary C_n of the triangle T_n gives

$$\oint_{C_n} f(z)\,dz = \oint_{C_n} f(z_0)\,dz + \oint_{C_n} (z - z_0)f'(z_0)\,dz + \oint_{C_n} h(z)(z - z_0)\,dz.$$

Since $f(z_0)$ and $f'(z_0)$ are constants and C_n is a closed path, the first two integrals on the right are zero, as follows from Cauchy's proof, which is applicable because the integrands do have continuous derivatives (0 and *const*, respectively). We thus have

$$\oint_{C_n} f(z)\,dz = \oint_{C_n} h(z)(z - z_0)\,dz.$$

Since $f'(z_0)$ is the limit of the difference quotient in (3), for given $\epsilon > 0$ we can find a $\delta > 0$ such that

$$|h(z)| < \epsilon \qquad \text{when} \qquad |z - z_0| < \delta. \tag{4}$$

We may now take n so large that the triangle T_n lies in the disk $|z - z_0| < \delta$. Let L_n be the length of C_n. Then $|z - z_0| < L_n$ for all z on C_n and z_0 in T_n. From this and (4) we have $|h(z)(z - z_0)| < \epsilon L_n$. The *ML*-inequality in Sec. 14.1 now gives

$$\left|\oint_{C_n} f(z)\,dz\right| = \left|\oint_{C_n} h(z)(z - z_0)\,dz\right| \leqq \epsilon L_n \cdot L_n = \epsilon {L_n}^2. \tag{5}$$

Now denote the length of C by L. Then the path C_1 has the length $L_1 = L/2$, the path C_2 has the length $L_2 = L_1/2 = L/4$, etc., and C_n has the length $L_n = L/2^n$. Hence ${L_n}^2 = L^2/4^n$. From (2) and (5) we thus obtain

$$\left|\oint_{C} f\,dz\right| \leqq 4^n\left|\oint_{C_n} f\,dz\right| \leqq 4^n\epsilon {L_n}^2 = 4^n\epsilon\,\frac{L^2}{4^n} = \epsilon L^2.$$

By choosing ϵ (> 0) sufficiently small we can make the expression on the right as small as we please, while the expression on the left is the definite value of an integral. Consequently, this value must be zero, and the proof is complete.

The proof for *the case in which C is the boundary of a polygon* follows from the previous proof by subdividing the polygon into triangles (Fig. 563). The integral corresponding to each such triangle is zero. The sum of these integrals is equal to the integral over C, because we integrate along each segment of subdivision in both directions, the corresponding integrals cancel out in pairs, and we are left with the integral over C.

The case of a general simple closed path C can be reduced to the preceding one by inscribing in C a closed polygon P of chords, which approximates C "sufficiently accurately," and it can be shown that there is a polygon P such that the integral over P differs from that over C by less than any preassigned positive real number $\tilde{\epsilon}$, no matter how small. The details of this proof are somewhat involved and can be found in Ref. [D6] listed in App. 1. ■

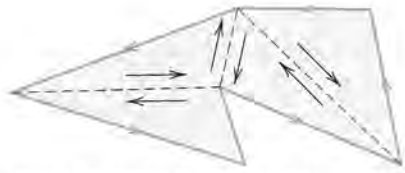

Fig. 563. Proof of Cauchy's integral theorem for a polygon

Section 15.1, page 667

PROOF OF THEOREM 4 **Cauchy's Convergence Principle for Series**

(a) In this proof we need two concepts and a theorem, which we list first.

1. A **bounded sequence** $s_1, s_2, \cdots$ is a sequence whose terms all lie in a disk of (sufficiently large, finite) radius K with center at the origin; thus $|s_n| < K$ for all n.

2. A **limit point** a of a sequence $s_1, s_2, \cdots$ is a point such that, given an $\epsilon > 0$, there are infinitely many terms satisfying $|s_n - a| < \epsilon$. (Note that this does *not* imply convergence, since there may still be infinitely many terms that do not lie within that circle of radius ϵ and center a.)

Example: $\frac{1}{4}, \frac{3}{4}, \frac{1}{8}, \frac{7}{8}, \frac{1}{16}, \frac{15}{16}, \cdots$ has the limit points 0 and 1 and diverges.

3. A bounded sequence in the complex plane has at least one limit point. (Bolzano–Weierstrass theorem; proof below. Recall that "sequence" always mean *infinite* sequence.)

(b) We now turn to the actual proof that $z_1 + z_2 + \cdots$ converges if and only if for every $\epsilon > 0$ we can find an N such that

$$|z_{n+1} + \cdots + z_{n+p}| < \epsilon \qquad \text{for every } n > N \text{ and } p = 1, 2, \cdots. \tag{1}$$

Here, by the definition of partial sums,

$$s_{n+p} - s_n = z_{n+1} + \cdots + z_{n+p}.$$

Writing $n + p = r$, we see from this that (1) is equivalent to

$$(1^*) \qquad |s_r - s_n| < \epsilon \qquad \text{for all } r > N \text{ and } n > N.$$

Suppose that $s_1, s_2, \cdots$ converges. Denote its limit by s. Then for a given $\epsilon > 0$ we can find an N such that

$$|s_n - s| < \frac{\epsilon}{2} \qquad \text{for every } n > N.$$

Hence, if $r > N$ and $n > N$, then by the triangle inequality (Sec. 13.2),

$$|s_r - s_n| = |(s_r - s) - (s_n - s)| \leqq |s_r - s| + |s_n - s| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon,$$

that is, (1*) holds.

(c) Conversely, assume that $s_1, s_2, \cdots$ satisfies (1*). We first prove that then the sequence must be bounded. Indeed, choose a fixed ϵ and a fixed $n = n_0 > N$ in (1*). Then (1*) implies that all s_r with $r > N$ lie in the disk of radius ϵ and center s_{n_0} and only *finitely many terms* $s_1, \cdots, s_N$ may not lie in this disk. Clearly, we can now find a circle so large that this disk and these finitely many terms all lie within this new circle. Hence the sequence is bounded. By the Bolzano–Weierstrass theorem, it has at least one limit point, call it s.

We now show that the sequence is convergent with the limit s. Let $\epsilon > 0$ be given. Then there is an N^* such that $|s_r - s_n| < \epsilon/2$ for all $r > N^*$ and $n > N^*$, by (1*). Also, by the definition of a limit point, $|s_n - s| < \epsilon/2$ for *infinitely many* n, so that we can find and fix an $n > N^*$ such that $|s_n - s| < \epsilon/2$. Together, for *every* $r > N^*$,

$$|s_r - s| = |(s_r - s_n) + (s_n - s)| \leqq |s_r - s_n| + |s_n - s| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon;$$

that is, the sequence $s_1, s_2, \cdots$ is convergent with the limit s. ■

THEOREM

Bolzano–Weierstrass Theorem[3]

A bounded infinite sequence $z_1, z_2, z_3, \cdots$ in the complex plane has at least one limit point.

PROOF It is obvious that we need both conditions: a finite sequence cannot have a limit point, and the sequence 1, 2, 3, $\cdots$, which is infinite but not bounded, has no limit point. To prove the theorem, consider a bounded infinite sequence $z_1, z_2, \cdots$ and let K be such that $|z_n| < K$ for all n. If only finitely many values of the z_n are different, then, since the sequence is infinite, some number z must occur infinitely many times in the sequence, and, by definition, this number is a limit point of the sequence.

We may now turn to the case when the sequence contains infinitely many *different* terms. We draw a large square Q_0 that contains all z_n. We subdivide Q_0 into four congruent squares, which we number 1, 2, 3, 4. Clearly, at least one of these squares (each taken

[3]BERNARD BOLZANO (1781–1848), Austrian mathematician and professor of religious studies, was a pioneer in the study of point sets, the foundation of analysis, and mathematical logic.

For Weierstrass, see Sec. 15.5.

with its complete boundary) must contain infinitely many terms of the sequence. The square of this type with the lowest number (1, 2, 3, or 4) will be denoted by Q_1. This is the first step. In the next step we subdivide Q_1 into four congruent squares and select a square Q_2 by the same rule, and so on. This yields an infinite sequence of squares Q_0, $Q_1, Q_2, \cdots, Q_n, \cdots$ with the property that the side of Q_n approaches zero as n approaches infinity, and Q_m contains all Q_n with $n > m$. It is not difficult to see that the number which belongs to all these squares,[4] call it $z = a$, is a limit point of the sequence. In fact, given an $\epsilon > 0$, we can choose an N so large that the side of the square Q_N is less than ϵ and, since Q_N contains infinitely many z_n, we have $|z_n - a| < \epsilon$ for infinitely many n. This completes the proof. ■

Section 15.3, pages 681–682

PART (b) OF THE PROOF OF THEOREM 5

We have to show that

$$\sum_{n=2}^{\infty} a_n \left[\frac{(z + \Delta z)^n - z^n}{\Delta z} - nz^{n-1} \right]$$

$$= \sum_{n=2}^{\infty} a_n \, \Delta z \left[(z + \Delta z)^{n-2} + 2z(z + \Delta z)^{n-3} + \cdots + (n - 1)z^{n-2} \right],$$

thus,

$$\frac{(z + \Delta z)^n - z^n}{\Delta z} - nz^{n-1}$$

$$= \Delta z \left[(z + \Delta z)^{n-2} + 2z(z + \Delta z)^{n-3} + \cdots + (n - 1)z^{n-2} \right].$$

If we set $z + \Delta z = b$ and $z = a$, thus $\Delta z = b - a$, this becomes simply

$$\text{(7a)} \qquad \frac{b^n - a^n}{b - a} - na^{n-1} = (b - a)A_n \qquad (n = 2, 3, \cdots),$$

where A_n is the expression in the brackets on the right,

$$\text{(7b)} \qquad A_n = b^{n-2} + 2ab^{n-3} + 3a^2b^{n-4} + \cdots + (n - 1)a^{n-2};$$

thus, $A_2 = 1$, $A_3 = b + 2a$, etc. We prove (7) by induction. When $n = 2$, then (7) holds, since then

$$\frac{b^2 - a^2}{b - a} - 2a = \frac{(b + a)(b - a)}{b - a} - 2a = b - a = (b - a)A_2.$$

Assuming that (7) holds for $n = k$, we show that it holds for $n = k + 1$. By adding and subtracting a term in the numerator and then dividing we first obtain

$$\frac{b^{k+1} - a^{k+1}}{b - a} = \frac{b^{k+1} - ba^k + ba^k - a^{k+1}}{b - a} = b \, \frac{b^k - a^k}{b - a} + a^k.$$

[4] The fact that such a unique number $z = a$ exists seems to be obvious, but it actually follows from an axiom of the real number system, the so-called *Cantor–Dedekind axiom:* see footnote 3 in App. A3.3.

By the induction hypothesis, the right side equals $b[(b - a)A_k + ka^{k-1}] + a^k$. Direct calculation shows that this is equal to

$$(b - a)\{bA_k + ka^{k-1}\} + aka^{k-1} + a^k.$$

From (7b) with $n = k$ we see that the expression in the braces $\{\cdots\}$ equals

$$b^{k-1} + 2ab^{k-2} + \cdots + (k - 1)ba^{k-2} + ka^{k-1} = A_{k+1}.$$

Hence our result is

$$\frac{b^{k+1} - a^{k+1}}{b - a} = (b - a)A_{k+1} + (k + 1)a^k.$$

Taking the last term to the left, we obtain (7) with $n = k + 1$. This proves (7) for any integer $n \geqq 2$ and completes the proof. ∎

Section 18.2, page 754

ANOTHER PROOF OF THEOREM 1 ***without the use of a harmonic conjugate***

We show that if $w = u + iv = f(z)$ is analytic and maps a domain D conformally onto a domain D^* and $\Phi^*(u, v)$ is harmonic in D^*, then

(1) $$\Phi(x, y) = \Phi^*(u(x, y), v(x, y))$$

is harmonic in D, that is, $\nabla^2\Phi = 0$ in D. We make no use of a harmonic conjugate of Φ^*, but use straightforward differentiation. By the chain rule,

$$\Phi_x = \Phi_u{}^* u_x + \Phi_v{}^* v_x.$$

We apply the chain rule again, underscoring the terms that will drop out when we form $\nabla^2\Phi$:

$$\Phi_{xx} = \underline{\Phi_u{}^* u_{xx}} + (\Phi^*_{uu}u_x + \underline{\Phi^*_{uv}v_x})u_x$$
$$+ \underline{\Phi_v{}^* v_{xx}} + (\underline{\Phi^*_{vu}u_x} + \Phi^*_{vv}v_x)v_x.$$

Φ_{yy} is the same with each x replaced by y. We form the sum $\nabla^2\Phi$. In it, $\Phi^*_{vu} = \Phi^*_{uv}$ is multiplied by

$$u_x v_x + u_y v_y$$

which is 0 by the Cauchy–Riemann equations. Also $\nabla^2 u = 0$ and $\nabla^2 v = 0$. There remains

$$\nabla^2\Phi = \Phi^*_{uu}(u_x{}^2 + u_y{}^2) + \Phi^*_{vv}(v_x{}^2 + v_y{}^2).$$

By the Cauchy–Riemann equations this becomes

$$\nabla^2\Phi = (\Phi^*_{uu} + \Phi^*_{vv})(u_x{}^2 + v_x{}^2)$$

and is 0 since Φ^* is harmonic. ∎

APPENDIX 5

Tables

For Tables of Laplace transforms see Secs. 6.8 and 6.9.
For Tables of Fourier transforms see Sec. 11.10.

If you have a Computer Algebra System (CAS), you may not need the present tables, but you may still find them convenient from time to time.

Table A1 Bessel Functions

For more extensive tables see Ref. [GR1] in App. 1.

Systems of Units. Some Important Conversion Factors

The most important systems of units are shown in the table below. The mks system is also known as the *International System of Units* (abbreviated *SI*), and the abbreviations s (instead of sec), g (instead of gm), and N (instead of nt) are also used.

System of units	Length	Mass	Time	Force
cgs system	centimeter (cm)	gram (gm)	second (sec)	dyne
mks system	meter (m)	kilogram (kg)	second (sec)	newton (nt)
Engineering system	foot (ft)	slug	second (sec)	pound (lb)

1 inch (in.) = 2.540000 cm

1 foot (ft) = 12 in. = 30.480000 cm

1 yard (yd) = 3 ft = 91.440000 cm

1 statute mile (mi) = 5280 ft = 1.609344 km

1 nautical mile = 6080 ft = 1.853184 km

1 acre = 4840 yd^2 = 4046.8564 m^2

1 mi^2 = 640 acres = 2.5899881 km^2

1 fluid ounce = 1/128 U.S. gallon = 231/128 $in.^3$ = 29.573730 cm^3

1 U.S. gallon = 4 quarts (liq) = 8 pints (liq) = 128 fl oz = 3785.4118 cm^3

1 British Imperial and Canadian gallon = 1.200949 U.S. gallons = 4546.087 cm^3

1 slug = 14.59390 kg

1 pound (lb) = 4.448444 nt

1 newton (nt) = 10^5 dynes

1 British thermal unit (Btu) = 1054.35 joules

1 joule = 10^7 ergs

1 calorie (cal) = 4.1840 joules

1 kilowatt-hour (kWh) = 3414.4 Btu = $3.6 \cdot 10^6$ joules

1 horsepower (hp) = 2542.48 Btu/h = 178.298 cal/sec = 0.74570 kW

1 kilowatt (kW) = 1000 watts = 3414.43 Btu/h = 238.662 cal/sec

$°F = °C \cdot 1.8 + 32$

$1° = 60' = 3600'' = 0.017453293$ radian

For further details see, for example, D. Halliday, R. Resnick, and J. Walker, *Fundamentals of Physics*. 7th ed., New York: Wiley, 2005. See also AN American National Standard, ASTM/IEEE Standard Metric Practice, Institute of Electrical and Electronics Engineers, Inc., 445 Hoes Lane, Piscataway, N. J. 08854.

Differentiation

$(cu)' = cu'$ (c constant)

$(u + v)' = u' + v'$

$(uv)' = u'v + v'u$

$$\left(\frac{u}{v}\right)' = \frac{u'v - v'u}{v^2}$$

$$\frac{du}{dx} = \frac{du}{dy} \cdot \frac{dy}{dx}$$ (Chain rule)

$(x^n)' = nx^{n-1}$

$(e^x)' = e^x$

$(a^x)' = a^x \ln a$

$(\sin x)' = \cos x$

$(\cos x)' = -\sin x$

$(\tan x)' = \sec^2 x$

$(\cot x)' = -\csc^2 x$

$(\sinh x)' = \cosh x$

$(\cosh x)' = \sinh x$

$$(\ln x)' = \frac{1}{x}$$

$$(\log_a x)' = \frac{\log_a e}{x}$$

$$(\arcsin x)' = \frac{1}{\sqrt{1 - x^2}}$$

$$(\arccos x)' = -\frac{1}{\sqrt{1 - x^2}}$$

$$(\arctan x)' = \frac{1}{1 + x^2}$$

$$(\operatorname{arccot} x)' = -\frac{1}{1 + x^2}$$

Integration

$$\int uv'\,dx = uv - \int u'v\,dx$$

$$\int x^n\,dx = \frac{x^{n+1}}{n+1} + c \qquad (n \neq -1)$$

$$\int \frac{1}{x}\,dx = \ln|x| + c$$

$$\int e^{ax}\,dx = \frac{1}{a}e^{ax} + c$$

$$\int \sin x\,dx = -\cos x + c$$

$$\int \cos x\,dx = \sin x + c$$

$$\int \tan x\,dx = -\ln|\cos x| + c$$

$$\int \cot x\,dx = \ln|\sin x| + c$$

$$\int \sec x\,dx = \ln|\sec x + \tan x| + c$$

$$\int \csc x\,dx = \ln|\csc x - \cot x| + c$$

$$\int \frac{dx}{x^2 + a^2} = \frac{1}{a}\arctan\frac{x}{a} + c$$

$$\int \frac{dx}{\sqrt{a^2 - x^2}} = \arcsin\frac{x}{a} + c$$

$$\int \frac{dx}{\sqrt{x^2 + a^2}} = \operatorname{arcsinh}\frac{x}{a} + c$$

$$\int \frac{dx}{\sqrt{x^2 - a^2}} = \operatorname{arccosh}\frac{x}{a} + c$$

$$\int \sin^2 x\,dx = \tfrac{1}{2}x - \tfrac{1}{4}\sin 2x + c$$

$$\int \cos^2 x\,dx = \tfrac{1}{2}x + \tfrac{1}{4}\sin 2x + c$$

$$\int \tan^2 x\,dx = \tan x - x + c$$

$$\int \cot^2 x\,dx = -\cot x - x + c$$

$$\int \ln x\,dx = x\ln x - x + c$$

$$\int e^{ax}\sin bx\,dx = \frac{e^{ax}}{a^2 + b^2}(a\sin bx - b\cos bx) + c$$

$$\int e^{ax}\cos bx\,dx = \frac{e^{ax}}{a^2 + b^2}(a\cos bx + b\sin bx) + c$$

Some Constants

$e = 2.71828\ 18284\ 59045\ 23536$
$\sqrt{e} = 1.64872\ 12707\ 00128\ 14685$
$e^2 = 7.38905\ 60989\ 30650\ 22723$

$\pi = 3.14159\ 26535\ 89793\ 23846$
$\pi^2 = 9.86960\ 44010\ 89358\ 61883$
$\sqrt{\pi} = 1.77245\ 38509\ 05516\ 02730$

$\log_{10} \pi = 0.49714\ 98726\ 94133\ 85435$
$\ln \pi = 1.14472\ 98858\ 49400\ 17414$
$\log_{10} e = 0.43429\ 44819\ 03251\ 82765$
$\ln 10 = 2.30258\ 50929\ 94045\ 68402$

$\sqrt{2} = 1.41421\ 35623\ 73095\ 04880$
$\sqrt[3]{2} = 1.25992\ 10498\ 94873\ 16477$
$\sqrt{3} = 1.73205\ 08075\ 68877\ 29353$
$\sqrt[3]{3} = 1.44224\ 95703\ 07408\ 38232$
$\ln 2 = 0.69314\ 71805\ 59945\ 30942$
$\ln 3 = 1.09861\ 22886\ 68109\ 69140$

$\gamma = 0.57721\ 56649\ 01532\ 86061$
$\ln \gamma = -0.54953\ 93129\ 81644\ 82234$
(see Sec. 5.6)
$1^\circ = 0.01745\ 32925\ 19943\ 29577$ rad
1 rad $= 57.29577\ 95130\ 82320\ 87680^\circ$
$= 57^\circ 17' 44.806''$

Polar Coordinates

$$x = r\cos\theta \qquad y = r\sin\theta$$

$$r = \sqrt{x^2 + y^2} \qquad \tan\theta = \frac{y}{x}$$

$$dx\,dy = r\,dr\,d\theta$$

Series

$$\frac{1}{1-x} = \sum_{m=0}^{\infty} x^m \quad (|x| < 1)$$

$$e^x = \sum_{m=0}^{\infty} \frac{x^m}{m!}$$

$$\sin x = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+1}}{(2m+1)!}$$

$$\cos x = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{(2m)!}$$

$$\ln(1-x) = -\sum_{m=1}^{\infty} \frac{x^m}{m} \quad (|x| < 1)$$

$$\arctan x = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+1}}{2m+1} \quad (|x| < 1)$$

PREFACE

General Character and Purpose of the Instructor's Manual

This Manual contains:

(I) Detailed solutions of the even-numbered problems.

(II) General comments on the purpose of each section and its classroom use, with mathematical and didactic information on teaching practice and pedagogical aspects. Some of the comments refer to whole chapters (and are indicated accordingly).

Changes in Problem Sets

The major changes in this edition of the text are listed and explained in the Preface of the book. They include global improvements produced by updating and streamlining chapters as well as many local improvements aimed at **simplification** of the whole text. Speedy orientation is helped by chapter summaries at the end of each chapter, as in the last edition, and by the subdivision of sections into subsections with unnumbered headings. Resulting effects of these changes on the problem sets are as follows.

The problems have been changed. The large total number of ***more than* 4000 *problems*** has been retained, increasing their overall usefulness by the following:

- Placing more emphasis on **modeling** and **conceptual thinking** and less emphasis on technicalities, to parallel recent and ongoing developments in calculus.
- **Balancing** by extending problem sets that seemed too short and contracting others that were too long, **adjusting the length to the relative importance of the material in a section,** so that important issues are reflected sufficiently well not only in the text but also in the problems. Thus, the danger of overemphasizing minor techniques and ideas is avoided as much as possible.
- **Simplification** by omitting a small number of very difficult problems that appeared in the previous edition, retaining the wide spectrum ranging from simple routine problems to more sophisticated engineering applications, and taking into account the ***"algorithmic thinking"*** that is developing along with computers.
- **Amalgamation** of text, examples, and problems by including the **large number of more than 600 worked-out examples in the text** and by providing problems closely related to those examples.
- Addition of **TEAM PROJECTS, CAS PROJECTS, and WRITING PROJECTS,** whose role is explained in the Preface of the book.
- Addition of **CAS EXPERIMENTS,** that is, the use of the computer in **"experimental mathematics"** for experimentation, discovery, and research, which often produces unexpected results for open-ended problems, deeper insights, and relations among practical problems.

These changes in the problem sets will help students in solving problems as well as in gaining a better understanding of practical aspects in the text. It will also enable instructors to explain ideas and methods in terms of examples supplementing and illustrating theoretical discussions—or even replacing some of them if so desired.

imfm.qxd 9/15/05 12:06 PM Page vi

"Show the details of your work."

This request repeatedly stated in the book applies to all the problem sets. Of course, it is intended to prevent the student from simply producing answers by a CAS instead of trying to understand the underlying mathematics.

Orientation on Computers

Comments on computer use are included in the Preface of the book. Software systems are listed in the book at the beginning of Chap. 19 on numeric analysis and at the beginning of Chap. 24 on probability theory.

Part A. ORDINARY DIFFERENTIAL EQUATIONS (ODEs)

CHAPTER 1 First-Order ODEs

Major Changes

There is more material on modeling in the text as well as in the problem set.

Some additions on population dynamics appear in Sec. 1.5.

Electric circuits are shifted to Chap. 2, where second-order ODEs will be available. This avoids repetitions that are unnecessary and practically irrelevant.

Team Projects, CAS Projects, and CAS Experiments are included in most problem sets.

SECTION 1.1. Basic Concepts. Modeling, page 2

Purpose. To give the students a first impression what an ODE is and what we mean by **solving** it.

Background Material. For the whole chapter we need integration formulas and techniques, which the student should review.

General Comments

This section should be covered relatively rapidly to get quickly to the actual solution methods in the next sections.

Equations (1)–(3) are just examples, not for solution, but the student will see that solutions of (1) and (2) can be found by calculus, and a solution $y = e^x$ of (3) by inspection.

Problem Set 1.1 will help the student with the tasks of

Solving $y' = f(x)$ by calculus

Finding particular solutions from given general solutions

Setting up an ODE for a given function as solution

Gaining a first experience in modeling, by doing one or two problems

Gaining a first impression of the importance of ODEs

without wasting time on matters that can be done much faster, once systematic methods are available.

Comment on "General Solution" and "Singular Solution"

Usage of the term "general solution" is not uniform in the literature. Some books use the term to mean a solution that includes *all* solutions, that is, both the particular and the singular ones. We do not adopt this definition for two reasons. First, it is frequently quite difficult to prove that a formula includes *all* solutions; hence, this definition of a general solution is rather useless in practice. Second, *linear* differential equations (satisfying rather general conditions on the coefficients) have no singular solutions (as mentioned in the text), so that for these equations a general solution as defined does include all solutions. For the latter reason, some books use the term "general solution" for linear equations only; but this seems very unfortunate.

im01.qxd 9/21/05 10:17 AM Page 2

SOLUTIONS TO PROBLEM SET 1.1, page 8

2. $y = -e^{-3x}/3 + c$ **4.** $y = (\sinh 4x)/4 + c$

6. Second order. **8.** First order.

10. $y = ce^{0.5x}$, $y(2) = ce = 2$, $c = 2/e$, $y = (2/e)e^{0.5x} = 0.736e^{0.5x}$

12. $y = ce^x + x + 1$, $y(0) = c + 1 = 3$, $c = 2$, $y = 2e^x + x + 1$

14. $y = c \sec x$, $y(0) = c/\cos 0 = c = \frac{1}{2}\pi$, $y = \frac{1}{2}\pi \sec x$

16. Substitution of $y = cx - c^2$ into the ODE gives

$$y'^2 - xy' + y = c^2 - xc + (cx - c^2) = 0.$$

Similarly,

$$y = \tfrac{1}{4}x^2, \qquad y' = \tfrac{1}{2}x, \qquad \text{thus} \qquad \tfrac{1}{4}x^2 - x(\tfrac{1}{2}x) + \tfrac{1}{4}x^2 = 0.$$

18. In Prob. 17 the constants of integration were set to zero. Here, by two integrations,

$$y'' = g, \qquad v = y' = gt + c_1, \qquad y = \tfrac{1}{2}gt^2 + c_1t + c_2, \qquad y(0) = c_2 = y_0,$$

and, furthermore,

$$v(0) = c_1 = v_0, \qquad \text{hence} \qquad y = \tfrac{1}{2}gt^2 + v_0t + y_0,$$

as claimed. Times of fall are 4.5 and 6.4 sec, from $t = \sqrt{100/4.9}$ and $\sqrt{200/4.9}$.

20. $y' = ky$. Solution $y = y_0e^{kx}$, where y_0 is the pressure at sea level $x = 0$. Now $y(18000) = y_0e^{k\cdot 18000} = \frac{1}{2}y_0$ (given). From this,

$$e^{k\cdot 18000} = \tfrac{1}{2}, \quad y(36000) = y_0e^{k\cdot 2\cdot 18000} = y_0(e^{k\cdot 18000})^2 = y_0(\tfrac{1}{2})^2 = \tfrac{1}{4}y_0.$$

22. For 1 year and annual, daily, and continuous compounding we obtain the values

$$y_a(1) = 1060.00, \qquad y_d(1) = 1000(1 + 0.06/365)^{365} = 1061.83,$$

$$y_c(1) = 1000e^{0.06} = 1061.84,$$

respectively. Similarly for 5 years,

$$y_a(5) = 1000 \cdot 1.06^5 = 1338.23, \quad y_d(5) = 1000(1 + 0.06/365)^{365\cdot 5} = 1349.83,$$

$$y_c(5) = 1000e^{0.06\cdot 5} = 1349.86.$$

We see that the difference between daily compounding and continuous compounding is very small.

The ODE for continuous compounding is $y_c' = ry_c$.

SECTION 1.2. Geometric Meaning of $y' = f(x, y)$. Direction Fields, page 9

Purpose. To give the student a feel for the nature of ODEs and the general behavior of fields of solutions. This amounts to a conceptual clarification before entering into formal manipulations of solution methods, the latter being restricted to relatively small—albeit important—classes of ODEs. This approach is becoming increasingly important, especially because of the graphical power of **computer software.** It is the analog of conceptual studies of the derivative and integral in calculus as opposed to formal techniques of differentiation and integration.

Comment on Isoclines

These could be omitted because students sometimes confuse them with solutions. In the computer approach to direction fields they no longer play a role.

im01.qxd 9/21/05 10:17 AM Page 3

Comment on Order of Sections

This section could equally well be presented later in Chap. 1, perhaps after one or two formal methods of solution have been studied.

SOLUTIONS TO PROBLEM SET 1.2, page 11

2. Semi-ellipse $x^2/4 + y^2/9 = 13/9$, $y > 0$. To graph it, choose the y-interval large enough, at least $0 \leqq y \leqq 4$.

4. Logistic equation (Verhulst equation; Sec. 1.5). Constant solutions $y = 0$ and $y = \frac{1}{2}$. For these, $y' = 0$. Increasing solutions for $0 < y(0) < \frac{1}{2}$, decreasing for $y(0) > \frac{1}{2}$.

6. The solution (not of interest for doing the problem) is obtained by using

$$dy/dx = 1/(dx/dy) \quad \text{and solving} \quad dx/dy = 1/(1 + \sin y) \quad \text{by integration,}$$

$$x + c = -2/(\tan \tfrac{1}{2}y + 1); \quad \text{thus} \quad y = -2 \arctan ((x + 2 + c)/(x + c)).$$

8. Linear ODE. The solution involves the error function.

12. By integration, $y = c - 1/x$.

16. The solution (not needed for doing the problem) of $y' = 1/y$ can be obtained by separating variables and using the initial condition; $y^2/2 = t + c$, $y = \sqrt{2t - 1}$.

18. The solution of this initial value problem involving the linear ODE $y' + y = t^2$ is $y = 4e^{-t} + t^2 - 2t + 2$.

20. CAS Project. (a) Verify by substitution that the general solution is $y = 1 + ce^{-x}$. Limit $y = 1$ ($y(x) = 1$ for all x), increasing for $y(0) < 1$, decreasing for $y(0) > 1$.

(b) Verify by substitution that the general solution is $x^4 + y^4 = c$. More "square-shaped," isoclines $y = kx$. Without the minus on the right you get "hyperbola-like" curves $y^4 - x^4 = const$ as solutions (verify!). The direction fields should turn out in perfect shape.

(c) The computer may be better if the isoclines are complicated; but the computer may give you nonsense even in simpler cases, for instance when $y(x)$ becomes imaginary. Much will depend on the choice of x- and y-intervals, a method of trial and error. Isoclines may be preferable if the explicit form of the ODE contains roots on the right.

SECTION 1.3. Separable ODEs. Modeling, page 12

Purpose. To familiarize the student with the first "big" method of solving ODEs, the separation of variables, and an extension of it, the reduction to separable form by a transformation of the ODE, namely, by introducing a new unknown function.

The section includes standard applications that lead to separable ODEs, namely,

1. the ODE giving $\tan x$ as solution

2. the ODE of the exponential function, having various applications, such as in radiocarbon dating

3. a mixing problem for a single tank

4. Newton's law of cooling

5. Torricelli's law of outflow.

im01.qxd 9/21/05 10:17 AM Page 4

In reducing to separability we consider

6. the transformation $u = y/x$, giving perhaps the most important reducible class of ODEs.

Ince's classical book [A11] contains many further reductions as well as a systematic theory of reduction for certain classes of ODEs.

Comment on Problem 5

From the implicit solution we can get two explicit solutions

$$y = +\sqrt{c - (6x)^2}$$

representing semi-ellipses in the upper half-plane, and

$$y = -\sqrt{c - (6x)^2}$$

representing semi-ellipses in the lower half-plane. [Similarly, we can get two explicit solutions $x(y)$ representing semi-ellipses in the left and right half-planes, respectively.] On the x-axis, the tangents to the ellipses are vertical, so that $y'(x)$ does not exist. Similarly for $x'(y)$ on the y-axis.

This also illustrates that it is natural to consider solutions of ODEs on *open* rather than on *closed* intervals.

Comment on Separability

An analytic function $f(x, y)$ in a domain D of the xy-plane can be factored in D, $f(x, y) = g(x)h(y)$, if and only if in D,

$$f_{xy}f = f_x f_y$$

[D. Scott, *American Math. Monthly* **92** (1985), 422–423]. Simple cases are easy to decide, but this may save time in cases of more complicated ODEs, some of which may perhaps be of practical interest. You may perhaps ask your students to derive such a criterion.

Comments on Application

Each of those examples can be modified in various ways, for example, by changing the application or by taking another form of the tank, so that each example characterizes a whole class of applications.

The many ODEs in the problem set, much more than one would ordinarily be willing and have the time to consider, should serve to convince the student of the practical importance of ODEs; so these are ODEs to choose from, depending on the students' interest and background.

Comment on Footnote 3

Newton conceived his method of fluxions (calculus) in 1665–1666, at the age of 22. *Philosophiae Naturalis Principia Mathematica* was his most influential work.

Leibniz invented calculus independently in 1675 and introduced notations that were essential to the rapid development in this field. His first publication on differential calculus appeared in 1684.

SOLUTIONS TO PROBLEM SET 1.3, page 18

2. $dy/y^2 = -(x + 2)\,dx$. The variables are now separated. Integration on both sides gives

$$-\frac{1}{y} = -\tfrac{1}{2}x^2 - 2x + c^*. \qquad \text{Hence} \qquad y = \frac{2}{x^2 + 4x + c}\,.$$

im01.qxd 9/21/05 10:17 AM Page 5

4. Set $y + 9x = v$. Then $y = v - 9x$. By substitution into the given ODE you obtain

$$y' = v' - 9 = v^2. \qquad \text{By separation,} \qquad \frac{dv}{v^2 + 9} = dx.$$

Integration gives

$$\frac{1}{3} \arctan \frac{v}{3} = x + c^*, \qquad \arctan \frac{v}{3} = 3x + c$$

and from this and substitution of $y = v - 9x$,

$$v = 3 \tan (3x + c), \qquad y = 3 \tan (3x + c) - 9x.$$

6. Set $u = y/x$. Then $y = xu$, $y' = u + xu'$. Substitution into the ODE and subtraction of u on both sides gives

$$y' = \frac{4x}{y} + \frac{y}{x} = u + xu' = \frac{4}{u} + u, \qquad xu' = \frac{4}{u}.$$

Separation of variables and replacement of u with y/x yields

$$2u\,du = \frac{8}{x}\,dx, \qquad u^2 = 8 \ln |x| + c, \qquad y^2 = x^2(8 \ln |x| + c).$$

8. $u = y/x$, $y = xu$, $y' = u + xu'$. Substitute u into the ODE, drop xu on both sides, and divide by x^2 to get

$$xy' = xu + x^2u' = \tfrac{1}{2}x^2u^2 + xu, \qquad u' = \tfrac{1}{2}u^2.$$

Separate variables, integrate, and solve algebraically for u:

$$\frac{du}{u^2} = \tfrac{1}{2}\,dx, \qquad -\frac{1}{u} = \tfrac{1}{2}(x + c^*), \qquad u = \frac{2}{c - x}.$$

Hence

$$y = xu = \frac{2x}{c - x}.$$

10. By separation, $y\,dy = -4x\,dx$. By integration, $y^2 = -4x^2 + c$. The initial condition $y(0) = 3$, applied to the last equation, gives $9 = 0 + c$. Hence $y^2 + 4x^2 = 9$.

12. Set $u = y/x$. Then $y' = u + xu'$. Divide the given ODE by x^2 and substitute u and u' into the resulting equation. This gives

$$2u(u + xu') = 3u^2 + 1.$$

Subtract $2u^2$ on both sides and separate the variables. This gives

$$2xuu' = u^2 + 1, \qquad \frac{2u\,du}{u^2 + 1} = \frac{dx}{x}.$$

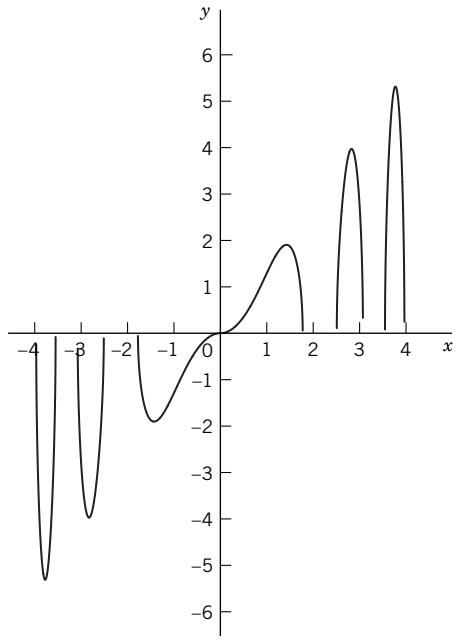
Integrate, take exponents, and then take the square root:

$$\ln (u^2 + 1) = \ln |x| + c^*, \qquad u^2 + 1 = cx, \qquad u = \pm\sqrt{cx - 1}.$$

Hence

$$y = xu = \pm x\sqrt{cx - 1}.$$

From this and the initial condition, $y(1) = \sqrt{c - 1} = 2$, $c = 5$. This gives the *answer* $y = x\sqrt{5x - 1}$.



im01.qxd 9/21/05 10:17 AM Page 6

14. Set $u = y/x$. Then $y = xu$, $y' = u + xu'$. Substitute this into the ODE, subtract u on both sides, simplify algebraically, and integrate:

$$xu' = \frac{2x^2}{u}\cos(x^2) \qquad uu' = 2x\cos(x^2), \qquad u^2/2 = \sin(x^2) + c.$$

Hence $y^2 = 2x^2(\sin(x^2) + c)$. By the initial condition, $\pi = \pi(\sin\frac{1}{2}\pi + c)$, $c = 0$,

$$y = xu = x\sqrt{2\sin(x^2)}.$$

Problem Set 1.3. Problem 14. First five real branches of the solution

16. $u = y/x$, $y = xu$, $y' = u + xu' = u + 4x^4\cos^2 u$. Simplify, separate variables, and integrate:

$$u' = 4x^3\cos^2 u, \qquad du/\cos^2 u = 4x^3\,dx, \qquad \tan u = x^4 + c.$$

Hence

$$y = xu = x\arctan(x^4 + c).$$

From the initial condition, $y(2) = 2\arctan(16 + c) = 0$, $c = -16$. *Answer:*

$$y = x\arctan(x^4 - 16).$$

18. Order terms:

$$\frac{dr}{d\theta}(1 - b\cos\theta) = br\sin\theta.$$

Separate variables and integrate:

$$\frac{dr}{r} = \frac{b\sin\theta}{1 - b\cos\theta}\,d\theta, \qquad \ln r = \ln(1 - b\cos\theta) + c^*.$$

im01.qxd 9/21/05 10:17 AM Page 7

Take exponents and use the initial condition:

$$r = c(1 - b\cos\theta), \qquad r\left(\frac{\pi}{2}\right) = c(1 - b \cdot 0) = \pi, \qquad c = \pi.$$

Hence the *answer* is $r = \pi(1 - b\cos\theta)$.

20. On the left, integrate $g(w)$ over w from y_0 to y. On the right, integrate $f(t)$ over t from x_0 to x. In Prob. 19,

$$\int_1^y we^{w^2}\,dw = \int_0^x (t - 1)\,dt.$$

22. Consider any straight line $y = ax$ through the origin. Its slope is $y/x = a$. The slope of a solution curve at a point of intersection (x, ax) is $y' = g(y/x) = g(a) = const$, independent of the point (x, y) on the straight line considered.

24. Let k_B and k_D be the constants of proportionality for the birth rate and death rate, respectively. Then $y' = k_B y - k_D y$, where $y(t)$ is the population at time t. By separating variables, integrating, and taking exponents,

$$dy/y = (k_B - k_D)\,dt, \qquad \ln y = (k_B - k_D)t + c^*, \qquad y = ce^{(k_B - k_D)t}.$$

26. The model is $y' = -Ay\ln y$ with $A > 0$. Constant solutions are obtained from $y' = 0$ when $y = 0$ and 1. Between 0 and 1 the right side is positive (since $\ln y < 0$), so that the solutions grow. For $y > 1$ we have $\ln y > 0$; hence the right side is negative, so that the solutions decrease with increasing t. It follows that $y = 1$ is stable. The general solution is obtained by separation of variables, integration, and two subsequent exponentiations:

$$dy/(y\ln y) = -A\,dt, \qquad \ln(\ln y) = -At + c^*,$$
$$\ln y = ce^{-At}, \qquad y = \exp(ce^{-At}).$$

28. The temperature of the water is decreasing exponentially according to Newton's law of cooling. The decrease during the first 30 min, call it d_1, is greater than that, d_2, during the next 30 min. Thus $d_1 > d_2 = 190 - 110 = 80$ as measured. Hence the temperature at the beginning of parking, if it had been 30 min earlier, before the arrest, would have been greater than $190 + 80 = 270$, which is impossible. Therefore Jack has no alibi.

30. The cross-sectional area A of the hole is multiplied by 4. In the particular solution, $15.00 - 0.000332t$ is changed to $15.00 - 4 \cdot 0.000332t$ because the second term contains A/B. This changes the time $t = 15.00/0.000332$ when the tank is empty, to $t = 15.00/(4 \cdot 0.000332)$, that is, to $t = 12.6/4 = 3.1$ hr, which is 1/4 of the original time.

32. According to the physical information given, you have

$$\Delta S = 0.15S\,\Delta\phi.$$

Now let $\Delta\phi \to 0$. This gives the ODE $dS/d\phi = 0.15S$. Separation of variables yields the general solution $S = S_0 e^{0.15\phi}$ with the arbitrary constant denoted by S_0. The angle ϕ should be so large that S equals 1000 times S_0. Hence $e^{0.15\phi} = 1000$, $\phi = (\ln 1000)/0.15 = 46 = 7.3 \cdot 2\pi$, that is, eight times, which is surprisingly little. Equally remarkable is that here we see another application of the ODE $y' = ky$ and a derivation of it by a ***general principle,*** namely, by working with small quantities and then taking limits to zero.

im01.qxd 9/21/05 10:17 AM Page 8

36. B now depends on h, namely, by the Pythagorean theorem,

$$B(h) = \pi r^2 = \pi(R^2 - (R - h)^2) = \pi(2Rh - h^2).$$

Hence you can use the ODE

$$h' = -26.56(A/B)\sqrt{h}$$

in the text, with constant A as before and the new B. The latter makes the further calculations different from those in Example 5.

From the given outlet size $A = 5$ cm^2 and $B(h)$ we obtain

$$\frac{dh}{dt} = -26.56 \cdot \frac{5}{\pi(2Rh - h^2)} \sqrt{h}.$$

Now $26.56 \cdot 5/\pi = 42.27$, so that separation of variables gives

$$(2Rh^{1/2} - h^{3/2})\, dh = -42.27\, dt.$$

By integration,

$$\tfrac{4}{3}Rh^{3/2} - \tfrac{2}{5}h^{5/2} = -42.27t + c.$$

From this and the initial condition $h(0) = R$ we obtain

$$\tfrac{4}{3}R^{5/2} - \tfrac{2}{5}R^{5/2} = 0.9333R^{5/2} = c.$$

Hence the particular solution (in implicit form) is

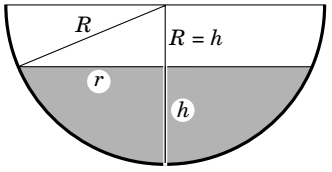
$$\tfrac{4}{3}Rh^{3/2} - \tfrac{2}{5}h^{5/2} = -42.27t + 0.9333R^{5/2}.$$

The tank is empty ($h = 0$) for t such that

$$0 = -42.27t + 0.9333R^{5/2}; \qquad \text{hence} \qquad t = \frac{0.9333}{42.27} R^{5/2} = 0.0221R^{5/2}.$$

For $R = 1$ m $= 100$ cm this gives

$$t = 0.0221 \cdot 100^{5/2} = 2210 \text{ [sec]} = 37 \text{ [min]}.$$



The tank has water level $R/2$ for t in the particular solution such that

$$\frac{4}{3} R \frac{R^{3/2}}{2^{3/2}} - \frac{2}{5} \frac{R^{5/2}}{2^{5/2}} = 0.9333R^{5/2} - 42.27t.$$

The left side equals $0.4007R^{5/2}$. This gives

$$t = \frac{0.4007 - 0.9333}{-42.27} R^{5/2} = 0.01260R^{5/2}.$$

For $R = 100$ this yields $t = 1260$ sec $= 21$ min. This is slightly more than half the time needed to empty the tank. This seems physically reasonable because if the water level is $R/2$, this means that 11/16 of the total water volume has flown out, and 5/16 is left—take into account that the velocity decreases monotone according to Torricelli's law.

Problem Set 1.3. Tank in Problem 36

im01.qxd 9/21/05 10:17 AM Page 9

SECTION 1.4. Exact ODEs. Integrating Factors, page 19

Purpose. This is the second "big" method in this chapter, after separation of variables, and also applies to equations that are not separable. The criterion (5) is basic. Simpler cases are solved by inspection, more involved cases by integration, as explained in the text.

Comment on Condition (5)

Condition (5) is equivalent to (6″) in Sec. 10.2, which is equivalent to (6) in the case of two variables x, y. Simple connectedness of D follows from our assumptions in Sec. 1.4. Hence the differential form is exact by Theorem 3, Sec. 10.2, part (b) and part (a), in that order.

Method of Integrating Factors

This greatly increases the usefulness of solving exact equations. It is important in itself as well as in connection with linear ODEs in the next section. Problem Set 1.4 will help the student gain skill needed in finding integrating factors. Although the method has somewhat the flavor of tricks, Theorems 1 and 2 show that at least in some cases one can proceed systematically—and one of them is precisely the case needed in the next section for *linear* ODEs.

SOLUTIONS TO PROBLEM SET 1.4, page 25

2. $(x - y)\,dx + (y - x)\,dy = 0$. Exact; the test gives -1 on both sides. Integrate $x - y$ over x:

$$u = \tfrac{1}{2}x^2 - xy + k(y).$$

Differentiate this with respect to y and compare with N:

$$u_y = -x + k' = y - x. \qquad \text{Thus} \qquad k' = y, \qquad k = \tfrac{1}{2}y^2 + c^*.$$

Answer: $\frac{1}{2}x^2 - xy + \frac{1}{2}y^2 = \frac{1}{2}(x - y)^2 = c$; thus $y = x + \tilde{c}$.

4. Exact; the test gives $e^y - e^x$ on both sides. Integrate M with respect to x to get

$$u = xe^y - ye^x + k(y).$$

Differentiate this with respect to y and equate the result to N:

$$u_y = xe^y - e^x + k' = N = xe^y - e^x.$$

Hence $k' = 0$, $k = const$. *Answer:* $xe^y - ye^x = c$.

6. Exact; the test gives $-e^x \sin y$ on both sides. Integrate M with respect to x:

$$u = e^x \cos y + k(y). \qquad \text{Differentiate:} \qquad u_y = -e^x \sin y + k'.$$

Equate this to $N = -e^x \sin y$. Hence $k' = 0$, $k = const$. *Answer:* $e^x \cos y = c$.

8. Exact; $-1/x^2 - 1/y^2$ on both sides of the equation. Integrate M with respect to x:

$$u = x^2 + \frac{x}{y} + \frac{y}{x} + k(y).$$

Differentiate this with respect to y and equate the result to N:

$$u_y = -\frac{x}{y^2} + \frac{1}{x} + k' = N, \qquad k' = 2y, \qquad k = y^2.$$

Answer:

$$x^2 + \frac{x}{y} + \frac{y}{x} + y^2 = c.$$

im01.qxd 9/21/05 10:17 AM Page 10

10. Exact; the test gives $-2x \sin(x^2)$ on both sides. Integrate N with respect to y to get

$$u = y \cos(x^2) + l(x).$$

Differentiate this with respect to x and equate the result to M:

$$u_x = -2xy \sin(x^2) + l' = M = -2xy \sin(x^2), \qquad l' = 0.$$

Answer: $y \cos(x^2) = c$.

12. Not exact. Try Theorem 1. In R you have

$$P_y - Q_x = e^{x+y} - 1 - e^{x+y}(x + 1) = -xe^{x+y} - 1 = -Q$$

so that $R = -1$, $F = e^{-x}$, and the exact ODE is

$$(e^y - ye^{-x})\,dx + (xe^y + e^{-x})\,dy = 0.$$

The test gives $e^y - e^{-x}$ on both sides of the equation. Integration of $M = FP$ with respect to x gives

$$u = xe^y + ye^{-x} + k(y).$$

Differentiate this with respect to y and equate it to $N = FQ$:

$$u_y = xe^y + e^{-x} + k' = N = xe^y + e^{-x}.$$

Hence $k' = 0$. *Answer:* $xe^y + ye^{-x} = c$.

14. Not exact; $2y \neq -y$. Try Theorem 1; namely,

$$R = (P_y - Q_x)/Q = (2y + y)/(-xy) = -3/x. \qquad \text{Hence} \qquad F = 1/x^3.$$

The exact ODE is

$$\left(x + \frac{y^2}{x^3}\right)dx - \frac{y}{x^2}\,dy = 0.$$

The test gives $2y/x^3$ on both sides of the equation. Obtain u by integrating $N = FQ$ with respect to y:

$$u = -\frac{y^2}{2x^2} + l(x). \qquad \text{Thus} \qquad u_x = \frac{y^2}{x^3} + l' = M = x + \frac{y^2}{x^3}.$$

Hence $l' = x$, $l = x^2/2$, $-y^2/2x^2 + x^2/2 = c^*$. Multiply by 2 and use the initial condition $y(2) = 1$:

$$x^2 - \frac{y^2}{x^2} = c = 3.75$$

because inserting $y(2) = 1$ into the last equation gives $4 - 0.25 = 3.75$.

16. The given ODE is exact and can be written as $d(\cos xy) = 0$; hence $\cos xy = c$, or you can solve it for y by the usual procedure. $y(1) = \pi$ gives $-1 = c$. *Answer:* $\cos xy = -1$.

18. Try Theorem 2. You have

$$R^* = (Q_x - P_y)/P = \left[\frac{1}{y}\cos xy - x \sin xy - \left(-x \sin xy - \frac{x}{y^2}\right)\right] \Big/ P = \frac{1}{y}.$$

Hence $F^* = y$. This gives the exact ODE

$$(y \cos xy + x)\,dx + (y + x \cos xy)\,dy = 0.$$

im01.qxd 9/21/05 10:17 AM Page 11

In the test, both sides of the equation are $\cos xy - xy \sin xy$. Integrate M with respect to x:

$$u = \sin xy + \tfrac{1}{2}x^2 + k(y). \qquad \text{Hence} \qquad u_y = x \cos xy + k'(y).$$

Equate the last equation to $N = y + x \cos xy$. This shows that $k' = y$; hence $k = y^2/2$. *Answer:* $\sin xy + \frac{1}{2}x^2 + \frac{1}{2}y^2 = c$.

20. Not exact; try Theorem 2:

$$\begin{aligned} R^* = (Q_x - P_y)/P &= [1 - (\cos^2 y - \sin^2 y - 2x \cos y \sin y)]/P \\ &= [2 \sin^2 y + 2x \cos y \sin y]/P \\ &= 2(\sin y)(\sin y + x \cos y)/(\sin y \cos y + x \cos^2 y) \\ &= 2(\sin y)/\cos y = 2 \tan y. \end{aligned}$$

Integration with respect to y gives $-2 \ln (\cos y) = \ln (1/\cos^2 y)$; hence $F^* = 1/\cos^2 y$. The resulting exact equation is

$$(\tan y + x)\, dx + \frac{x}{\cos^2 y}\, dy = 0.$$

The exactness test gives $1/\cos^2 y$ on both sides. Integration of M with respect to x yields

$$u = x \tan y + \tfrac{1}{2}x^2 + k(y). \qquad \text{From this,} \qquad u_y = \frac{x}{\cos^2 y} + k'.$$

Equate this to $N = x/\cos^2 y$ to see that $k' = 0$, $k = const$. *Answer:* $x \tan y + \frac{1}{2}x^2 = c$.

22. (a) Not exact. Theorem 2 applies and gives $F^* = 1/y$ from

$$R^* = (Q_x - P_y)/P = (0 - \cos x)/(y \cos x) = -\frac{1}{y}.$$

Integrating M in the resulting exact ODE

$$\cos x\, dx + \frac{1}{y^2}\, dy = 0$$

with respect to x gives

$$u = \sin x + k(y). \qquad \text{From this,} \qquad u_y = k' = N = \frac{1}{y^2}.$$

Hence $k = -1/y$. *Answer:* $\sin x - 1/y = c$.

Note that the integrating factor $1/y$ could have been found by inspection and by the fact that an ODE of the general form

$$f(x)\, dx + g(y)\, dy = 0$$

is always exact, the test resulting in 0 on both sides.

(b) Yes. Separation of variables gives

$$dy/y^2 = -\cos x\, dx. \qquad \text{By integration,} \qquad -1/y = -\sin x + c^*$$

in agreement with the solution in (a).

(d) seems better than (c). But this may depend on your CAS. In (d) the CAS may draw vertical asymptotes that disturb the figure.

From the solution in (a) or (b) the student should conclude that for each nonzero $y(x_0) = y_0$ there is a unique particular solution because

$$\sin x_0 - 1/y_0 = c.$$

im01.qxd 9/21/05 10:17 AM Page 12

24. **(A)** $e^y \cosh x = c$.

(B) $R^* = \tan y$, $F = 1/\cos y$. Separation:

$$dy/\cos^2 y = -(1 + 2x)\,dx, \qquad \tan y = -x - x^2 + c.$$

(C) $R = -2/x$, $F = 1/x^2$, $x - y^2/x = c$. $v = y/x$, and separation:

$$2v\,dv/(1 - v^2) = dx/x, \qquad x^2 - y^2 = cx;$$

divide by x.

(D) Separation is simplest. $y = cx^{-3/4}$. $R = -9/(4x)$, $F(x) = x^{-9/4}$, $x^3y^4 = c$. $R^* = 3/y$, $F^*(y) = y^3$.

SECTION 1.5. Linear ODEs. Bernoulli Equation. Population Dynamics, page 26

Purpose. Linear ODEs are of great practical importance, as Problem Set 1.5 illustrates (and even more so are second-order linear ODEs in Chap. 2). We show that the homogeneous ODE of the first order is easily separated and the nonhomogeneous ODE is solved, once and for all, in the form of an integral (4) by the method of integrating factors. Of course, in simpler cases one does not need (4), as our examples illustrate.

Comment on Notation

We write

$$y' + p(x)y = r(x).$$

$p(x)$ seems standard. $r(x)$ suggests *"right side."* The notation

$$y' + p(x)y = q(x)$$

used in some calculus books (which are not concerned with higher order ODEs) would be shortsighted here because later, in Chap. 2, we turn to second-order ODEs

$$y'' + p(x)y' + q(x)y = r(x),$$

where we need $q(x)$ on the left, thus in a quite different role (and on the right we would have to choose another letter different from that used in the first-order case).

Comment on Content

Bernoulli's equation appears occasionally in practice, so the student should remember how to handle it.

A special Bernoulli equation, the **Verhulst equation,** plays a central role in population dynamics of humans, animals, plants, and so on, and we give a short introduction to this interesting field, along with one reference in the text.

Riccati and **Clairaut equations** are less important than Bernoulli's, so we have put them in the problem set; they will not be needed in our further work.

Input and **output** have become common terms in various contexts, so we thought this a good place to mention them.

Problems 37–42 express properties that make linearity important, notably in obtaining new solutions from given ones. The counterparts of these properties will, of course, reappear in Chap. 2.

Comment on Footnote 5

Eight members of the Bernoulli family became known as mathematicians; for more details, see p. 220 in Ref. [GR2] listed in App. 1.

im01.qxd 9/21/05 10:17 AM Page 13

SOLUTIONS TO PROBLEM SET 1.5, page 32

4. The standard form (1) is $y' - 4y = x$, so that (4) gives

$$y = e^{4x}\left[\int e^{-4x}x\,dx + c\right] = ce^{4x} - x/4 - 1/16.$$

6. The standard form (1) is $y' + \dfrac{3}{x}y = \dfrac{1}{x^3}$. From this and (4) we obtain, with $c = -2$ from the initial condition,

$$y = x^{-3}\left[\int x^3x^{-3}\,dx + c\right] = x^{-3}[x + c] = x^{-2} - 2x^{-3}.$$

8. From (4) with $p = 2$, $h = 2x$, $r = 4\cos 2x$ we obtain

$$y = e^{-2x}\left[\int e^{2x}\,4\cos 2x\,dx + c\right] = e^{-2x}[e^{2x}(\cos 2x + \sin 2x) + c].$$

It is perhaps worthwhile mentioning that integrals of this type can more easily be evaluated by undetermined coefficients. Also, the student should verify the result by differentiation, even if it was obtained by a CAS. From the initial condition we obtain

$$y(\tfrac{1}{4}\pi) = ce^{-\pi/2} + 0 + 1 = 2; \qquad \text{hence} \qquad c = e^{\pi/2}.$$

The *answer* can be written

$$y = e^{\pi/2-2x} + \cos 2x + \sin 2x.$$

10. In (4) we have $p = 4x^2$; hence $h = 4x^3/3$, so that (4) gives

$$y = e^{-4x^3/3}\left[\int e^{(4x^3/3)-x^2/2}\,(4x^2 - x)\,dx + c\right].$$

The integral can be evaluated by noting that the factor of the exponential function under the integral sign is the derivative of the exponent of that function. We thus obtain

$$y = e^{-4x^3/3}\,[e^{(4x^3/3)-x^2/2} + c] = ce^{-4x^3/3} + e^{-x^2/2}.$$

12. $y'\tan x = 2(y - 4)$. Separation of variables gives

$$\frac{dy}{y-4} = 2\,\frac{\cos x}{\sin x}\,dx. \qquad \text{By integration,} \qquad \ln|y - 4| = 2\ln|\sin x| + c^*.$$

Taking exponents on both sides gives

$$y - 4 = c\sin^2 x, \qquad y = c\sin^2 x + 4.$$

The desired particular solution is obtained from the initial condition

$$y(\tfrac{1}{2}\pi) = c + 4 = 0, \quad c = -4. \qquad \textit{Answer: } y = 4 - 4\sin^2 x.$$

14. In (4) we have $p = \tan x$, $h = -\ln(\cos x)$, $e^h = 1/\cos x$, so that (4) gives

$$y = (\cos x)\left[\int \frac{\cos x}{\cos x}\,e^{-0.01x}\,dx + c\right] = [-100\,e^{-0.01x} + c]\cos x.$$

im01.qxd 9/21/05 10:17 AM Page 14

The initial condition gives $y(0) = -100 + c = 0$; hence $c = 100$. The particular solution is

$$y = 100(1 - e^{-0.01x}) \cos x.$$

The factor 0.01, which we included in the exponent, has the effect that the graph of y shows a long transition period. Indeed, it takes $x = 460$ to let the exponential function $e^{-0.01x}$ decrease to 0.01. Choose the x-interval of the graph accordingly.

16. The standard form (1) is

$$y' + \frac{3}{\cos^2 x}\, y = \frac{1}{\cos^2 x}\,.$$

Hence $h = 3 \tan x$, and (4) gives the general solution

$$y = e^{-3 \tan x} \left[\int \frac{e^{3 \tan x}}{\cos^2 x}\, dx + c \right].$$

To evaluate the integral, observe that the integrand is of the form

$$\tfrac{1}{3}(3 \tan x)'\, e^{3 \tan x};$$

that is,

$$\tfrac{1}{3}(e^{3 \tan x})'.$$

Hence the integral has the value $\frac{1}{3}e^{3 \tan x}$. This gives the general solution

$$y = e^{-3 \tan x}\, [\tfrac{1}{3}e^{3 \tan x} + c] = \tfrac{1}{3} + ce^{-3 \tan x}.$$

The initial condition gives from this

$$y(\tfrac{1}{4}\pi) = \tfrac{1}{3} + ce^{-3} = \tfrac{4}{3}; \qquad \text{hence} \qquad c = e^3.$$

The *answer* is $y = \frac{1}{3} + e^{3-3 \tan x}$.

18. Bernoulli equation. *First solution method:* Transformation to linear form. Set $y = 1/u$. Then $y' + y = -u'/u^2 + 1/u = 1/u^2$. Multiplication by $-u^2$ gives the linear ODE in standard form

$$u' - u = -1. \qquad \text{General solution} \qquad u = ce^x + 1.$$

Hence the given ODE has the general solution

$$y = 1/(ce^x + 1).$$

From this and the initial condition $y(0) = -1$ we obtain

$$y(0) = 1/(c + 1) = -1, \quad c = -2, \qquad \textit{Answer:} \qquad y = 1/(1 - 2e^x).$$

Second solution method: Separation of variables and use of partial fractions.

$$\frac{dy}{y(y-1)} = \left(\frac{1}{y-1} - \frac{1}{y}\right) dy = dx.$$

Integration gives

$$\ln|y - 1| - \ln|y| = \ln\left|\frac{y-1}{y}\right| = x + c^*.$$

Taking exponents on both sides, we obtain

$$\frac{y-1}{y} = 1 - \frac{1}{y} = \tilde{c}e^x, \qquad \frac{1}{y} = 1 - \tilde{c}e^x, \qquad y = \frac{1}{1 + ce^x}\,.$$

We now continue as before.

im01.qxd 9/21/05 10:17 AM Page 15

20. Separate variables, integrate, and take exponents:

$$\cot y\, dy = -dx/(x^2 + 1), \qquad \ln|\sin y| = -\arctan x + c^*$$

and

$$\sin y = ce^{-\arctan x}.$$

Now use the initial condition $y(0) = \frac{1}{2}\pi$:

$$1 = ce^0, \qquad c = 1.$$

Answer: $y = \arcsin(e^{-\arctan x})$.

22. *First solution method:* by setting $z = \cos 2y$ (*linearization*): From z we have

$$z' = (-2\sin 2y)y'. \qquad \text{From the ODE,} \qquad -\tfrac{1}{2}z' + xz = 2x.$$

This is a linear ODE. Its standard form is

$$z' - 2xz = -4x. \qquad \text{In (4) this gives} \qquad p = -2x, \quad h = -x^2.$$

Hence (4) gives the solution in terms of z in the form

$$z = e^{x^2}\left[\int e^{-x^2}(-4x)\, dx + c\right] = e^{x^2}[2e^{-x^2} + c] = 2 + ce^{x^2}.$$

From this we obtain the solution

$$y = \tfrac{1}{2}\arccos z = \tfrac{1}{2}\arccos(2 + ce^{x^2}).$$

Second solution method: Separation of variables. By algebra,

$$y'\sin 2y = x(-\cos 2y + 2).$$

Separation of variables now gives

$$\frac{\sin 2y}{2 - \cos 2y}\, dy = x\, dx. \qquad \text{Integrate:} \qquad \tfrac{1}{2}\ln|2 - \cos 2y| = \tfrac{1}{2}x^2 + c^*.$$

Multiply by 2 and take exponents:

$$\ln|2 - \cos 2y| = x^2 + 2c^*, \qquad 2 - \cos 2y = \tilde{c}e^{x^2}.$$

Solve this for y:

$$\cos 2y = 2 - \tilde{c}e^{x^2}, \qquad y = \tfrac{1}{2}\arccos(2 - \tilde{c}e^{x^2}).$$

24. Bernoulli ODE. Set $u = y^3$ and note that $u' = 3y^2y'$. Multiply the given ODE by $3y^2$ to obtain

$$3y^2y' + 3x^2y^3 = e^{-x^3}\sinh x.$$

In terms of u this gives the linear ODE

$$u' + 3x^2u = e^{-x^3}\sinh x.$$

In (4) we thus have $h = x^3$. The solution is

$$u = e^{-x^3}\left[\int e^{x^3}e^{-x^3}\sinh x\, dx + c\right] = e^{-x^3}[\cosh x + c]$$

and $y = u^{1/3}$.

im01.qxd 9/21/05 10:17 AM Page 16

26. The salt content in the inflow is $50(1 + \cos t)$. Let $y(t)$ be the salt content in the tank to be determined. Then $y(t)/1000$ is the salt content per gallon. Hence $(50/1000)y(t)$ is the salt content in the outflow per minute. The rate of change y' equals the balance,

$$y' = \text{In} - \text{Out} = 50(1 + \cos t) - 0.05y.$$

Thus $y' + 0.05y = 50(1 + \cos t)$. Hence $p = 0.05$, $h = 0.05t$, and (4) gives the general solution

$$\begin{aligned} y &= e^{-0.05t}\left(\int e^{0.05t}\, 50(1 + \cos t)\, dt + c\right) \\ &= e^{-0.05t}\,(e^{0.05t}\,(1000 + a\cos t + b\sin t) + c) \\ &= 1000 + a\cos t + b\sin t + ce^{-0.05t} \end{aligned}$$

where $a = 2.5/(1 + 0.05^2) = 2.494$ and $b = 50/(1 + 0.05^2) = 49.88$, which we obtained by evaluating the integral. From this and the initial condition $y(0) = 200$ we have

$$y(0) = 1000 + a + c = 200, \qquad c = 200 - 1000 - a = -802.5.$$

Hence the solution of our problem is

$$y(t) = 1000 + 2.494\cos t + 49.88\sin t - 802.5e^{-0.05t}.$$

Figure 20 shows the solution $y(t)$. The last term in $y(t)$ is the only term that depends on the initial condition (because c does). It decreases monotone. As a consequence, $y(t)$ increases but keeps oscillating about 1000 as the limit of the mean value.

This mean value is also shown in Fig. 20. It is obtained as the solution of the ODE

$$y' + 0.05y = 50.$$

Its solution satisfying the initial condition is

$$y = 1000 - 800e^{-0.05t}.$$

28. $k_1(T - T_a)$ follows from Newton's law of cooling. $k_2(T - T_w)$ models the effect of heating or cooling. $T > T_w$ calls for cooling; hence $k_2(T - T_w)$ should be negative in this case; this is true, since k_2 is assumed to be negative in this formula. Similarly for heating, when heat should be added, so that the temperature increases.

The given model is of the form

$$T' = kT + K + k_1C\cos(\pi/12)t.$$

This can be seen by collecting terms and introducing suitable constants, $k = k_1 + k_2$ (because there are two terms involving T), and $K = -k_1A - k_2T_w + P$. The general solution is

$$T = ce^{kt} - K/k + L(-k\cos(\pi t/12) + (\pi/12)\sin(\pi t/12)),$$

where $L = k_1C/(k^2 + \pi^2/144)$. The first term solves the homogeneous ODE $T' = kT$ and decreases to zero. The second term results from the constants A (in T_a), T_w, and P. The third term is sinusoidal, of period 24 hours, and time-delayed against the outside temperature, as is physically understandable.

30. $y' = ky(1 - y) = f(y)$, where $k > 0$ and y is the proportion of infected persons. Equilibrium solutions are $y = 0$ and $y = 1$. The first, $y = 0$, is unstable because

im01.qxd 9/21/05 10:17 AM Page 17

$f(y) > 0$ if $0 < y < 1$ but $f(y) < 0$ for negative y. The solution $y = 1$ is stable because $f(y) > 0$ if $0 < y < 1$ and $f(y) < 0$ if $y > 1$. The general solution is

$$y = \frac{1}{1 + ce^{-kt}} .$$

It approaches 1 as $t \to \infty$. This means that eventually everybody in the population will be infected.

32. The model is

$$y' = Ay - By^2 - Hy = Ky - By^2 = y(K - By)$$

where $K = A - H$. Hence the general solution is given by (9) in Example 4 with A replaced by $K = A - H$. The equilibrium solutions are obtained from $y' = 0$; hence they are $y_1 = 0$ and $y_2 = K/B$. The population y_2 remains unchanged under harvesting, and the fraction Hy_2 of it can be harvested indefinitely—hence the name.

34. For the first 3 years you have the solution

$$y_1 = 4/(5 - 3e^{-0.8t})$$

from Prob. 32. The idea now is that, by continuity, the value $y_1(3)$ at the end of the first period is the initial value for the solution y_2 during the next period. That is,

$$y_2(3) = y_1(3) = 4/(5 - 3e^{-2.4}).$$

Now y_2 is the solution of $y' = y - y^2$ (no fishing!). Because of the initial condition this gives

$$y_2 = 4/(4 + e^{3-t} - 3e^{0.6-t}).$$

Check the continuity at $t = 3$ by calculating

$$y_2(3) = 4/(4 + e^{0} - 3e^{-2.4}).$$

Similarly, for t from 6 to 9 you obtain

$$y_3 = 4/(5 - e^{4.8-0.8t} + e^{1.8-0.8t} - 3e^{-0.6-0.8t}).$$

This is a period of fishing. Check the continuity at $t = 6$:

$$y_3(6) = 4/(5 - e^{0} + e^{-3} - 3e^{-5.4}).$$

This agrees with

$$y_2(6) = 4/(4 + e^{-3} - 3e^{-5.4}).$$

36. $y_1 = 1/u_1$,

$$u_1(0) = 1/y_1(0) = 0.5,$$

$$y_1' = -u_1'/{u_1}^2 = 0.8y_1 - {y_1}^2 = 0.8/u_1 - 1/{u_1}^2,$$

$$u_1' + 0.8u_1 = 1,$$

$$u_1 = 1.25 + c_1e^{-0.8t}$$

$$= 1.25 - 0.75e^{-0.8t} = 1/y_1$$

for $0 < t < 3$. $u_2' + u_2 = 1$, $u_2 = 1 + c_2e^{-t}$. The continuity condition is

$$u_2(3) = 1 + c_2e^{-3} = u_1(3) = 1.25 - 0.75e^{-2.4}.$$

im01.qxd 9/21/05 10:17 AM Page 18

For c_2 this gives

$$c_2 = e^3(-1 + 1.25 - 0.75e^{-2.4}) = 0.25e^3 - 0.75e^{0.6}.$$

This gives for $3 < t < 6$

$$u_2 = 1 + 0.25e^{3-t} - 0.75e^{0.6-t} = 1/y_2.$$

Finally, for $6 < t < 9$ we have the ODE is $u_3' + 0.8u_3 = 1$, whose general solution is

$$u_3 = 1.25 + c_3e^{-0.8t}.$$

c_3 is determined by the continuity condition at $t = 6$, namely,

$$u_3(6) = 1.25 + c_3e^{-4.8} = u_2(6) = 1 + 0.25e^{-3} - 0.75e^{-5.4}.$$

This gives

$$\begin{aligned} c_3 &= e^{4.8}(-1.25 + 1 + 0.25e^{-3} - 0.75e^{-5.4}) \\ &= -0.25e^{4.8} + 0.25e^{1.8} - 0.75e^{-0.6}. \end{aligned}$$

Substitution gives the solution for $6 < t < 9$:

$$u_3 = 1.25 + (-0.25e^{4.8} + 0.25e^{1.8} - 0.75e^{-0.6})e^{-0.8t} = 1/y_3.$$

38. Substitution gives the identity $0 = 0$.

These problems are of importance because they show why linear ODEs are preferable over nonlinear ones in the modeling process. Thus one favors a linear ODE over a nonlinear one if the model is a faithful mathematical representation of the problem. Furthermore, these problems illustrate the difference between homogeneous and nonhomogeneous ODEs.

40. We obtain

$$\begin{aligned} (y_1 - y_2)' + p(y_1 - y_2) &= y_1' - y_2' + py_1 - py_2 \\ &= (y_1' + py_1) - (y_2' + py_2) \\ &= r - r \\ &= 0. \end{aligned}$$

42. The sum satisfies the ODE with $r_1 + r_2$ on the right. This is important as the key to the method of developing the right side into a series, then finding the solutions corresponding to single terms, and finally, adding these solutions to get a solution of the given ODE. For instance, this method is used in connection with Fourier series, as we shall see in Sec. 11.5.

44. **(a)** $y = Y + v$ reduces the Riccati equation to a Bernoulli equation by removing the term $h(x)$. The second transformation, $v = 1/u$, is the usual one for transforming a Bernoulli equation with y^2 on the right into a linear ODE.

Substitute $y = Y + 1/u$ into the Riccati equation to get

$$Y' - u'/u^2 + p(Y + 1/u) = g(Y^2 + 2Y/u + 1/u^2) + h.$$

Since Y is a solution, $Y' + pY = gY^2 + h$. There remains

$$-u'/u^2 + p/u = g(2Y/u + 1/u^2).$$

Multiplication by $-u^2$ gives $u' - pu = -g(2Yu + 1)$. Reshuffle terms to get

$$u' + (2Yg - p)u = -g,$$

the linear ODE as claimed.

im01.qxd 9/21/05 10:17 AM Page 19

(b) Substitute $y = Y = x$ to get $1 - 2x^4 - x = -x^4 - x^4 - x + 1$, which is true. Now substitute $y = x + 1/u$. This gives

$$1 - u'/u^2 - (2x^3 + 1)(x + 1/u) = -x^2(x^2 + 2x/u + 1/u^2) - x^4 - x + 1.$$

Most of the terms cancel on both sides. There remains $-u'/u^2 - 1/u = -x^2/u^2$. Multiplication by $-u^2$ finally gives $u' + u = x^2$. The general solution is

$$u = ce^{-x} + x^2 - 2x + 2$$

and $y = x + 1/u$. Of course, instead performing this calculation we could have used the general formula in (a), in which

$$2Yg - p = 2x(-x^2) + 2x^3 + 1 = 1 \qquad \text{and} \qquad -g = +x^2.$$

(c) Substitution of $Y = x^2$ shows that this is a solution. In the ODE for u you find

$$2Yg - p = 2x^2\,(-\sin x) - (3 - 2x^2 \sin x) = -3.$$

Also, $g = -\sin x$. Hence the ODE for u is $u' - 3u = \sin x$. Solution:

$$u = ce^{3x} - 0.1 \cos x - 0.3 \sin x \qquad \text{and} \qquad y = x^2 + 1/u.$$

(e) $y' = y' + xy'' - y''/y'^2$ by the chain rule. Hence $y''(x - 1/y'^2) = 0$.

(A) From $y'' = 0$ we obtain by integrations $y = cx + a$. Substitution into the given ODE gives $cx + a = xc + 1/c$; hence $a = 1/c$. This is a family of straight lines.

(B) The other factor is zero when $x = 1/y'^2$. By integration, $y = 2x^{1/2} + c^*$. Substituting y and $y' = x^{-1/2}$ into the given equation $y = xy' + 1/y'$, we obtain

$$2x^{1/2} + c^* = x \cdot x^{-1/2} + 1/x^{-1/2};$$

hence $c^* = 0$. This gives the singular solution $y = 2\sqrt{x}$, a curve, to which those straight lines in (A) are tangent.

(f) By differentiation, $2y'y'' - y' - xy'' + y' = 0$, $y''(2y' - x) = 0$, (A) $y'' = 0$, $y = cx + a$. By substitution, $c^2 - xc + cx + a = 0$, $a = -c^2$, $y = cx - c^2$, a family of straight lines. (B) $y' = x/2$, $y = x^2/4 + c^*$. By substitution into the given ODE, $x^2/4 - x^2/2 + x^2/4 + c^* = 0$, $c^* = 0$, $y = x^2/4$, the envelope of the family; see Fig. 6 in Sec. 1.1.

SECTION 1.6. Orthogonal Trajectories. *Optional,* page 35

Purpose. To show that families of curves $F(x, y, c) = 0$ can be described by ODEs $y' = f(x, y)$ and the switch to $\tilde{y}' = -1/f(x, \tilde{y})$ produces as general solution the orthogonal trajectories. This is a nice application that may also help the student to gain more self-confidence, skill, and a deeper understanding of the nature of ODEs.

We leave this section ***optional,*** for reasons of time. This will cause no gap.

The reason why ODEs can be applied in this fashion results from the fact that general solutions of ODEs involve an arbitrary constant that serves as the parameter of this one-parameter family of curves determined by the given ODE, and then another general solution similarly determines the one-parameter family of the orthogonal trajectories.

Curves and their orthogonal trajectories play a role in several physical applications (e.g., in connection with electrostatic fields, fluid flows, and so on).

im01.qxd 9/21/05 10:17 AM Page 20

SOLUTIONS TO PROBLEM SET 1.6, page 36

2. $xy = c$, and by differentiation, $y + xy' = 0$; hence $y' = -y/x$. The ODE of the trajectories is $\tilde{y}' = x/\tilde{y}$. By separation and integration, $\tilde{y}^2/2 = x^2/2 + c^*$. Hyperbolas. (So are the given curves.)

4. By differentiation, $2yy' = 4x$; hence $y' = 2x/y$. Thus the ODE of the trajectories is $\tilde{y}' = -\tilde{y}/2x$. By separating, integrating, and taking exponents on both sides,

$$d\tilde{y}/\tilde{y} = -\,dx/2x, \qquad \ln|\tilde{y}| = -\tfrac{1}{2}\ln|x| + c^{**}, \qquad \tilde{y} = c^*/\sqrt{x}.$$

6. $ye^{3x} = c$. Differentiation gives

$$(y' + 3y)e^{3x} = 0.$$

Hence the ODE of the given family is $y' = -3y$. For the trajectories we obtain

$$\tilde{y}' = 1/(3\tilde{y}), \qquad \tilde{y}\tilde{y}' = \tfrac{1}{3}, \qquad \tfrac{1}{2}\tilde{y}^2 = \tfrac{1}{3}x + c^{**}, \qquad \tilde{y} = \sqrt{\tfrac{2}{3}x + c^*}.$$

8. $2x - 2yy' = 0$, so that the ODE of the curves is $y' = x/y$.

Hence the ODE of the trajectories is $\tilde{y}' = -\tilde{y}/x$. Separating variables, integrating, and taking exponents gives hyperbolas as trajectories; namely,

$$\tilde{y}'/\tilde{y} = -1/x, \qquad \ln|\tilde{y}| = -\ln|x| + c^{**}, \qquad x\tilde{y} = c^*.$$

10. $xy^{-1/2} = \hat{c}$, or $x^2y^{-1} = c$. By differentiation,

$$2xy^{-1} - x^2y^{-2}y' = 0, \qquad y' = 2y/x.$$

This is the ODE of the given family. Hence the orthogonal trajectories have the ODE

$$\tilde{y}' = -\frac{x}{2\tilde{y}}. \qquad \text{Thus} \qquad 2\tilde{y}\tilde{y}' = -x, \qquad \tilde{y}^2 = -\tfrac{1}{2}x^2 + c^* \qquad \text{(ellipses).}$$

12. $x^2 + y^2 - 2cy = 0$. Solve algebraically for $2c$:

$$\frac{x^2 + y^2}{y} = \frac{x^2}{y} + y = 2c.$$

Differentiation gives

$$\frac{2x}{y} - \frac{x^2y'}{y^2} + y' = 0.$$

By algebra,

$$y'\left(-\frac{x^2}{y^2} + 1\right) = -\frac{2x}{y}.$$

Solve for y':

$$y' = -\frac{2x}{y}\Big/\left(\frac{y^2 - x^2}{y^2}\right) = \frac{-2xy}{y^2 - x^2}.$$

This is the ODE of the given family. Hence the ODE of the trajectories is

$$\tilde{y}' = \frac{\tilde{y}^2 - x^2}{2x\tilde{y}} = \frac{1}{2}\left(\frac{\tilde{y}}{x} - \frac{x}{\tilde{y}}\right).$$

To solve this equation, set $u = \tilde{y}/x$. Then

$$\tilde{y}' = xu' + u = \frac{1}{2}\left(u - \frac{1}{u}\right).$$

im01.qxd 9/21/05 10:17 AM Page 21

Subtract u on both sides to get

$$xu' = -\frac{u^2 + 1}{2u}.$$

Now separate variables, integrate, and take exponents, obtaining

$$\frac{2u\,du}{u^2 + 1} = -\frac{dx}{x}, \qquad \ln(u^2 + 1) = -\ln|x| + c_1, \qquad u^2 + 1 = \frac{c_2}{x}.$$

Write $u = \tilde{y}/x$ and multiply by x^2 on both sides of the last equation. This gives

$$\tilde{y}^2 + x^2 = c_2 x.$$

The *answer* is

$$(x - c_3)^2 + \tilde{y}^2 = c_3{}^2.$$

Note that the given circles all have their centers on the y-axis and pass through the origin. The result shows that their orthogonal trajectories are circles, too, with centers on the x-axis and passing through the origin.

14. By differentiation, $g_x\,dx + g_y\,dy = 0$. Hence $y' = -g_x/g_y$. This implies that the trajectories are obtained from

$$\tilde{y}' = g_{\tilde{y}}/g_x.$$

For Prob. 6 we obtain $ye^{3x} = c$ and by differentiation,

$$\tilde{y}' = \frac{e^{3x}}{3\tilde{y}e^{3x}} = \frac{1}{3\tilde{y}}, \qquad \tilde{y}\tilde{y}' = \frac{1}{3}, \qquad \frac{\tilde{y}^2}{2} = \frac{x}{3} + c^{**}$$

and so forth.

16. Differentiating $xy = c$, we have $y + xy' = 0$, so that the ODE of the given hyperbolas is $y' = -y/x$. The trajectories are thus obtained by solving $\tilde{y}' = x/\tilde{y}$. By separation of variables and integration we obtain

$$\tilde{y}\tilde{y}' = x \qquad \text{and} \qquad \tilde{y}^2 - x^2 = c^*$$

(hyperbolas).

18. Setting $y = 0$ gives from $x^2 + (y - c)^2 = 1 + c^2$ the equation $x^2 + c^2 = 1 + c^2$; hence $x = -1$ and $x = 1$, which verifies that those circles all pass through -1 and 1, each of them simultaneously through both points. Subtracting c^2 on both sides of the given equation, we obtain

$$x^2 + y^2 - 2cy = 1, \qquad x^2 + y^2 - 1 = 2cy, \qquad \frac{x^2 - 1}{y} + y = 2c.$$

Emphasize to your class that the ODE for the given curves must always be free of c. Having accomplished this, we can now differentiate. This gives

$$\frac{2x}{y} - \left(\frac{x^2 - 1}{y^2} - 1\right) y' = 0.$$

This is the ODE of the given curves. Replacing y' with $-1/\tilde{y}'$ and y with $\tilde{y}$, we obtain the ODE of the trajectories:

$$\frac{2x}{\tilde{y}} - \left(\frac{x^2 - 1}{\tilde{y}^2} - 1\right) \Big/ (-\tilde{y}') = 0.$$

im01.qxd 9/21/05 10:17 AM Page 22

Multiplying this by y', we get

$$\frac{2x\tilde{y}'}{\tilde{y}} + \frac{x^2 - 1}{\tilde{y}^2} - 1 = 0.$$

Multiplying this by $\tilde{y}^2/x^2$, we obtain

$$\frac{2\tilde{y}\tilde{y}'}{x} + 1 - \frac{1}{x^2} - \frac{\tilde{y}^2}{x^2} = \frac{d}{dx}\left(\frac{\tilde{y}^2}{x}\right) + 1 - \frac{1}{x^2} = 0.$$

By integration,

$$\frac{\tilde{y}^2}{x} + x + \frac{1}{x} = 2c^*. \qquad \text{Thus,} \qquad \tilde{y}^2 + x^2 + 1 = 2c^*x.$$

We see that these are the circles

$$\tilde{y}^2 + (x - c^*)^2 = c^{*2} - 1$$

dashed in Fig. 25, as claimed.

20. (B) By differentiation,

$$\frac{2x}{a^2} + \frac{2yy'}{b^2} = 0, \qquad y' = -\frac{2x/a^2}{2y/b^2} = -\frac{b^2x}{a^2y}.$$

Hence the ODE of the orthogonal trajectories is

$$\tilde{y}' = \frac{a^2\tilde{y}}{b^2x}. \qquad \text{By separation,} \qquad \frac{d\tilde{y}}{\tilde{y}} = \frac{a^2}{b^2}\,\frac{dx}{x}.$$

Integration and taking exponents gives

$$\ln|\tilde{y}| = \frac{a^2}{b^2}\ln|x| + c^{**}, \qquad \tilde{y} = c^*x^{a^2/b^2}.$$

This shows that the ratio a^2/b^2 has substantial influence on the form of the trajectories. For $a^2 = b^2$ the given curves are circles, and we obtain straight lines as trajectories. $a^2/b^2 = 2$ gives quadratic parabolas. For higher integer values of a^2/b^2 we obtain parabolas of higher order. Intuitively, the "flatter" the ellipses are, the more rapidly the trajectories must increase to have orthogonality.

Note that our discussion also covers families of parabolas; simply interchange the roles of the curves and their trajectories.

(C) For hyperbolas we have a minus sign in the formula of the given curves. This produces a plus sign in the ODE for the curves and a minus sign in the ODE for the trajectories:

$$y' = -\frac{a^2y}{b^2x}.$$

Separation of variables and integration gives

$$y = c^*x^{-a^2/b^2}.$$

For $a^2/b^2 = 1$ we obtain the hyperbolas $y = c^*x$, and for higher values of a^2/b^2 we obtain less familiar curves.

(D) The problem set of this section contains other families of curves whose trajectories can be readily obtained by solving the corresponding ODEs.

im01.qxd 9/21/05 10:17 AM Page 23

SECTION 1.7. Existence and Uniqueness of Solutions, page 37

Purpose. To give the student at least some impression of the theory that would occupy a central position in a more theoretical course on a higher level.
Short Courses. This section can be omitted.

Comment on Iteration Methods

Iteration methods were used rather early in history, but it was Picard who made them popular. Proofs of the theorems in this section (given in books of higher level, e.g., [A11]) are based on the Picard iteration (see CAS Project 10).

Iterations are well suited for the computer because of their modest storage demand and usually short programs in which the same loop or loops are used many times, with different data. Because integration is generally not difficult for a CAS, Picard's method has gained some popularity during the past few decades.

SOLUTIONS TO PROBLEM SET 1.7, page 41

2. The initial condition is given at the point $x = 1$. The coefficient of y' is 0 at that point, so from the ODE we already see that something is likely to go wrong. Separating variables, integrating, and taking exponents gives

$$\frac{dy}{y} = \frac{2\,dx}{x-1}, \qquad \ln|y| = 2\ln|x-1| + c^*, \qquad y = c(x-1)^2.$$

This last expression is the general solution. It shows that $y(1) = 0$ for any c. Hence the initial condition $y(1) = 1$ cannot be satisfied. This does not contradict the theorems because we first have to write the ODE in standard form:

$$y' = f(x, y) = \frac{2y}{x-1}.$$

This shows that f is not defined when $x = 1$ (to which the initial condition refers).

4. For $k \neq 0$ we still get no solution, violating the existence as in Prob. 2. For $k = 0$ we obtain infinitely many solutions, because c remains unspecified. Thus in this case the uniqueness is violated. Neither of the two theorems is violated in either case.

6. By separation and integration,

$$\frac{dy}{y} = \frac{2x-4}{x^2-4x}\,dx, \qquad \ln|y| = \ln|x^2-4x| + c^*.$$

Taking exponents gives the general solution

$$y = c(x^2 - 4x).$$

From this we can see the *answers:*

No solution if $y(0) = k \neq 0$ or $y(4) = k \neq 0$.
A unique solution if $y(x_0)$ equals any y_0 and $x_0 \neq 0$ or $x_0 \neq 4$.
Infinitely many solutions if $y(0) = 0$ or $y(4) = 0$.

This does not contradict the theorems because

$$f(x, y) = \frac{2x-4}{x^2-4x}$$

is not defined when $x = 0$ or 4.

im01.qxd 9/21/05 10:17 AM Page 24

8. **(A)** The student should gain an understanding for the "intermediate" position of a Lipschitz condition: it is more than continuity but less than partial differentiability.

(B) Here the student should realize that the linear ODE is basically simpler than a nonlinear ODE. The calculation is straightforward because

$$f(x, y) = r(x) - p(x)y$$

and implies that

$$|f(x, y_2) - f(x, y_1)| = |p(x)|\,|y_2 - y_1| \leqq M|y_2 - y_1|$$

where the boundedness $|p(x)| \leqq M$ for $|x - x_0| \leqq a$ follows from the continuity of p in this closed interval.

10. **(B)** $y_n = \dfrac{x^2}{2!} + \dfrac{x^3}{3!} + \cdots + \dfrac{x^{n+1}}{(n+1)!}$, $\quad y = e^x - x - 1$

(C) $y_0 = 1$, $y_1 = 1 + 2x$, $y_2 = 1 + 2x + 4x^2 + \dfrac{8x^3}{3}$, $\cdots$

$$y(x) = \frac{1}{1 - 2x} = 1 + 2x + 4x^2 + 8x^3 + \cdots$$

(D) $y = (x - 1)^2$, $y = 0$. It approximates $y = 0$. General solution $y = (x + c)^2$.

(E) $y' = y$ would be a good candidate to begin with. Perhaps you write the initial choice as $y_0 + a$; then $a = 0$ corresponds to the choice in the text, and you see how the expressions in a are involved in the approximations. The conjecture is true for any choice of a constant (or even of a continuous function of x).

It was mentioned in footnote 9 that Picard used his iteration for proving his existence and uniqueness theorems. Since the integrations involved in the method can be handled on the computer quite efficiently, the method has gained in importance in numerics.

SOLUTIONS TO CHAP. 1 REVIEW QUESTIONS AND PROBLEMS, page 42

12. Linear ODE. Formula (4) in Sec. 1.5 gives, since $p = -3$, $h = -3x$,

$$y = e^{3x}\left(\int e^{-3x}(-2x)\,dx + c\right) = e^{3x}(e^{-3x}(\tfrac{2}{3}x + \tfrac{2}{9}) + c) = ce^{3x} + \tfrac{2}{3}x + \tfrac{2}{9}.$$

14. Separate variables. $y\,dy = 16x\,dx$, $\frac{1}{2}y^2 = 8x^2 + c^*$, $y^2 - 16x^2 = c$. Hyperbolas.

16. Linear ODE. Standard form $y' - xy = -x^3 + x$. Use (4), Sec. 1.5, with $p = -x$, $h = -x^2/2$, obtaining the general solution

$$y = e^{x^2/2}\left(\int e^{-x^2/2}\,(-x^3 + x)\,dx + c\right) = e^{x^2/2}[e^{-x^2/2}(x^2 + 1) + c]$$
$$= ce^{x^2/2} + x^2 + 1.$$

18. Exact; the exactness test gives $-3\pi \sin \pi x \sinh 3y$ on both sides. Integrate the coefficient function of dx with respect to x, obtaining

$$u = \int M\,dx = \cos \pi x \cosh 3y + k(y).$$

Differentiate this with respect to y and equate the result to the coefficient function of dy:

$$u_y = 3 \cos \pi x \sinh 3y + k'(y) = N. \qquad \text{Hence } k' = 0.$$

im01.qxd 9/21/05 10:17 AM Page 25

The implicit general solution is

$$\cos \pi x \cosh 3y = c.$$

20. Solvable (A) as a Bernoulli equation or (B) by separating variables.

(A) Set $y^2 = u$ since $a = -1$; hence $1 - a = 2$. Differentiate $u = y^2$, substitute y' from the given ODE, and express the resulting equation in terms of u; that is,

$$u' = 2yy' = 2y(y + 1/y) = 2u + 2.$$

This is a linear ODE with unknown u. Its standard form is $u' - 2u = 2$. Solve it by (4) in Sec. 1.5 or by noting that the homogeneous ODE has the general solution ce^{2x}, and a particular solution of the nonhomogeneous ODE is -1. Hence $u = ce^{2x} - 1$, and $u = y^2$.

(B) $y' = y + 1/y = (y^2 + 1)/y, \quad y\,dy/(y^2 + 1) = dx$. Integrate and take exponents on both sides:

$$\tfrac{1}{2} \ln (y^2 + 1) = x + c^*, \qquad y^2 + 1 = ce^{2x}.$$

22. The argument of the tangent suggests to set $y/x = u$. Then $y = xu$, and by differentiation and use of the given ODE divided by x,

$$y' = u + xu' = \tan u + u; \qquad \text{hence} \qquad xu' = \tan u.$$

Separation of variables gives

$$\cot u\,du = dx/x, \qquad \ln |\sin u| = \ln |x| + c^*, \qquad \sin u = cx.$$

This yields the general solution

$$y = xu = x \arcsin cx.$$

24. We set $y - 2x = z$ as indicated. Then $y = z + 2x$, $y' = z' + 2$ and by substitution into the given ODE,

$$xy' = xz' + 2x = z^2 + z + 2x.$$

Subtraction of $2x$ on both sides gives $xz' = z^2 + z$. By separation of variables and integration we obtain

$$\frac{dz}{z^2 + z} = \left(\frac{1}{z} - \frac{1}{z + 1}\right) dz = \frac{dx}{x}, \qquad \ln \left|\frac{z}{z + 1}\right| = \ln |x| + c^*.$$

We now take exponents and simplify algebraically. This yields

$$\frac{z}{z + 1} = \frac{y - 2x}{y - 2x + 1} = cx, \qquad y = 2x + cx(y - 2x + 1).$$

Solving for y, we finally have

$$(1 - cx)y = 2x(1 - cx) + cx, \qquad y = 2x - 1 + 1/(1 - cx).$$

26. The first term on the right suggests the substitution $u = y/x$. Then $y = xu$, and from the ODE, $xy' = x(u + xu') = u^3 + xu$. Subtract xu on both sides to get $x^2u' = u^3$. Separate variables and integrate:

$$u^{-3}\,du = x^{-2}\,dx, \qquad -\tfrac{1}{2}u^{-2} = -x^{-1} + c^*; \qquad \text{hence} \qquad u^2 = \frac{1}{c + 2/x}.$$

This gives the general solution

$$y = \pm xu = \pm \frac{x}{\sqrt{c + 2/x}}.$$

im01.qxd 9/21/05 10:17 AM Page 26

28. Logistic equation. $y = 1/u$, $y' = -u'/u^2 = 3/u - 12/u^2$. Multiplication by $-u^2$ gives the linear ODE

$$u' = -3u + 12. \qquad \text{Solution:} \qquad u = ce^{-3x} + 4.$$

Hence the general solution of the given ODE is

$$y = 1/u = 1/(ce^{-3x} + 4).$$

From the given initial condition we obtain $y(0) = 1/(c + 4) = 2$; hence $c = -3.5$. The *answer* is

$$y = \frac{1}{-3.5e^{-3x} + 4}.$$

30. Linear ODE. The corresponding homogeneous ODE has the general solution $y = ce^{-\pi x}$. A solution of the nonhomogeneous equation can be found without integration by parts and recursion if we substitute

$$y = A\cos \pi x + B \sin \pi x \qquad \text{and} \qquad y' = -A\pi \sin \pi x + B\pi \cos \pi x$$

and equate the result to the right side; that is,

$$y' + \pi y = (B + A)\pi \cos \pi x + (-A + B)\pi \sin \pi x = 2b \cos \pi x.$$

This gives $A = B = b/\pi$. The general solution is

$$y = ce^{-\pi x} + \frac{b}{\pi}(\cos \pi x + \sin \pi x). \qquad \text{Thus} \qquad y(0) = c + b/\pi = 0,\ c = -b/\pi.$$

32. Not exact; in the test we get $2 + 2y/x$ on the left but 1 on the right. Theorem 1 in Sec. 1.4 gives an integrating factor depending only on x, namely, $F(x) = x$; this follows from

$$R = \frac{1}{x + 2y}\left(2 + \frac{2y}{x} - 1\right) = \frac{1}{x}$$

by integrating R and taking exponents. The resulting exact equation is

$$[2xy + y^2 + e^x(1 + x)]\,dx + (x^2 + 2xy)\,dy = 0.$$

From it we calculate by integration with respect to y

$$u = \int N\,dy = x^2y + xy^2 + l(x).$$

We differentiate this with respect to x and equate the result to the coefficient of dx in the exact ODE. This gives

$$u_x = 2xy + y^2 + l' = 2xy + y^2 + e^x(x + 1); \qquad \text{hence} \qquad l' = e^x(x + 1)$$

and by integration, $l = xe^x$. The general implicit solution is

$$u(x, y) = x^2y + xy^2 + xe^x = c.$$

From the initial condition, $u(1, 1) = 1 + 1 + e = 2 + e$. The particular solution of the initial value problem is

$$u(x, y) = x^2y + xy^2 + xe^x = 2 + e.$$

im01.qxd 9/21/05 10:17 AM Page 27

34. In problems of this sort we need two conditions, because we must determine the arbitrary constant c in the general solution and the constant k in the exponent. In the present case, these are the initial temperature $T(0) = 10$ and the temperature $T(5) = 20$ after 5 minutes. Newton's law of cooling gives the model

$$T' = k(T - 25).$$

By separation of variables and integration we obtain

$$T = ce^{kt} + 25.$$

The initial condition gives $T(0) = c + 25 = 10$; hence $c = -15$. From the second given condition we obtain

$$T(5) = -15e^{5k} + 25 = 20, \qquad 15e^{5k} = 5, \qquad k = (\ln \tfrac{1}{3})/5 = -0.2197.$$

We can now determine the time when T reaches 24.9, namely, from

$$-15e^{kt} + 25 = 24.9, \qquad e^{kt} = 0.1/15.$$

Hence

$$t = [\ln (0.1/15)]/k = -5.011/(-0.2197) = 23 \text{ [min]}.$$

36. This will give a **general formula** for determining the half-life H from two measurements y_1 and y_2 at times t_1 and t_2, respectively. Accordingly, we use letters and insert the given numeric data only at the end of the derivation. We have

$$y' = ky, \qquad y = y_0 e^{kt}$$

and from this

$$y_1 = y(t_1) = y_0 e^{kt_1}, \qquad y_2 = y(t_2) = y_0 e^{kt_2}.$$

Taking the quotient of the two measurements y_1 and y_2 eliminates y_0 (the initial amount) and gives a formula for k in terms of these measurements and the corresponding times, namely,

$$y_2/y_1 = \exp [k(t_2 - t_1)], \qquad k = \frac{\ln (y_2/y_1)}{t_2 - t_1}.$$

Knowing k, we can now readily determine the half-life H directly from its definition

$$e^{kH} = 0.5.$$

This gives

$$H = \frac{\ln 0.5}{k} = (\ln 0.5)\, \frac{t_2 - t_1}{\ln (y_2/y_1)}.$$

For the given data we obtain from this formula

$$H = -0.69315\, \frac{10 - 5}{\ln (0.015/0.02)} = 12.05.$$

Thus the half-life of the substance is about 12 days and 1 hour.

38. Let y denote the amount of fresh air measured in cubic feet. Then the model is obtained from the balance equation

"Inflow minus Outflow equals the rate of change";

that is,

$$y' = 600 - \frac{600}{20000}\, y = 600 - 0.03y.$$

im01.qxd 9/21/05 10:17 AM Page 28

The general solution of this linear ODE is

$$y = ce^{-0.03t} + 20000.$$

The initial condition is $y(0) = 0$ (initially no fresh air) and gives

$$y(0) = c + 20000 = 0; \qquad \text{hence} \qquad c = -20000.$$

The particular solution of our problem is

$$y = 20000(1 - e^{-0.03t}).$$

This equals 90% if t is such that

$$e^{-0.03t} = 0.1$$

thus if $t = (\ln 0.1)/(-0.03) = 77$ [min].

40. We use separation of variables. To evaluate the integral, we apply reduction by partial fractions. This yields

$$\frac{dy}{(a - y)(b - y)} = \left[\frac{A}{y - a} + \frac{B}{y - b}\right] dy = k\,dx,$$

where

$$A = \frac{1}{a - b} \qquad \text{and} \qquad B = \frac{1}{b - a} = -A.$$

By integration,

$$A[\ln|y - a| - \ln|y - b|] = A \ln\left|\frac{y - a}{y - b}\right| = kt + c^*.$$

We multiply this on both sides by $1/A = a - b$, obtaining

$$\ln\left|\frac{y - a}{y - b}\right| = (kt + c^*)(a - b).$$

We now take exponents. In doing so, we can set $c = e^{c^*}$ and have

$$\frac{y - a}{y - b} = ce^{(a-b)kt}.$$

We denote the right side by E and solve algebraically for y; then

$$y - a = (y - b)E, \qquad y(1 - E) = a - bE$$

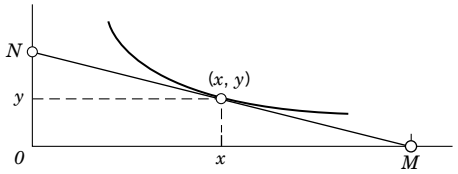
and from the last expression we finally have

$$y = \frac{a - bE}{1 - E}.$$

42. Let the tangent of such a curve $y(x)$ at (x, y) intersect the x-axis at M and the y-axis at N, as shown in the figure. Then because of the bisection we have

$$OM = 2x, \qquad ON = 2y,$$

where O is the origin. Since the slope of the tangent is the slope $y'(x)$ of the curve, by the definition of a tangent, we obtain



$$y' = -\text{ON/OM} = -y/x.$$

im01.qxd 9/21/05 10:17 AM Page 29

By separation of variables, integration, and taking exponents, we see that

$$\frac{dy}{y} = -\frac{dx}{x}, \qquad \ln|y| = -\ln|x| + c^*, \qquad xy = c.$$

This is a family of hyperbolas.

im02.qxd 9/21/05 10:57 AM Page 30

CHAPTER 2 Second-Order Linear ODEs

Major Changes

Among linear ODEs those of second order are by far the most important ones from the viewpoint of applications, and from a theoretical standpoint they illustrate the theory of linear ODEs of any order (except for the role of the Wronskian). For these reasons we consider linear ODEs of third and higher order in a separate chapter, Chap. 3.

The new Sec. 2.2 combines all three cases of the roots of the characteristic equation of a homogeneous linear ODE with constant coefficients. (In the last edition the complex case was discussed in a separate section.)

Modeling applications of the method of undetermined coefficients (Sec. 2.7) follow immediately after the derivation of the method (mass–spring systems in Sec. 2.8, electric circuits in Sec. 2.9), before the discussion of variation of parameters (Sec. 2.10).

The new Sec. 2.9 combines the old Sec. 1.7 on modeling electric circuits by first-order ODEs and the old Sec. 2.12 on electric circuits modeled by second-order ODEs. This avoids discussing the physical aspects and foundations twice.

SECTION 2.1. Homogeneous Linear ODEs of Second-Order, page 45

Purpose. To extend the basic concepts from first-order to second-order ODEs and to present the basic properties of linear ODEs.

Comment on the Standard Form (1)

The form (1), with 1 as the coefficient of y'', is practical, because if one starts from

$$f(x)y'' + g(x)y' + h(x)y = \tilde{r}(x),$$

one usually considers the equation in an interval I in which $f(x)$ is nowhere zero, so that in I one can divide by $f(x)$ and obtain an equation of the form (1). Points at which $f(x) = 0$ require a special study, which we present in Chap. 5.

Main Content, Important Concepts

Linear and nonlinear ODEs

Homogeneous linear ODEs (to be discussed in Secs. 2.1−2.6)

Superposition principle for homogeneous ODEs

General solution, basis, linear independence

Initial value problem (2), (4), particular solution

Reduction to first order (text and Probs. 15−22)

Comment on the Three ODEs after (2)

These are for illustration, not for solution, but should a student ask, answers are that the first will be solved by methods in Sec. 2.7 and 2.10, the second is a Bessel equation (Sec. 5.5) and the third has the solutions $\pm\sqrt{c_1x + c_2}$ with any c_1 and c_2.

Comment on Footnote 1

In 1760, Lagrange gave the first methodical treatment of the calculus of variations. The book mentioned in the footnote includes all major contributions of others in the field and made him the founder of analytical mechanics.

im02.qxd 9/21/05 10:57 AM Page 31

Comment on Terminology

p and q are called the **coefficients** of (1) and (2). The function r on the right is *not* called a coefficient, to avoid the misunderstanding that r must be constant when we talk about an ODE *with constant coefficients*.

SOLUTIONS TO PROBLEM SET 2.1, page 52

2. $\cos 5x$ and $\sin 5x$ are linearly independent on any interval because their quotient, $\cot 5x$, is not constant. General solution:

$$y = a \cos 5x + b \sin 5x.$$

We also need the derivative

$$y' = -5a \sin 5x + 5b \cos 5x.$$

At $x = 0$ we have from this and the initial conditions

$$y(0) = a = 0.8, \qquad y'(0) = 5b = -6.5, \qquad b = -1.3.$$

Hence the solution of the initial value problem is

$$y = 0.8 \cos 5x - 1.3 \sin 5x.$$

4. e^{3x} and xe^{3x} form a linearly independent set on any interval because $xe^{3x}/e^{3x} = x$ is not constant. The corresponding general solution is

$$y = (c_1 x + c_2)e^{3x}$$

and has the derivative

$$y' = (c_1 + 3c_1 x + 3c_2)e^{3x}.$$

From this and the initial conditions we obtain

$$y(0) = c_2 = -1.4, \qquad y'(0) = c_1 + 3c_2 = c_1 - 4.2 = 4.6, \qquad c_1 = 8.8.$$

The *answer* is the particular solution

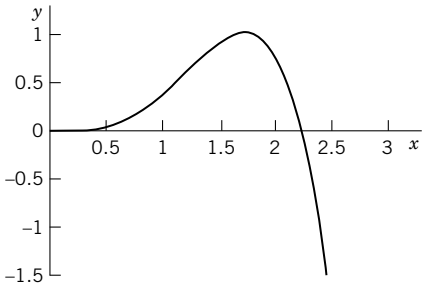
$$y = (8.8x - 1.4)e^{3x}.$$

6. This is an example of an Euler–Cauchy equation $x^2y'' + axy' + by = 0$, which we shall consider systematically in Sec. 2.5. Substitution shows that x^3 and x^5 are solutions of the given ODE, and they are linearly independent on any interval because their quotient $x^5/x^3 = x^2$ is not constant. Hence the corresponding general solution is

$$y = c_1 x^3 + c_2 x^5.$$

Its derivative is

$$y' = 3c_1 x^2 + 5c_2 x^4.$$



From this and the initial conditions we have

$$y(1) = c_1 + c_2 = 0.4, \qquad y'(1) = 3c_1 + 5c_2 = 1.0.$$

Hence $c_1 = 0.5$ and $c_2 = -0.1$, so that the solution (the particular solution satisfying the initial conditions) is (see the figure)

$$y = 0.5x^3 - 0.1x^5.$$

im02.qxd 9/21/05 10:57 AM Page 32

Section 2.1. Problem 6

8. Yes when $n \neq 2$. Emphasize that we also have linear independence when $n = 0$.

The intervals given in Probs. 7−14 serve as reminder that linear independence and dependence always refer to an interval, never just to a single point, and they also help exclude points at which one of the functions is not defined.

Linear independence is important in connection with general solutions, and these problems are such that the computer is of no great help.

The functions are selected as they will occur in some of the later work. They also encourage the student to think of functional relations between those functions. For instance, $\ln x^2 = 2 \ln x$ in Prob. 11 and the formula for $\sin 2x$ in Prob. 13 help in obtaining the right answer (linear dependence).

10. Yes. The relation $\cos^2 x + \sin^2 x = 1$ is irrelevant here.

12. Yes. Consider the quotient.

14. No. Once and for all, we have linear dependence of two (or more) functions if one of them is identically 0. This problem is important.

16. $y'' = \dfrac{dy'}{dx} = \dfrac{dy'}{dy}\dfrac{dy}{dx} = \dfrac{dz}{dy}\,z$

18. $z' = 1 + z^2$, $dz/(1 + z^2) = dx$, $\arctan z = x + c_1$, $z = \tan(x + c_1)$, $y = -\ln|\cos(x + c_1)| + c_2$

This is an obvious use of problems from Chap. 1 in setting up problems for this section. The only difficulty may be an unpleasant additional integration.

20. The formula in the text was derived under the assumption that the ODE is in standard form; in the present case,

$$y'' + \frac{2}{x}\,y' + y = 0.$$

Hence $p = 2/x$, so that $e^{-\int p\,dx} = x^{-2}$. It follows from (9) in the text that

$$U = \frac{x^2}{\cos^2 x} \cdot \frac{1}{x^2} = \frac{1}{\cos^2 x}\,.$$

The integral of U is $\tan x$; we need no constants of integration because we merely want to obtain a particular solution. The *answer* is

$$y_2 = y_1 \tan x = \frac{\sin x}{x}\,.$$

22. The standard form is

$$y'' - \frac{2x}{1 - x^2}\,y' + \frac{2}{1 - x^2}\,y = 0.$$

im02.qxd 9/21/05 10:57 AM Page 33

Hence in (9) we have

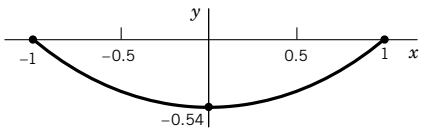
$$-\int p\,dx = \int \frac{2x}{1-x^2}\,dx = -\ln|1-x^2| = \ln\left|\frac{1}{1-x^2}\right|.$$

This gives, in terms of partial fractions,

$$U = \frac{1}{x^2}\cdot\frac{1}{1-x^2} = \frac{1}{x^2} + \frac{1/2}{x+1} - \frac{1/2}{x-1}.$$

By integration we get the *answer*

$$y_2 = y_1 u = y_1 \int U\,dx = -1 + \tfrac{1}{2}x \ln\left|\frac{x+1}{x-1}\right|.$$



The equation is Legendre's equation with parameter $n = 1$ (as, of course, need *not* be mentioned to the student), and the solution is essentially a Legendre function. This problem shows the usefulness of the reduction method because it is not difficult to see that $y_1 = x$ is a solution. In contrast, the power series method (the standard method) would give the second solution as an infinite series, whereas by our present method we get the solution directly, bypassing infinite series in the present special case $n = 1$.

Also note that the transition to $n = 2, 3, \cdots$ is not very complicated because U depends only on the coefficient p of the ODE, which remains the same for all n, since n appears only in the last term of the ODE. Hence if we want the answer for other n, all we have to do is insert another Legendre polynomial for y_1 instead of the present $y_1 = x$.

24. $z' = (1+z^2)^{1/2}$, $(1+z^2)^{-1/2}\,dz = dx$, $\operatorname{arcsinh} z = x + c_1$. From this, $z = \sinh(x + c_1)$, $y = \cosh(x + c_1) + c_2$. From the boundary conditions $y(1) = 0$, $y(-1) = 0$ we get

$$\cosh(1 + c_1) + c_2 = 0 = \cosh(-1 + c_1) + c_2.$$

Hence $c_1 = 0$ and then $c_2 = -\cosh 1$. The *answer* is (see the figure) $y = \cosh x - \cosh 1$.

Section 2.1. Problem 24

SECTION 2.2. Homogeneous Linear ODEs with Constant Coefficients, page 53

Purpose. To show that homogeneous linear ODEs with constant coefficients can be solved by algebra, namely, by solving the quadratic characteristics equation (3). The roots may be:

(Case I) Real distinct roots

(Case II) A real double root ("Critical case")

(Case III) Complex conjugate roots.

In Case III the roots are conjugate because the coefficients of the ODE, and thus of (3), are real, a fact the student should remember.

im02.qxd 9/21/05 10:57 AM Page 34

To help poorer students, we have shifted the derivation of the real form of the solutions in Case III to the end of the section, but the verification of these real solutions is done immediately when they are introduced. This will also help to a better understanding.

The student should become aware of the fact that Case III includes both undamped (harmonic) oscillations (if $c = 0$) and damped oscillations.

Also it should be emphasized that in the transition from the complex to the real form of the solutions we use the superposition principle.

Furthermore, one should emphasize the general importance of the Euler formula (11), which we shall use on various occasions.

Comment on How to Avoid Working in Complex

The average engineering student will profit from working a little with complex numbers. However, if one has reasons for avoiding complex numbers here, one may apply the method of eliminating the first derivative from the equation, that is, substituting $y = uv$ and determining v so that the equation for u does not contain u'. For v this gives

$$2v' + av = 0. \qquad \text{A solution is} \qquad v = e^{-ax/2}.$$

With this v, the equation for u takes the form

$$u'' + (b - \tfrac{1}{4}a^2)u = 0$$

and can be solved by remembering from calculus that $\cos \omega x$ and $\sin \omega x$ reproduce under two differentiations, multiplied by $-\omega^2$. This gives (9), where

$$\omega = \sqrt{b - \tfrac{1}{4}a^2}.$$

Of course, ***the present approach can be used to handle all three cases.*** In particular, $u'' = 0$ in Case II gives $u = c_1 + c_2x$ at once.

SOLUTIONS TO PROBLEM SET 2.2, page 59

2. The standard form is

$$y'' - 0.7y' + 0.12y = 0.$$

The characteristic equation

$$\lambda^2 - 0.7\lambda + 0.12 = (\lambda - 0.4)(\lambda - 0.3) = 0$$

has the roots 0.4 and 0.3, so that the corresponding general solution is

$$y_1 = c_1e^{0.4x} + c_2e^{0.3x}.$$

4. The characteristic equation $\lambda^2 + 4\pi\lambda + 4\pi^2 = (\lambda + 2\pi)^2 = 0$ has the double root -2π, so that the corresponding general solution is

$$y = (c_1 + c_2x)e^{-2\pi x}.$$

6. The characteristic equation $\lambda^2 + 2\lambda + 5 = (\lambda + 1)^2 + 4 = 0$ has the roots $-1 \pm 2i$, so that the general solution is

$$y = e^{-x}(A \cos 2x + B \sin 2x).$$

8. The characteristic equation is $\lambda^2 + 2.6\lambda + 1.69 = (\lambda + 1.3)^2 = 0$, so that we obtain the general solution

$$y = (c_1 + c_2x)e^{-1.3x}.$$

im02.qxd 9/21/05 10:57 AM Page 35

10. From the characteristic equation $\lambda^2 - 2 = (\lambda + \sqrt{2})(\lambda - \sqrt{2}) = 0$ we see that the corresponding general solution is

$$y = c_1 e^{-x\sqrt{2}} + c_2 e^{x\sqrt{2}}$$

12. The characteristic equation $\lambda^2 + 2.4\lambda + 4 = (\lambda + 1.2)^2 + 1.6^2 = 0$ has the roots $-1.2 \pm 1.6i$. The corresponding general solution is

$$y = e^{-1.2x}(A \cos 1.6x + B \sin 1.6x).$$

14. The characteristic equation $\lambda^2 + \lambda - 0.96 = (\lambda - 0.6)(\lambda + 1.6) = 0$ has the roots 0.6 and -1.6 and thus gives the general solution

$$y = c_1 e^{0.6x} + c_2 e^{-1.6x}.$$

16. To the given basis there corresponds the characteristic equation

$$(\lambda - 0.5)(\lambda + 3.5) = \lambda^2 + 3\lambda - 1.75 = 0.$$

The corresponding ODE is

$$y'' + 3y' - 1.75y = 0.$$

18. The characteristic equation $\lambda(\lambda + 3) = \lambda^2 + 3\lambda = 0$ gives the ODE $y'' + 3y' = 0$.

20. We see that the characteristic equation is

$$(\lambda + 1 - i)(\lambda + 1 + i) = \lambda^2 + 2\lambda + 2 = 0$$

and obtain from it the ODE

$$y'' + 2y' + 2y = 0.$$

22. From the characteristic equation

$$\lambda^2 + 2\lambda + 1 = (\lambda + 1)^2 = 0$$

we obtain the general solution

$$y = (c_1 + c_2 x)e^{-x}.$$

Its derivative is

$$y' = (c_2 - c_1 - c_2 x)e^{-x}.$$

Setting $x = 0$, we obtain

$$y(0) = c_1 = 4, \qquad y'(0) = c_2 - c_1 = c_2 - 4 = -6, \qquad c_2 = -2.$$

This gives the particular solution

$$y = (4 - 2x)e^{-x}.$$

24. The characteristic equation is

$$10\lambda^2 - 50\lambda + 65 = 10[\lambda^2 - 5\lambda + 6.5] = 10[(\lambda - 2.5)^2 + 0.25] = 0.$$

Hence a general solution is

$$y = e^{2.5x}(A \cos 0.5x + B \sin 0.5x) \qquad \text{and} \qquad y(0) = A = 1.5.$$

From this we obtain the derivative

$$y' = e^{2.5x}(2.5 \cdot 1.5 \cos 0.5x + 2.5B \sin 0.5x - 0.75 \sin 0.5x + 0.5B \cos 0.5x).$$

im02.qxd 9/21/05 10:57 AM Page 36

From this and the second initial condition we obtain

$$y'(0) = 3.75 + 0.5B = 1.5; \qquad \text{hence} \qquad B = -4.5.$$

The *answer* is

$$y = e^{2.5x}(1.5 \cos 0.5x - 4.5 \sin 0.5x).$$

26. Dividing the ODE by 10 to get the standard form, we see that the characteristic equation is

$$\lambda^2 + 1.8\lambda + 0.56 = (\lambda + 0.4)(\lambda + 1.4) = 0.$$

Hence a general solution is

$$y = c_1e^{-0.4x} + c_2e^{-1.4x}.$$

Now $y(0) = c_1 + c_2 = 4$ from the first initial condition, and by differentiation and from the second initial condition,

$$-0.4c_1 - 1.4c_2 = -3.8.$$

The solution of this system of equations is $c_1 = 1.8$, $c_2 = 2.2$. Hence the initial value problem has the solution

$$y = 1.8e^{-0.4x} + 2.2e^{-1.4x}.$$

28. The roots of the characteristic equation $\lambda^2 - 9 = 0$ are 3 and -3. Hence a general solution is

$$y = c_1e^{-3x} + c_2e^{3x}.$$

Now $c_1 + c_2 = -2$ from the first initial condition. By differentiation and from the second initial condition, $-3c_1 + 3c_2 = -12$. The solution of these two equations is $c_1 = 1$, $c_2 = -3$. Hence the *answer* is

$$y = e^{-3x} - 3e^{3x}.$$

30. The characteristic equation is

$$\lambda^2 + 2k\lambda + (k^2 + \omega^2) = (\lambda + k)^2 + \omega^2 = 0.$$

Its roots are $-k \pm i\omega$. Hence a general solution is

$$y = e^{-kx}(A \cos \omega x + B \sin \omega x).$$

For $x = 0$ this gives $y(0) = A = 1$. With this value of A the derivative is

$$y' = e^{-kx}(-k \cos \omega x - Bk \sin \omega x - \omega \sin \omega x + B\omega \cos \omega x).$$

For $x = 0$ we obtain from this and the second initial condition

$$y'(0) = -k + B\omega = -k; \qquad \text{hence} \qquad B = 0.$$

The *answer* is

$$y = e^{-kx} \cos \omega x.$$

32. The characteristic equation is $\lambda^2 - 2\lambda - 24 = (\lambda - 6)(\lambda + 4) = 0$. This gives as a general solution

$$y = c_1e^{6x} + c_2e^{-4x}.$$

Hence $y(0) = c_1 + c_2 = 0$, and by differentiation, $6c_1 - 4c_2 = y'(0) = 20$. The *answer* is

$$y = 2e^{6x} - 2e^{-4x}.$$

im02.qxd 9/21/05 10:57 AM Page 37

34. Team Project. (A) We obtain

$$(\lambda - \lambda_1)(\lambda - \lambda_2) = \lambda^2 - (\lambda_1 + \lambda_2)\lambda + \lambda_1\lambda_2 = \lambda^2 + a\lambda + b = 0.$$

Comparison of coefficients gives $a = -(\lambda_1 + \lambda_2)$, $b = \lambda_1\lambda_2$.

(B) $y'' + ay' = 0$. (i) $y = c_1e^{-ax} + c_2e^{0x} = c_1e^{-ax} + c_2$. (ii) $z' + az = 0$, where $z = y'$, $z = ce^{-ax}$ and the second term comes in by integration:

$$y = \int z\,dx = \tilde{c}_1e^{-ax} + \tilde{c}_2.$$

(D) $e^{(k+m)x}$ and e^{kx} satisfy $y'' - (2k + m)y' + k(k + m)y = 0$, by the coefficient formulas in part (A). By the superposition principle, another solution is

$$\frac{e^{(k+m)x} - e^{kx}}{m}.$$

We now let $m \to 0$. This becomes 0/0, and by l'Hôpital's rule (differentiation of numerator and denominator separately with respect to m, not x!) we obtain

$$xe^{kx}/1 = xe^{kx}.$$

The ODE becomes $y'' - 2ky' + k^2y = 0$. The characteristic equation is

$$\lambda^2 - 2k\lambda + k^2 = (\lambda - k)^2 = 0$$

and has a double root. Since $a = -2k$, we get $k = -a/2$, as expected.

SECTION 2.3. Differential Operators. *Optional,* page 59

Purpose. To take a short look at the operational calculus of second-order differential operators with constant coefficients, which parallels and confirms our discussion of ODEs with constant coefficients.

SOLUTIONS TO PROBLEM SET 2.3, page 61

2. $(8D^2 + 2D - I)(\cosh \frac{1}{2}x) = 8 \cdot \frac{1}{4}\cosh \frac{1}{2}x + 2 \cdot \frac{1}{2}\sinh \frac{1}{2}x - \cosh \frac{1}{2}x = e^{x/2}$. The same result is obtained for $\sinh \frac{1}{2}x$. By addition of these two results we obtain the result $2e^{x/2}$ for $e^{x/2}$.

4. $(D + 5I)(D - I) = (D - I)(D + 5I)$, and

$$(D - I)(D + 5I)(e^{-5x}\sin x) = (D - I)(-5e^{-5x}\sin x + e^{-5x}\cos x + 5e^{-5x}\sin x)$$

$$= (D - I)(e^{-5x}\cos x)$$

$$= -6e^{-5x}\cos x - e^{-5x}\sin x.$$

For the second given function the *answer* is $40e^{5x}$ and for the third it is $-5x^2 + 8x + 2$.

6. $(D - 3.7I)(D - 1.8I)$, $y = c_1e^{3.7x} + c_2e^{1.8x}$

8. $(D - 0.7I)(D + 0.7I)$, $y = c_1e^{0.7x} + c_2e^{-0.7x}$

10. $(D + (0.1 + 0.4i)I)(D + (0.1 - 0.4i)I)$, $y = e^{-0.1x}(A\cos 0.4x + B\sin 0.4x)$

12. $4(D + \frac{1}{2}\pi I)^2$, $y = (c_1 + c_2x)e^{-\pi x/2}$

14. y is a solution, as follows from the superposition principle in Sec. 2.1 because the ODE is homogeneous linear. In the application of l'Hôpital's rule, y is regarded as a function of μ, the variable that is approaching the limit, whereas λ is fixed.

im02.qxd 9/21/05 10:57 AM Page 38

Accordingly, differentiation of the numerator with respect to μ gives $xe^{\mu x} - 0$, and differentiation of the denominator gives 1. The limit of this is $xe^{\lambda x}$.

16. The two conditions follow trivially from the condition in the text. Conversely, by combining the two conditions we have

$$L(cy + kw) = L(cy) + L(kw) = cLy + kLw.$$

SECTION 2.4. Modeling: Free Oscillations (Mass–Spring System), page 61

Purpose. To present a main application of second-order constant-coefficient ODEs

$$my'' + cy' + ky = 0$$

resulting as models of motions of a mass m on an elastic spring of modulus k (> 0) under linear damping c ($\geqq 0$) by applying Newton's second law and Hooke's law. These are free motions (no driving force). Forced motions follow in Sec. 2.8.

This system should be regarded as a basic building block of more complicated systems, a prototype of a vibrating system that shows the essential features of more sophisticated systems as they occur in various forms and for various purposes in engineering.

The quantitative agreement between experiments of the physical system and its mathematical model is surprising. Indeed, the student should not miss performing experiments if there is an opportunity, as I had as a student of Prof. Blaess, the inventor of a (now obscure) graphical method for solving ODEs.

Main Content, Important Concepts

Restoring force ky, damping force cy', force of inertia my''

No damping, harmonic oscillations (4), natural frequency $\omega_0/(2\pi)$

Overdamping, critical damping, nonoscillatory motions (7), (8)

Underdamping, damped oscillations (10)

SOLUTIONS TO PROBLEM SET 2.4, page 68

2. (i) $\sqrt{k_1/m}/(2\pi) = 3/(2\pi)$, (ii) $5/(2\pi)$

(iii) Let K denote the modulus of the springs in parallel. Let F be some force that stretches the combination of springs by an amount s_0. Then $F = Ks_0$. Let $k_1 s_0 = F_1$, $k_2 s_0 = F_2$. Then

$$F = F_1 + F_2 = (k_1 + k_2)s_0.$$

By comparison, $K = k_1 + k_2 = 102$ [nt/m], $\sqrt{K/m}/(2\pi) = \sqrt{34}/(2\pi) = 5.83/(2\pi)$.

(iv) Let $F = k_1 s_1$, $F = k_2 s_2$. Then if we attach the springs in series, the extensions s_1 and s_2 under F add, so that $F = k(s_1 + s_2)$, where k is the modulus of the combination. Substitution of s_1 and s_2 from the other two equations gives

$$F = k(F/k_1 + F/k_2).$$

Division by kF gives

$$1/k = 1/k_1 + 1/k_2, \qquad k = k_1 k_2/(k_1 + k_2) = 19.85.$$

Hence the frequency is

$$f = \sqrt{k/m}/(2\pi) = \sqrt{6.62}/(2\pi) = 2.57/(2\pi).$$

im02.qxd 9/21/05 10:57 AM Page 39

4. $mg = ks_0$ by Hooke's law. Hence $k = mg/s_0$, and

$$f = (1/2\pi)\sqrt{k/m} = (1/2\pi)\sqrt{mg/s_0 m} = (1/2\pi)\sqrt{g/s_0} = (1/2\pi)\sqrt{9.80/0.1}.$$

The numeric value of the last expression is 1.58 sec^{-1}, approximately; here, $s_0 = 10$ cm $= 0.1$ m is given.

6. $my'' = -\pi \cdot 0.3^2 y\gamma$, where $\pi \cdot 0.3^2 y$ is the volume of water displaced when the buoy is depressed y meters from its equilibrium position, and $\gamma = 9800$ nt is the weight of water per cubic meter. Thus $y'' + \omega_0{}^2 y = 0$, where $\omega_0{}^2 = \pi \cdot 0.3^2\gamma/m$ and the period is $2\pi/\omega_0 = 2$; hence

$$m = \pi \cdot 0.3^2\gamma/\omega_0{}^2 = 0.3^2\gamma/\pi = 281$$

$$W = mg = 281 \cdot 9.80 = 2754 \text{ [nt]} \quad \text{(about 620 lb)}.$$

8. Team Project. (a) $W = ks_0 = 25$, $s_0 = 2$, $m = W/g$, and

$$\omega_0 = \sqrt{k/m} = \sqrt{(W/s_0)/(W/g)} = \sqrt{980/2} = 22.14.$$

This gives the general solution

$$y = A \cos 22.14t + B \sin 22.14t.$$

Now $y(0) = A = 0$, $y' = 22.14B \cos 22.14t$, $y'(0) = 22.14B = 15$, $B = 0.6775$. Hence the particular solution satisfying the given initial conditions is

$$y = 0.6775 \sin 22.14t \text{ [cm]}.$$

(b) $\omega_0 = \sqrt{K/I_0} = \sqrt{17.64} = 4.2 \text{ sec}^{-1}$. Hence a general solution is

$$\theta = A \cos 4.2t + B \sin 4.2t.$$

The derivative is

$$\theta' = -4.2A \sin 4.2t + 4.2B \cos 4.2t.$$

The initial conditions give $\theta(0) = A = \pi/4 = 0.7854$ rad (45°) and

$\theta'(0) = \pi/12 = 0.2618 \text{ rad} \cdot \text{sec}^{-1}$ (15°sec^{-1}), hence $B = 0.2618/4.2 = 0.0623$.

The *answer* is

$$\theta = 0.7854 \cos 4.2t + 0.0623 \sin 4.2t.$$

(c) The force of inertia in Newton's second law is my'', where $m = 5$ kg is the mass of the water. The dark blue portion of the water in Fig. 45, a column of height $2y$, is the portion that causes the restoring force of the vibration. Its volume is $\pi \cdot 0.02^2 \cdot 2y$. Hence its weight is $\pi \cdot 0.02^2 \cdot 2y\gamma$, where $\gamma = 9800$ nt is the weight of water per cubic meter. This gives the ODE

$$y'' + \omega_0{}^2 y = 0$$

where

$$\omega_0{}^2 = \frac{\pi \cdot 0.02^2 \cdot 2 \cdot \gamma}{5} = 0.000\,5027\gamma = 4.926$$

and $\omega_0 = 2.219$. Hence the corresponding general solution is

$$y = A \cos 2.219t + B \sin 2.219t.$$

The frequency is $\omega_0/(2\pi) = 0.353$ [sec^{-1}], so that the water makes about 20 oscillations per minute, or one cycle in about 3 sec.

im02.qxd 9/21/05 10:57 AM Page 40

10. $y' = e^{-2t}(-2\cos t - \sin t) = 0$, $\tan t = -2$, $t = 2.0344 + n\pi$, $n = 0, 1, \cdots$.

12. If an extremum is at t_0, the next one is at $t_1 = t_0 + \pi/\omega^*$, by Prob. 11. Since the cosine and sine in (10) have period $2\pi/\omega^*$, the amplitude ratio is

$$\exp(-\alpha t_0)/\exp(-\alpha t_1) = \exp(-\alpha(t_0 - t_1)) = \exp(\alpha\pi/\omega^*).$$

The natural logarithm is $\alpha\pi/\omega^*$, and maxima alternate with minima. Hence $\Delta = 2\pi\alpha/\omega^*$ follows.

For the ODE, $\Delta = 2\pi \cdot 1/(\frac{1}{2}\sqrt{4 \cdot 5 - 2^2}) = \pi$.

14. $2\pi/\omega^* = 2$ sec; $\omega^* = \pi$. The time for 15 cycles is $t = 30$ sec. The quotient of the corresponding amplitudes at t_0 and $t_0 + 30$ is

$$e^{-\alpha(t_0+30)}/e^{-\alpha t_0} = e^{-\alpha \cdot 30} = 0.25.$$

Thus $e^{30\alpha} = 4$, $\alpha = (\ln 4)/30 = 0.0462$. Now $\alpha = c/(2m) = c/4$; hence $c = 4\alpha = 0.1848$.

To check this, use $\omega^{*2} \cdot 4m^2 = 4mk - c^2$ by (9) which gives

$$k = \frac{1}{4m}(4m^2\omega^{*2} + c^2) = \frac{1}{4m}(4m^2\pi^2 + c^2) = 19.74,$$

and solve $2y'' + 0.1848y' + 19.74y = 0$ to get

$$y = e^{-0.0462t}(A\cos 3.14t + B\sin 3.14t) \qquad \text{and} \qquad e^{-0.0462 \cdot 30} = \tfrac{1}{4}.$$

16. $y = c_1e^{-(\alpha-\beta)t} + c_2e^{-(\alpha+\beta)t}$, $y(0) = c_1 + c_2 = y_0$. By differenting and setting $t = 0$ it follows that

$$y'(0) = (-\alpha + \beta)c_1 + (-\alpha - \beta)c_2 = v_0.$$

From the first equation, $c_2 = y_0 - c_1$. By substitution and simplification,

$$(-\alpha + \beta)c_1 + (-\alpha - \beta)(y_0 - c_1) = v_0$$

$$c_1(-\alpha + \beta + \alpha + \beta) = v_0 + (\alpha + \beta)y_0.$$

This yields the *answer*

$$c_1 = [(\alpha + \beta)y_0 + v_0]/(2\beta), \qquad c_2 = [(\beta - \alpha)y_0 - v_0]/(2\beta).$$

18. CAS Project. (a) The three cases appear, along with their typical solution curves, regardless of the numeric values of k/m, $y(0)$, etc.

(b) The first step is to see that Case II corresponds to $c = 2$. Then we can choose other values of c by experimentation. In Fig. 46 the values of c (omitted on purpose; the student should choose!) are 0 and 0.1 for the oscillating curves, 1, 1.5, 2, 3 for the others (from below to above).

(c) This addresses a general issue arising in various problems involving heating, cooling, mixing, electrical vibrations, and the like. One is generally surprised how quickly certain states are reached whereas the theoretical time is infinite.

(d) General solution $y(t) = e^{-ct/2}(A\cos\omega^*t + B\sin\omega^*t)$, where $\omega^* = \frac{1}{2}\sqrt{4 - c^2}$. The first initial condition $y(0) = 1$ gives $A = 1$. For the second initial condition we need the derivative (we can set $A = 1$)

$$y'(t) = e^{-ct/2}\left(-\frac{c}{2}\cos\omega^*t - \frac{c}{2}B\sin\omega^*t - \omega^*\sin\omega^*t + \omega^*B\cos\omega^*t\right).$$

im02.qxd 9/21/05 10:57 AM Page 41

From this we obtain $y'(0) = -c/2 + \omega^* B = 0$, $B = c/(2\omega^*) = c/\sqrt{4 - c^2}$. Hence the particular solution (with c still arbitrary, $0 < c < 2$) is

$$y(t) = e^{-ct/2}\left(\cos \omega^* t + \frac{c}{\sqrt{4 - c^2}} \sin \omega^* t\right).$$

Its derivative is, since the cosine terms drop out,

$$y'(t) = e^{-ct/2}(-\sin \omega^* t)\left(\frac{c^2}{2\sqrt{4 - c^2}} + \frac{1}{2}\sqrt{4 - c^2}\right)$$

$$= \frac{-2}{\sqrt{4 - c^2}} e^{-ct/2} \sin \omega^* t.$$

The tangent of the y-curve is horizontal when $y' = 0$, for the first positive time when $\omega^* t = \pi$; thus $t = t_2 = \pi/\omega^* = 2\pi/\sqrt{4 - c^2}$. Now the y-curve oscillates between $\pm e^{-ct/2}$, and (11) is satisfied if $e^{-ct/2}$ does not exceed 0.001. Thus $ct = 2 \ln 1000$, and $t = t_2$ gives the best c satisfying (11). Hence

$$c = (2 \ln 1000)/t_2, \qquad c^2 = \frac{(\ln 1000)^2}{\pi^2}(4 - c^2).$$

The solution of this is $c = 1.821$, approximately. For this c we get by substitution $\omega^* = 0.4141$, $t_2 = 7.587$, and the particular solution

$$y(t) = e^{-0.9103t}(\cos 0.4141t + 2.199 \sin 0.4141t).$$

The graph shows a positive maximum near 15, a negative minimum near 23, a positive maximum near 30, and another negative minimum at 38.

(e) The main difference is that Case II gives

$$y = (1 - t)e^{-t}$$

which is negative for $t > 1$. The experiments with the curves are as before in this project.

SECTION 2.5. Euler–Cauchy Equations, page 69

Purpose. Algebraic solution of the Euler–Cauchy equation, which appears in certain applications (see our Example 4) and which we shall need again in Sec. 5.4 as the simplest equation to which the Frobenius method applies. We have three cases; this is similar to the situation for constant-coefficient equations, to which the Euler–Cauchy equation can be transformed (Team Project 16); however, this fact is of theoretical rather than of practical interest.

Comment on Footnote 4

Euler worked in St. Petersburg 1727–1741 and 1766–1783 and in Berlin 1741–1766. He investigated Euler's constant (Sec. 5.6) first in 1734, used Euler's formula (Secs. 2.2, 13.5, 13.6) beginning in 1740, introduced integrating factors (Sec. 1.4) in 1764, and studied conformal mappings (Chap. 17) starting in 1770. His main influence on the development of mathematics and mathematical physics resulted from his textbooks, in particular from his famous *Introductio in analysin infinitorum* (1748), in which he also introduced many of the modern notations (for trigonometric functions, etc.). Euler was the central figure of the mathematical activity of the 18th century. His Collected Works are still incomplete, although some seventy volumes have already been published.

im02.qxd 9/21/05 10:57 AM Page 42

Cauchy worked in Paris, except during 1830–1838, when he was in Turin and Prague. In his two fundamental works, *Cours d'Analyse* (1821) and *Résumé des leçons données à l'École royale polytechnique* (vol. 1, 1823), he introduced more rigorous methods in calculus, based on an exactly defined limit concept; this also includes his convergence principle (Sec. 15.1). Cauchy also was the first to give existence proofs in ODEs. He initiated complex analysis; we discuss his main contributions to this field in Secs. 13.4, 14.2−14.4, and 15.2. His famous integral theorem (Sec. 14.2) was published in 1825 and his paper on complex power series and their radius of convergence (Sec. 15.2), in 1831.

SOLUTIONS TO PROBLEM SET 2.5, page 72

2. $4m(m-1)+4m-1=4(m-\frac{1}{2})(m+\frac{1}{2})=0$, $c_1\sqrt{x}+c_2/\sqrt{x}$

4. $(c_1+c_2\ln x)/x$

6. $2[m(m-1)+2m+2.5]=2(m^2+m+2.5)=2\big[(m+\frac{1}{2})^2+1.5^2\big]=0$. The roots are $-0.5\pm 1.5i$. Hence the corresponding real general solution is

$$y=x^{-0.5}[A\cos(1.5\ln|x|)+B\sin(1.5\ln|x|)].$$

8. $4(m(m-1)+\frac{1}{4})=4(m-\frac{1}{2})^2=0$ has the double root $m=\frac{1}{2}$; hence a general solution is

$$y=(c_1+c_2\ln|x|)\sqrt{x}.$$

10. $10m(m-1)+6m+0.5=10[m(m-1)+0.6m+0.05]=10[m^2-0.4m+0.05]$ $=10\big[(m-0.2)^2+0.1^2\big]=0$. Hence a real general solution is

$$y=x^{0.2}[A\cos(0.1\ln|x|)+B\sin(0.1\ln|x|)].$$

12. The auxiliary equation is

$$m(m-1)+3m+1=m^2+2m+1=(m+1)^2=0.$$

It has the double root -1. Hence a general solution is

$$y=(c_1+c_2\ln|x|)/x.$$

The first initial condition gives $y(1)=c_1=4$. The derivative of y is

$$y'=c_2/x^2+(c_1+c_2\ln|x|)/(-x^2).$$

Hence the second initial condition gives $y'(1)=c_2-c_1=-2$. Thus $c_2=2$. This gives the particular solution

$$y=(4+2\ln|x|)/x.$$

Make sure to explain to the student why we cannot prescribe initial conditions at $t=0$, where the coefficients of the ODE written in standard form (divide by x^2) become infinite.

14. The auxiliary equation is

$$m(m-1)-2m+2.25=m^2-3m+2.25=(m-1.5)^2=0,$$

so that a general solution is

$$y=(c_1+c_2\ln|x|)x^{1.5}.$$

The first initial condition gives $y(1)=c_1=2.2$. The derivative is

$$y'=(c_2/x)x^{1.5}+1.5(c_1+c_2\ln|x|)x^{0.5}.$$

im02.qxd 9/21/05 10:57 AM Page 43

From this and the second initial condition we obtain

$$y'(1) = c_2 + 1.5c_1 = 2.5;$$

hence

$$c_2 = 2.5 - 1.5c_1 = -0.8.$$

16. Team Project. (A) The student should realize that the present steps are the same as in the general derivation of the method in Sec. 2.1. An advantage of such specific derivations may be that the student gets a somewhat better understanding of the method and feels more comfortable with it. Of course, once a general formula is available, there is no objection to applying it to specific cases, but often a direct derivation may be simpler. In that respect the present situation resembles, for instance, that of the integral solution formula for first-order linear ODEs in Sec. 1.5.

(B) The Euler–Cauchy equation to start from is

$$x^2y'' + (1 - 2m - s)xy' + m(m + s)y = 0$$

where $m = (1 - a)/2$, the exponent of the one solution we first have in the critical case. For $s \to 0$ the ODE becomes

$$x^2y'' + (1 - 2m)xy' + m^2y = 0.$$

Here $1 - 2m = 1 - (1 - a) = a$, and $m^2 = (1 - a)^2/4$, so that this is the Euler–Cauchy equation in the critical case. Now the ODE is homogeneous and linear; hence another solution is

$$Y = (x^{m+s} - x^m)/s.$$

L'Hôpital's rule, applied to Y as a function of s (not x, because the limit process is with respect to s, not x), gives

$$(x^{m+s} \ln |x|)/1 \to x^m \ln |x| \qquad \text{as } s \to 0.$$

This is the expected result.

(C) This is less work than perhaps expected, an exercise in the technique of differentiation (also necessary in other cases). We have $y = x^m \ln x$, and with $(\ln x)' = 1/x$ we get

$$y' = mx^{m-1} \ln |x| + x^{m-1}$$

$$y'' = m(m - 1)x^{m-2} \ln |x| + mx^{m-2} + (m - 1)x^{m-2}.$$

Since $x^m = x^{(1-a)/2}$ is a solution, in the substitution into the ODE the ln-terms drop out. Two terms from y'' and one from y' remain and give

$$x^2(mx^{m-2} + (m - 1)x^{m-2}) + ax^m = x^m(2m - 1 + a) = 0$$

because $2m = 1 - a$.

(D) $t = \ln x$, $dt/dx = 1/x$, $y' = \dot{y}t' = \dot{y}/x$, where the dot denotes the derivative with respect to t. By another differentiation,

$$y'' = (\dot{y}/x)' = \ddot{y}/x^2 + \dot{y}/(-x^2).$$

Substitution of y' and y'' into (1) gives the constant-coefficient ODE

$$\ddot{y} - \dot{y} + a\dot{y} + by = \ddot{y} + (a - 1)\dot{y} + by = 0.$$

im02.qxd 9/21/05 10:57 AM Page 44

The corresponding characteristic equation has the roots

$$\lambda = \tfrac{1}{2}(1 - a) \pm \sqrt{\tfrac{1}{4}(1 - a)^2 - b}.$$

With these λ, solutions are $e^{\lambda t} = (e^t)^\lambda = (e^{\ln |x|})^\lambda = x^\lambda$.

(E) $te^{\lambda t} = (\ln |x|)e^{\lambda \ln |x|} = (\ln |x|)(e^{\ln |x|})^\lambda = x^\lambda \ln |x|$.

SECTION 2.6. Existence and Uniqueness of Solutions. Wronskian, page 73

Purpose. To explain the theory of existence of solutions of ODEs with variable coefficients in standard form (that is, with y'' as the first term, not, say, $f(x)y''$)

$$y'' + p(x)y' + q(x)y = 0$$

and of their uniqueness if initial conditions

$$y(x_0) = K_0, \qquad y'(x_0) = K_1$$

are imposed. Of course, no such theory was needed in the last sections on ODEs for which we were able to write all solutions explicitly.

Main Content

Continuity of coefficients suffices for existence and uniqueness.

Linear independence if and only if the Wronskian is not zero

A general solution exists and includes all solutions.

Comment on Wronskian

For $n = 2$, where linear independence and dependence can be seen immediately, the Wronskian serves primarily as a tool in our proofs; the practical value of the independence criterion will appear for higher n in Chap. 3.

Comment on General Solution

Theorem 4 shows that linear ODEs (actually, of any order) have no singular solutions. This also justifies the term "general solution," on which we commented earlier. We did not pay much attention to singular solutions, which sometimes occur in geometry as envelopes of one-parameter families of straight lines or curves.

SOLUTIONS TO PROBLEM SET 2.6, page 77

2. $y'' + \pi^2 y = 0$. Wronskian

$$W = \begin{vmatrix} \cos \pi x & \sin \pi x \\ -\pi \sin \pi x & \pi \cos \pi x \end{vmatrix} = \pi.$$

4. Auxiliary equation $(m - 3)(m + 2) = m^2 - m - 6 = m(m - 1) - 6 = 0$. Hence the ODE is $x^2y'' - 6y = 0$. The Wronskian is

$$W = \begin{vmatrix} x^3 & x^{-2} \\ 3x^2 & -2x^{-3} \end{vmatrix} = -2 - 3 = -5.$$

6. Characteristic equation $(\lambda - 3.4)(\lambda + 2.5) = \lambda^2 - 0.9\lambda - 8.5 = 0$. Hence the ODE is $y'' - 0.9y' - 8.5y = 0$. Wronskian

$$W = \begin{vmatrix} e^{3.4x} & e^{-2.5x} \\ 3.4e^{3.4x} & -2.5e^{-2.5x} \end{vmatrix} = -5.9e^{0.9x}.$$

im02.qxd 9/21/05 10:57 AM Page 45

8. Characteristic equation $(\lambda + 2)^2 = 0$, ODE $y'' + 4y' + 4y = 0$, Wronskian

$$W = \begin{vmatrix} e^{-2x} & xe^{-2x} \\ -2e^{-2x} & (1 - 2x)e^{-2x} \end{vmatrix} = e^{-4x}.$$

10. Auxiliary equation $(m + 3)^2 = m^2 + 6m + 9 = m(m - 1) + 7m + 9 = 0$. Hence the ODE (an Euler–Cauchy equation) is

$$x^2y'' + 7xy' + 9y = 0.$$

The Wronskian is

$$W = \begin{vmatrix} x^{-3} & x^{-3} \ln |x| \\ -3x^{-4} & -3x^{-4} \ln |x| + x^{-4} \end{vmatrix} = x^{-7}.$$

12. The characteristic equation is

$$(\lambda + 2)^2 + \omega^2 = \lambda^2 + 4\lambda + 4 + \omega^2 = 0.$$

Hence the ODE is

$$y'' + 4y' + (4 + \omega^2)y = 0.$$

The Wronskian is

$$W = \begin{vmatrix} ec & es \\ e(-2c - \omega s) & e(-2s + \omega c) \end{vmatrix} = \omega e^{-4x}$$

where $e = e^{-2x}$, $c = \cos \omega x$, and $s = \sin \omega x$.

14. The auxiliary equation is

$$(m + 1)^2 + 1 = m^2 + 2m + 2 = m(m - 1) + 3m + 2 = 0.$$

Hence the Euler–Cauchy equation is

$$x^2y'' + 3xy' + 2y = 0.$$

The Wronskian is

$$W = \begin{vmatrix} x^{-1}\, c & x^{-1}\, s \\ -x^{-2}c - x^{-1}sx^{-1} & -x^{-2}s + x^{-1}cx^{-1} \end{vmatrix} = x^{-3}$$

where x^{-1} in the second row results from the chain rule and $(\ln |x|)' = 1/x$. Here, $c = \cos (\ln |x|)$, $s = \sin (\ln |x|)$.

16. The characteristic equation is

$$(\lambda + k)^2 + \pi^2 = 0.$$

This gives the ODE

$$y'' + 2ky' + (k^2 + \pi^2)y = 0.$$

The Wronskian is

$$W = \begin{vmatrix} ec & es \\ e(-kc - s\pi) & e(-ks + c\pi) \end{vmatrix} = \pi e^{-2kx}$$

where $e = e^{-kx}$, $c = \cos \pi x$, $s = \sin \pi x$.

18. Team Project. (A) $c_1e^x + c_2e^{-x} = c_1^* \cosh x + c_2^* \sinh x$. Expressing cosh and sinh in terms of exponential functions [see (17) in App. 3.1], we have

$$\tfrac{1}{2}(c_1^* + c_2^*)e^x + \tfrac{1}{2}(c_1^* - c_2^*)e^{-x};$$

im02.qxd 9/21/05 10:57 AM Page 46

hence $c_1 = \frac{1}{2}(c_1^* + c_2^*)$, $c_2 = \frac{1}{2}(c_1^* - c_2^*)$. The student should become aware that for second-order ODEs there are several possibilities for choosing a basis and making up a general solution. For this reason we say "*a* general solution," whereas for first-order ODEs we said "*the* general solution."

(B) If two solutions are 0 at the same point x_0, their Wronskian is 0 at x_0, so that these solutions are linearly dependent by Theorem 2.

(C) The derivatives would be 0 at that point. Hence so would be their Wronskian W, implying linear dependence.

(D) By the quotient rule of differentiation and by the definition of the Wronskian,

$$(y_2/y_1)' = (y_2'y_1 - y_2y_1')/{y_1}^2 = W/{y_1}^2.$$

In Prob. 10 we have $(y_2/y_1)'{y_1}^2 = (\ln |x|)'x^{-6} = x^{-7}$.

y_2/y_1 is constant in the case of linear dependence; hence the derivative of this quotient is 0, whereas in the case of linear independence this is not the case. This makes it likely that such a formula should exist.

(E) The first two derivatives of y_1 and y_2 are continuous at $x = 0$ (the only x at which something could happen). Hence these functions qualify as solutions of a second-order ODE. y_1 and y_2 are linearly dependent for $x \geqq 0$ as well as for $x < 0$ because in each of these two intervals, one of the functions is identically 0. On $-1 < x < 1$ they are linearly independent because $c_1y_1 + c_2y_2 = 0$ gives $c_1 = 0$ when $x \geqq 0$, and $c_2 = 0$ when $x < 0$. The Wronskian is

$$W = y_1y_2' - y_2y_1' = \begin{Bmatrix} 0 \cdot 3x^2 - x^3 \cdot 0 \\ x^3 \cdot 0 - 0 \cdot 3x^2 \end{Bmatrix} = 0 \qquad \text{if } \begin{matrix} x < 0 \\ x \geqq 0 \end{matrix}.$$

The Euler–Cauchy equation satisfied by these functions has the auxiliary equation

$$(m - 3)m = m(m - 1) - 2m = 0.$$

Hence the ODE is

$$xy'' - 2y' = 0.$$

Indeed, $xy_1'' - 2y_1' = x \cdot 6x - 2 \cdot 3x^2 = 0$ if $x \geqq 0$, and $0 = 0$ for $x < 0$. Similarly for y_2. Now comes the point. In the present case the standard form, as we use it in all our present theorems, is

$$y'' - \frac{2}{x}\,y' = 0$$

and shows that $p(x)$ is not continuous at 0, as required in Theorem 2. Thus there is no contradiction.

This illustrates why the continuity assumption for the two coefficients is quite important.

(F) According to the hint given in the enunciation, the first step is to write the ODE (1) for y_1 and then again for y_2. That is,

$$y_1'' + py_1' + qy_1 = 0$$
$$y_2'' + py_2' + qy_2 = 0$$

where p and q are variable. The hint then suggests eliminating q from these two ODEs. Multiply the first equation by $-y_2$, the second by y_1, and add:

$$(y_1y_2'' - y_1''y_2) + p(y_1y_2' - y_1'y_2) = W' + pW = 0$$

im02.qxd 9/21/05 10:57 AM Page 47

where the expression for W' results from the fact that $y_1'y_2'$ appears twice and drops out. Now solve this by separating variables or as a homogeneous linear ODE.

In Prob. 12 we have $p = 4$; hence $W = ce^{-4x}$ by integration from 0 to x, where $c = y_1(0)y_2'(0) - y_2(0)y_1'(0) = 1 \cdot \omega - 0 \cdot (-2) = \omega$.

SECTION 2.7. Nonhomogeneous ODEs. page 78

Purpose. We show that for getting a general solution y of a nonhomogeneous linear ODE we must find a general solution y_h of the corresponding homogeneous ODE and then—this is our new task—any particular solution y_p of the nonhomogeneous ODE,

$$y = y_h + y_p.$$

Main Content, Important Concepts

General solution, particular solution

Continuity of p, q, r suffices for existence and uniqueness.

A general solution exists and includes all solutions.

Comment on Methods for Particular Solutions

The method of undetermined coefficients is simpler than that of variation of parameters (Sec. 2.10), as is mentioned in the text, and it is sufficient for many applications, of which Secs. 2.8 and 2.9 show standard examples.

Comment on General Solution

Theorem 2 shows that the situation with respect to general solutions is practically the same for homogeneous and nonhomogeneous linear ODEs.

Comment on Table 2.1

It is clear that the table could be extended by the inclusion of products of polynomials times cosine or sine and other cases of limited practical value. Also, $\alpha = 0$ in the last pair of lines gives the previous two lines, which are listed separately because of their practical importance.

SOLUTIONS TO PROBLEM SET 2.7, page 83

2. $y = c_1e^{-1.5x} + c_2e^{-2.5x} - 2.72 \cos 5x + 2.56 \sin 5x$. This is a typical solution of a forced oscillation problem in the overdamped case. The general solution of the homogeneous ODE dies out, practically after some short time (theoretically never), and the transient solution goes over into a harmonic oscillation whose frequency is equal to that of the driving force (or electromotive force).

4. $y = A \cos 3x + B \sin 3x + \frac{1}{8} \cos x + \frac{1}{18}x \sin 3x$. An important point is that the Modification Rule applies to the second term on the right. Hence the best way seems to split y_p additively, $y_p = y_{p1} + y_{p2}$, where

$$y_{p1} = K_1 \cos x + M_1 \sin x, \qquad y_{p2} = K_2x \cos 3x + M_2x \sin 3x.$$

In the previous problem (Prob. 3) the situation is similar.

6. $y = (c_1 + c_2x)e^{-2x} - \frac{1}{4}e^{-2x} \sin 2x$. The characteristic equation of the homogeneous ODE has the double root -2. The function on the right is such that the Modification Rule does not apply.

im02.qxd 9/21/05 10:57 AM Page 48

8. -5 is a double root. $100 \sinh 5x = 50e^{5x} - 50e^{-5x}$. Hence we may choose $y_p = y_{p1} + y_{p2}$ with $y_{p2} = Cx^2e^{-5x}$ according to the Modification Rule. Substitution gives $y_{p1} = \frac{1}{2}e^{5x}$, $y_{p2} = -25x^2e^{-5x}$. *Answer:*

$$y = (c_1 + c_2x)e^{-5x} + \tfrac{1}{2}e^{5x} - 25x^2e^{-5x}.$$

10. $y = e^{-2x}(A \cos 1.5x + B \sin 1.5x) + 0.5x^2 + 0.36x + 0.1096$. The solution of the homogeneous ODE approaches 0, and the term in x^2 becomes the dominant term.

12. Corresponding to the right side, write $y_p = y_{p1} + y_{p2}$. Find $y_{p1} = 2x$ by inspection or as usual. Since $\sin 3x$ is a solution of the homogeneous ODE, write by the Modification Rule for a simple root $y_p = x(K \cos 3x + M \sin 3x)$. *Answer:* $y = A \cos 3x + B \sin 3x + 2x - 6x \cos 3x$.

14. $2x \sin x$ is not listed in the table because it is of minor practical importance. However, by looking at its derivatives, we see that

$$y_p = Kx \cos x + Mx \sin x + N \cos x + P \sin x$$

should be general enough. Indeed, by substitution and collecting cosine and sine terms separately we obtain

(1) $$(2K + 2Mx + 2P + 2M) \cos x = 0$$

(2) $$(-2Kx + 2M - 2N - 2K) \sin x = 2x \sin x.$$

In (1) we must have $2Mx = 0$; hence $M = 0$ and then $P = -K$. In (2) we must have $-2Kx = 2x$; hence $K = -1$, so that $P = 1$ and from (2), finally, $-2N - 2K = 0$, hence $N = 1$. *Answer:*

$$y = (c_1 + c_2x)e^{-x} + (1 - x) \cos x + \sin x.$$

16. $y = y_h + y_p = (c_1 + c_2x)e^{1.5x} + 12x^2 + 20x + 16$. From this and the initial conditions,

$$y = 4[(1 + x)e^{1.5x} + 3x^2 + 5x + 4].$$

18. $y_h = c_1e^{2x} + c_2$, $y_p = C_1xe^{2x} + C_2e^{-2x}$ by the Modification Rule for a simple root. *Answer:*

$$y = 2e^{2x} - 3 + 6xe^{2x} - e^{-2x}.$$

20. The Basic Rule and the Sum Rule are needed. We obtain

$$y_h = e^{-x}(A \cos 3x + B \sin 3x)$$

$$y = e^{-x} \cos 3x - 0.4 \cos x + 1.8 \sin x + 6 \cos 3x - \sin 3x.$$

22. Team Project. (b) Perhaps the simplest way is to take a specific ODE, e.g.,

$$x^2y'' + 6xy' + 6y = r(x)$$

and then experiment by taking various $r(x)$ to find the form of choice functions. The simplest case is a single power of x. However, almost all the functions that work as $r(x)$ in the case of an ODE with constant coefficients can also be used here.

SECTION 2.8. Modeling: Forced Oscillations. Resonance, page 84

Purpose. To extend Sec. 2.4 from free to forced vibrations by adding an input (a driving force, here assumed to be sinusoidal). Mathematically, we go from a homogeneous to a nonhomogeneous ODE, which we solve by undetermined coefficients.

im02.qxd 9/21/05 10:57 AM Page 49

New Features

Resonance (11) $y = At \sin \omega_0 t$ in the undamped case

Beats (12) $y = B(\cos \omega t - \cos \omega_0 t)$ if input frequency is close to natural

Large amplitude if (15*) $\omega^2 = {\omega_0}^2 - c^2/(2m^2)$ (Fig. 56)

Phase lag between input and output

SOLUTIONS TO PROBLEM SET 2.8, page 90

2. $y_p = -0.6 \cos 1.5t + 0.2 \sin 1.5t$. Note that a general solution of the homogeneous ODE is $y_h = e^{-t}(A \cos 1.5t + B \sin 1.5t)$, and the student should perhaps be reminded that *this is not resonance*, of course.

4. $y_p = 0.25 \cos t$. Note that $y_h = e^{-2t}(A \cos t + B \sin t)$; of course, *this is not resonance.* Furthermore, it is interesting that whereas a single term on the right will generate two terms in the solution, here we have—by chance—the converse.

6. $y_p = \frac{1}{10} \cos t + \frac{1}{5} \sin t - \frac{1}{90} \cos 3t + \frac{1}{45} \sin 3t$

8. $y_p = 2 \cos 4t + 1.5 \sin 4t$

10. $y = (c_1 + c_2 t)e^{-2t} - 0.03 \cos 4t + 0.04 \sin 4t$

12. $y = c_1 e^{-t} + c_2 e^{-4t} - 0.1 \cos 2t$. Note that, ordinarily, y_p will consist of two terms if $r(x)$ consists of a single trigonometric term.

14. $y = e^{-t}(A \cos 2t + B \sin 2t) + 0.2 - 0.1 \cos t + 0.2 \sin t$

16. $y = -\frac{1}{63} \cos 8t + \frac{1}{8} \sin 8t + \frac{1}{63} \cos t$. From the graph one can see the effect of $(\cos t)/63$. There is no corresponding sine term because there is no damping and hence no phase shift.

18. $y = (33 + 31t)e^{-t} - 37.5 \cos t + 6 \cos 2t + 4.5 \sin 2t - 1.5 \cos 3t - 2 \sin 3t$

20. $y = 100 \cos 4.9t - 98 \cos 5t$

22. The form of solution curves varies continuously with c. Hence if you start from $c = 0$ and let c increase, you will at first obtain curves similar to those in the case of $c = 0$. For instance, consider $y'' + 0.01y' + 25y = 100 \cos 4.9t - 98 \cos 5t$.

24. CAS Experiment. The choice of ω needs experimentation, inspection of the curves obtained, and then changes on a trial-and-error basis. It is interesting to see how in the case of beats the period gets increasingly longer and the maximum amplitude gets increasingly larger as $\omega/(2\pi)$ approaches the resonance frequency.

26. If $0 \leqq t \leqq \pi$, then a particular solution

$$y_p = K_0 + K_1 t + K_2 t^2$$

gives $y_p'' = 2K_2$ and

$$y_p'' + y_p = K_0 + 2K_2 + K_1 t + K_2 t^2 = 1 - \frac{1}{\pi^2} t^2;$$

thus,

$$K_2 = -\frac{1}{\pi^2}, \qquad K_1 = 0, \qquad K_0 = 1 - 2K_2 = 1 + \frac{2}{\pi^2}.$$

Hence a general solution is

$$y = A \cos t + B \sin t + 1 + \frac{2}{\pi^2} - \frac{1}{\pi^2} t^2.$$

im02.qxd 9/21/05 10:57 AM Page 50

From this and the first initial condition,

$$y(0) = A + 1 + \frac{2}{\pi^2} = 0, \qquad A = -\left(1 + \frac{2}{\pi^2}\right).$$

The derivative is

$$y' = -A \sin t + B \cos t - \frac{2}{\pi^2}\, t$$

and gives $y'(0) = B = 0$. Hence the solution is

(I) $$y(t) = (1 + 2/\pi^2)(1 - \cos t) - t^2/\pi^2 \qquad \text{if } 0 \leqq t \leqq \pi,$$

and if $t > \pi$, then

(II) $$y = y_2 = A_2 \cos t + B_2 \sin t$$

with A_2 and B_2 to be determined from the continuity conditions

$$y(\pi) = y_2(\pi), \qquad y'(\pi) = y_2'(\pi).$$

So we need from (I) and (II)

$$y(\pi) = 2(1 + 2/\pi^2) - 1 = 1 + 4/\pi^2 = y_2(\pi) = -A_2$$

and

$$y'(t) = (1 + 2/\pi^2) \sin t - 2t/\pi^2$$

and from this and (II),

$$y'(\pi) = -2/\pi = B \cos \pi = -B_2.$$

This gives the solution

$$y = -(1 + 4/\pi^2) \cos t + (2/\pi) \sin t \qquad \text{if} \quad t > \pi.$$

Answer:

$$y = \begin{cases} (1 + 2/\pi^2)(1 - \cos t) - t^2/\pi^2 & \text{if} \quad 0 \leqq t \leqq \pi \\ -(1 + 4/\pi^2) \cos t + (2/\pi) \sin t & \text{if} \quad t > \pi \end{cases}.$$

The function in the second line gives a harmonic oscillation because we disregarded damping.

SECTION 2.9. Modeling: Electric Circuits, page 91

Purpose. To discuss the current in the *RLC*-circuit with sinusoidal input $E_0 \sin \omega t$. **ATTENTION!** The right side in (1) is $E_0\omega \cos \omega t$, because of differentiation.

Main Content

Modeling by Kirchhoff's law KVL

Electrical–mechanical strictly quantitative analogy (Table 2.2)

Transient tending to harmonic steady-state current

A popular complex method is discussed in Team Project 20.

im02.qxd 9/21/05 10:57 AM Page 51

SOLUTIONS TO PROBLEM SET 2.9, page 97

2. The occurring integral can be evaluated by integration by parts, as is shown (with other notations) in standard calculus texts. From (4) in Sec. 1.5 we obtain

$$\begin{aligned} I &= e^{-Rt/L}\left[\frac{E_0}{L}\int e^{Rt/L}\sin\omega t\,dt + c\right] \\ &= ce^{-Rt/L} + \frac{E_0}{R^2+\omega^2L^2}\,(R\sin\omega t - \omega L\cos\omega t) \\ &= ce^{-Rt/L} + \frac{E_0}{\sqrt{R^2+\omega^2L^2}}\sin(\omega t-\delta), \qquad \delta = \arctan\frac{\omega L}{R}. \end{aligned}$$

4. This is another special case of a circuit that leads to an ODE of first order,

$$RI' + I/C = E' = \omega E_0\cos\omega t.$$

Integration by parts gives the solution

$$\begin{aligned} I(t) &= e^{-t/(RC)}\left[\frac{\omega E_0}{R}\int e^{t/(RC)}\cos\omega t\,dt + c\right] \\ &= ce^{-t/(RC)} + \frac{\omega E_0 C}{1+(\omega RC)^2}\,(\cos\omega t + \omega RC\sin\omega t) \\ &= ce^{-t/(RC)} + \frac{\omega E_0 C}{\sqrt{1+(\omega RC)^2}}\sin(\omega t-\delta), \end{aligned}$$

where $\tan\delta = -1/(\omega RC)$. The first term decreases steadily as t increases, and the last term represents the steady-state current, which is sinusoidal. The graph of $I(t)$ is similar to that in Fig. 62.

6. $E = t^2$, $E' = 2t$, $0.5I'' + (10^4/8)I = 2t$, $I'' + 2500I = 4t$, $I(0) = 0$ is given. $I'(0) = 0$ follows from

$$LI'(0) + Q(0)/C = E(0) = 0.$$

Answer:

$$I = 0.0016(t - 0.02\sin 50t).$$

8. Write $\lambda_1 = -\alpha + \beta$ and $\lambda_2 = -\alpha - \beta$, as in the text before Example 1. Here $\alpha = R/(2L) > 0$, and β can be real or imaginary. If β is real, then $\beta \leqq R/(2L)$ because $R^2 - 4L/C \leqq R^2$. Hence $\lambda_1 < 0$ (and $\lambda_2 < 0$, of course). If β is imaginary, then $I_h(t)$ represents a damped oscillation, which certainly goes to zero as $t \to \infty$.

10. $E' = 200\cos 2t$, $0.5I'' + 8I' + 10I = 200\cos 2t$, so that the steady-state solution is

$$I = 5\cos 2t + 10\sin 2t \text{ A}.$$

12. The ODE is

$$I'' + 2I' + 20I = \tfrac{157}{3}\cos 3t.$$

The steady-state solution is $I_p = 2\sin 3t + \frac{11}{3}\cos 3t$.

Note that if you let C decrease, the sine term in the solution will become increasingly smaller, compared with the cosine term.

14. The ODE is

$$0.1I'' + 0.2I' + 0.5I = 377\cos 0.5t.$$

im02.qxd 9/21/05 10:57 AM Page 52

Its characteristic equation is

$$0.1[(\lambda + 1)^2 + 4] = 0.$$

Hence a general solution of the homogeneous ODE is

$$e^{-t}(A \cos 2t + B \sin 2t).$$

The transient solution is

$$I = e^{-t}(A \cos 2t + B \sin 2t) + 760 \cos 0.5t + 160 \sin 0.5t.$$

16. The ODE is

$$0.1I'' + 4I' + 40I = 100 \cos 10t.$$

A general solution is

$$I = (c_1 + c_2 t)e^{-20t} + 1.2 \cos 10t + 1.6 \sin 10t.$$

The initial conditions are $I(0) = 0$, $Q(0) = 0$, which because of $(1')$, that is,

$$LI'(0) + RI(0) + \frac{Q(0)}{C} = E(0) = 0,$$

leads to $I'(0) = 0$. This gives

$$I(0) = c_1 + 1.2 = 0, \qquad c_1 = -1.2$$

$$I'(0) = -20c_1 + c_2 + 16 = 0, \qquad c_2 = -40.$$

Hence the answer is

$$I = -(1.2 + 40t)e^{-20t} + 1.2 \cos 10t + 1.6 \sin 10t.$$

18. The characteristic equation of the homogeneous ODE is

$$0.2(\lambda + 8)(\lambda + 10) = 0.$$

The initial conditions are $I(0) = 0$ as given, $I'(0) = E(0)/L = 164/0.2 = 820$ by formula $(1')$ in the text and $Q(0) = 0$. Also, $E' = -1640 \sin 10t$. The ODE is

$$0.2I'' + 3.6I' + 16I = -1640 \sin 10t.$$

The *answer* is

$$I = 160\, e^{-8t} - 205e^{-10t} + 45 \cos 10t + 5 \sin 10t.$$

20. Team Project. (a) $\tilde{I}_p = Ke^{i\omega t}$, $\tilde{I}_p' = i\omega Ke^{i\omega t}$, $\tilde{I}_p'' = -\omega^2 Ke^{i\omega t}$. Substitution gives

$$\left(-\omega^2 L + i\omega R + \frac{1}{C}\right) Ke^{i\omega t} = E_0 \omega e^{i\omega t}.$$

Divide this by $\omega e^{i\omega t}$ on both sides and solve the resulting equation algebraically for K, obtaining

(A) $$K = \frac{E_0}{-\left(\omega L - \dfrac{1}{\omega C}\right) + iR} = \frac{E_0}{-S + iR}$$

where S is the reactance given by (3). To make the denominator real, multiply the numerator and the denominator of the last expression by $-S - iR$. This gives

$$K = \frac{-E_0(S + iR)}{S^2 + R^2}.$$

im02.qxd 9/21/05 10:57 AM Page 53

The real part of $Ke^{i\omega t}$ is

$$(\text{Re } K)(\text{Re } e^{i\omega t}) - (\text{Im } K)(\text{Im } e^{i\omega t}) = \frac{-E_0 S}{S^2 + R^2} \cos \omega t + \frac{E_0 R}{S^2 + R^2} \sin \omega t$$

$$= \frac{-E_0}{S^2 + R^2} (S \cos \omega t - R \sin \omega t),$$

in agreement with (2) and (4).

(b) See (A).

(c) $R = 2\ \Omega$, $L = 1$ H, $C = \frac{1}{3}$ F, $\omega = 1$, $S = 1 - 3 = -2$, $E_0 = 20$.

From this and (4) it follows that $a = 5$, $b = 5$; hence

$$I_p = 5 \cos t + 5 \sin t.$$

For the complex method we obtain from (A)

$$K = \frac{20}{2 + 2i} = \frac{20(2 - 2i)}{8} = 5 - 5i.$$

Hence

$$I_p = \text{Re}(Ke^{it}) = \text{Re}[(5 - 5i)(\cos t + i \sin t)]$$

$$= 5 \cos t + 5 \sin t.$$

SECTION 2.10. Solution by Variation of Parameters, page 98

Purpose. To discuss the general method for particular solutions, which applies in any case but may often lead to difficulties in integration (which we by and large have avoided in our problems, as the subsequent solutions show).

Comments

The ODE must be in ***standard form,*** with 1 as the coefficient of y''—students tend to forget that.

Here we do need the Wronskian, in contrast with Sec. 2.6 where we could get away without it.

SOLUTIONS TO PROBLEM SET 2.10, page 101

2. $y_1 = e^{2x}$, $y_2 = xe^{2x}$, $W = e^{4x}$, $y_h = (c_1 + c_2 x)e^{2x}$,

$$y_p = -e^{2x} \int x^3 e^{-x}\, dx + xe^{2x} \int x^2 e^{-x}\, dx = (x^2 + 4x + 6)e^x.$$

4. $y_h = (c_1 + c_2 x)e^x$, $y_p = e^x(A \cos x + B \sin x)$, $A = 0$ from the cosine terms, $B = -1$ from the sine terms, so that

$$y_p = -e^x \sin x.$$

6. Division by x^2 gives the standard form, and $r = x^{-1} \ln |x|$. A basis of solutions is $y_1 = x$, $y_2 = x \ln |x|$; $W = x$. The corresponding particular solution obtained from (2) is

$$y_p = -x \int (x \ln |x|)(x^{-1} \ln |x|)x^{-1}\, dx + (x \ln |x|) \int x(x^{-1} \ln |x|)x^{-1}\, dx$$

$$= -x \int (\ln |x|)^2 x^{-1}\, dx + x \ln |x| \int (\ln |x|)x^{-1}\, dx$$

$$= x (\ln |x|)^3/6.$$

im02.qxd 9/21/05 10:57 AM Page 54

8. $y_h = (c_1 + c_2x)e^{2x}$, $y_1 = e^{2x}$, $y_2 = xe^{2x}$, $W = e^{4x}$. From (2) we thus obtain

$$y_p = -12e^{2x}\int x^{-3}\,dx + 12xe^{2x}\int x^{-4}\,dx = 2x^{-2}e^{2x}.$$

10. The right side suggests the following choice of a basis of solutions:

$$y_1 = \cosh x, \qquad y_2 = \sinh x.$$

Then $W = 1$, and

$$y_p = -\cosh x\int (\sinh x)/\cosh x\,dx + \sinh x\int (\cosh x)/\cosh x\,dx$$

$$= -(\cosh x)\ln|\cosh x| + x\sinh x.$$

12. Divide by x^2 to get the standard form with $r = 3x^{-3} + 3x^{-1}$. A basis of solutions is $y_1 = x^{1/2}$, $y_2 = x^{-1/2}$. The Wronskian is $W = -x^{-1}$. From this and (2) we obtain

$$y_p = -x^{1/2}\int x^{-1/2}(3x^{-3} + 3x^{-1})(-x)\,dx$$

$$+ x^{-1/2}\int x^{1/2}(3x^{-3} + 3x^{-1})(-x)\,dx$$

$$= 4x^{-1} + 4x.$$

14. $y_1 = x^{-2}$, $y_2 = x^2$, $W = -4x^{-1}$. Hence (2) gives

$$y_p = -x^{-2}\int x^2x^{-4}(x/4)\,dx + x^2\int x^{-2}x^{-4}(x/4)\,dx$$

$$= -\tfrac{1}{4}x^{-2}\ln|x| - \tfrac{1}{16}x^{-2}.$$

16. $y = ux^{-1/2}$ leads to $u'' + u = 0$ by substitution. (This is a special case of the method of elimination of the first derivative, to be discussed in general in Prob. 29 of Problem Set 5.5 on the Bessel equation. The given homogeneous ODE is a special Bessel equation for which the Bessel functions reduce to elementary functions, namely, to cosines and sines times powers of x.) Hence a basis of solutions of the homogeneous ODE corresponding to the given ODE is

$$y_1 = x^{-1/2}\cos x, \qquad y_2 = x^{-1/2}\sin x.$$

The Wronskian is $W = x^{-1}$ and $r = x^{-1/2}\cos x$. Hence (2) gives

$$y_p = -x^{-1/2}\cos x\int x^{-1/2}\,(\sin x)\,x^{-1/2}\,(\cos x)\,x\,dx$$

$$+ x^{-1/2}\sin x\int x^{-1/2}\,(\cos x)\,x^{-1/2}\,(\cos x)\,x\,dx$$

$$= -x^{-1/2}\cos x\int \sin x\cos x\,dx + x^{-1/2}\sin x\int \cos^2 x\,dx$$

$$= \tfrac{1}{2}x^{1/2}\sin x.$$

Note that here we have used that the ODE must be in standard form before we can apply (2). This is similar to the case of the Euler–Cauchy equations in this problem set.

18. Team Project. (a) Undetermined coefficients: Substitute

$$y_p = A\cos 5x + B\sin 5x$$

$$y_p' = -5A\sin 5x + 5B\cos 5x$$

$$y_p'' = -25A\cos 5x - 25B\sin 5x.$$

im02.qxd 9/21/05 10:57 AM Page 55

The cosine terms give $-25A + 10B - 15A = 0$; hence $B = 4A$. The sine terms give

$$-25B - 10A - 15B = -170A = 17; \qquad \text{hence} \qquad A = -0.1, \qquad B = -0.4.$$

For the method of variation of parameters we need

$$y_1 = e^{3x}, \qquad y_2 = e^{-5x}; \qquad \text{hence} \qquad W = -8e^{-2x}.$$

From this and formula (2) we obtain integrals that are not too pleasant to evaluate, namely,

$$\begin{aligned} y_p &= -e^{3x}\int e^{-5x}\cdot 17\sin 5x\,(-e^{2x}/8)\,dx \\ &\quad + e^{-5x}\int e^{3x}\cdot 17\sin 5x\,(-e^{2x}/8)\,dx \\ &= -0.1\cos 5x - 0.4\sin 5x. \end{aligned}$$

(b) Apply variation of parameters to the first term, $y_{p1} = \sec 3x$, using $y_1 = \cos 3x$, $y_2 = \sin 3x$, and $W = 3$. Formula (2) gives

$$\begin{aligned} y_{p1} &= -\cos 3x\int(\sin 3x\sec 3x)/3\,dx \\ &\quad + \sin 3x\int(\cos 3x\sec 3x)/3\,dx \\ &= \tfrac{1}{9}\cos 3x\ln|\cos 3x| + \tfrac{1}{3}x\sin 3x. \end{aligned}$$

For y_{p2} the method of undetermined coefficients gives

$$y_{p2} = -\tfrac{1}{6}x\cos 3x.$$

SOLUTIONS TO CHAP. 2 REVIEW QUESTIONS AND PROBLEMS, page 102

10. Undetermined coefficients, where -3 is a double root of the characteristic equation of the homogeneous ODE, so that the Modification Rule applies. The second term on the right, $-27x^2$, requires a quadratic polynomial. A general solution is

$$y = (c_1 + c_2x)e^{-3x} + \tfrac{1}{2}x^2e^{-3x} - 3x^2 + 4x - 2.$$

12. $y' = z$, $y'' = (dz/dy)z$ by the chain rule, $yz\,dz/dy = 2z^2$, $dz/z = 2\,dy/y$,

$$\ln|z| = 2\ln|y| + c^*,\ z = c_1y^2 = y',\ dy/y^2 = c_1\,dx,\ -1/y = c_1x + c_2;$$

hence

$$y = 1/(\tilde{c}_1x + \tilde{c}_2).$$

Also, $y = 0$ is a solution.

14. $y_1 = x^{-2}$, $y_2 = x^{-3}$, $W = -x^{-6}$, $r = 1$ because to apply (2), one must first cast the given ODE into standard form. Then (2) gives

$$y_p = -x^{-2}\int x^{-3}\cdot 1(-x^6)\,dx + x^{-3}\int x^{-2}\cdot 1(-x^6)\,dx = x^2(\tfrac{1}{4} - \tfrac{1}{5}) = \tfrac{1}{20}x^2.$$

16. $y_1 = e^{2x}\cos x$, $y_2 = e^{2x}\sin x$, $W = e^{4x}$, so that (2) gives

$$\begin{aligned} y_p &= -e^{2x}\cos x\int e^{2x}\sin x\,e^{2x}\csc x\,e^{-4x}\,dx \\ &\quad + e^{2x}\sin x\int e^{2x}\cos x\,e^{2x}\csc x\,e^{-4x}\,dx \\ &= -e^{2x}(\cos x)\,x + e^{2x}(\sin x)\ln|\sin x|. \end{aligned}$$

im02.qxd 9/21/05 10:57 AM Page 56

18. This is an Euler–Cauchy equation, with the right-side 0 replaced with $36x^5$. The homogeneous ODE has the auxiliary equation

$$4m(m-1) - 24m + 49 = 4(m^2 - 7m + 3.5^2) = 4(m-3.5)^2 = 0.$$

$m = 3.5$ is a double root, so that a general solution of the homogeneous ODE is

$$y_h = x^{3.5}(c_1 + c_2 \ln |x|).$$

We try

$$y_p = Cx^5. \qquad \text{Then} \qquad y_p' = 5Cx^4, \qquad y_p'' = 20Cx^3.$$

Substitution gives

$$(4 \cdot 20 - 24 \cdot 5 + 49)Cx^5 = 9Cx^5 = 36x^4; \qquad \text{hence} \qquad C = 4.$$

This yields the general solution

$$y = x^{3.5}(c_1 + c_2 \ln |x|) + 4x^5$$

of the nonhomogeneous ODE.

Variation of parameters is slightly less convenient because of the integrations. For this we need $y_1 = x^{3.5}$, $y_2 = x^{3.5} \ln |x|$, $W = x^6$. The ODE must be written in standard form (divide by $4x^2$), so that $r = 9x^3$. With these functions, equation (2) yields

$$\begin{aligned} y_p &= -x^{3.5} \int x^{3.5} \ln |x| \cdot 9x^3/x^6 \, dx \\ &\quad + x^{3.5} \ln |x| \int x^{3.5} \cdot 9x^3/x^6 \, dx \\ &= -9x^{3.5} \int x^{1/2} \ln |x| \, dx + 9x^{3.5} \ln |x| \int x^{1/2} \, dx \\ &= -x^5(6 \ln |x| - 4) + x^5 \cdot 6 \ln |x| = 4x^5. \end{aligned}$$

20. The characteristic equation is

$$\lambda^2 + 6\lambda + 18 = (\lambda + 3)^2 + 3^2 = 0.$$

Hence a general solution is

$$y = e^{-3x}(A \cos 3x + B \sin 3x)$$

and the initial values give $A = 5$ and $B = -2$.

22. The auxiliary equation is

$$m(m-1) + 15m + 49 = (m+7)^2 = 0.$$

Hence a general solution is

$$y = (c_1 + c_2 \ln |x|)x^{-7}.$$

From the initial conditions, $c_1 = 2$, $c_2 = 3$.

24. The characteristic equation is

$$\lambda^2 + \lambda + 2.5 = (\lambda + 0.5)^2 + 1.5^2 = 0.$$

Hence a general solution of the homogeneous ODE is

$$y_h = e^{-0.5x}(A \cos 1.5x + B \sin 1.5x).$$

A particular solution of the given ODE is $6 \cos x + 4 \sin x$ (by undetermined coefficients). Hence

$$y = e^{-0.5x}(A \cos 1.5x + B \sin 1.5x) + 6 \cos x + 4 \sin x$$

and from the initial conditions, $A = 2$, $B = 1$.

im02.qxd 9/21/05 10:57 AM Page 57

26. The ODE is

$$4y'' + 4y' + 17y = 202 \cos 3t.$$

Thus

$$y'' + y' + 4.25y = 50.5 \cos 3t.$$

The steady-state solution is obtained by the method of undetermined coefficients:

$$y_p = 4.8 \sin 3t - 7.6 \cos 3t.$$

28. $y = e^{-0.5t}(A \cos 2t + B \sin 2t) - 7.6 \cos 3t + 4.8 \sin 3t$. From this general solution and the initial conditions we obtain

$$y(0) = A - 7.6 = 10. \qquad \text{Hence} \qquad A = 17.6$$

and by differentiating and setting $t = 0$

$$y'(0) = -0.5A + 2B + 3 \cdot 4.8 = 0.$$

Hence

$$B = 0.5(0.5A - 14.4) = -2.8.$$

30. The ODE is

$$2y'' + 6y' + 27y = 10 \cos \omega t.$$

The amplitude $C^*(\omega)$ is given by (14) in Sec. 2.8. Its maximum is obtained by equating the derivative to zero; this gives the location ω as solution of (15) in Sec. 2.8. In our case this is

$$36 = 2 \cdot 2^2(13.5 - \omega^2).$$

The solution is (15*); in our case,

$$\omega_{\max}{}^2 = 13.5 - 4.5 = 9; \qquad \text{thus} \qquad \omega_{\max} = 3.$$

For this $\omega = \omega_{\max}$ we obtain the maximum value of the amplitude from (16), Sec. 2.8; in our case,

$$C^*(\omega_{\max}) = \frac{2 \cdot 2 \cdot 10}{6\sqrt{4 \cdot 2^2 \cdot 13.5 - 36}} = \frac{\sqrt{20}}{9} = 0.496904.$$

By undetermined coefficients we obtain

$$y_p = \tfrac{2}{9} \cos 3t + \tfrac{4}{9} \sin 3t.$$

The amplitude is

$$C = \sqrt{a^2 + b^2} = \sqrt{(2/9)^2 + (4/9)^2}; = \sqrt{20}\,/\,9,$$

in agreement with our previous result.

32. $0.1I'' + 20I' + 5000I = 110 \cdot 415 \cos 415t$. The characteristic equation of the homogeneous ODE is

$$\lambda^2 + 200\lambda + 50000 = (\lambda + 100)^2 + 200^2 = 0.$$

Hence a general solution of the homogeneous ODE is

$$I_h = e^{-100t}(A \cos 200t + B \sin 200t).$$

The method of undetermined coefficients gives the following particular solution of the nonhomogeneous ODE:

$$I_p = 1.735825 \sin 415t - 2.556159 \cos 415t.$$

im02.qxd 9/21/05 10:57 AM Page 58

34. The real ODE is

$$0.4I'' + 40I' + 10000I = 220 \cdot 314 \cos 314t.$$

The complex ODE is

$$0.4\tilde{I}'' + 40\tilde{I}' + 10000\tilde{I} = 220 \cdot 314\, e^{314it}.$$

Substitution of

$$\tilde{I} = Ke^{314it}, \qquad \tilde{I}' = 314iKe^{314it}, \qquad \tilde{I}'' = -314^2 Ke^{314it}$$

into the complex ODE gives

$$(0.4(-314^2) + 40 \cdot 314i + 10000)Ke^{314it} = 220 \cdot 314e^{314it}.$$

Solve this for K. Denote the expression $(\cdots)$ on the left by M. Then

$$K = \frac{220 \cdot 314}{M} = -1.985219 - 0.847001i.$$

Furthermore, the desired particular solution I_p of the real ODE is the real part of Ke^{314it}; that is,

$$\begin{aligned}\text{Re}(Ke^{314it}) &= \text{Re } K \,\text{Re}(e^{314it}) - \text{Im } K \,\text{Im}(e^{314it}) \\ &= -1.985219 \cos 314t - (-0.847001) \sin 314t.\end{aligned}$$

im03.qxd 9/21/05 11:04 AM Page 59

CHAPTER 3 Higher Order Linear ODEs

This chapter is new. Its material is a rearranged and somewhat extended version of material previously contained in some of the sections of Chap 2. The rearrangement is such that the presentation parallels that in Chap. 2 for second-order ODEs, to facilitate comparisons.

Root Finding

For higher order ODEs you may need Newton's method or some other method from Sec. 19.2 (which is independent of other sections in numerics) in work on a calculator or with your CAS (which may give you a root-finding method directly).

Linear Algebra

The typical student may have taken an elementary linear algebra course simultaneously with a course on calculus and will know much more than is needed in Chaps. 2 and 3. Thus Chaps. 7 and 8 need not be taken before Chap. 3.

In particular, although the Wronskian becomes useful in Chap. 3 (whereas for $n = 2$ one hardly needs it), a very modest knowledge of determinants will suffice. (For $n = 2$ and 3, determinants are treated in a reference section, Sec. 7.6.)

SECTION 3.1. Homogeneous Linear ODEs, page 105

Purpose. Extension of the basic concepts and theory in Secs. 2.1 and 2.6 to homogeneous linear ODEs of any order *n.* This shows that practically all the essential facts carry over without change. Linear independence, now more involved as for $n = 2$, causes the Wronskian to become indispensable (whereas for $n = 2$ it played a marginal role).

Main Content, Important Concepts

Superposition principle for the homogeneous ODE (2)

General solution, basis, particular solution

General solution of (2) with continuous coefficients exists.

Existence and uniqueness of solution of initial value problem (2), (5)

Linear independence of solutions, Wronskian

General solution includes all solutions of (2).

Comment on Order of Material

In Chap. 2 we first gained practical experience and skill and presented the theory of the homogeneous linear ODE at the end of the discussion, in Sec. 2.6. In this chapter, with all the experience gained on second-order ODEs, it is more logical to present the whole theory at the beginning and the solution methods (for linear ODEs with constant coefficients) afterward. Similarly, the same logic applies to the nonhomogeneous linear ODE, for which Sec. 3.3 contains the theory as well as the solution methods.

SOLUTIONS TO PROBLEM SET 3.1, page 111

2. Problems 1–5 should give the student a first impression of the changes occurring in the transition from $n = 2$ to general *n.*

im03.qxd 9/21/05 11:04 AM Page 60

8. Let $y_1 = x + 1$, $y_2 = x + 2$, $y_3 = x$. Then

$$y_2 - 2y_1 + y_3 = 0$$

shows linear dependence.

10. Linearly independent

12. Linear dependence, since one of the functions is the zero function

14. $\cos 2x = \cos^2 x - \sin^2 x$; linearly dependent

16. $(x - 1)^2 - (x + 1)^2 + 4x = 0$; linearly dependent

18. Linearly independent

20. Team Project. (a) (1) No. If $y_1 \equiv 0$, then (4) holds with any $k_1 \neq 0$ and the other k_j all zero.

(2) Yes. If S were linearly dependent on I, then (4) would hold with a $k_j \neq 0$ on I, hence also on J, contradicting the assumption.

(3) Not necessarily. For instance, x^2 and $x|x|$ are linearly dependent on the interval $0 < x < 1$, but linearly independent on $-1 < x < 1$.

(4) Not necessarily. See the answer to (3).

(5) Yes. See the answer to (2).

(6) Yes. By assumption, $k_1y_1 + \cdots + k_py_p = 0$ with $k_1, \cdots, k_p$ not all zero (this refers to the functions in S), and for T we can add the further functions with coefficients all zero; then the condition for linear dependence of T is satisfied.

(b) We can use the Wronskian for testing linear independence only if we know that the given functions are solutions of a homogeneous linear ODE with continuous coefficients. Other means of testing are the use of functional relations, e.g., $\ln x^2 = 2 \ln x$ or trigonometric identities, or the evaluation of the given functions at several values of x, to see whether we can discover proportionality.

SECTION 3.2. Homogeneous Linear ODEs with Constant Coefficients, page 111

Purpose. Extension of the algebraic solution method for constant-coefficient ODEs from $n = 2$ (Sec. 2.2) to any n, and discussion of the increased number of possible cases:

Real different roots

Complex simple roots

Real multiple roots

Complex multiple roots

Combinations of the preceding four basic cases

Explanation of these cases in terms of typical examples

Comment on Numerics

In practical cases, one may have to use Newton's method or another method for computing (approximate values of) roots in Sec. 19.2.

SOLUTIONS TO PROBLEM SET 3.2, page 115

2. The form of the given functions shows that the characteristic equation has a triple root -2; hence it is

$$(\lambda + 2)^3 = \lambda^3 + 6\lambda^2 + 12\lambda + 8 = 0.$$

im03.qxd 9/21/05 11:04 AM Page 61

Hence the ODE is

$$y''' + 6y'' + 12y' + 8y = 0.$$

4. The first two functions result from a factor $\lambda^2 + 1$ of the characteristic equation, and the other two solutions show that the roots i and $-i$ are double roots, so that the characteristic equation is

$$(\lambda^2 + 1)^2 = 0$$

and the ODE is

$$y^{iv} + 2y'' + y = 0.$$

6. The given functions show that the characteristic equation is

$$(\lambda + 2)(\lambda + 1)(\lambda - 1)(\lambda - 2)\lambda = \lambda^5 - 5\lambda^3 + 4\lambda = 0.$$

This gives the ODE

$$y^v - 5y''' + 4y' = 0.$$

8. The characteristic equation is quadratic in $\mu = \lambda^2$. The roots are

$$\mu = \frac{29}{2} \pm \sqrt{\frac{29^2}{4} - 100} = \frac{29}{2} \pm \frac{21}{2} = \begin{cases} 50/2 \\ 8/2. \end{cases}$$

The roots of this are $\lambda = \pm 5$ and ± 2. Hence a general solution is

$$y = c_1e^{-2x} + c_2e^{2x} + c_3e^{-5x} + c_4e^{5x}.$$

10. The characteristic equation is

$$16(\lambda^4 - \tfrac{1}{2}\lambda^2 + \tfrac{1}{16}) = 16(\lambda^2 - \tfrac{1}{4})^2 = 0.$$

It has the double roots $\lambda = \pm\frac{1}{2}$. This gives the general solution

$$y = (c_1 + c_2x)e^{x/2} + (c_3 + c_4x)e^{-x/2}.$$

12. The characteristic equation is

$$\lambda^4 + 3\lambda^2 - 4 = (\lambda^2 - 1)(\lambda^2 + 4) = 0.$$

Its roots are ± 1 and $\pm 2i$. Hence the corresponding real general solution is

$$y = c_1e^x + c_2e^{-x} + c_3 \cos 2x + c_4 \sin 2x.$$

14. The particular solution, solving the initial value problem, is

$$y = 4e^{-x} + 5e^{-x/2} \cos 3x.$$

From it, the general solution is obvious.

16. $y = e^x(\frac{5}{16} \cos x - \frac{3}{16} \sin x) + e^{-x}(\frac{3}{16} \cos x - \frac{23}{16} \sin x)$

18. $y = 10e^{-4x}(\cos 1.5x - \sin 1.5x) + 0.05e^{0.5x}$

20. Project. (a) Divide the characteristic equation by $\lambda - \lambda_1$ if $e^{\lambda_1 x}$ is known.

(b) The idea is the same as in Sec. 2.1.

(c) We first produce the standard form because this is the form under which the equation for z was derived. Division by x^3 gives

$$y''' - \frac{3}{x}\,y'' + \left(\frac{6}{x^2} - 1\right)y' - \left(\frac{6}{x^3} - \frac{1}{x}\right)y = 0.$$

im03.qxd 9/21/05 11:04 AM Page 62

With $y_1 = x$, $y_1' = 1$, $y_1'' = 0$, and the coefficients p_1 and p_2 from the standard equation, we obtain

$$xz'' + \left[3 + \left(-\frac{3}{x}\right)x\right]z' + \left[2\left(-\frac{3}{x}\right) \cdot 1 + \left(\frac{6}{x^2} - 1\right)x\right]z = 0.$$

Simplification gives

$$xz'' + \left(-\frac{6}{x} + \frac{6}{x} - x\right)z = x(z'' - z) = 0.$$

Hence

$$z = c_1e^x + \tilde{c}_2e^{-x}.$$

By integration we get the *answer*

$$y_2 = x\int z\,dx = (c_1e^x + c_2e^{-x} + c_3)x.$$

SECTION 3.3. Nonhomogeneous Linear ODEs, page 116

Purpose. To show that the transition from $n = 2$ (Sec. 2.7) to general n introduces no new ideas but generalizes all results and practical aspects in a straightforward fashion; this refers to existence, uniqueness, and the need for a particular solution y_p to get a general solution in the form

$$y = y_h + y_p.$$

Comment on Elastic Beams

This is an important standard example of a fourth-order ODE that needs no lengthy preparations and explanations.

Vibrating beams follow in Problem Set 12.3. This leads to PDEs, since time t comes in as an additional variable.

Comment on Variation of Parameters

This method looks perhaps more complicated than it is; also the integrals may often be difficult to evaluate, and handling the higher order determinants that occur may require some more skill than the average student will have at this time. Thus it may be good to discuss this matter only rather briefly.

SOLUTIONS TO PROBLEM SET 3.3, page 122

2. The characteristic equation is

$$\lambda^3 + 3\lambda^2 - 5\lambda - 39 = (\lambda^2 + 6\lambda + 13)(\lambda - 3) = [(\lambda + 3)^2 + 4](\lambda - 3) = 0.$$

Hence a general solution of the homogeneous ODE is

$$y_h = e^{-3x}(c_1 \cos 2x + c_2 \sin 2x) + c_3e^{3x}.$$

Using the method of undetermined coefficients, substitute $y_p = a \cos x + b \sin x$, obtaining

$$y_p = -0.7 \cos x - 0.1 \sin x.$$

4. The characteristic equation is

$$\lambda^3 + 2\lambda^2 - 5\lambda - 6 = (\lambda + 1)(\lambda - 2)(\lambda + 3) = 0.$$

im03.qxd 9/21/05 11:04 AM Page 63

Hence a general solution of the homogeneous ODE is

$$y_h = c_1e^{-x} + c_2e^{2x} + c_3e^{-3x}.$$

Since both terms on the right are solutions of the homogeneous ODE, the Modification Rule for undetermined coefficients applies. Substitution into the nonhomogeneous ODE gives the particular solution

$$y_p = (7 + 10x)e^{-3x} + (\tfrac{1}{2} - 3x)e^{-x}.$$

6. The homogeneous Euler–Cauchy equation can be solved as usual by substituting x^m. The auxiliary equation has the roots -2, 0, 1; hence a general solution is

$$y_h = c_1x^{-2} + c_2 + c_3x.$$

This result can also be obtained by separating variables and integrating twice; that is,

$$y'''/y'' = -4/x, \qquad \ln y'' = -4 \ln x + c, \qquad y'' = c_1x^{-4},$$

and so on. Variation of parameters gives

$$y_p = 8e^x(x^{-1} - x^{-2}).$$

8. The characteristic equation of the homogeneous ODE

$$\lambda^3 - 2\lambda^2 - 9\lambda + 18 = 0$$

has the roots -3, 2, and 3. Hence a general solution of the homogeneous ODE is

$$y_h = c_1e^{-3x} + c_2e^{2x} + c_3e^{3x}.$$

This also shows that the function on the right is a solution of the homogeneous ODE. Hence the Modification Rule applies, and the particular solution obtained is

$$y_p = -0.2xe^{2x}.$$

10. The characteristic equation of the homogeneous ODE is

$$\lambda^4 - 16 = (\lambda^2 - 4)(\lambda^2 + 4) = 0.$$

Hence a general solution of the homogeneous ODE is

$$y_h = c_1e^{-2x} + c_2e^{2x} + c_3 \cos 2x + c_4 \sin 2x.$$

A particular solution y_p of the nonhomogeneous ODE can be obtained by the method of undetermined coefficients; this y_p can be written in terms of exponential or hyperbolic functions:

$$y_p = -1.5(e^{-2x} + e^{2x}) - 2x(e^{-2x} - e^{2x})$$

$$= -3 \cosh 2x + 4x \sinh 2x.$$

Applying the initial conditions, we obtain the *answer*

$$y = 4e^{-2x} + 16 \sin 2x + y_p,$$

from which we cannot immediately recognize a basis of solutions. Of course, when $\sin 2x$ occurs, $\cos 2x$ must be in the basis. But e^{2x} remains hidden and cannot be seen from the answer.

12. The characteristic equation is quadratic in λ^2, the roots being -5, -1, 1, 5. The right side requires a quadratic polynomial whose coefficients can be determined by

im03.qxd 9/21/05 11:04 AM Page 64

substitution. Finally, the initial conditions are used to determine the four arbitrary constants in the general solution of the nonhomogeneous ODE thus obtained. The *answer* is

$$y = 5e^{-x} + e^{-5x} + 6.16 + 4x + 2x^2.$$

Again, two of four possible terms resulting from the homogeneous ODE are not visible in the answer. The student should recognize that all or some or none of the solutions of a basis of the homogeneous ODE may be present in the final answer; this will depend on the initial conditions, so the student should experiment a little with this problem to see what is going on.

14. The method of undetermined coefficients gives

$$y_p = 0.08 \cos x + 0.04 \sin x.$$

A basis of solutions of the homogeneous ODE is e^{-2x}, e^{2x}, $e^{x/2}$. From this and the initial conditions we obtain the *answer*

$$y = 0.11e^{-2x} - 0.15e^{2x} + 0.96e^{x/2} + y_p$$

in which all three basis functions occur.

16. The first equation has as a general solution

$$y = (c_1 + c_2x + c_3x^2)e^{4x} + \tfrac{8}{105}x^{7/2}e^{4x}.$$

Hence in cases such as this, one can try

$$y_p = x^{1/2}(a_0 + a_1x + a_2x^2 + a_3x^3)e^{4x}.$$

One can now modify the right side systematically and see how the solution changes.

The second ODE has as a general solution

$$y = c_1x^{-2} + c_2x + c_3x^3 - \tfrac{1}{216}x(18(\ln |x|)^2 + 6 \ln |x| + 7).$$

This shows that undetermined coefficients would not be suitable—the function on the right gives no clue of what y_p may look like.

Of course, the dependence on the left side also remains to be explored.

SOLUTIONS TO CHAP. 3 REVIEW QUESTIONS AND PROBLEMS, page 122

6. The characteristic equation is

$$\lambda^3 + 6\lambda^2 + 18\lambda + 40 = [(\lambda + 1)^2 + 9](\lambda + 4) = 0.$$

Hence a general solution is

$$y = c_1e^{-4x} + e^{-x}(c_2 \cos 3x + c_3 \sin 3x).$$

8. The characteristic equation is quadratic in λ^2; namely,

$$(\lambda^2 + 1)(\lambda^2 + 9) = 0.$$

Hence a general solution is

$$y = c_1 \cos x + c_2 \sin x + c_3 \cos 3x + c_4 \sin 3x.$$

10. The characteristic equation has the triple root -1 because it is

$$(\lambda + 1)^3 = 0.$$

im03.qxd 9/21/05 11:04 AM Page 65

Hence a general solution of the homogeneous ODE is

$$y_h = (c_1 + c_2x + c_3x^2)e^{-x}.$$

The method of undetermined coefficients gives the particular solution

$$y_p = x^2 - 6x + 12.$$

12. The characteristic equation is

$$\lambda^2(\lambda + 2)(\lambda - 4) = 0.$$

Hence a general solution of the homogeneous ODE is

$$y_h = c_1 + c_2x + c_3e^{4x} + c_4e^{-2x}.$$

The method of undetermined coefficients gives the particular solution of the nonhomogeneous ODE in the form

$$y_p = 0.3 \cos 2x + 0.1 \sin 2x.$$

14. The auxiliary equation of the homogeneous ODE

$$x^3y''' + ax^2y'' + bxy' + cy = 0$$

is

$$m(m - 1)(m - 2) + am(m - 1) + bm + c$$

$$= m^3 + (a - 3)m^2 + (b - a + 2)m + c = 0.$$

In our equation, $a = -3$, $b = 6$, and $c = -6$. Accordingly, the auxiliary equation becomes

$$m^3 - 6m^2 + 11m - 6 = (m - 1)(m - 2)(m - 3) = 0.$$

Hence a general solution of the homogeneous ODE is

$$y_h = c_1x + c_2x^2 + c_3x^3.$$

Variation of parameters gives the particular solution

$$y_p = -0.5x^{-2}.$$

16. The characteristic equation of the ODE is

$$\lambda^3 - 2\lambda^2 + 4\lambda - 8 = (\lambda - 2)(\lambda^2 + 4) = 0.$$

Hence a general solution is

$$y_h = c_1e^{2x} + c_2 \cos 2x + c_3 \sin 2x.$$

Using the initial conditions, we obtain the particular solution

$$y = 3e^{2x} - 4 \cos 2x + 12 \sin 2x.$$

18. The characteristic equation of the homogeneous ODE is

$$\lambda(\lambda^2 + 25) = 0.$$

Hence a general solution of the homogeneous ODE is

$$y_h = c_1 + c_2 \cos 5x + c_3 \sin 5x.$$

im03.qxd 9/21/05 11:04 AM Page 66

Using $\cos^2 x = \frac{1}{2}(1 + \cos 2x)$, we can apply the method of undetermined coefficients to obtain a particular solution of the nonhomogeneous ODE in the form

$$y_p = \tfrac{16}{25}x - \tfrac{2}{39}\sin 8x.$$

Finally, from the initial conditions we obtain the *answer*

$$y = -\frac{224}{4875}\sin 5x + y_p.$$

20. We can use the formula in the solution of Prob. 14,

$$m^3 + (a - 3)m^2 + (b - a + 2)m + c = 0,$$

where, in our present ODE, $a = 5$, $b = 2$, and $c = -2$. Hence this formula becomes

$$m^3 + 2m^2 - m - 2 = (m - 1)(m + 1)(m + 2) = 0$$

and gives the basis of solutions x, x^{-1}, x^{-2}. Variation of parameters gives the particular solution of the nonhomogeneous ODE

$$y_p = 1.6x^{3/2}.$$

From this and the initial conditions we obtain the *answer*

$$y = 5x^{-2} + 4x + 1.6x^{3/2}.$$

im04.qxd 9/21/05 11:08 AM Page 67

CHAPTER 4 Systems of ODEs. Phase Plane. Qualitative Methods

Major Changes

This chapter was completely rewritten in the previous edition, on the basis of suggestions by instructors who have taught from it and my own recent experience. The main reason for rewriting was the increasing emphasis on **linear algebra** in our standard curricula, so that we can expect that students taking material from Chap. 4 have at least some working knowledge of 2×2 matrices.

Accordingly, Chap. 4 makes modest use of 2×2 matrices. $n \times n$ matrices are mentioned only in passing and are immediately followed by illustrative examples of systems of two ODEs in two unknown functions, involving 2×2 matrices only. Section 4.2 and the beginning of Sec. 4.3 are intended to give the student the impression that for first-order systems, one can develop a theory that is conceptually and structurally similar to that in Chap. 2 for a single ODE. Hence if the instructor feels that the class may be disturbed by $n \times n$ matrices, omission of the latter and explanation of the material in terms of two ODEs in two unknown functions will entail no disadvantage and will leave no gaps of understanding or skill.

To be completely on the safe side, Sec. 4.0 is included for reference, so that the student will have no need to search through Chap. 7 or 8 for a concept or fact needed in Chap. 4.

Basic throughout Chap. 4 is the **eigenvalue problem** (for 2×2 matrices), consisting first of the determination of the eigenvalues λ_1, λ_2 (not necessarily numerically distinct) as solutions of the characteristic equation, that is, the quadratic equation

$$\begin{vmatrix} a_{11} - \lambda & a_{12} \\ a_{21} & a_{22} - \lambda \end{vmatrix} = (a_{11} - \lambda)(a_{22} - \lambda) - a_{12}a_{21}$$

$$= \lambda^2 - (a_{11} + a_{22})\lambda + a_{11}a_{22} - a_{12}a_{21} = 0,$$

and then an eigenvector corresponding to λ_1 with components x_1, x_2 from

$$(a_{11} - \lambda_1)x_1 + a_{12}x_2 = 0$$

and an eigenvector corresponding to λ_2 from

$$(a_{11} - \lambda_2)x_1 + a_{12}x_2 = 0.$$

It may be useful to emphasize early that eigenvectors are determined only up to a nonzero factor and that in the present context, normalization (to obtain unit vectors) is hardly of any advantage.

If there are students in the class who have not seen eigenvalues before (although the elementary theory of these problems does occur in every up-to-date introductory text on beginning linear algebra), they should not have difficulties in readily grasping the meaning of these problems and their role in this chapter, simply because of the numerous examples and applications in Sec. 4.3 and in later sections.

Section 4.5 includes three famous applications, namely, the **pendulum** and **van der Pol equations** and the **Lotka–Volterra predator–prey population model.**

im04.qxd 9/21/05 11:08 AM Page 68

SECTION 4.0. Basics of Matrices and Vectors, page 124

Purpose. This section is for reference and review only, the material being restricted to what is actually needed in this chapter, to make it self-contained.

Main Content

Matrices, vectors

Algebraic matrix operations

Differentiation of vectors

Eigenvalue problems for 2×2 matrices

Important Concepts and Facts

Matrix, column vector and row vector, multiplication

Linear independence

Eigenvalue, eigenvector, characteristic equation

Some Details on Content

Most of the material is explained in terms of 2×2 matrices, which play the major role in Chap. 4; indeed, $n \times n$ matrices for general n occur only briefly in Sec. 4.2 and at the beginning in Sec. 4.3. Hence the demand of linear algebra on the student in Chap. 4 will be very modest, and Sec. 4.0 is written accordingly.

In particular, eigenvalue problems lead to quadratic equations only, so that nothing needs to be said about difficulties encountered with 3×3 or larger matrices.

Example 1. Although the later sections include many eigenvalue problems, the complete solution of such a problem (the determination of the eigenvalues and corresponding eigenvectors) is given in Sec. 4.0.

SECTION 4.1. Systems of ODEs as Models, page 130

Purpose. In this section the student will gain a first impression of the importance of systems of ODEs in physics and engineering and will learn why they occur and why they lead to eigenvalue problems.

Main Content

Mixing problem

Electrical network

Conversion of single equations to systems (*Theorem* 1)

The possibility of switching back and forth between systems and single ODEs is practically quite important because, depending on the situation, the system or the single ODE will be the better source for obtaining the information sought in a specific case.

Background Material. Secs. 2.4, 2.8.

Short Courses. Take a quick look at Sec. 4.1, skip Sec. 4.2 and the beginning of Sec. 4.3, and proceed directly to solution methods in terms of the examples in Sec. 4.3.

Some Details on Content

Example 1 extends the physical system in Sec. 1.3, consisting of a single tank, to a system of two tanks. The principle of modeling remains the same. The problem leads to a typical eigenvalue problem, and the solutions show typical exponential increases and decreases.

im04.qxd 9/21/05 11:08 AM Page 69

Example 2 leads to a nonhomogeneous first-order system (a kind of system to be considered in Sec. 4.6). The vector **g** on the right in (5) causes the term $+3$ in I_1 but has no effect on I_2, which is interesting to observe. If time permits, one could add a little discussion of particular solutions corresponding to different initial conditions.

Reduction of single equations to systems (Theorem 1) should be emphasized. Example 3 illustrates it, and further applications follow in Sec. 4.5. It helps to create a "uniform" theory centered around first-order systems, along with the possibility of reducing higher order systems to first order.

SOLUTIONS TO PROBLEM SET 4.1, page 135

2. The two balance equations (Inflow minus Outflow) change to

$$y_1' = 0.004y_2 - 0.02y_1$$
$$y_2' = 0.02y_1 - 0.004y_2$$

where 0.004 appears because we divide through the content of the new tank, which is five times that of the old T_2. Ordering the system by interchanging the two terms on the right in the first equation and writing the system as a vector equation, we have

$$\mathbf{y}' = \mathbf{Ay}, \qquad \text{where} \qquad \mathbf{A} = \begin{bmatrix} -0.02 & 0.004 \\ 0.02 & -0.004 \end{bmatrix}.$$

The characteristic polynomial is $\lambda^2 + 0.024\lambda = \lambda(\lambda + 0.024)$. Hence the eigenvalues are 0 (as before) and -0.024. Eigenvectors can be obtained from the first component of the vector equation $\mathbf{Ax} = \lambda\mathbf{x}$; that is,

$$-0.02x_1 + 0.004x_2 = \lambda x_1.$$

For $\lambda = \lambda_1 = 0$ this is $0.02x_1 = 0.004x_2$, say, $x_1 = 1$, $x_2 = 5$. For $\lambda = \lambda_2 = -0.024$ this is $-0.02x_1 + 0.004x_2 = -0.024x_1$. This simplifies to

$$0.004x_1 + 0.004x_2 = 0. \qquad \text{A solution is} \qquad x_1 = 1, \quad x_2 = -1.$$

Hence a general solution of the system of ODEs is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 5 \end{bmatrix} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-0.024t}.$$

For $t = 0$ this becomes, using the initial conditions $y_1(0) = 0$, $y_2(0) = 150$,

$$\mathbf{y}(0) = \begin{bmatrix} c_1 + c_2 \\ 5c_1 - c_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 150 \end{bmatrix}. \qquad \text{Solution:} \qquad c_1 = 25, \quad c_2 = -25.$$

This gives the particular solution

$$y = 25 \begin{bmatrix} 1 \\ 5 \end{bmatrix} - 25 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-0.024t}.$$

The situation described in the answer to Example 1 can no longer be achieved with the new tank, because the limits are 25 lb and 125 lb, as the particular solution shows.

im04.qxd 9/21/05 11:08 AM Page 70

4. With

$$a = \frac{\text{Flow rate}}{\text{Tank size}}$$

we can write the system that models the process in the following form:

$$y_1' = ay_2 - ay_1$$
$$y_2' = ay_1 - ay_2,$$

ordered as needed for the proper vector form

$$y_1' = -ay_1 + ay_2$$
$$y_2' = \quad ay_1 - ay_2.$$

In vector form,

$$\mathbf{y}' = \mathbf{Ay}, \qquad \text{where} \qquad \mathbf{A} = \begin{bmatrix} -a & a \\ a & -a \end{bmatrix}.$$

The characteristic equation is

$$(\lambda + a)^2 - a^2 = \lambda^2 + 2a\lambda = 0.$$

Hence the eigenvalues are 0 and $-2a$. Corresponding eigenvectors are

$$\begin{bmatrix} 1 \\ 1 \end{bmatrix} \qquad \text{and} \qquad \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

respectively. The corresponding "general solution" is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-2at}.$$

This result is interesting. It shows that the solution depends only on the ratio a, not on the tank size or the flow rate alone. Furthermore, the larger a is, the more rapidly y_1 and y_2 approach their limit.

The term "general solution" is in quotation marks because this term has not yet been defined *formally,* although it is clear what is meant.

6. The matrix of the system is

$$\mathbf{A} = \begin{bmatrix} -0.02 & 0.02 & 0 \\ 0.02 & -0.04 & 0.02 \\ 0 & 0.02 & -0.02 \end{bmatrix}.$$

The characteristic polynomial is

$$\lambda^3 + 0.08\lambda^2 + 0.0012\lambda = \lambda(\lambda + 0.02)(\lambda + 0.06).$$

This gives the eigenvalues and corresponding eigenvectors

$$\lambda_1 = 0, \quad \mathbf{x}^{(1)} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \quad \lambda_2 = -0.02, \quad \mathbf{x}^{(2)} = \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}, \quad \lambda_3 = -0.06, \quad x^{(3)} = \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix}.$$

im04.qxd 9/21/05 11:08 AM Page 71

Hence a "general solution" is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_2 \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix} e^{-0.02t} + c_3 \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix} e^{-0.06t}.$$

We use quotation marks since the concept of a general solution has not yet been defined *formally,* although it is clear what is meant.

8. $R_1 = 8$ changes the first ODE to

$$I_1' = -8I_1 + 8I_2 + 12.$$

$R_1 = 8$ and $R_2 = 12$ change the second ODE to

$$12I_2 + 8(I_2 - I_1) + 4\int I_2 = 0.$$

By differentiation and simplification,

$$20I_2' - 8I_1' + 4I_2 = 0.$$

Divide by 20 and get rid of I_1' by using the first ODE,

$$I_2' - 0.4(-8I_1 + 8I_2 + 12) + 0.2I_2 = 0.$$

Simplify and order terms to get

$$I_2' = -3.2I_1 + 3.0I_2 + 4.8.$$

In vector form this gives

$$\mathbf{J}' = \mathbf{A}\mathbf{J} + \mathbf{g} = \begin{bmatrix} -8 & 8 \\ -3.2 & 3.0 \end{bmatrix} \begin{bmatrix} I_1 \\ I_2 \end{bmatrix} + \begin{bmatrix} 12 \\ 4.8 \end{bmatrix}.$$

The eigenvalues are $\lambda_1 = -4.656$ and $\lambda_2 = -0.3436$ (rounded values). Corresponding eigenvectors are

$$\mathbf{x}^{(1)} = \begin{bmatrix} 1 \\ 0.4180 \end{bmatrix} \qquad \text{and} \qquad \mathbf{x}^{(2)} = \begin{bmatrix} 1 \\ 0.9570 \end{bmatrix}.$$

From these we can construct a "general solution" of the homogeneous system. A "particular solution" $\mathbf{J}_p$ of the nonhomogeneous system is suggested by the constant vector **g,** namely, to try constant

$$\mathbf{J}_p = \begin{bmatrix} a_1 \\ a_2 \end{bmatrix}.$$

Then $\mathbf{J}_p' = \mathbf{0},$ and substitution into the formula for $\mathbf{J}'$ gives

$$\mathbf{J}' = \mathbf{A}\mathbf{J}_p + \mathbf{g} = \mathbf{0},$$

in components,

$$-8a_1 + 8a_2 = -12$$
$$-3.2a_1 + 3.0a_2 = -4.8.$$

The solution is $a_1 = 1.5$, $a_2 = 0$. Hence the *answer* is

$$\mathbf{J} = c_1 \begin{bmatrix} 1 \\ 0.4180 \end{bmatrix} e^{-4.656t} + c_2 \begin{bmatrix} 1 \\ 0.9570 \end{bmatrix} e^{-0.3436t} + \begin{bmatrix} 1.5 \\ 0 \end{bmatrix}.$$

im04.qxd 9/21/05 11:08 AM Page 72

10. The first ODE remains unchanged. The second is changed to

$$I_2' = 0.4I_1' - 0.54I_2.$$

Substitution of the first ODE into the new second one gives

$$I_2' = -1.6I_1 + 1.06I_2 + 4.8.$$

The matrix of the new system is

$$\mathbf{A} = \begin{bmatrix} -4 & 4 \\ -1.6 & 1.06 \end{bmatrix}.$$

Its eigenvalues are -1.5 and -1.44. Corresponding eigenvectors are

$$\mathbf{x}^{(1)} = \begin{bmatrix} 1 \\ 0.625 \end{bmatrix} \quad \text{and} \quad \mathbf{x}^{(2)} = \begin{bmatrix} 1 \\ 0.64 \end{bmatrix}.$$

Hence the corresponding general solution of the homogeneous system is

$$\mathbf{J}_h = c_1\mathbf{x}^{(1)}e^{-1.5t} + c_2\mathbf{x}^{(2)}e^{-1.44t}.$$

A particular solution of the nonhomogeneous system is obtained as in Example 2 from

$$\begin{bmatrix} -4 & 4 \\ -1.6 & 1.06 \end{bmatrix}\begin{bmatrix} a_1 \\ a_2 \end{bmatrix} + \begin{bmatrix} 12 \\ 4.8 \end{bmatrix} = 0. \qquad \text{Solution:} \qquad \mathbf{a} = \begin{bmatrix} 3 \\ 0 \end{bmatrix}.$$

Hence a general solution of the nonhomogeneous system is

$$\mathbf{J} = c_1 \begin{bmatrix} 1 \\ 0.625 \end{bmatrix} e^{-1.5t} + c_2 \begin{bmatrix} 1 \\ 0.64 \end{bmatrix} e^{-1.44t} + \begin{bmatrix} 3 \\ 0 \end{bmatrix}.$$

From this and the initial conditions we have

$$\begin{aligned} c_1 + \quad c_2 &= -3 \\ 0.625c_1 + 0.64c_2 &= 0. \end{aligned}$$

The solution is $c_1 = -128$, $c_2 = 125$.

12. The system is

$$\begin{aligned} y_1' &= \quad y_2 \\ y_2' &= 24y_1 - 2y_2. \end{aligned}$$

The matrix has the eigenvalues 4 and -6, as can be seen from the characteristic polynomial

$$\lambda^2 + 2\lambda - 24 = (\lambda - 4)(\lambda + 6).$$

Corresponding eigenvectors are $[1 \quad 4]^T$ and $[1 \quad -6]^T$. A general solution is

$$y_1 = c_1e^{4t} + c_2e^{-6t} = y$$

and its derivative is

$$y_2 = 4c_1e^{4t} - 6c_2e^{-6t} = y'.$$

14. $y_1' = y_2$, $y_2' = -50y_1 - 15y_2$. The matrix is

$$\mathbf{A} = \begin{bmatrix} 0 & 1 \\ -50 & -15 \end{bmatrix}.$$

im04.qxd 9/21/05 11:08 AM Page 73

The characteristic equation is $\lambda^2 + 15\lambda + 50 = (\lambda + 5)(\lambda + 10) = 0$. The roots are -5 and -10. Eigenvectors are

$$\mathbf{x}^{(1)} = \begin{bmatrix} 1 \\ -5 \end{bmatrix} \qquad \text{and} \qquad \mathbf{x}^{(2)} = \begin{bmatrix} 1 \\ -10 \end{bmatrix}.$$

The corresponding general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ -5 \end{bmatrix} e^{-5t} + c_2 \begin{bmatrix} 1 \\ -10 \end{bmatrix} e^{-10t}.$$

16. Team Project. (a) From Sec. 2.4 we know that the undamped motions of a mass on an elastic spring are governed by $my'' + ky = 0$ or

$$my'' = -ky$$

where $y = y(t)$ is the displacement of the mass. By the same arguments, for the two masses on the two springs in Fig. 80 we obtain the linear homogeneous system

$$\begin{aligned} m_1 y_1'' &= -k_1 y_1 + k_2(y_2 - y_1) \\ m_2 y_2'' &= -k_2(y_2 - y_1) \end{aligned} \tag{11}$$

for the unknown displacements $y_1 = y_1(t)$ of the first mass m_1 and $y_2 = y_2(t)$ of the second mass m_2. The forces acting on the first mass give the first ODE, and the forces acting on the second mass give the second ODE. Now $m_1 = m_2 = 1$, $k_1 = 12$, and $k_2 = 8$ in Fig. 80 so that by ordering (11) we obtain

$$\begin{aligned} y_1'' &= -20y_1 + 8y_2 \\ y_2'' &= \quad 8y_1 - 8y_2 \end{aligned}$$

or, written as a single vector equation,

$$\mathbf{y}'' = \begin{bmatrix} y_1'' \\ y_2'' \end{bmatrix} = \begin{bmatrix} -20 & 8 \\ 8 & -8 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}.$$

(b) As for a single equation, we try an exponential function of t,

$$\mathbf{y} = \mathbf{x}e^{\omega t}. \qquad \text{Then} \qquad \mathbf{y}'' = \omega^2 \mathbf{x}e^{\omega t} = \mathbf{A}\mathbf{x}e^{\omega t}.$$

Writing $\omega^2 = \lambda$ and dividing by $e^{\omega t}$, we get

$$\mathbf{A}\mathbf{x} = \lambda \mathbf{x}.$$

Eigenvalues and eigenvectors are

$$\lambda_1 = -4, \qquad \mathbf{x}^{(1)} = \begin{bmatrix} 1 \\ 2 \end{bmatrix} \qquad \text{and} \qquad \lambda_2 = -24, \qquad \mathbf{x}^{(2)} = \begin{bmatrix} 2 \\ -1 \end{bmatrix}.$$

Since $\omega = \sqrt{\lambda}$ and $\sqrt{-4} = \pm 2i$ and $\sqrt{-24} = \pm i\sqrt{24}$, we get

$$\mathbf{y} = \mathbf{x}^{(1)}(c_1 e^{2it} + c_2 e^{-2it}) + \mathbf{x}^{(2)}(c_3 e^{i\sqrt{24}\,t} + c_4 e^{-i\sqrt{24}\,t})$$

or, by (10) in Sec. 2.2,

$$\mathbf{y} = a_1 \mathbf{x}^{(1)} \cos 2t + b_1 \mathbf{x}^{(1)} \sin 2t + a_2 \mathbf{x}^{(2)} \cos \sqrt{24}t + b_2 \mathbf{x}^{(2)} \sin \sqrt{24}t$$

im04.qxd 9/21/05 11:08 AM Page 74

where $a_1 = c_1 + c_2$, $b_1 = i(c_1 - c_2)$, $a_2 = c_3 + c_4$, $b_2 = i(c_3 - c_4)$. These four arbitrary constants can be specified by four initial conditions. In components, this solution is

$$y_1 = a_1 \cos 2t + b_1 \sin 2t + 2a_2 \cos \sqrt{24}t + 2b_2 \sin \sqrt{24}t$$
$$y_2 = 2a_1 \cos 2t + 2b_1 \sin 2t - a_2 \cos \sqrt{24}t - b_2 \sin \sqrt{24}t.$$

(c) The first two terms in y_1 and y_2 give a slow harmonic motion, and the last two a fast harmonic motion. The slow motion occurs if at some instant both masses are moving downward or both upward. For instance, if $a_1 = 1$ and all other arbitrary constants are zero, we get $y_1 = \cos 2t$, $y_2 = 2 \cos 2t$; this is an example of such a motion. The fast motion occurs if at each instant the two masses are moving in opposite directions, so that one of the two springs is extended, whereas the other is simultaneously compressed. For instance, if $a_2 = 1$ and all other constants are zero, we have $y_1 = 2 \cos \sqrt{24}\, t$, $y_2 = -\cos \sqrt{24}\, t$; this is a fast motion of the indicated type. Depending on the initial conditions, one or the other motion will occur, or a superposition of both.

SECTION 4.2. Basic Theory of Systems of ODEs, page 136

Purpose. This survey of some basic concepts and facts on nonlinear and linear systems is intended to give the student an impression of the conceptual and structural similarity of the theory of systems to that of single ODEs.

Content, Important Concepts

Standard form of first-order systems

Form of corresponding initial value problems

Existence of solutions

Basis, general solution, Wronskian

Background Material. Sec. 2.6 contains the analogous theory for single equations. See also Sec. 1.7.

Short Courses. This section may be skipped, as mentioned before.

SECTION 4.3. Constant-Coefficient Systems. Phase Plane Method, page 139

Purpose. Typical examples show the student the rich variety of pattern of solution curves (trajectories) near critical points in the phase plane, along with the process of actually solving homogeneous linear systems. This will also prepare the student for a good understanding of the systematic discussion of critical points in the phase plane in Sec. 4.4.

Main Content

Solution method for homogeneous linear systems

Examples illustrating types of critical points

Solution when no basis of eigenvectors is available (Example 6)

Important Concepts and Facts

Trajectories as solution curves in the phase plane

Phase plane as a means for the simultaneous (qualitative) discussion of a large number of solutions

Basis of solutions obtained from basis of eigenvectors

im04.qxd 9/21/05 11:08 AM Page 75

Background Material. Short review of eigenvalue problems from Sec. 4.0, if needed.

Short Courses. Omit Example 6.

Some Details on Content

In addition to developing skill in solving homogeneous linear systems, the student is supposed to become aware that it is the kind of eigenvalues that determine the type of critical point. The examples show important cases. (A systematic discussion of *all* cases follows in the next section.)

Example 1. Two negative eigenvalues give a **node.**

Example 2. A real double eigenvalue gives a **node.**

Example 3. Real eigenvalues of opposite sign give a **saddle point.**

Example 4. Pure imaginary eigenvalues give a **center,** and working in complex is avoided by a standard trick, which can also be useful in other contexts.

Example 5. Genuinely complex eigenvalues give a **spiral point.** Some work in complex can be avoided, if desired, by differentiation and elimination. The first ODE is

(a) $$y_2 = y_1' + y_1.$$

By differentiation and from the second ODE as well as from (a),

$$y_1'' = -y_1' + y_2' = -y_1' - y_1 - (y_1' + y_1) = -2y_1' - 2y_1.$$

Complex solutions $e^{(-1\pm i)t}$ give the real solution

$$y_1 = e^{-t}(A\cos t + B\sin t).$$

From this and (a) there follows the expression for y_2 given in the text.

Example 6 shows that the present method can be extended to include cases when **A** does not provide a basis of eigenvectors, but then becomes substantially more involved. In this way the student will recognize the importance of bases of eigenvectors, which also play a role in many other contexts.

SOLUTIONS TO PROBLEM SET 4.3, page 146

2. The eigenvalues are 5 and -5. Eigenvectors are $[1 \quad 1]^T$ and $[1 \quad -1]^T$, respectively. Hence a general solution is

$$y_1 = c_1e^{5t} + c_2e^{-5t}$$
$$y_2 = c_1e^{5t} - c_2e^{-5t}.$$

4. The eigenvalues are 13.5 and 4.5. Eigenvectors are $[3 \quad 1]^T$ and $[3 \quad -1]^T$, respectively. Hence a general solution is

$$y_1 = 3c_1e^{13.5t} + 3c_2e^{4.5t}$$
$$y_2 = \ c_1e^{13.5t} - \ c_2e^{4.5t}.$$

6. The eigenvalues are complex, $2 + 2i$ and $2 - 2i$. Corresponding complex eigenvectors are $[1 \quad -i]^T$ and $[1 \quad i]^T$, respectively. Hence a complex general solution is

$$y_1 = c_1e^{(2+2i)t} + c_2e^{(2-2i)t}$$
$$y_2 = -ic_1e^{(2+2i)t} + ic_2e^{(2-2i)t}.$$

im04.qxd 9/21/05 11:08 AM Page 76

From this and the Euler formula we obtain a real general solution

$$\begin{aligned} y_1 &= e^{2t}[(c_1 + c_2)\cos 2t + i(c_1 - c_2)\sin 2t] \\ &= e^{2t}(A\cos 2t + B\sin 2t), \\ y_2 &= e^{2t}[(-ic_1 + ic_2)\cos 2t + i(-ic_1 - ic_2)\sin 2t] \\ &= e^{2t}(-B\cos 2t + A\sin 2t) \end{aligned}$$

where $A = c_1 + c_2$ and $B = i(c_1 - c_2)$.

8. The eigenvalue of algebraic multiplicity 2 is 9. An eigenvector is $[1 \quad -1]^T$. There is no basis of eigenvectors. A first solution is

$$\mathbf{y}^{(1)} = \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{9t}.$$

A second linearly independent solution is (see Example 6 in the text)

$$\mathbf{y}^{(2)} = \begin{bmatrix} 1 \\ -1 \end{bmatrix} te^{9t} + \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} e^{9t}$$

with $[u_1 \quad u_2]^T$ determined from

$$(\mathbf{A} - 9\mathbf{I})\mathbf{u} = \begin{bmatrix} -1 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \end{bmatrix}.$$

Thus $u_1 + u_2 = -1$. We can take $u_1 = 0$, $u_2 = -1$. This gives the general solution

$$\mathbf{y} = c_1\mathbf{y}^{(1)} + c_2\mathbf{y}^{(2)} = (c_1 + c_2 t)\begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{9t} + c_2 \begin{bmatrix} 0 \\ -1 \end{bmatrix} e^{9t}.$$

10. The eigenvalues are 3 and -1. Eigenvectors are $[1 \quad 2]^T$ and $[1 \quad -2]^T$, respectively. Hence a general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 2 \end{bmatrix} e^{3t} + c_2 \begin{bmatrix} 1 \\ -2 \end{bmatrix} e^{-t}.$$

From this and the initial condition we obtain

$$\mathbf{y}(0) = c_1 \begin{bmatrix} 1 \\ 2 \end{bmatrix} + c_2 \begin{bmatrix} 1 \\ -2 \end{bmatrix} = \begin{bmatrix} 1 \\ 6 \end{bmatrix}.$$

Hence $c_1 + c_2 = 1$, $c_1 - c_2 = 3$, $c_1 = 2$, $c_2 = -1$. The *answer* is

$$y_1 = 2e^{3t} - e^{-t}, \qquad y_2 = 4e^{3t} + 2e^{-t}.$$

12. The eigenvalues are 5 and 1. Eigenvectors are $[1 \quad 1]^T$ and $[1 \quad -1]^T$, respectively. A general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{5t} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{t}.$$

From this and the initial conditions we obtain $c_1 + c_2 = 7$, $c_1 - c_2 = 7$, $c_1 = 7$, $c_2 = 0$. This gives the *answer*

$$y_1 = 7e^{5t}, \qquad y_2 = 7e^{5t}.$$

im04.qxd 9/21/05 11:08 AM Page 77

14. The eigenvalues are complex, $1 + i$ and $1 - i$. Eigenvectors are $[2 - i \quad 1]^T$ and $[2 + i \quad 1]^T$, respectively. Using the Euler formula, we get from this the general solution

$$\mathbf{y} = e^t\left(c_1\begin{bmatrix}2-i\\1\end{bmatrix}(\cos t + i\sin t) + c_2\begin{bmatrix}2+i\\1\end{bmatrix}(\cos t - i\sin t)\right).$$

In terms of components this equals

$$y_1 = e^t[(c_1(2-i) + c_2(2+i))\cos t + (ic_1(2-i) - ic_2(2+i))\sin t]$$
$$y_2 = e^t[(c_1 + c_2)\cos t + (ic_1 - ic_2)\sin t].$$

Setting $A = c_1 + c_2$ and $B = i(c_1 - c_2)$, we can write this in the form

$$y_1 = e^t[(2A - B)\cos t + (A + 2B)\sin t]$$
$$y_2 = e^t[A\cos t + B\sin t].$$

From this and the initial conditions we obtain $y_1(0) = 2A - B = 7$, $y_2(0) = A = 2$, $B = -3$. The *answer* is

$$y_1 = e^t(7\cos t - 4\sin t)$$
$$y_2 = e^t(2\cos t - 3\sin t).$$

16. The system is

(a) $$y_1' = 8y_1 - y_2$$

(b) $$y_2' = y_1 + 10y_2.$$

10(a) + (b) gives $10y_1' + y_2' = 81y_1$; hence

(c) $$y_2' = -10y_1' + 81y_1.$$

Differentiating (a) and using (c) gives

$$\begin{aligned}0 &= y_1'' - 8y_1' + y_2'\\ &= y_1'' - 8y_1' - 10y_1' + 81y_1\\ &= y_1'' - 18y_1' + 81y_1.\end{aligned}$$

A general solution is

$$y_1 = (c_1 + c_2t)e^{9t}.$$

From this and (a) we obtain

$$y_2 = -y_1' + 8y_1 = [-c_2 - 9(c_1 + c_2t) + 8(c_1 + c_2t)]e^{9t}$$
$$= (-c_2 - c_1 - c_2t)e^{9t},$$

in agreement with the answer to Prob. 8.

18. The restriction of the inflow from outside to pure water is necessary to obtain a homogeneous system. The principle involved in setting up the model is

$$\text{Time rate of change} = \text{Inflow} - \text{Outflow}.$$

For Tank T_1 this is (see Fig. 87)

$$y_1' = \left(48\cdot 0 + \frac{16}{400}\,y_2\right) - \frac{64}{400}\,y_1.$$

im04.qxd 9/21/05 11:08 AM Page 78

For Tank T_2 it is

$$y_2' = \frac{64}{400}\, y_1 - \frac{16 + 48}{400}\, y_2.$$

Performing the divisions and ordering terms, we have

$$\begin{aligned} y_1' &= -0.16y_1 \quad + 0.04y_2 \\ y_2' &= \quad 0.16y_1 \quad - 0.16y_2. \end{aligned}$$

The eigenvalues of the matrix of this system are -0.24 and -0.08. Eigenvectors are $[1 \quad -2]^T$ and $[1 \quad 2]^T$, respectively. The corresponding general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ -2 \end{bmatrix} e^{-0.24t} + c_2 \begin{bmatrix} 1 \\ 2 \end{bmatrix} e^{-0.08t}.$$

The initial conditions are $y_1(0) = 100$, $y_2(0) = 40$. This gives $c_1 = 40$, $c_2 = 60$. In components the *answer* is

$$\begin{aligned} y_1 &= 40e^{-0.24t} + 60e^{-0.08t} \\ y_2 &= -80e^{-0.24t} + 120e^{-0.08t}. \end{aligned}$$

Both functions approach zero as $t \to \infty$, a reasonable result, because pure water flows in and mixture flows out.

SECTION 4.4. Criteria for Critical Points. Stability, page 147

Purpose. Systematic discussion of critical points in the phase plane from the standpoints of both the geometrical shapes of trajectories and **stability.**

Main Content

Table 4.1 for the types of critical points

Table 4.2 for the stability behavior

Stability chart (Fig. 91), giving Tables 4.1 and 4.2 graphically

Important Concepts

Node, saddle point, center, spiral point

Stable and attractive, stable, unstable

Background Material. Sec. 2.4 (needed in Example 2).
Short Courses. Since all these types of critical points already occurred in the previous section, one may perhaps present just a short discussion of stability.

Some Details on Content

The types of critical points in Sec. 4.3 now recur, and the discussion shows that they exhaust all possibilities. With the examples of Sec. 4.3 fresh in mind, the student will acquire a deeper understanding by discussing the **stability chart** and by reconsidering those examples from the viewpoint of stability. This gives the instructor an opportunity to emphasize that the general importance of stability in engineering can hardly be overestimated.

Example 2, relating to the familiar free vibrations in Sec. 2.4, gives a good illustration of stability behavior, namely, depending on c, attractive stability, stability (and instability if one includes "negative damping," with $c < 0$, as it will recur in the next section in connection with the famous van der Pol equation).

im04.qxd 9/21/05 11:08 AM Page 79

SOLUTIONS TO PROBLEM SET 4.4, page 150

2. $p = 7$, $q = 12 > 0$, $\Delta = 49 - 48 > 0$, unstable node, $y_1 = c_1e^{4t}$, $y_2 = c_2e^{3t}$

4. $p = -2$, $q = 5$, $\Delta = 4 - 20 < 0$, stable and attractive spiral. The components of a general solution are

$$\begin{aligned} y_1 &= c_1e^{(-1+2i)t} + c_2e^{(-1-2i)t} \\ &= e^{-t}((c_1 + c_2)\cos 2t + i(c_1 - c_2)\sin 2t) \\ &= e^{-t}(A\cos 2t + B\sin 2t), \\ y_2 &= (-1 + 2i)c_1e^{(-1+2i)t} + (-1 - 2i)c_2e^{(-1-2i)t} \\ &= e^{-t}((-c_1 - c_2 + 2ic_1 - 2ic_2)\cos 2t + i(2ic_1 + 2ic_2 - c_1 + c_2)\sin 2t) \\ &= e^{-t}((-A + 2B)\cos 2t - (2A + B)\sin 2t) \end{aligned}$$

where $A = c_1 + c_2$ and $B = i(c_1 - c_2)$.

6. $p = -7$, $q = -78$, saddle point, unstable,

$$\begin{aligned} y_1 &= c_1e^{-13t} + c_2e^{6t} \\ y_2 &= -1.4c_1e^{-13t} + 0.5c_2e^{6t} \end{aligned}$$

8. $p = 0$, $q = 16$, center, stable, eigenvalues $4i$, $-4i$, eigenvectors $[1 \quad -0.6 + 0.8i]^T$ and $[1 \quad -0.6 - 0.8i]^T$, respectively, solution:

$$\begin{aligned} y_1 &= c_1e^{4it} + c_2e^{-4it} = A\cos 4t + B\sin 4t \\ y_2 &= (-0.6 + 0.8i)c_1e^{4it} + (-0.6 - 0.8i)c_2e^{-4it} \\ &= (-0.6 + 0.8i)c_1(\cos 4t + i\sin 4t) + (-0.6 - 0.8i)c_2(\cos 4t - i\sin 4t) \\ &= (-0.6(c_1 + c_2) + 0.8i(c_1 - c_2))\cos 4t \\ &\quad + (-0.6i(c_1 - c_2) - 0.8(c_1 + c_2))\sin 4t \\ &= (-0.6A + 0.8B)\cos 4t - (0.6B + 0.8A)\sin 4t \end{aligned}$$

where $A = c_1 + c_2$ and $B = i(c_1 - c_2)$.

10. $y_1 = y = c_1e^{-5t} + c_2$, $y_2 = y' = -5c_1e^{-5t} = -5(y_1 - c_2)$, parallel straight lines $5y_1 + y_2 = const$

12. $y_1 = y = A\cos\frac{1}{4}t + B\sin\frac{1}{4}t$, $y_2 = y' = -\frac{1}{4}A\sin\frac{1}{4}t + \frac{1}{4}B\cos\frac{1}{4}t$; hence

$$y_1^2 + 16y_2^2 = (A^2 + B^2)(\cos^2\tfrac{1}{4}t + \sin^2\tfrac{1}{4}t) = const.$$

Ellipses.

14. $y_1' = -dy_1/d\tau$, $y_2' = -dy_2/d\tau$, reversal of the direction of motion. To get the usual form, we have to multiply the transformed system by -1. This amounts to multiplying the matrix by -1, changing p into $-p$ (changing stability into instability and conversely when $p \neq 0$) but leaving q and Δ unchanged.

16. We have $p = 0$ and $q > 0$. We get $\tilde{p} = 2k \neq 0$ and

$$\tilde{q} = (a_{11} + k)(a_{22} + k) - a_{12}a_{21} = q + k(a_{11} + a_{22}) + k^2 = q + k^2 > 0$$

and

$$\tilde{\Delta} = \tilde{p}^2 - 4\tilde{q} = (2k)^2 - 4(q + k^2) = -4q < 0.$$

This gives a spiral point, which is stable and attractive if $k < 0$ and unstable if $k > 0$.

im04.qxd 9/21/05 11:08 AM Page 80

SECTION 4.5. Qualitative Methods for Nonlinear Systems, page 151

Purpose. As a most important step, in this section we extend phase plane methods from linear to nonlinear systems and nonlinear ODEs.

Main Content

Critical points of nonlinear systems

Their discussion by linearization

Transformation of single autonomous ODEs

Applications of linearization and transformation techniques

Important Concepts and Facts

Linearized system (3), condition for applicability

Linearization of pendulum equations

Self-sustained oscillations, van der Pol equation

Short Courses. Linearization at different critical points seems the main issue that the student is supposed to understand and handle practically. Examples 1 and 2 may help students to gain skill in that technique. The other material can be skipped without loss of continuity.

Some Details on Content

This section is very important, because from it the student should learn not only techniques (linearization, etc.) but also the fact that phase plane methods are particularly powerful and important in application to systems or single ODEs that cannot be solved explicitly. The student should also recognize that it is quite surprising how much information these methods can give. This is demonstrated by the **pendulum equation** (Examples 1 and 2) for a relatively simple system, and by the famous **van der Pol equation** for a single ODE, which has become a prototype for self-sustained oscillations of electrical systems of various kinds.

We also discuss the famous **Lotka–Volterra predator–prey model.**

For the **Rayleigh** and **Duffing equations,** see the problem set.

SOLUTIONS TO PROBLEM SET 4.5, page 158

2. Writing the system in the form

$$y_1' = y_1(4 - y_1)$$
$$y_2' = y_2$$

we see that the critical points are (0, 0) and (4, 0). For (0, 0) the linearized system is

$$y_1' = 4y_1$$
$$y_2' = y_2.$$

The matrix is

$$\begin{bmatrix} 4 & 0 \\ 0 & 1 \end{bmatrix}.$$

Hence $p = 5$, $q = 4$, $\Delta = 25 - 16 = 9$. This shows that the critical point at (0, 0) is an unstable node.

im04.qxd 9/21/05 11:08 AM Page 81

For (4, 0) the translation to the origin is

$$y_1 = 4 + \tilde{y}_1, \qquad y_2 = \tilde{y}_2.$$

This gives the transformed system

$$\tilde{y}_1' = (4 + \tilde{y}_1)(-\tilde{y}_1)$$
$$\tilde{y}_2' = \tilde{y}_2$$

and the corresponding linearized system

$$\tilde{y}_1' = -4\tilde{y}_1$$
$$\tilde{y}_2' = \tilde{y}_2.$$

Its matrix is

$$\begin{bmatrix} -4 & 0 \\ 0 & 1 \end{bmatrix}.$$

Hence $\tilde{p} = -3$, $\tilde{q} = -4$. Thus the critical point at (4, 0) is a saddle point, which is always unstable.

4. Writing the system as

(a) $$y_1' = -3y_1 + y_2(1 - y_2)$$

(b) $$y_2' = y_1 - 3y_2$$

we see that a critical point is at (0, 0). A second critical point is obtained by noting that the right side of (b) is zero when $y_1 = 3y_2$. Substitution into (a) gives $-9y_2 + y_2(1 - y_2)$, which is zero when $y_2 = -8$. Then $y_1 = 3y_2 = -24$. Hence a second critical point it at $(-24, -8)$.

At (0, 0) the linearized system is

$$y_1' = -3y_1 + y_2$$
$$y_2' = y_1 - 3y_2.$$

Its matrix is

$$\begin{bmatrix} -3 & 1 \\ 1 & -3 \end{bmatrix}.$$

Hence $p = -6$, $q = 8$, $\Delta = 36 - 32 = 4 > 0$. The critical point at (0, 0) is a stable and attractive node.

We turn to $(-24, -8)$. The translation to the origin is

$$y_1 = -24 + \tilde{y}_1, \qquad y_2 = -8 + \tilde{y}_2.$$

The transformed system is

$$\begin{aligned} \tilde{y}_1' &= -3(-24 + \tilde{y}_1) + (-8 + \tilde{y}_2)(1 - (-8 + \tilde{y}_2)) \\ &= -3\tilde{y}_1 + 17\tilde{y}_2 - \tilde{y}_2^2 \\ \tilde{y}_2' &= -24 + \tilde{y}_1 + 24 - 3\tilde{y}_2 \\ &= \tilde{y}_1 - 3\tilde{y}_2. \end{aligned}$$

Its linearization is

$$\tilde{y}_1' = -3\tilde{y}_1 + 17\tilde{y}_2$$
$$\tilde{y}_2' = \tilde{y}_1 - 3\tilde{y}_2.$$

im04.qxd 9/21/05 11:08 AM Page 82

Its matrix is

$$\begin{bmatrix} -3 & 17 \\ 1 & -3 \end{bmatrix}.$$

Hence $\tilde{q} = -8$. The critical point at $(-24, -8)$ is a saddle point.

6. The system may be written

$$y_1' = y_2(1 - y_2)$$
$$y_2' = y_1(1 - y_1).$$

From this we see immediately that there are four critical points, at (0, 0), (0, 1), (1, 0), (1, 1).

At (0, 0) the linearized system is

$$y_1' = y_2$$
$$y_2' = y_1.$$

The matrix is

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

Hence $p = 0$, $q = -1$, so that we have a saddle point.

At (0, 1) the transformation is $y_1 = \tilde{y}_1$, $y_2 = 1 + \tilde{y}_2$. This gives the transformed system

$$\tilde{y}_1' = (1 + \tilde{y}_2)(-\tilde{y}_2)$$
$$\tilde{y}_2' = \tilde{y}_1(1 - \tilde{y}_1).$$

Linearization gives

$$\tilde{y}_1' = -\tilde{y}_2 \qquad \tilde{y}_2' = \tilde{y}_1 \qquad \text{with matrix} \qquad \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

for which $\tilde{p} = 0$, $\tilde{q} = 1$, $\tilde{\Delta} = -4$, and we have a center.

At (1, 0) the transformation is $y_1 = 1 + \tilde{y}_1$, $y_2 = \tilde{y}_2$. The transformed system is

$$\tilde{y}_1' = \tilde{y}_2(1 - \tilde{y}_2)$$
$$\tilde{y}_2' = (1 + \tilde{y}_1)(-\tilde{y}_1).$$

Its linearization is

$$\tilde{y}_1' = \tilde{y}_2 \qquad \tilde{y}_2' = -\tilde{y}_1 \qquad \text{with matrix} \qquad \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$$

for which $\tilde{p} = 0$, $\tilde{q} = 1$, $\tilde{\Delta} = -4$, so that we get another center.

At (1, 1) the transformation is

$$y_1 = 1 + \tilde{y}_1, \qquad y_2 = 1 + \tilde{y}_2.$$

The transformed system is

$$\tilde{y}_1' = (1 + \tilde{y}_2)(-\tilde{y}_2)$$
$$\tilde{y}_2' = (1 + \tilde{y}_1)(-\tilde{y}_1).$$

Linearization gives

$$\tilde{y}_1' = -\tilde{y}_2 \qquad \tilde{y}_2' = -\tilde{y}_1 \qquad \text{with matrix} \qquad \begin{bmatrix} 0 & -1 \\ -1 & 0 \end{bmatrix}$$

for which $\tilde{p} = 0$, $\tilde{q} = -1$, and we have another saddle point.

im04.qxd 9/21/05 11:08 AM Page 83

8. $y_1' = y_2$, $y_2' = y_1(-9 - y_1)$. (0, 0) is a critical point. The linearized system at (0, 0) is

$$\begin{aligned} y_1' &= \quad y_2 \\ y_2' &= -9y_1 \end{aligned} \qquad \text{with matrix} \qquad \begin{bmatrix} 0 & 1 \\ -9 & 0 \end{bmatrix}$$

for which $p = 0$ and $q = 9 > 0$, so that we have a center.

A second critical point is at $(-9, 0)$. The transformation is

$$y_1 = -9 + \tilde{y}_1, \qquad y_2 = \tilde{y}_2.$$

This gives the transformed system

$$\begin{aligned} \tilde{y}_1' &= \tilde{y}_2 \\ \tilde{y}_2' &= (-9 + \tilde{y}_1)(-\tilde{y}_1). \end{aligned}$$

Its linearization is

$$\begin{aligned} \tilde{y}_1' &= \quad \tilde{y}_2 \\ \tilde{y}_2' &= 9\tilde{y}_1 \end{aligned} \qquad \text{with matrix} \qquad \begin{bmatrix} 0 & 1 \\ 9 & 0 \end{bmatrix}$$

for which $\tilde{q} = -9 < 0$, so that we have a saddle point.

10. The system is

$$\begin{aligned} y_1' &= y_2 \\ y_2' &= -\sin y_1. \end{aligned}$$

The critical points occur at $(\pm n\pi, 0)$, $n = 0, 1, \cdots$, where the sine is zero and $y_2 = 0$.

At (0, 0) the linearized system is

$$\begin{aligned} y_1' &= \quad y_2 \\ y_2' &= -y_1. \end{aligned}$$

Its matrix is

$$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}.$$

Hence $p = 0$ and $q = 1$, so that we have a center. By periodicity, the points $(\pm 2n\pi, 0)$ are centers.

We consider $(\pi, 0)$. The transformation is

$$y_1 = \pi + \tilde{y}_1, \qquad y_2 = \tilde{y}_2.$$

This gives the transformed system

$$\begin{aligned} \tilde{y}_1' &= \tilde{y}_2 \\ \tilde{y}_2' &= -\sin(\pi + \tilde{y}_1) = \sin \tilde{y}_1. \end{aligned}$$

Linearization gives the system

$$\begin{aligned} \tilde{y}_1' &= \tilde{y}_2 \\ \tilde{y}_2' &= \tilde{y}_1. \end{aligned}$$

The matrix is

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

Hence $\tilde{q} = -1$. This is a saddle point. By periodicity the critical points at $(\pi \pm 2n\pi, 0)$ are saddle points.

im04.qxd 9/21/05 11:08 AM Page 84

12. The system is

$$y_1' = y_2$$
$$y_2' = -y_1(2 - y_1) - y_2.$$

The critical points are (0, 0) and (2, 0). At (0, 0) the linearized system is

$$y_1' = \quad y_2$$
$$y_2' = -2y_1 - y_2.$$

Its matrix is

$$\begin{bmatrix} 0 & 1 \\ -2 & -1 \end{bmatrix}.$$

Hence $p = -1$, $q = 2$, $\Delta = 1 - 8 < 0$. This gives a stable and attractive spiral point.

At (2, 0) the transformation is

$$y_1 = 2 + \tilde{y}_1, \qquad y_2 = \tilde{y}_2.$$

This gives the transformed system

$$\tilde{y}_1' = \tilde{y}_2$$
$$\tilde{y}_2' = -(2 + \tilde{y}_1)(-\tilde{y}_1) - \tilde{y}_2.$$

Its linearization is

$$\tilde{y}_1' = \quad \tilde{y}_2$$
$$\tilde{y}_2' = 2\tilde{y}_1 - \tilde{y}_2.$$

Its matrix is

$$\begin{bmatrix} 0 & 1 \\ 2 & -1 \end{bmatrix}.$$

Hence $\tilde{p} = -1$, $\tilde{q} = -2 < 0$. This gives a saddle point.

14. The system is

(a) $$y_1' = y_2$$

(b) $$y_2' = 4y_1 - {y_1}^3.$$

Multiply the left side of (a) by the right side of (b) and the right side of (a) by the left side of (b), obtaining

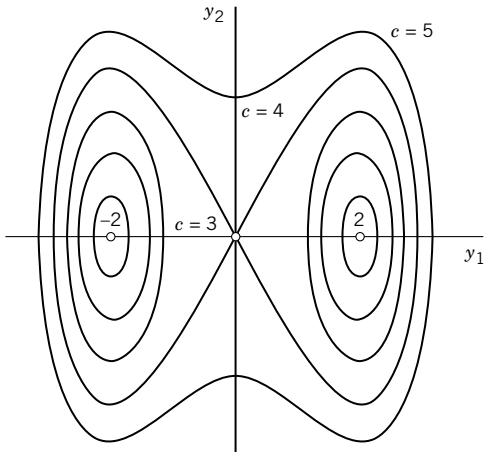
$$y_2 y_2' = (4y_1 - {y_1}^3)y_1'.$$

Integrate and multiply by 2:

$${y_2}^2 = 4{y_1}^2 - \tfrac{1}{2}{y_1}^4 + c^*.$$

Setting $c^* = c^2/2 - 8$, write this as

$${y_2}^2 = \tfrac{1}{2}(c + 4 - {y_1}^2)(c - 4 + {y_1}^2).$$



Some of these curves are shown in the figure.

16. The system is

$$y_1' = y_2$$
$$y_2' = -2y_2 + 4y_1 - {y_1}^3$$
$$\quad = -y_1(y_1 - 2)(y_1 + 2) - 2y_2.$$

Hence the critical points are (0, 0), (2, 0), (−2, 0).

im04.qxd 9/21/05 11:08 AM Page 85

Section 4.5. Problem 14

At (0, 0) the linearized system is

$$\begin{aligned} y_1' &= \quad y_2 \\ y_2' &= 4y_1 - 2y_2 \end{aligned} \qquad \text{with matrix} \qquad \begin{bmatrix} 0 & 1 \\ 4 & -2 \end{bmatrix}.$$

Hence $p = -2$, $q = -4 < 0$, which gives a saddle point.

At (2, 0) the transformation is $y_1 = 2 + \tilde{y}_1$, $y_2 = \tilde{y}_2$. This gives the system

$$\begin{aligned} \tilde{y}_1' &= \tilde{y}_2 \\ \tilde{y}_2' &= -(2 + \tilde{y}_1)\tilde{y}_1(\tilde{y}_1 + 4) - 2\tilde{y}_2 \end{aligned}$$

linearized

$$\begin{aligned} \tilde{y}_1' &= \quad \tilde{y}_2 \\ \tilde{y}_2' &= -8\tilde{y}_1 - 2\tilde{y}_2 \end{aligned} \qquad \text{with matrix} \qquad \begin{bmatrix} 0 & 1 \\ -8 & -2 \end{bmatrix}.$$

Hence $\tilde{p} = -2$, $\tilde{q} = 8$, $\tilde{\Delta} = 4 - 32 < 0$. This gives a stable and attractive spiral point.

At $(-2, 0)$ the transformation is $y_1 = -2 + \tilde{\tilde{y}}_1$, $y_2 = \tilde{\tilde{y}}_2$. This gives the system

$$\begin{aligned} \tilde{\tilde{y}}_1' &= \tilde{\tilde{y}}_2 \\ \tilde{\tilde{y}}_2' &= -(-2 + \tilde{\tilde{y}}_1)(-4 + \tilde{\tilde{y}}_1)\tilde{\tilde{y}}_1 - 2\tilde{\tilde{y}}_2. \end{aligned}$$

Linearization gives

$$\begin{aligned} \tilde{\tilde{y}}_1' &= \quad \tilde{\tilde{y}}_2 \\ \tilde{\tilde{y}}_2' &= -8\tilde{\tilde{y}}_1 - 2\tilde{\tilde{y}}_2 \end{aligned} \qquad \text{with matrix} \qquad \begin{bmatrix} 0 & 1 \\ -8 & -2 \end{bmatrix}$$

as before, so that we obtain another stable and attractive spiral point.

Note the similarity to the situation in the case of the undamped and damped pendulum.

18. A limit cycle is approached by trajectories (from inside and outside). No such approach takes place for a closed trajectory.

20. Team Project. (a) Unstable node if $\mu \geqq 2$, unstable spiral point if $2 > \mu > 0$, center if $\mu = 0$, stable and attractive spiral point if $0 > \mu > -2$, stable and attractive node if $\mu \leqq -2$.

im04.qxd 9/21/05 11:08 AM Page 86

(c) As a system we obtain

(A) $y_1' = y_2$

(B) $y_2' = -(\omega_0^2 y_1 + \beta y_1^3)$.

The product of the left side of (A) and the right side of (B) equals the product of the right side of (A) and the left side of (B):

$$y_2' y_2 = -(\omega_0^2 y_1 + \beta y_1^3) y_1'.$$

Integration on both sides and multiplication by 2 gives

$$y_2^2 + \omega_0^2 y_1^2 + \tfrac{1}{2}\beta y_1^4 = const.$$

For positive β these curves are closed because then βy^3 is a proper restoring term, adding to the restoring due to the y-term. If β is negative, the term βy^3 has the opposite effect, and this explains why then some of the trajectories are no longer closed but extend to infinity in the phase plane.

For generalized van der Pol equations, see e.g., K. Klotter and E. Kreyszig, On a class of self-sustained oscillations. *J. Appl. Math.* **27**(1960), 568–574.

SECTION 4.6. Nonhomogeneous Linear Systems of ODEs, page 159

Purpose. We now turn from homogeneous linear systems considered so far to solution methods for nonhomogeneous systems.

Main Content

Method of undetermined coefficients

Modification for special right sides

Method of variation of parameters

Short Courses. Select just one of the preceding methods.

Some Details on Content

In addition to understanding the solution methods as such, the student should observe the conceptual and technical similarities to the handling of nonhomogeneous linear ODEs in Secs. 2.7−2.10 and understand the reason for this, namely, that systems can be converted to single equations and conversely. For instance, in connection with Example 1 in this section, one may point to the Modification Rule in Sec. 2.7, or, if time permits, establish an even more definite relation by differentiation and elimination of y_2,

$$\begin{aligned} y_1'' &= -3y_1' + y_2' + 12e^{-2t} \\ &= -3y_1' + (y_1 - 3y_2 + 2e^{-2t}) + 12e^{-2t} \\ &= -3y_1' + y_1 - 3(y_1' + 3y_1 + 6e^{-2t}) + 14e^{-2t} \\ &= -6y_1' - 8y_1 - 4e^{-2t}, \end{aligned}$$

solving this for y_1 and then getting y_2 from the solution.

SOLUTIONS TO PROBLEM SET 4.6, page 162

2. We determine $\mathbf{y}^{(h)}$. The matrix is

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

im04.qxd 9/21/05 11:08 AM Page 87

It has the eigenvalues 1 and -1 with eigenvectors $[1 \quad 1]^T$ and $[1 \quad -1]^T$, respectively. Hence

$$y_1^{(h)} = c_1 e^t + c_2 e^{-t}$$
$$y_2^{(h)} = c_1 e^t - c_2 e^{-t}.$$

We determine $\mathbf{y}^{(p)}$ by the method of undetermined coefficients, starting from

$$y_1^{(p)} = a_1 t + b_1$$
$$y_2^{(p)} = a_2 t + b_2.$$

By differentiation, $\mathbf{y}^{(p)\prime} = [a_1 \quad a_2]^T$. Substitution into

$$\mathbf{y}^{(p)\prime} = \mathbf{A}\mathbf{y}^{(p)} + \mathbf{g}$$

with $\mathbf{g} = [t \quad -3t]^T$ gives

$$a_1 = a_2 t + b_2 + t$$
$$a_2 = a_1 t + b_1 - 3t.$$

From the first equation, $a_2 = -1$, $b_2 = a_1$. From the second equation, $a_1 = 3$, $b_1 = a_2$. This gives the *answer*

$$y_1 = c_1 e^t + c_2 e^{-t} + 3t - 1$$
$$y_2 = c_1 e^t - c_2 e^{-t} - t + 3.$$

4. The matrix of the system has the eigenvalues 2 and -2. Eigenvectors are $[1 \quad 1]^T$ and $[1 \quad -3]^T$, respectively. Hence a general solution of the homogeneous system is

$$\mathbf{y}^{(h)} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{2t} + c_2 \begin{bmatrix} 1 \\ -3 \end{bmatrix} e^{-2t}.$$

We determine $\mathbf{y}^{(p)}$ by the method of undetermined coefficients, starting from

$$\mathbf{y}^{(p)} = \begin{bmatrix} a_1 \cos t + b_1 \sin t \\ a_2 \cos t + b_2 \sin t \end{bmatrix}.$$

Substituting this and its derivative into the given nonhomogeneous system, we obtain, in terms of components,

$$-a_1 \sin t + b_1 \cos t = (a_1 + a_2) \cos t + (b_1 + b_2) \sin t + 5 \cos t$$
$$-a_2 \sin t + b_2 \cos t = (3a_1 - a_2) \cos t + (3b_1 - b_2) \sin t - 5 \sin t.$$

By equating the coefficients of the cosine and of the sine in the first of these two equations we obtain

$$b_1 = a_1 + a_2 + 5, \qquad -a_1 = b_1 + b_2.$$

Similarly from the second equation,

$$b_2 = 3a_1 - a_2, \qquad -a_2 = 3b_1 - b_2 - 5$$

The solution is $a_1 = -1$, $b_1 = 2$, $a_2 = -2$, $b_2 = -1$. This gives the *answer*

$$y_1 = c_1 e^{2t} + c_2 e^{-2t} - \cos t + 2 \sin t$$
$$y_2 = c_1 e^{2t} - 3c_2 e^{-2t} - 2 \cos t - \sin t.$$

im04.qxd 9/21/05 11:08 AM Page 88

6. $\mathbf{y}^{(h)}$ can be obtained from Example 5 in Sec. 4.3 in the form

$$\mathbf{y}^{(h)} = c_1 \begin{bmatrix} 1 \\ i \end{bmatrix} e^{(-1+i)t} + c_2 \begin{bmatrix} 1 \\ -i \end{bmatrix} e^{(-1-i)t}$$
$$= \begin{bmatrix} e^{-t}(A \cos t + B \sin t) \\ e^{-t}(B \cos t - A \sin t) \end{bmatrix}$$

where $A = c_1 + c_2$ and $B = i(c_1 - c_2)$.

$\mathbf{y}^{(p)}$ is obtained by the method of undetermined coefficients, starting from $\mathbf{y}^{(p)} = [a_1 \quad a_2]^{\mathsf{T}} e^{-2t}$. Differentiation and substitution into the given nonhomogeneous system gives, in components,

$$-2a_1 e^{-2t} = (-a_1 + a_2)e^{-2t} + e^{-2t}$$
$$-2a_2 e^{-2t} = (-a_1 - a_2)e^{-2t} - e^{-2t}.$$

Dropping e^{-2t}, we have

$$-2a_1 = -a_1 + a_2 + 1$$
$$-2a_2 = -a_1 - a_2 - 1.$$

The solution is $a_1 = -1$, $a_2 = 0$. We thus obtain the *answer*

$$y_1 = e^{-t}(A \cos t + B \sin t) - e^{-2t}$$
$$y_2 = e^{-t}(B \cos t - A \sin t).$$

It is remarkable that y_2 is the same as for the homogeneous system.

8. The matrix of the homogeneous system

$$\begin{bmatrix} 10 & -6 \\ 6 & -10 \end{bmatrix}$$

has the eigenvalues 8 and -8 with eigenvectors $[3 \quad 1]^{\mathsf{T}}$ and $[1 \quad 3]^{\mathsf{T}}$, respectively. Hence a general solution of the homogeneous system is

$$\mathbf{y}^{(h)} = c_1 \begin{bmatrix} 3 \\ 1 \end{bmatrix} e^{8t} + c_2 \begin{bmatrix} 1 \\ 3 \end{bmatrix} e^{-8t}.$$

We determine a particular solution $\mathbf{y}^{(p)}$ of the nonhomogeneous system by the method of undetermined coefficients. We start from

$$\mathbf{y}^{(p)} = \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} t^2 + \begin{bmatrix} b_1 \\ b_2 \end{bmatrix} t + \begin{bmatrix} k_1 \\ k_2 \end{bmatrix}.$$

Differentiation and substitution gives, in terms of components,

$$2a_1 t + b_1 = (10a_1 - 6a_2)t^2 + (10b_1 - 6b_2)t + 10k_1 - 6k_2 - 10t^2 - 10t + 10$$
$$2a_2 t + b_2 = (6a_1 - 10a_2)t^2 + (6b_1 - 10b_2)t + 6k_1 - 10k_2 - 6t^2 - 20t + 4.$$

By equating the sum of the coefficients of t^2 in each equation to zero we get

$$10a_1 - 6a_2 - 10 = 0$$
$$6a_1 - 10a_2 - 6 = 0.$$

im04.qxd 9/21/05 11:08 AM Page 89

The solution is $a_1 = 1$, $a_2 = 0$. Similarly for the terms in t we obtain

$$2a_1 = 10b_1 - 6b_2 - 10$$
$$2a_2 = 6b_1 - 10b_2 - 20.$$

The solution is $b_1 = 0$, $b_2 = -2$. Finally, for the constant terms we obtain

$$b_1 = 10k_1 - 6k_2 + 10$$
$$b_2 = 6k_1 - 10k_2 + 4.$$

The solution is $k_1 = -1$, $k_2 = 0$. The *answer* is $\mathbf{y} = \mathbf{y}^{(h)} + \mathbf{y}^{(p)}$ with $\mathbf{y}^{(h)}$ given above and

$$\mathbf{y}^{(p)} = \begin{bmatrix} t^2 - 1 \\ -2t \end{bmatrix}.$$

12. The matrix of the homogeneous system

$$\begin{bmatrix} 0 & 4 \\ -1 & 0 \end{bmatrix}$$

has the eigenvalues $2i$ and $-2i$ and eigenvectors $[2 \quad i]^\mathsf{T}$ and $[2 \quad -i]^\mathsf{T}$, respectively. Hence a complex general solution is

$$\mathbf{y}^{(h)} = c_1 \begin{bmatrix} 2 \\ i \end{bmatrix} e^{2it} + c_2 \begin{bmatrix} 2 \\ -i \end{bmatrix} e^{-2it}.$$

By Euler's formula this becomes, in components,

$$y_1^{(h)} = (2c_1 + 2c_2)\cos 2t + i(2c_1 - 2c_2)\sin 2t$$
$$y_2^{(h)} = (ic_1 - ic_2)\cos 2t + (-c_1 - c_2)\sin 2t.$$

Setting $A = c_1 + c_2$ and $B = i(c_1 - c_2)$, we can write

$$y_1^{(h)} = 2A\cos 2t + 2B\sin 2t$$
$$y_2^{(h)} = B\cos 2t - A\sin 2t.$$

Before we can consider the initial conditions, we must determine a particular solution $\mathbf{y}^{(p)}$ of the given system. We do this by the method of undetermined coefficients, setting

$$y_1^{(p)} = a_1e^t + b_1e^{-t}$$
$$y_2^{(p)} = a_2e^t + b_2e^{-t}.$$

Differentiation and substitution gives

$$a_1e^t - b_1e^{-t} = 4a_2e^t + 4b_2e^{-t} + 5e^t$$
$$a_2e^t - b_2e^{-t} = -a_1e^t - b_1e^{-t} - 20e^{-t}.$$

Equating the coefficients of e^t on both sides, we get

$$a_1 = 4a_2 + 5, \qquad a_2 = -a_1, \qquad \text{hence} \qquad a_1 = 1, \qquad a_2 = -1.$$

Equating the coefficients of e^{-t}, we similarly obtain

$$-b_1 = 4b_2, \qquad -b_2 = -b_1 - 20, \qquad \text{hence} \qquad b_1 = -16, \qquad b_2 = 4.$$

im04.qxd 9/21/05 11:08 AM Page 90

Hence a general solution of the given nonhomogeneous system is

$$y_1 = 2A\cos 2t + 2B\sin 2t + e^t - 16e^{-t}$$
$$y_2 = \ B\cos 2t - \ A\sin 2t - e^t + 4e^{-t}.$$

From this and the initial conditions we obtain

$$y_1(0) = 2A + 1 - 16 = 1, \qquad y_2(0) = B - 1 + 4 = 0.$$

The solution is $A = 8$, $B = -3$. This gives the *answer* (the solution of the initial value problem)

$$y_1 = 16\cos 2t - 6\sin 2t + e^t - 16e^{-t}$$
$$y_2 = -3\cos 2t - 8\sin 2t - e^t + 4e^{-t}.$$

14. The matrix of the homogeneous system

$$\begin{bmatrix} 3 & -4 \\ 1 & -2 \end{bmatrix}$$

has the eigenvalues -1 and 2, with eigenvectors $[1 \quad 1]^\mathsf{T}$ and $[4 \quad 1]^\mathsf{T}$, respectively. Hence a general solution of the homogeneous system is

$$y^{(h)} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-t} + c_2 \begin{bmatrix} 4 \\ 1 \end{bmatrix} e^{2t}.$$

We determine a particular solution $\mathbf{y}^{(p)}$ of the nonhomogeneous system by the method of undetermined coefficients, starting from

$$\mathbf{y}^{(p)} = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \cos t + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} \sin t.$$

Differentiation and substitution gives, in terms of components,

(1) $-A_1\sin t + B_1\cos t = 3A_1\cos t + 3B_1\sin t - 4A_2\cos t - 4B_2\sin t + 20\cos t$

(2) $-A_2\sin t + B_2\cos t = A_1\cos t + B_1\sin t - 2A_2\cos t - 2B_2\sin t.$

The coefficients of the cosine terms in (1) give

$$B_1 = 3A_1 - 4A_2 + 20$$

and for the sine terms we get

$$-A_1 = 3B_1 - 4B_2.$$

The coefficients of the cosine terms in (2) give

$$B_2 = A_1 - 2A_2$$

and for the sine terms we get

$$-A_2 = B_1 - 2B_2.$$

Hence $A_1 = -14$, $A_2 = -6$, $B_1 = 2$, $B_2 = -2$. Consequently, a general solution of the given system is, in terms of components,

$$y_1 = c_1e^{-t} + 4c_2e^{2t} - 14\cos t + 2\sin t$$

$$y_2 = c_1e^{-t} + c_2e^{2t} - 6\cos t - 2\sin t.$$

im04.qxd 9/21/05 11:08 AM Page 91

From this and the initial condition we obtain

$$y_1(0) = c_1 + 4c_2 - 14 = 0, \qquad y_2(0) = c_1 + c_2 - 6 = 8.$$

Hence $c_1 = 14$, $c_2 = 0$. This gives the *answer*

$$y_1 = 14e^{-t} - 14\cos t + 2\sin t$$
$$y_2 = 14e^{-t} - 6\cos t - 2\sin t.$$

16. The matrix of the homogeneous system

$$\begin{bmatrix} 4 & 8 \\ 6 & 2 \end{bmatrix}$$

has the eigenvalues 10 and -4 with eigenvectors $[4 \quad 3]^T$ and $[1 \quad -1]^T$, respectively. Hence a general solution of the homogeneous system is

$$\mathbf{y}^{(h)} = c_1 \begin{bmatrix} 4 \\ 3 \end{bmatrix} e^{10t} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-4t}.$$

A particular solution of the nonhomogeneous system is obtained by the method of undetermined coefficients. We start from

$$\mathbf{y}^{(p)} = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \cos t + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} \sin t.$$

Differentiation and substitution gives, in components and $\sin t$ and $\cos t$ abbreviated by s and c, respectively,

(1) $$-A_1 s + B_1 c = 4A_1 c + 4B_1 s + 8A_2 c + 8B_2 s + 2c - 16s$$

(2) $$-A_2 s + B_2 c = 6A_1 c + 6B_1 s + 2A_2 c + 2B_2 s + c - 14s.$$

Equating the coefficients of the cosine terms in (1), we obtain

$$B_1 = 4A_1 + 8A_2 + 2.$$

Similarly, for the sine terms,

$$-A_1 = 4B_1 + 8B_2 - 16.$$

From (2) we obtain the two equations

$$B_2 = 6A_1 + 2A_2 + 1$$
$$-A_2 = 6B_1 + 2B_2 - 14.$$

The solution is $A_1 = A_2 = 0$, $B_1 = 2$, $B_2 = 1$. Hence a general solution of the nonhomogeneous system is

$$y_1 = 4c_1 e^{10t} + c_2 e^{-4t} + 2\sin t$$
$$y_2 = 3c_1 e^{10t} - c_2 e^{-4t} + \sin t.$$

From this and the initial conditions we obtain

$$y_1(0) = 4c_1 + c_2 = 15, \qquad y_2(0) = 3c_1 - c_2 = 13.$$

Hence $c_1 = 4$, $c_2 = -1$. This gives the *answer* (the solution of the initial value problem)

$$y_1 = 16e^{10t} - e^{-4t} + 2\sin t$$
$$y_2 = 12e^{10t} + e^{-4t} + \sin t.$$

im04.qxd 9/21/05 11:08 AM Page 92

18. For the left circuit, Kirchhoff's voltage law gives

$$10I_1' + I_1 - I_2 = 10^4.$$

For the right circuit,

$$I_2 - I_1 + 0.8\int I_2\,dt = 0.$$

The first equation gives

$$I_1' = -0.1I_1 + 0.1I_2 + 1000.$$

By differentiation of the second equation and substitution of the first one (in the form just obtained) we obtain

$$\begin{aligned} I_2' &= I_1' - 0.8I_2 \\ &= -0.1I_1 + 0.1I_2 + 1000 - 0.8I_2. \end{aligned}$$

Hence the system of ODEs to be solved is

$$\text{(A)} \qquad \begin{aligned} I_1' &= -0.1I_1 + 0.1I_2 + 1000 \\ I_2' &= -0.1I_1 - 0.7I_2 + 1000. \end{aligned}$$

The matrix of the homogeneous system is

$$\begin{bmatrix} -0.1 & 0.1 \\ -0.1 & -0.7 \end{bmatrix}.$$

It has the eigenvalues $-0.4 \pm 0.2\sqrt{2}$. An eigenvector for $-0.4 + 0.2\sqrt{2} = -0.11716$ is

$$\mathbf{x}^{(1)} = [1 \qquad -3 + 2\sqrt{2}]^{\mathsf{T}} = [1 \qquad -0.17157].^{\mathsf{T}}$$

An eigenvector for $-0.4 - 0.2\sqrt{2} = -0.68284$ is

$$\mathbf{x}^{(2)} = [1 \qquad -3 - 2\sqrt{2}]^{\mathsf{T}} = [1 \qquad -5.8284]^{\mathsf{T}}.$$

A particular solution of the nonhomogeneous system is $[10000 \quad 0]^{\mathsf{T}}$. We thus obtain as a general solution of the system (A)

$$\mathbf{I} = c_1\mathbf{x}^{(1)}e^{-0.11716t} + c_2\mathbf{x}^{(2)}e^{-0.68284t} + \begin{bmatrix} 10000 \\ 0 \end{bmatrix}$$

where $\mathbf{x}^{(1)}$ and $\mathbf{x}^{(2)}$ are those eigenvectors, and the initial conditions yield $c_1 = -10303$ and $c_2 = 303.30$. With these values those conditions are satisfied, except for a roundoff error.

20. Writing Project. The problem set contains a number of special cases, and the student should compare them systematically with our earlier application of the method to single ODEs in Chap. 2 to fully understand how the method extends to systems of ODEs.

SOLUTIONS TO CHAP. 4 REVIEW QUESTIONS AND PROBLEMS, page 163

12. The matrix

$$\begin{bmatrix} 9 & 0 \\ 0 & 1 \end{bmatrix}$$

im04.qxd 9/21/05 11:08 AM Page 93

has the eigenvalues 9 and 1 with eigenvectors $[1 \quad 0]^T$ and $[0 \quad 1]^T$, respectively. Hence a general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 0 \end{bmatrix} e^{9t} + c_2 \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^{t}.$$

Since $p = 10$, $q = 9$, $\Delta = 100 - 36 > 0$, the critical point is an unstable node.

14. The matrix

$$\begin{bmatrix} 3 & -3 \\ 3 & 3 \end{bmatrix}$$

has the eigenvalues $3 + 3i$ and $3 - 3i$ with eigenvectors $[1 \quad -i]^T$ and $[1 \quad i]^T$, respectively. Hence a complex general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ -i \end{bmatrix} e^{(3+3i)t} + c_2 \begin{bmatrix} 1 \\ i \end{bmatrix} e^{(3-3i)t}.$$

By Euler's formula, this becomes

$$y = e^{3t} \left(c_1 \begin{bmatrix} 1 \\ -i \end{bmatrix} (\cos 3t + i \sin 3t) + c_2 \begin{bmatrix} 1 \\ i \end{bmatrix} (\cos 3t - i \sin 3t) \right).$$

Setting $A = c_1 + c_2$, $B = i(c_1 - c_2)$, we can write this, in components,

$$\begin{aligned} y_1 &= e^{3t}(c_1 + c_2) \cos 3t + (ic_1 - ic_2) \sin 3t) \\ &= e^{3t}(A \cos 3t + B \sin 3t) \\ y_2 &= e^{3t}((-ic_1 + ic_2) \cos 3t + (c_1 + c_2) \sin 3t) \\ &= e^{3t}(-B \cos 3t + A \sin 3t). \end{aligned}$$

Since $p = 6$, $q = 18$, $\Delta = 36 - 72 < 0$, the critical point is an unstable spiral point.

16. The matrix

$$\begin{bmatrix} -3 & -2 \\ -2 & -3 \end{bmatrix}$$

has the eigenvalues -5 and -1 with eigenvectors $[1 \quad 1]^T$ and $[1 \quad -1]^T$, respectively. Hence a general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-5t} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-t}.$$

Since $p = -6$, $q = 5$, $\Delta = 36 - 20 > 0$, the critical point is a stable and attractive node.

18. The matrix

$$\begin{bmatrix} 3 & 5 \\ -5 & -3 \end{bmatrix}$$

has the eigenvalues $4i$ and $-4i$ with eigenvectors $[1 \quad -0.6 + 0.8i]^T$ and $[1 \quad -0.6 - 0.8i]^T$, respectively. Hence a complex general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ -0.6 + 0.8i \end{bmatrix} e^{4it} + c_2 \begin{bmatrix} 1 \\ -0.6 - 0.8i \end{bmatrix} e^{-4it}.$$

im04.qxd 9/21/05 11:08 AM Page 94

Setting $A = c_1 + c_2$, $B = i(c_1 - c_2)$ and using Euler's formula, we obtain, in terms of components,

$$\begin{aligned} y_1 &= (c_1 + c_2)\cos 4t + i(c_1 - c_2)\sin 4t \\ &= A\cos 4t + B\sin 4t \\ y_2 &= (-0.6c_1 + 0.8c_1 i - 0.6c_2 - 0.8c_2 i)\cos 4t \\ &\quad + (-i\cdot 0.6c_1 + i\cdot 0.6c_2 - 0.8c_1 - 0.8c_2)\sin 4t \\ &= (-0.6A + 0.8B)\cos 4t + (-0.6B - 0.8A)\sin 4t. \end{aligned}$$

Since $p = 0$ and $q = -9 + 25 > 0$, the critical point is a center.

20. The matrix of the homogeneous system

$$\begin{bmatrix} 0 & 3 \\ 12 & 0 \end{bmatrix}$$

has the eigenvalues 6 and -6 with eigenvectors $[1 \quad 2]^T$ and $[1 \quad -2]^T$, respectively. A particular solution of the nonhomogeneous system is obtained by the method of undetermined coefficients. We set

$$y_1^{(p)} = a_1 t + b_1, \qquad y_2^{(p)} = a_2 t + b_2.$$

Differentiation and substitution gives

$$a_1 = 3a_2 t + 3b_2 + 6t, \qquad a_2 = 12a_1 t + 12b_1 + 1.$$

Hence $a_1 = 0$, $b_1 = -\frac{1}{4}$, $a_2 = -2$, $b_2 = 0$. The *answer* is

$$y_1 = c_1 e^{6t} + c_2 e^{-6t} - \tfrac{1}{4}$$

$$y_2 = 2c_1 e^{6t} - 2c_2 e^{-6t} - 2t.$$

22. The matrix

$$\begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix}$$

has the eigenvalues 3 and -1 with eigenvectors $[1 \quad 2]^T$ and $[1 \quad -2]^T$, respectively. A particular solution of the nonhomogeneous system is obtained by the method of undetermined coefficients. We set

$$y_1^{(p)} = a_1 \cos t + b_1 \sin t, \qquad y_2^{(p)} = a_2 \cos t + b_2 \sin t.$$

Differentiation and substitution gives the following two equations, where $c = \cos t$ and $s = \sin t$,

(1) $$-a_1 s + b_1 c = a_1 c + b_1 s + a_2 c + b_2 s + s$$

(2) $$-a_2 s + b_2 c = 4a_1 c + 4b_1 s + a_2 c + b_2 s.$$

From the cosine terms and the sine terms in (1) we obtain

$$b_1 = a_1 + a_2, \qquad -a_1 = b_1 + b_2 + 1.$$

Similarly from (2),

$$b_2 = 4a_1 + a_2, \qquad -a_2 = 4b_1 + b_2.$$

Hence $a_1 = -0.3$, $a_2 = 0.4$, $b_1 = 0.1$, $b_2 = -0.8$. This gives the *answer*

$$y_1 = c_1 e^{3t} + c_2 e^{-t} - 0.3\cos t + 0.1\sin t$$

$$y_2 = 2c_1 e^{3t} - 2c_2 e^{-t} + 0.4\cos t - 0.8\sin t.$$

im04.qxd 9/21/05 11:08 AM Page 95

24. The matrix of the homogeneous system

$$\begin{bmatrix} 1 & -2 \\ 3 & -4 \end{bmatrix}$$

has the eigenvalues -2 and -1 with eigenvectors $[1 \quad 1.5]^T$ and $[1 \quad 1]^T$, respectively. A particular solution is obtained by the method of undetermined coefficients. The *answer* is

$$y_1 = c_1e^{-2t} + c_2e^{-t} + 1.3\cos t - 0.1\sin t$$
$$y_2 = 1.5c_1e^{-2t} + c_2e^{-t} + 0.7\cos t + 0.1\sin t.$$

26. The balance equations are

$$y_1' = -\tfrac{16}{200}y_1 + \tfrac{6}{100}y_2$$
$$y_2' = \tfrac{16}{200}y_1 - \tfrac{16}{100}y_2.$$

Note that the denominators differ. Note further that the outflow to the right must be included in the balance equation for T_2. The matrix is

$$\begin{bmatrix} -0.08 & 0.06 \\ 0.08 & -0.16 \end{bmatrix}.$$

It has the eigenvalues -0.2 and -0.04 with eigenvectors $[1 \quad -2]^T$ and $[1.5 \quad 1]^T$, respectively. The initial condition is $y_1(0) = 160$, $y_2(0) = 0$. This gives the *answer*

$$y_1 = 40e^{-0.2t} + 120e^{-0.04t}$$
$$y_2 = -80e^{-0.2t} + 80e^{-0.04t}.$$

28. From the figure we obtain by Kirchhoff's voltage law for the left loop

$$0.4I_1' + 0.5(I_1 - I_2) + 0.7I_1 = 1000$$

and for the right loop

$$0.5I_2' + 0.5(I_2 - I_1) = 0.$$

Written in the usual form, we obtain

$$I_1' = -3I_1 + 1.25I_2 + 2500$$
$$I_2' = I_1 - I_2.$$

The matrix of the homogeneous system is

$$\begin{bmatrix} -3 & 1.25 \\ 1 & -1 \end{bmatrix}.$$

It has the eigenvalues -3.5 and -0.5 with eigenvectors $[5 \quad -2]^T$ and $[1 \quad 2]^T$, respectively. From this and the initial conditions we obtain the solution

$$I_1 = -\tfrac{12500}{21}e^{-3.5t} - \tfrac{2500}{3}e^{-0.5t} + \tfrac{10000}{7}$$
$$I_2 = \tfrac{5000}{21}e^{-3.5t} - \tfrac{5000}{3}e^{-0.5t} + \tfrac{10000}{7}.$$

30. The second ODE may be written

$$y_1'' = y_2' = y_1(2 - y_1)(2 + y_1).$$

im04.qxd 9/21/05 11:08 AM Page 96

Hence the critical points are (0, 0), (2, 0), (−2, 0).

Linearization at (0, 0) gives the system

$$y_1' = y_2$$
$$y_2' = 4y_1.$$

Since $q = -4$, this is a saddle point.

At (2, 0) the transformation is $y_1 = 2 + \tilde{y}_1$. Hence the right side of the second ODE becomes $(2 + \tilde{y}_1)(-\tilde{y}_1)(4 + \tilde{y}_1)$, so that the linearized system is

$$\tilde{y}_1' = \tilde{y}_2$$
$$\tilde{y}_2' = -8\tilde{y}_1.$$

Since $\tilde{p} = 0$ and $\tilde{q} = 8 > 0$, this is a center.

Similarly at (−2, 0), the transformation is $y_1 = -2 + \tilde{\tilde{y}}_1$, so that the right side becomes $(-2 + \tilde{\tilde{y}}_1)(4 - \tilde{\tilde{y}}_1)\tilde{\tilde{y}}_1$, and the linearized system is the same and thus has a center as its critical point.

32. $\cos y_2 = 0$ when $y_2 = (2n + 1)\pi/2$, where n is any integer. This gives the location of the critical points, which lie on the y_2-axis $y_1 = 0$ in the phase plane.

For $(0, \frac{1}{2}\pi)$ the transformation is $y_2 = \frac{1}{2}\pi + \tilde{y}_2$. Now

$$\cos y_2 = \cos(\tfrac{1}{2}\pi + \tilde{y}_2) = -\sin \tilde{y}_2 \approx -\tilde{y}_2.$$

Hence the linearized system is

$$\tilde{y}_1' = -\tilde{y}_2$$
$$\tilde{y}_2' = 3\tilde{y}_1.$$

For its matrix

$$\begin{bmatrix} 0 & -1 \\ 3 & 0 \end{bmatrix}$$

we obtain $\tilde{p} = 0$, $\tilde{q} = 3 > 0$, so that this is a center. Similarly, by periodicity, the critical points at $(4n + 1)\pi/2$ are centers.

For $(0, -\frac{1}{2}\pi)$ the transformation is $y_2 = -\frac{1}{2}\pi + \tilde{\tilde{y}}_2$. From

$$\cos y_2 = \cos(-\tfrac{1}{2}\pi + \tilde{\tilde{y}}_2) = \sin \tilde{\tilde{y}}_2 \approx \tilde{\tilde{y}}_2$$

we obtain the linearized system

$$\tilde{\tilde{y}}_1' = \tilde{\tilde{y}}_2$$
$$\tilde{\tilde{y}}_2' = 3\tilde{\tilde{y}}_1$$

with matrix

$$\begin{bmatrix} 0 & 1 \\ 3 & 0 \end{bmatrix}$$

for which $\tilde{\tilde{q}} = -3 < 0$, so that this point and the points with $y_2 = (4n - 1)\pi/2$ on the y_2-axis are saddle points.

im05.qxd 9/21/05 11:10 AM Page 97

CHAPTER 5 Series Solutions of ODEs. Special Functions

Changes of Text

Minor changes, streamlining the text to make it more teachable, retaining the general structure of the chapter and the opportunity to familiarize the student with an overview of some of the techniques used in connection with **higher special functions,** also in connection with a CAS.

SECTION 5.1. Power Series Method, page 167

Purpose. A simple introduction to the technique of the power series method in terms of simple examples whose solution the student knows very well.

SOLUTIONS TO PROBLEM SET 5.1, page 170

2. $y = a_0(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - + \cdots) = a_0 e^{-x^2/2}$

4. A general solution is $y = c_1e^x + c_2e^{-x}$. Both functions of the basis contain every power of x. The power series method automatically gives a general solution in which one function of the basis is even and the other is odd,

$$y = a_0(1 + \tfrac{1}{2}x^2 + \tfrac{1}{24}x^4 + \cdots) + a_1(x + \tfrac{1}{6}x^3 + \tfrac{1}{120}x^5 + \cdots) = a_0 \cosh x + a_1 \sinh x.$$

6. $y = a_0(1 - 3x + \frac{9}{2}x^2 - \frac{11}{2}x^3 + \frac{51}{8}x^4 - + \cdots)$. Even if the solution turns out to be a known function, as in the present case,

$$y = a_0 \exp(-3x - x^3)$$

as obtained by separating variables, it is generally not easy to recognize this from a power series obtained. Of course, this is generally not essential, because the method is primarily designed for ODEs whose solutions define *new* functions. The task of recognizing a power series as a known function does however occur in practice, for instance, in proving that certain Bessel functions or hypergeometric functions reduce to familiar known functions (see Secs. 5.4, 5.5).

8. Substitution of the power series for y and y' gives

$$\begin{aligned}
&(x^5 + 4x^3)(a_1 + 2a_2x + 3a_3x^2 + \cdots) \\
&= 4a_1x^3 + 8a_2x^4 + (12a_3 + a_1)x^5 + \cdots \\
&= (5x^4 + 12x^2)(a_0 + a_1x + a_2x^2 + \cdots) \\
&= 12a_0x^2 + 12a_1x^3 + (12a_2 + 5a_0)x^4 + (12a_3 + 5a_1)x^5 + \cdots
\end{aligned}$$

Comparing coefficients of each power of x, we obtain

$$\begin{aligned}
x^2&: \quad a_0 = 0 \\
x^3&: \quad 4a_1 = 12a_1, \qquad a_1 = 0 \\
x^4&: \quad 8a_2 = 12a_2 + 5a_0, \qquad a_2 = 0 \\
x^5&: \quad 12a_3 + a_1 = 12a_3 + 5a_1, \qquad a_3 \text{ arbitrary} \\
x^6&: \quad 16a_4 + 2a_2 = 12a_4 + 5a_2, \qquad a_4 = 0 \\
x^7&: \quad 3a_3 + 20a_5 = 5a_3 + 12a_5, \qquad a_5 = \tfrac{1}{4}a_3 \\
x^8&: \quad 4a_4 + 24a_6 = 5a_4 + 12a_6, \qquad 24a_6 = 12a_6, \qquad a_6 = 0, \qquad \text{etc.}
\end{aligned}$$

im05.qxd 9/21/05 11:10 AM Page 98

Here we see why a power series may terminate in some cases. The *answer* is

$$y = a_3(x^3 + \tfrac{1}{4}x^5).$$

10. $y = a_0\left(1 - \dfrac{1}{2!}\,x^2 - \dfrac{1}{4!}\,x^4 - \dfrac{3}{6!}\,x^6 - \dfrac{3 \cdot 5}{8!}\,x^8 - \cdots\right) + a_1x$

12. $s = x + \frac{1}{3}x^3 + \frac{2}{15}x^5$, $s(\frac{1}{4}\pi) = 0.98674$, a good approximation of the exact value $1 = \tan \frac{1}{4}\pi$.

Through these calculations of values the student should realize that a series can be used for numeric work just like a solution formula, with proper caution regarding convergence and accuracy.

14. $s = 4 - x^2 - \frac{1}{3}x^3 + \frac{1}{30}x^5$, $s(2) = -\frac{8}{5}$. This x is too large to give useful values. The exact solution

$$y = (x - 2)^2e^x$$

shows that the value should be 0.

16. $s = \frac{15}{8}x - \frac{35}{4}x^3 + \frac{63}{8}x^5$. This is the Legendre polynomial P_5, a solution of this Legendre equation with parameter $n = 5$, to be discussed in Sec. 5.3. The initial conditions were chosen accordingly, so that a second linearly independent solution (a Legendre function) does not appear in the answer. $s(0.5) = 0.089844$.

18. This should encourage the student to use the library or to browse the Web, to learn where to find relevant information, to see in passing that there are various other expansions of functions (other series, products, continued fractions, etc.), and to take a look into various standard books. The limited task at hand should beware the student of getting lost in the flood of books. Lists such as the one required can be very helpful; similarly in connection with Fourier series.

SECTION 5.2. Theory of the Power Series Method, page 170

Purpose. Review of power series and a statement of the basic existence theorem for power series solutions (without proof, which would exceed the level of our presentation).

Main Content, Important Concepts

Radius of convergence (7)

Differentiation, multiplication of power series

Technique of index shift

Real analytic function (needed again in Sec. 5.4)

Comment

Depending on the preparation of the class, skip the section or discuss just a few less known facts.

SOLUTIONS TO PROBLEM SET 5.2, page 176

2. $\left|\dfrac{a_{m+1}}{a_m}\right| = \dfrac{1/(3^{m+1}(m+2)^2)}{1/(3^m(m+1)^2)} \to \dfrac{1}{3}$. Hence the convergence radius of the series, considered as a function of $t = (x + 1)^2$, is 3. This gives the *answer* $\sqrt{3}$. (In Probs. 3 and 6 the situation is similar.)

4. 1

im05.qxd 9/21/05 11:10 AM Page 99

6. ∞, as is obvious from the occurrence of the factorial.

8. The quotient whose limit will give the reciprocal of the convergence radius is

$$\frac{(4m+4)!/(m+1)!^4}{(4m)!/(m!)^4} = \frac{(4m+4)(4m+3)(4m+2)(4m+1)}{(m+1)^4}.$$

The limit as $m \to \infty$ is $4^4 = 256$. Hence the convergence radius is fairly small, 1/256.

10. 0

12. ∞

14. $m-3=s$, $m=s+3$, $\displaystyle\sum_{s=0}^{\infty} \frac{(-1)^{s+4}}{4^{s+3}} x^s$; $R=4$. Of course, $(-1)^{s+4} = (-1)^s$.

16. $a_0(1 - \frac{1}{6}x^3 + \frac{1}{180}x^6 - \frac{1}{12960}x^9 + - \cdots) + a_1(x - \frac{1}{12}x^4 + \frac{1}{504}x^7 - + \cdots)$. This solution can be expressed in terms of Airy or Bessel functions, but in a somewhat complicated fashion, so that in many cases for numeric and other purposes it will be practical to use the power series (a partial sum with sufficiently many terms) directly.

18. We obtain

$$a_0(1 - \tfrac{1}{6}x^3 - \tfrac{1}{24}x^4 - \tfrac{1}{120}x^5 + \cdots) + a_1(x + \tfrac{1}{2}x^2 + \tfrac{1}{6}x^3 - \tfrac{1}{24}x^4 - \tfrac{1}{30}x^5 - \cdots).$$

The solution has a (complicated) representation in terms of Airy functions, and the remark in the solution of Prob. 16 applies equally well, even more. The students should also be told that many ODEs can be reduced to the standard ones that we discuss in the text, so that in this way they can save work in deriving formulas for the various solutions.

20. We obtain

$$a_0(1 - \tfrac{1}{2}x^2 + \tfrac{5}{24}x^4 - \tfrac{1}{16}x^6 + - \cdots) + a_1(x - \tfrac{1}{2}x^3 + \tfrac{7}{40}x^5 - \tfrac{11}{240}x^7 + - \cdots).$$

This solution can be expressed in terms of Bessel and exponential functions.

22. We obtain

$$a_0(1 + x^2 + \tfrac{1}{2}x^4 + \tfrac{1}{6}x^6 + \tfrac{1}{24}x^8 + \cdots) + a_1(x + x^3 + \tfrac{1}{2}x^5 + \tfrac{1}{6}x^7 + \cdots).$$

This can be written as $(a_0 + a_1x)$ times the same power series, which obviously represents e^{x^2}.

24. Team Project. The student should see that power series reveal many basic properties of the functions they represent. Familiarity with the functions considered should help students in understanding the basic idea without being irritated by unfamiliar notions or notations and more involved formulas. (d) illustrates that not *all* properties become visible directly from the series. For instance, the periodicity of $\cos x$ and $\sin x$, the boundedness, and the location of the zeros are properties of this kind.

SECTION 5.3. Legendre's Equation. Legendre Polynomials $P_n(x)$, page 177

Purpose. This section on Legendre's equation, one of the most important ODEs, and its solutions is more than just an exercise on the power series method. It should give the student a feel for the usefulness of power series in exploring properties of **special functions** and for the wealth of relations between functions of a one-parameter family (with parameter n).

Legendre's equation occurs again in Secs. 5.7 and 5.8.

Comment on Literature and History

For literature on Legendre's equation and its solutions, see Refs. [GR1] and [GR10].

im05.qxd 9/21/05 11:10 AM Page 100

Legendre's work on the subject appeared in 1785 and Rodrigues's contribution (see Prob. 8), in 1816.

SOLUTIONS TO PROBLEM SET 5.3, page 180

4. This follows from (4), giving the limit 1 as $s \to \infty$ (note that n is fixed):

$$\left| \frac{a_{s+2}}{a_s} \right| = \frac{|n - s|(n + s + 1)}{(s + 2)(s + 1)} \to 1.$$

8. We have

$$(x^2 - 1)^n = \sum_{m=0}^{n} (-1)^m \binom{n}{m} (x^2)^{n-m}.$$

Differentiating n times, we can express the product of occurring factors $(2n - 2m)(2n - 2m - 1) \cdots$ as a quotient of factorials and get

$$\frac{d^n}{dx^n} [(x^2 - 1)^n] = \sum_{m=0}^{M} (-1)^m \frac{n!}{m!(n - m)!} \frac{(2n - 2m)!}{(n - 2m)!} x^{n-2m}$$

with M as in (11). Divide by $n!2^n$. Then the left side equals the right side in Rodrigues's formula, and the right side equals the right side of (11).

10. We know that at the endpoints of the interval $-1 \leqq x \leqq 1$ all the Legendre polynomials have the values ± 1. It is interesting that in between they are strictly less than 1 in absolute value (P_0 excluded). Furthermore, absolute values between $\frac{1}{2}$ and 1 are taken only near the endpoints, so that in an interval, say $-0.8 \leqq x \leqq 0.8$, they are less than $\frac{1}{2}$ in absolute value (P_0, P_1, P_2 excluded).

14. Team Project. (a) Following the hint, we obtain

$$\text{(A)} \qquad (1 - 2xu + u^2)^{-1/2} = 1 + \frac{1}{2}(2xu - u^2) + \cdots + \frac{1 \cdot 3 \cdots (2n - 1)}{2 \cdot 4 \cdots (2n)} (2xu - u^2)^n + \cdots$$

and for the general term on the right,

$$\text{(B)} \qquad (2xu - u^2)^m = (2x)^m u^m - m(2x)^{m-1} u^{m+1} + \frac{m(m - 1)}{2!} (2x)^{m-2} u^{m+2} + \cdots.$$

Now u^n occurs in the first term of the expansion (B) of $(2xu - u^2)^n$, in the second term of the expansion (B) of $(2xu - u^2)^{n-1}$, and so on. From (A) and (B) we see that the coefficients of u^n in those terms are

$$\frac{1 \cdot 3 \cdots (2n - 1)}{2 \cdot 4 \cdots (2n)} (2x)^n = a_n x^n \qquad \text{[see (8)]},$$

$$-\frac{1 \cdot 3 \cdots (2n - 3)}{2 \cdot 4 \cdots (2n - 2)} (n - 1)(2x)^{n-2} = -\frac{2n}{2n - 1} \frac{n - 1}{4} a_n x^{n-2} = a_{n-2} x^{n-2}$$

and so on. This proves the assertion.

(b) Set $u = r_1/r_2$ and $x = \cos \theta$.

im05.qxd 9/21/05 11:10 AM Page 101

(c) Use the formula for the sum of the geometric series and set $x = 1$ and $x = -1$. Then set $x = 0$ and use

$$(1 + u^2)^{-1/2} = \sum \binom{-1/2}{m} u^{2m}.$$

(d) Abbreviate $1 - 2xu + u^2 = U$. Differentiation of (13) with respect to u gives

$$-\frac{1}{2} U^{-3/2}(-2x + 2u) = \sum_{n=0}^{\infty} nP_n(x)u^{n-1}.$$

Multiply this equation by U and represent $U^{-1/2}$ by (13):

$$(x - u)\sum_{n=0}^{\infty} P_n(x)u^n = (1 - 2xu + u^2)\sum_{n=0}^{\infty} nP_n(x)u^{n-1}.$$

In this equation, u^n has the coefficients

$$xP_n(x) - P_{n-1}(x) = (n + 1)P_{n+1}(x) - 2nxP_n(x) + (n - 1)P_{n-1}(x).$$

Simplifying gives the asserted Bonnet recursion.

SECTION 5.4. Frobenius Method, page 182

Purpose. To introduce the student to the Frobenius method (an extension of the power series method), which is important for ODEs with coefficients that have **singularities,** notably **Bessel's equation,** so that the power series method can no longer handle them. This extended method requires more patience and care.

Main Content, Important Concepts

Regular and singular points

Indicial equation, three cases of roots (one unexpected)

Frobenius theorem, forms of bases in those cases

Short Courses. Take a quick look at those bases in Frobenius's theorem, say how it fits with the Euler–Cauchy equation, and omit everything else.

Comment on "Regular Singular" and "Irregular Singular"

These terms are used in some books and papers, but there is hardly any need for confusing the student by using them, simply because we cannot do (and don't do) anything about "irregular singular points." A simple use of "regular" and "singular" (as in complex analysis, where holomorphic functions are also known as "regular analytic functions") may thus be the best terminology.

Comment on Footnote 5

Gauss was born in Braunschweig (Brunswick) in 1777. At the age of 16, in 1793 he discovered the method of least squares (Secs. 20.5, 25.9). From 1795 to 1798 he studied at Göttingen. In 1799 he obtained his doctor's degree at Helmstedt. In 1801 he published his first masterpiece, *Disquisitiones arithmeticae* (*Arithmetical Investigations,* begun in 1795), thereby initiating modern number theory. In 1801 he became generally known when his calculations enabled astronomers (Zach, Olbers) to rediscover the planet Ceres, which had been discovered in 1801 by Piazzi at Palermo but had been visible only very briefly. He became the director of the Göttingen observatory in 1807 and remained there until his

im05.qxd 9/21/05 11:10 AM Page 102

death. In 1809 he published his famous *Theoria motus corporum coelestium in sectionibus conicis solem ambientium* (*Theory of the Heavenly Bodies Moving About the Sun in Conic Sections;* Dover Publications, 1963), resulting from his further work in astronomy. In 1814 he developed his method of numeric integration (Sec. 19.5). His *Disquisitiones generales circa superficies curvas* (*General Investigations Regarding Curved Surfaces,* 1828) represents the foundation of the differential geometry of surfaces and contributes to conformal mapping (Sec. 17.1). His clear conception of the complex plane dates back to his thesis, whereas his first publication on this topic was not before 1831. This is typical: Gauss left many of his most outstanding results (non-Euclidean geometry, elliptic functions, etc.) unpublished. His paper on the hypergeometric series published in 1812 is the first systematic investigation into the convergence of a series. This series, generalizing the geometric series, allows a study of many special functions from a common point of view.

SOLUTIONS TO PROBLEM SET 5.4, page 187

2. The indicial equation is $r(r-1)-2=(r-2)(r+1)=0$. The roots are $r_1=2$, $r_2=-1$. This is Case 3. $y_1=(x+2)^2$, $y_2=1/(x+2)$. *Check:* Set $x+2=t$ to get an Euler–Cauchy equation, $t^2\ddot{y}-2y=0$.

4. To determine r_1, r_2 from (4), we write the ODE in the form (1′),

$$x^2y''+(\tfrac{3}{2}x-2x^2)y'+(x^2-\tfrac{3}{2}x)y=0.$$

Then we see that $b=\frac{3}{2}-2x$, $b_0=\frac{3}{2}$, $c_0=0$, hence

$$r(r-1)+\tfrac{3}{2}r=r(r+\tfrac{1}{2})=0, \qquad r_1=0, \quad r_2=-\tfrac{1}{2}.$$

We obtain the first solution by substituting (2) with $r=0$ into the ODE (which we can take in the given form):

$$\sum_{m=0}^{\infty}[2m(m-1)a_mx^{m-1}+3ma_mx^{m-1}-4ma_mx^m+2a_mx^{m+1}-3a_mx^m]=0.$$

Hence equating the sum of the coefficients of the power x^s to zero, we have

$$2(s+1)sa_{s+1}+3(s+1)a_{s+1}-4sa_s+2a_{s-1}-3a_s=0.$$

Combining terms, we can write this in the form

$$(2s^2+5s+3)a_{s+1}-(4s+3)a_s+2a_{s-1}=0.$$

For $s=0$, since there is no coefficient a_{-1}, we obtain $3a_1-3a_0=0$. Hence $a_1=a_0$. For $s=1$ we obtain

$$10a_2-7a_1+2a_0=0, \qquad 10a_2=5a_0, \qquad a_2=\tfrac{1}{2}a_0.$$

This already was a special case of the recurrence formula obtained by solving the previous equation for a_{s+1}, namely,

$$a_{s+1}=\frac{1}{(s+1)(2s+3)}[(4s+3)a_s-2a_{s-1}].$$

For $s=2$, taking $a_0=1$ this gives after simplification $a_3=1/3!$ and in general $a_{s+1}=1/(s+1)!$. Hence a first solution is $y_1(x)=e^x$.

Second Solution. Since $r_1=0$, $r_2=-\frac{1}{2}$, we are in Case 1 and have to substitute

$$y_2(x)=x^{-1/2}(A_0+A_1x+\cdots)$$

im05.qxd 9/21/05 11:10 AM Page 103

and determine these coefficients. We first have, using m as the summation letter, as before,

$$\sum_{m=0}^{\infty} [2(m-\tfrac{1}{2})(m-\tfrac{3}{2})A_m x^{m-3/2} + 3(m-\tfrac{1}{2})A_m x^{m-3/2} - 4(m-\tfrac{1}{2})A_m x^{m-1/2} + 2A_m x^{m+1/2} - 3A_m x^{m-1/2}] = 0.$$

Hence equating the sum of the coefficients of the power $x^{s-1/2}$ to zero, we obtain

$$2(s+\tfrac{1}{2})(s-\tfrac{1}{2})A_{s+1} + 3(s+\tfrac{1}{2})A_{s+1} - 4(s-\tfrac{1}{2})A_s + 2A_{s-1} - 3A_s = 0.$$

Solving for A_{s+1} in terms of A_s and A_{s-1}, we obtain

$$A_{s+1} = \frac{1}{(s+1)(2s+1)}\,[(4s+1)A_s - 2A_{s-1}].$$

Noting that there is no A_{-1}, we successively get, taking $A_0 = 1$,

$$A_1 = A_0 = 1 \quad (s=0), \qquad A_2 = \frac{1}{2\cdot 3}\,[5A_1 - 2A_0] = \frac{1}{2!} \quad (s=1)$$

$$A_3 = 1/3!, \qquad A_4 = 1/4!$$

etc. This gives as a second linearly independent solution $y_2 = e^x/\sqrt{x}$.

6. Substitution of (2) and the derivatives (2*) gives

$$\text{(A)} \qquad 4\sum_{m=0}^{\infty}(m+r)(m+r-1)a_m x^{m+r-1} + 2\sum_{m=0}^{\infty}(m+r)a_m x^{m+r-1} + \sum_{m=0}^{\infty} a_m x^{m+r} = 0.$$

Writing this out, we have

$$\begin{aligned} &4r(r-1)a_0x^{r-1} + 4(r+1)ra_1x^r + 4(r+2)(r+1)a_2x^{r+1} + \cdots \\ &\quad + 2ra_0x^{r-1} + 2(r+1)\,a_1x^r + \qquad 2(r+2)a_2x^{r+1} + \cdots \\ &\qquad\quad + \qquad a_0x^r + \qquad\qquad a_1x^{r+1} + \cdots = 0. \end{aligned}$$

By equating the sum of the coefficients of x^{r-1} to zero we obtain the indicial equation

$$4r(r-1) + 2r = 0; \qquad \text{thus} \qquad r^2 - \tfrac{1}{2}r = 0.$$

The roots are $r_1 = \frac{1}{2}$ and $r_2 = 0$. This is Case 1.

By equating the sum of the coefficients of x^{r+s} in (A) to zero we obtain (take $m + r - 1 = r + s$, thus $m = s + 1$ in the first two series and $m = s$ in the last series)

$$4(s+r+1)(s+r)a_{s+1} + 2(s+r+1)a_{s+1} + a_s = 0.$$

By simplification we find that this can be written

$$4(s+r+1)(s+r+\tfrac{1}{2})a_{s+1} + a_s = 0.$$

We solve this for a_{s+1} in terms of a_s:

$$\text{(B)} \qquad a_{s+1} = -\frac{a_s}{(2s+2r+2)(2s+2r+1)} \qquad (s = 0, 1, \cdots).$$

im05.qxd 9/21/05 11:10 AM Page 104

First solution. We determine a first solution $y_1(x)$ corresponding to $r_1 = \frac{1}{2}$. For $r = r_1$, formula (B) becomes

$$a_{s+1} = -\frac{a_s}{(2s+3)(2s+2)} \qquad (s = 0, 1, \cdots).$$

From this we get successively

$$a_1 = -\frac{a_0}{3 \cdot 2}, \qquad a_2 = -\frac{a_1}{5 \cdot 4}, \qquad a_3 = -\frac{a_2}{7 \cdot 6}, \qquad \text{etc.}$$

In many practical situations an explicit formula for a_m will be rather complicated. Here it is simple: by successive substitution we get

$$a_1 = -\frac{a_0}{3!}, \qquad a_2 = \frac{a_0}{5!}, \qquad a_3 = -\frac{a_0}{7!}, \qquad \cdots$$

and in general, taking $a_0 = 1$,

$$a_m = \frac{(-1)^m}{(2m+1)!} \qquad (m = 0, 1, \cdots).$$

Hence the first solution is

$$y_1(x) = x^{1/2} \sum_{m=0}^{\infty} \frac{(-1)^m}{(2m+1)!} x^m = \sqrt{x}\left(1 - \frac{1}{6}x + \frac{1}{120}x^2 - + \cdots\right) = \sin\sqrt{x}.$$

Second Solution. If you recognize y_1 as a familiar function, apply reduction of order (see Sec. 2.1). If not, start from (6) with $r_2 = 0$. For $r = r_2 = 0$, formula (B) [with A_{s+1} and A_s instead of a_{s+1} and a_s] becomes

$$A_{s+1} = -\frac{A_s}{(2s+2)(2s+1)} \qquad (s = 0, 1, \cdots).$$

From this we get successively

$$A_1 = -\frac{A_0}{2 \cdot 1}, \qquad A_2 = -\frac{A_1}{4 \cdot 3}, \qquad A_3 = -\frac{A_2}{6 \cdot 5},$$

and by successive substitution we have

$$A_1 = -\frac{A_0}{2!}, \qquad A_2 = \frac{A_0}{4!}, \qquad A_3 = -\frac{A_0}{6!}, \qquad \cdots$$

and in general, taking $A_0 = 1$,

$$A_m = \frac{(-1)^m}{(2m)!}.$$

Hence the second solution, of the form (6) with $r_2 = 0$, is

$$y_2(x) = \sum_{m=0}^{\infty} \frac{(-1)^m}{(2m)!} x^m = 1 - \tfrac{1}{2}x + \tfrac{1}{24}x^2 - + \cdots = \cos\sqrt{x}.$$

8. $y_1 = x\left(1 + \dfrac{x}{1!2!} + \dfrac{x^2}{2!3!} + \dfrac{x^3}{3!4!} + \cdots\right)$. From this and (10) we obtain

$$y_2 = y_1 \ln x + 1 - \tfrac{3}{4}x^2 - \tfrac{7}{36}x^3 - \tfrac{35}{1728}x^4 - \cdots.$$

In the present case, k and A_1 in (10) are at first arbitrary, and our y_2 corresponds to the choice $k = 1$ and $A_1 = 0$. Choosing $A_1 \neq 0$, we obtain the above expression for y_2 plus $A_1 y_1$.

im05.qxd 9/21/05 11:10 AM Page 105

10. $b_0 = 0$, $c_0 = -2$, $r(r-1) - 2 = (r-2)(r+1)$, $r_1 = 2$, $r_2 = -1$,

$$y_1 = x^2\left(1 - \frac{1}{2}x^2 + \frac{9}{56}x^4 - \frac{13}{336}x^6 + \cdots\right)$$

$$y_2 = \frac{1}{x}\left(12 - 6x^2 + \frac{9}{2}x^4 - \frac{7}{4}x^6 + \cdots\right).$$

12. $b_0 = 6$, $c_0 = 6$, $r_1 = -2$, $r_2 = -3$; the series are

$$y_1 = \frac{1}{x^2} - \frac{2}{3} + \frac{2}{15}x^2 - \frac{4}{315}x^4 + - \cdots = \frac{1}{2}\,\frac{\sin 2x}{x^3}$$

$$y_2 = \frac{1}{x^3} - \frac{2}{x} + \frac{2}{3}x - \frac{4}{45}x^3 + - \cdots = \frac{\cos 2x}{x^3}.$$

14. We obtain

$$y_1 = 1 + \frac{x^2}{2^2} + \frac{x^4}{(2\cdot 4)^2} + \frac{x^6}{(2\cdot 4\cdot 6)^2} + \cdots,$$

$$y_2 = y_1 \ln x - \frac{x^2}{4} - \frac{3x^4}{8\cdot 16} - \frac{11x^6}{64\cdot 6\cdot 36} - \cdots.$$

16. We obtain

$$y_1 = \frac{1}{x} + \frac{x}{6} + \frac{x^3}{120} + \frac{x^5}{5040} + \cdots = \frac{\sinh x}{x^2}$$

$$y_2 = \frac{1}{x^2} + \frac{1}{2} + \frac{x^2}{24} + \frac{x^4}{720} + \cdots = \frac{\cosh x}{x^2}.$$

18. Team Project. (b) In (7b) of Sec. 5.2,

$$\frac{a_{n+1}}{a_n} = \frac{(a+n)(b+n)}{(n+1)(c+n)} \to 1,$$

hence $R = 1$.

(c) In the third and fourth lines,

$$\arctan x = x - \tfrac{1}{3}x^3 + \tfrac{1}{5}x^5 - \tfrac{1}{7}x^7 + - \cdots \qquad (|x| < 1)$$

$$\arcsin x = x + \frac{1}{2\cdot 3}x^3 + \frac{1\cdot 3}{2\cdot 4\cdot 5}x^5 + \frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6\cdot 7}x^7 + \cdots \qquad (|x| < 1).$$

(d) The roots can be read off from (15), brought to the form (1′) by multiplying it by x and dividing by $1 - x$; then $b_0 = c$ in (4) and $c_0 = 0$.

20. $a = 1$, $b = 1$, $c = -\frac{1}{2}$, $y = AF(1, 1, -\frac{1}{2}; x) + Bx^{3/2}F(\frac{5}{2}, \frac{5}{2}, \frac{5}{2}; x)$

22. $y = c_1F(-1, \frac{1}{3}, \frac{1}{3}; t+1) + c_2(t+1)^{2/3}F(-\frac{1}{3}, 1, \frac{5}{3}; t+1)$

24. $t^2 - 3t + 2 = (t-1)(t-2) = 0$. Hence the transformation is $x = t - 1$. It gives the ODE

$$4(x^2 - x)y'' - 2y' + y = 0.$$

To obtain the standard form of the hypergeometric equation, multiply this ODE by $-\frac{1}{4}$. It is clear that the factor 4 must be absorbed, but don't forget the factor -1; otherwise your values for a, b, c will not be correct. The result is

$$x(1-x)y'' + \tfrac{1}{2}y' - \tfrac{1}{4}y = 0.$$

im05.qxd 9/21/05 11:10 AM Page 106

Hence $ab = 1/4$, $b = \dfrac{1}{4a}$, $a + b + 1 = a + \dfrac{1}{4a} + 1 = 0$, $a = -\frac{1}{2}$, $b = -\frac{1}{2}$, $c = \frac{1}{2}$.

This gives

$$y_1 = F(-\tfrac{1}{2}, -\tfrac{1}{2}, \tfrac{1}{2}; t - 1).$$

In y_2 we have $a - c + 1 = -\frac{1}{2} - \frac{1}{2} + 1 = 0$; hence y_2 terminates after the first term, and, since $1 - c = \frac{1}{2}$,

$$y_2 = x^{1/2} \cdot 1 = \sqrt{t - 1}.$$

SECTION 5.5. Bessel's Equation. Bessel Functions $J_\nu(x)$, page 189

Purpose. To derive the Bessel functions of the first kind J_ν and $J_{-\nu}$ by the Frobenius method. (This is a major application of that method.) To show that these functions constitute a basis if ν is not an integer but are linearly dependent for integer $\nu = n$ (so that we must look later, in Sec. 5.6, for a second linearly independent solution). To show that various ODEs can be reduced to Bessel's equation (see Problem Set 5.5).

Main Content, Important Concepts

Derivation just mentioned

Linear independence of J_ν and $J_{-\nu}$ if ν is not an integer

Linear dependence of J_ν and $J_{-\nu}$ if $\nu = n = 1, 2, \cdots$

Gamma function as a tool

Short Courses. No derivation of any of the series. Discussion of J_0 and J_1 (which are similar to cosine and sine). Mention Theorem 2.

Comment on Special Functions

Since various institutions no longer find time to offer a course in special functions, Bessel functions may give another opportunity (together with Sec. 5.3) for getting at least some feel for the flavor of the theory of special functions, which will continue to be of significance to the engineer and physicist. For this reason we have added some material on basic relations for Bessel functions in this section.

SOLUTIONS TO PROBLEM SET 5.5, page 197

2. We obtain the following values. Note that the error of this very crude approximation is rather small.

x	Approximation	Exact (4D)	Relative Error
0	1.0000	1.0000	0
0.1	0.9975	0.9975	0
0.2	0.9900	0.9900	0
0.3	0.9775	0.9776	0.0001
0.4	0.9600	0.9604	0.0004
0.5	0.9375	0.9385	0.0010
0.6	0.9100	0.9120	0.0020
0.7	0.8775	0.8812	0.0042
0.8	0.8400	0.8463	0.0074
0.9	0.7975	0.8075	0.0124
1.0	0.7500	0.7652	0.0199

im05.qxd 9/21/05 11:10 AM Page 107

4. Zeros of Bessel functions are important, as the student will see in connection with vibrating membranes in Chap. 12, and there are other applications. These numeric problems (2−4) should give the student a feel for the applicability and accuracy of the formulas discussed in the text. In the present problem this refers to the asymptotic formula (14). A corresponding formula for Y is included in the next problem set.

Zeros of $J_0(x)$

13.35177	13.32369	−0.02808

6. $y = c_1 J_{1/4}(x) + c_2 J_{-1/4}(x)$

8. $y = c_1 J_1(2x + 1)$; J_1 and J_{-1} are linearly dependent by Theorem 2; actually, $J_{-1}(x) = -J_1(x)$.

10. $y = c_1 J_{1/2}(\frac{1}{2}x) + c_2 J_{-1/2}(\frac{1}{2}x) = x^{-1/2}(\tilde{c}_1 \sin \frac{1}{2}x + \tilde{c}_2 \cos \frac{1}{2}x)$

12. $y = c_1 J_\nu(x^2) + c_2 J_{-\nu}(x^2)$, $\nu \neq 0, \pm 1, \pm 2, \cdots$

14. $y = c_1 J_{1/3}(e^x) + c_2 J_{-1/3}(e^x)$

16. $y = x^{1/4}(c_1 J_{1/4}(x^{1/4}) + c_2 J_{-1/4}(x^{1/4}))$

18. $y = c_1 J_0(4x^{1/4})$. Second independent solution not yet available.

20. $y = x^\nu(c_1 J_\nu(x^\nu) + c_2 J_{-\nu}(x^\nu))$, $\nu \neq 0, \pm 1, \pm 2, \cdots$

22. $J_0' = 0$ at least once between two consecutive zeros of J_0, by Rolle's theorem. Now (24b) with $\nu = 0$ is

$$J_0' = -J_1.$$

Together, J_1 has at least one zero between two consecutive zeros of J_0.

Furthermore, $(xJ_1)' = 0$ at least once between two consecutive zeros of xJ_1, hence of J_1 (also at $x = 0$ since $J_1(0) = 0$), by Rolle's theorem. Now (24a) with $\nu = 1$ is

$$(xJ_1)' = xJ_0.$$

Together, J_0 has at least one zero between two consecutive zeros of J_1.

24. (24b) with $\nu - 1$ instead of ν is

$$(x^{-\nu+1}J_{\nu-1})' = -x^{-\nu+1}J_\nu.$$

Now use (24a) $(x^\nu J_\nu)' = x^\nu J_{\nu-1}$; solve it for $J_{\nu-1}$ to obtain

$$J_{\nu-1} = x^{-\nu}(x^\nu J_\nu)' = x^{-\nu}(\nu x^{\nu-1}J_\nu + x^\nu J_\nu') = \nu x^{-1}J_\nu + J_\nu'.$$

im05.qxd 9/21/05 11:10 AM Page 108

Substitute this into the previous equation on the left. Then perform the indicated differentiation:

$$(x^{-\nu+1}(\nu x^{-1}J_\nu + J_\nu'))' = (\nu x^{-\nu}J_\nu + x^{-\nu+1}J_\nu')'$$

$$= -\nu^2 x^{-\nu-1}J_\nu + \nu x^{-\nu}J_\nu' + (-\nu+1)x^{-\nu}J_\nu' + x^{-\nu+1}J_\nu''.$$

Equating this to the right side of the first equation and dividing by $x^{-\nu+1}$ gives

$$J_\nu'' + \frac{1}{x}J_\nu' - \frac{\nu^2}{x^2}J_\nu = -J_\nu.$$

Taking the term on the right to the left (with a plus sign) and multiplying by x^2 gives (1).

26. We obtain

$$\int x^{-1}J_4(x)\,dx = \int x^2(x^{-3}J_4(x))\,dx \qquad \text{(trivial)}$$

$$= \int x^2(-x^{-3}J_3(x))'\,dx \qquad \text{((24b) with } \nu = 3)$$

$$= -x^2x^{-3}J_3(x) + \int 2xx^{-3}J_3(x)\,dx \qquad \text{(by parts)}$$

$$= -x^{-1}J_3(x) + 2\int x^{-2}J_3(x)\,dx \qquad \text{(simplify)}$$

$$= -x^{-1}J_3(x) + 2\int(-x^{-2}J_2)'\,dx \qquad \text{((24b) with } \nu = 2)$$

$$= -x^{-1}J_3(x) - 2x^{-2}J_2(x) + c \qquad \text{(trivial).}$$

28. Use (24d) to get

$$\int J_5(x)\,dx = -2J_4(x) + \int J_3(x)\,dx$$

$$= -2J_4(x) - 2J_2(x) + \int J_1(x)\,dx$$

$$= -2J_4(x) - 2J_2(x) - J_0(x) + c.$$

30. For $\nu = \pm\frac{1}{2}$ the ODE (27) in Prob. 29 becomes

$$u'' + u = 0.$$

Hence for y we obtain the general solution

$$y = x^{-1/2}u = x^{-1/2}(A\cos x + B\sin x).$$

We can now obtain A and B by comparing with the first term in (20). Using $\Gamma(\frac{3}{2}) = \frac{1}{2}\Gamma(\frac{1}{2}) = \frac{1}{2}\sqrt{\pi}$ (see (26)) we obtain for $\nu = \frac{1}{2}$ the first term

$$x^{1/2}/(2^{1/2}\cdot\tfrac{1}{2}\Gamma(\tfrac{1}{2})) = \sqrt{2x/\pi}.$$

This gives (25a) because the series of $\sin x$ starts with the power x.

For $\nu = -\frac{1}{2}$ the first term is $x^{-1/2}/(2^{1/2}\cdot\frac{1}{2}\Gamma(\frac{1}{2})) = \sqrt{2/\pi x}$. This gives (25b).

32. Team Project. (a) Since α is assumed to be small, we can regard $W(x)$ to be approximately equal to the tension acting tangentially in the moving cable. The restoring force is the horizontal component of the tension. For the difference in force we use the mean value theorem of differential calculus. By Newton's second law this equals the mass $\rho\,\Delta x$ times the acceleration u_{tt} of this portion of the cable. The substitution of u first gives

$$-\omega^2 y\cos(\omega t + \delta) = g[(L-x)y']'\cos(\omega t + \delta).$$

im05.qxd 9/21/05 11:10 AM Page 109

Now drop the cosine factor, perform the differentiation, and order the terms.

(b) $dx = -dz$ and by the chain rule,

$$z\,\frac{d^2y}{dz^2} + \frac{dy}{dz} + \lambda^2 y = 0.$$

In the next transformation the chain rule gives

$$\frac{dy}{dz} = \frac{dy}{ds}\,\lambda z^{-1/2}, \qquad \frac{d^2y}{dz^2} = \frac{d^2y}{ds^2}\,\lambda^2 z^{-1} - \frac{1}{2}\,\frac{dy}{ds}\,\lambda z^{-3/2}.$$

Substitution gives

$$\lambda^2\,\frac{d^2y}{ds^2} + \left(-\frac{1}{2}\,\lambda z^{-1/2} + \lambda z^{-1/2}\right)\frac{dy}{ds} + \lambda^2 y = 0.$$

Now divide by λ^2 and remember that $s = 2\lambda z^{1/2}$. This gives Bessel's equation.

(c) This follows from the fact that the upper end ($x = 0$) is fixed. The second normal mode looks similar to the portion of J_0 between the second positive zero and the origin. Similarly for the third normal mode. The first positive zero is about 2.405. For the cable of length 2 m this gives the frequency

$$\frac{\omega}{2\pi} = \frac{2.405}{2 \cdot 2\pi\sqrt{L/g}} = \frac{2.405}{4\pi\sqrt{2.00/9.80}} = 0.424\ [\text{sec}^{-1}] = 25.4\ [\text{cycles/min}].$$

Similarly, we obtain 11.4 cycles/min for the long cable.

SECTION 5.6. Bessel Functions of the Second Kind $Y_\nu(x)$, page 198

Purpose. Derivation of a second independent solution, which is still missing in the case of $\nu = n = 0, 1, \cdots$.

Main Content

Detailed derivation of $Y_0(x)$

Cursory derivation of $Y_n(x)$ for any n

General solution (9) valid for all ν, integer or not

Short Courses. Omit this section.

Comment on Hankel Functions and Modified Bessel Functions

These are included for completeness, but will not be needed in our further work.

SOLUTIONS TO PROBLEM SET 5.6, page 202

2. $y = c_1 J_{1/3}(3x) + c_2 Y_{1/3}(3x)$. $J_{-1/3}$ could be used.

4. $y = c_1 J_0(12\sqrt{x}) + c_2 Y_0(12\sqrt{x})$

6. $y = c_1 J_{1/3}(\frac{1}{3}x^3) + c_2 Y_{1/3}(\frac{1}{3}x^3)$. $J_{-1/3}$ could be used.

8. $y = \sqrt{x}(c_1 J_{1/4}(x^2) + c_2 Y_{1/4}(x^2))$. $J_{-1/4}$ could be used.

10. $y = x^{-3}(c_1 J_3(2x) + c_2 Y_3(2x))$

12. CAS Experiment. (a) Y_0 and Y_1, similarly as for J_0 and J_1.

(b) Accuracy is best for Y_0. x_n increases with n; actual values will depend on the scales used for graphing.

im05.qxd 9/21/05 11:10 AM Page 110

(c), (d)

m	Y_0		Y_1		Y_2	
	By (11)	Exact	By (11)	Exact	By (11)	Exact
1	0.785	0.894	2.356	2.197	3.927	3.384
2	3.9270	3.958	5.498	5.430	7.0686	6.794
3	7.0686	7.086	8.639	8.596	10.210	10.023
4	10.210	10.222	11.781	11.749	13.352	13.210
5	13.352	13.361	14.923	14.897	16.493	16.379
6	16.493	16.501	18.064	18.043	19.635	19.539
7	19.635	19.641	21.206	21.188	22.777	22.694
8	22.777	22.782	24.347	24.332	25.918	25.846
9	25.918	25.923	27.489	27.475	29.060	28.995
10	29.060	29.064	30.631	30.618	32.201	32.143

These values show that the accuracy increases with x (for fixed n), as expected. For a fixed m (number of zero) it decreases with increasing n (order of Y_n).

14. For $x \neq 0$ all the terms of the series are real and positive.

SECTION 5.7. Sturm–Liouville Problems. Orthogonal Functions, page 203

Purpose. Discussion of eigenvalue problems for ordinary second-order ODEs (1) under boundary conditions (2).

Main Content, Important Concepts

Sturm–Liouville equations, Sturm–Liouville problem

Reality of eigenvalues

Orthogonality of eigenfunctions

Orthogonality of Legendre polynomials and Bessel functions

Short Courses. Omit this section.

Comment on Importance

This theory owes its significance to two factors. On the one hand, boundary value problems involving practically important ODEs (Legendre's, Bessel's, etc.) can be cast into Sturm–Liouville form, so that here we have a general theory with several important particular cases. On the other hand, the theory gives important general results on the spectral theory of those problems.

Comment on Existence of Eigenvalues

This theory is difficult. Quite generally, in problems where we can have *infinitely many* eigenvalues, the existence problem becomes nontrivial, in contrast with matrix eigenvalue problems (Chap. 8), where existence is trivial, a consequence of the fact that a polynomial equation $f(x) = 0$ (f not constant) has at least one solution and at most n numerically different ones (where n is the degree of the polynomial).

SOLUTIONS TO PROBLEM SET 5.7, page 209

2. If y_m is a solution of (1), so is z_m because (1) is linear and homogeneous; here, $\lambda = \lambda_m$ is the eigenvalue corresponding to y_m. Also, multiplying (2) with $y = y_m$ by c, we see that z_m also satisfies the boundary conditions. This proves the assertion.

im05.qxd 9/21/05 11:10 AM Page 111

4. $a = -\pi$, $b = \pi$, $c = \pi$, $k = 0$.

6. Perform the differentiations in (1), divide by p, and compare; that is,

$$py'' + p'y' + (q + \lambda r)y = 0, \qquad y'' + \frac{p'}{p}\,y' + \left(\frac{q}{p} + \lambda\,\frac{r}{p}\right)y = 0.$$

Hence $f = p'/p$, $p = \exp(\int f\,dx$, $q/p = g$, $q = gp$, $r/p = h$, $r = hp$. A reason for performing this transformation may be the discovery of the weight function needed for determining the orthogonality. We see that

$$r(x) = h(x)p(x) = h(x)\exp\left(\int f(x)\,dx\right).$$

8. We need

$$y = A\cos kx + B\sin kx$$
$$y' = -Ak\sin kx + Bk\cos kx$$

where $k = \sqrt{\lambda}$. From the first boundary condition, $y'(0) = Bk = 0$. With $B = 0$ there remains

$$y' = -Ak\sin kx.$$

From this and the second boundary condition,

$$y'(\pi) = -Ak\sin \pi k = 0, \qquad k\pi = m\pi, \qquad k = m = 0, 1, 2, \cdots.$$

Hence

$$\lambda_m = m^2, \quad m = 0, 1, \cdots; \quad y_0 = 1, \quad y_m = \cos mx \quad (m = 1, 2, \cdots).$$

10. y and y' as in Prob. 8. From the boundary conditions,

$$y(0) = A = y(1) = A\cos k + B\sin k$$

$$y'(0) = Bk = y'(1) = -Ak\sin k + Bk\cos k.$$

Ordering gives

$$(1 - \cos k)A - (\sin k)B = 0$$

$$(k\sin k)A + k(1 - \cos k)B = 0.$$

By eliminating A and then letting $B \neq 0$ (to have $y \neq 0$, an eigenfunction) or simply by noting that for this homogeneous system to have a nontrivial solution A, B, the determinant of its coefficients must be zero; that is,

$$k(1 - \cos k)^2 + k\sin^2 k = k(2 - 2\cos k) = 0;$$

hence $\cos k = 1$, $k = 2m\pi$, so that the eigenvalues and eigenfunctions are

$$\lambda_m = (2m\pi)^2, \quad m = 0, 1, \cdots;$$
$$y_0 = 1, \quad y_m(x) = \cos(2m\pi x), \sin(2m\pi x), \quad m = 1, 2, \cdots.$$

12. Use y and y' as given in Prob. 8. The first boundary condition gives

$$y(0) + y'(0) = A + Bk = 0; \qquad \text{thus} \qquad A = -Bk.$$

From this and the second boundary condition,

$$y(1) + y'(1) = A\cos k + B\sin k - Ak\sin k + Bk\cos k$$
$$= -Bk\cos k + B\sin k + Bk^2\sin k + Bk\cos k = 0.$$

im05.qxd 9/21/05 11:10 AM Page 112

Canceling two terms, dividing by $\cos k$, and collecting the remaining terms, we obtain

$$(1 + k^2) \tan k = 0, \qquad k = k_m = m\pi,$$

and the eigenvalues and eigenfunctions are

$$\lambda_m = m^2\pi^2; \qquad y_0 = 1, \qquad y_m = \cos m\pi x, \sin m\pi x, \quad m = 1, 2, \cdots.$$

14. $x = e^t$, $t = \ln |x|$ transforms the given ODE into

$$e^{-t} \frac{d}{dt} \left(e^t e^{-t} \frac{d\tilde{y}}{dt} \right) + e^{-t}\lambda\tilde{y} = 0$$

that is,

$$\frac{d^2\tilde{y}}{dt^2} + k^2\tilde{y} = 0 \qquad (k^2 = \lambda).$$

For the new variable t, the boundary conditions are $\tilde{y}(0) = 0$, $\dot{\tilde{y}}(1) = 0$. A general solution and its derivative are

$$\tilde{y} = A \cos kt + B \sin kt, \qquad \dot{\tilde{y}} = -Ak \sin kt + Bk \cos kt.$$

Hence $\tilde{y}(0) = A = 0$ and then, with $B = 1$, $\dot{\tilde{y}}(1) = k \cos k = 0$. It follows that $k = k_m = (2m + 1)\pi/2$, $m = 0, 1, \cdots$, $\lambda_m = k_m{}^2$, and

$$\tilde{y}_m = \sin k_m t = \sin (k_m \ln |x|), \qquad m = 0, 1, \cdots.$$

16. A general solution $y = e^x(A \cos kx + B \sin kx)$, $k = \sqrt{\lambda}$, of this ODE with constant coefficients is obtained as usual. The Sturm–Liouville form of the ODE is obtained by using the formulas in Prob. 6,

$$(e^{-2x}y')' + e^{-2x}(k^2 + 1)y = 0.$$

From this and the boundary conditions we expect the eigenfunctions to be orthogonal on $0 \leqq x \leqq 1$ with respect to the weight function e^{-2x}. Now from that general solution and $y(0) = A = 0$ we see that we are left with

$$y = e^x \sin kx.$$

From the second boundary condition $y(1) = 0$ we now obtain

$$y(1) = e \sin k = 0, \qquad k = m\pi, \quad m = 1, 2, \cdots.$$

Hence the eigenvalues and eigenfunctions are

$$\lambda_m = (m\pi)^2, \qquad y_m = e^x \sin m\pi x.$$

The orthogonality is as expected (because e^x cancels).

18. From Prob. 6 we obtain the Sturm–Liouville form

$$(x^2y')' + k^2x^2y = 0 \qquad k^2 = \lambda.$$

By the indicated transformation or by a CAS we obtain as a general solution

$$y = A \frac{\cos kx}{x} + B \frac{\sin kx}{x}.$$

From this and the boundary conditions we obtain

$$y(\pi) = A \frac{\cos k\pi}{k\pi} + B \frac{\sin k\pi}{k\pi} = 0$$

$$y(2\pi) = A \frac{\cos 2k\pi}{2k\pi} + B \frac{\sin 2k\pi}{2k\pi} = 0.$$

im05.qxd 9/21/05 11:10 AM Page 113

Eliminate A and divide the resulting equation by B (which must be different from zero to have $y \neq 0$, as is needed for an eigenfunction). Or equate the determinant of the coefficients of the two equations to zero, as a condition for obtaining a nontrivial solution A, B, not both zero; here we can drop the denominators. We obtain

$$\begin{vmatrix} \cos k\pi & \sin k\pi \\ \cos 2k\pi & \sin 2k\pi \end{vmatrix} = \cos k\pi \sin 2k\pi - \cos 2k\pi \sin k\pi.$$

By the addition formula for the sine (see App. 3.1 in the book if necessary) the right side equals $\sin(2k\pi - k\pi) = \sin k\pi$. This is zero for $k\pi = m\pi$, $m = 0, 1, \cdots$. Eigenvalues are $\lambda_m = m^2$, $m = 1, 2, \cdots$. Eigenfunctions are $y_m = x^{-1} \sin mx$, $m = 1, 2, \cdots$. These functions are orthogonal on $\pi \leqq x \leqq 2\pi$ with respect to the weight function $r = x^2$.

20. Team Project. (a) We integrate over x from -1 to 1, hence over θ defined by $x = \cos\theta$ from π to 0. Using $(1 - x^2)^{-1/2}\,dx = -d\theta$, we thus obtain

$$\int_{-1}^{1} \cos(m \arccos x) \cos(n \arccos x)(1 - x^2)^{-1/2}\,dx$$
$$= \int_0^{\pi} \cos m\theta \cos n\theta\,d\theta = \frac{1}{2}\int_0^{\pi} (\cos(m + n)\theta + \cos(m - n)\theta)\,d\theta,$$

which is zero for integer $m \neq n$.

(b) Following the hint, we calculate $\int e^{-x}x^k L_n\,dx = 0$ for $k < n$:

$$\int_0^{\infty} e^{-x}x^k L_n(x)\,dx = \frac{1}{n!}\int_0^{\infty} x^k \frac{d^n}{dx^n}(x^n e^{-x})\,dx = -\frac{k}{n!}\int_0^{\infty} x^{k-1}\frac{d^{n-1}}{dx^{n-1}}(x^n e^{-x})\,dx$$
$$= \cdots = (-1)^k \frac{k!}{n!}\int_0^{\infty} \frac{d^{n-k}}{dx^{n-k}}(x^n e^{-x})\,dx = 0.$$

SECTION 5.8. Orthogonal Eigenfunction Expansions, page 210

Purpose. To show how families (sequences) of orthogonal functions, as they arise in eigenvalue problems and elsewhere, are used in series for representing other functions, and to show how orthogonality becomes crucial in simplifying the determination of the coefficients of such a series by integration.

Main Content, Important Concepts

Standard notation (y_m, y_n)

Orthogonal expansion (3), eigenfunction expansion

Fourier constants (4)

Fourier series (5), Euler formulas (6)

Short Courses. Omit this section.

Comment on Flexibility on Fourier Series

Since Sec. 5.8, with the definition of orthogonality taken from Sec. 5.7 and Examples 2 and 3 omitted, is independent of other sections in this chapter, it could also be used after Chap. 11 on Fourier series. We did not put it there for reasons of time and because Chap. 11 is intimately related to the main applications of Fourier series (to partial differential equations) in Chap. 12.

im05.qxd 9/21/05 11:10 AM Page 114

Comment on Notation

(y_m, y_n) is not a must, but has become standard; perhaps if it is written out a few times, poorer students will no longer be irritated by it.

SOLUTIONS TO PROBLEM SET 5.8, page 216

2. $\frac{2}{3}P_2(x) + 2P_1(x) + \frac{4}{3}P_0(x)$. This is probably most simply obtained by the method of undetermined coefficients, beginning with the highest power, x^2 and $P_2(x)$. The point of these problems is to make the student aware that these developments look totally different from the usual expansions in terms of powers of x.

4. $P_0(x)$, $P_1(x)$, $\frac{2}{3}P_2(x) + \frac{1}{3}P_0(x)$, $\frac{2}{5}P_3(x) + \frac{3}{5}P_1(x)$

6. $m_0 = 5$. The size of m_0, that is, the rapidity of convergence seems to depend on the variability of $f(x)$. A discontinuous derivative (e.g., as for $|\sin x|$ occurring in connection with rectifiers) makes it virtually impossible to reach the goal. Let alone when $f(x)$ itself is discontinuous. In the present case the series is

$$f(x) = 0.95493P_1(x) - 1.15824P_3(x) + 0.21429P_5(x) - + \cdots.$$

Rounding seems to have considerable influence in all of these problems.

8. $f(x) = -1.520P_2(x) + 0.5825P_4(x) - 0.0653P_6(x) + \cdots$, $m_0 = 6$

10. $f(x) = -0.1689P_2(x) - 0.8933P_4(x) - 1.190P_6(x) + \cdots$, $m_0 = 12$

12. $f(x) = 0.7470P_0(x) - 0.4458P_2(x) + 0.0765P_4(x) - \cdots$, $m_0 = 4$

14. $f(x) = 0.6116P_0(x) - 0.7032P_2(x) + 0.0999P_4(x) + \cdots$, $m_0 = 4$

16. $f(x) = 0.5385P_1(x) - 0.6880P_3(x) + 0.1644P_5(x) + \cdots$, $m_0 = 5$ or 7

18. Team Project. (b) A Maclaurin series $f(t) = \sum_{n=0}^{\infty} a_n t^n$ has the coefficients $a_n = f^{(n)}(0)/n!$. We thus obtain

$$f^{(n)}(0) = \frac{d^n}{dt^n}\,(e^{tx-t^2/2})\,\Big|_{t=0} = e^{x^2/2}\,\frac{d^n}{dt^n}\,(e^{-(x-t)^2/2})\,\Big|_{t=0}.$$

If we set $x - t = z$, this becomes

$$f^{(n)}(0) = e^{x^2/2}(-1)^n\,\frac{d^n}{dz^n}\,(e^{-z^2/2})\,\Big|_{z=x} = (-1)^n\,e^{x^2/2}\,\frac{d^n}{dx^n}\,(e^{-x^2/2}) = He_n(x).$$

(c) $G_x = \sum a_n'(x)t^n = \sum He_n'(x)t^n/n! = tG = \sum He_{n-1}(x)t^n/(n-1)!$, etc.

(d) We write $e^{-x^2/2} = v$, $v^{(n)} = d^n v/dx^n$, etc., and use (21). By integrations by parts, for $n > m$,

$$\begin{aligned}\int_{-\infty}^{\infty} vHe_m He_n\,dx &= (-1)^n\int_{-\infty}^{\infty} He_m v^{(n)}\,dx = (-1)^{n-1}\int_{-\infty}^{\infty} He_m' v^{(n-1)}\,dx \\ &= (-1)^{n-1}m\int_{-\infty}^{\infty} He_{m-1}v^{(n-1)}\,dx = \cdots \\ &= (-1)^{n-m}m!\int_{-\infty}^{\infty} He_0 v^{(n-m)}\,dx = 0.\end{aligned}$$

(e) $nHe_n = nxHe_{n-1} - nHe_{n-1}'$ from (22) with $n-1$ instead of n. In this equation, the first term on the right equals xHe_n' by (21). The last term equals $-He_n''$, as follows by differentiation of (21).

im05.qxd 9/21/05 11:10 AM Page 115

We write $y = Ew$, where $E = e^{x^2/4}$. Then

$$y' = \tfrac{1}{2}xEw + Ew'$$
$$y'' = \tfrac{1}{2}Ew + \tfrac{1}{4}x^2Ew + xEw' + Ew''.$$

If we substitute this into the ODE (23) and divide by E, we obtain the result. The point is that the new ODE does not contain a first derivative; hence our transformation is precisely that for eliminating the first derivative from (23).

SOLUTIONS TO CHAP. 5 REVIEW QUESTIONS AND PROBLEMS, page 217

12. $1/(1 - x)$, $(1 - x)^3$. An Euler–Cauchy equation in $t = x - 1$.

14. x^2, $x^2 \ln x$. An Euler–Cauchy equation with a double root.

16. $x^2 \cos x$, $x^2 \sin x$

18. We take the term $-1 \cdot y''$ to the right and substitute the usual power series and its derivatives into the ODE. The general term on the right is $m(m - 1)a_m x^{m-2}$. To get the same general power x^m throughout, we replace in this term $m - 2$ with m; then the right side has the general term $(m + 2)(m + 1)a_{m+2}x^m$.

On the left we collect terms, obtaining

$$(m(m - 1) - 2m + 2)a_m x^m = (m - 2)(m - 1)a_m x^m.$$

This gives the recursion formula

$$a_{m+2} = \frac{(m - 2)(m - 1)}{(m + 2)(m + 1)}\, a_m \qquad (m = 0, 1, \cdots)$$

a_0 and a_1 remain arbitrary. If we set $a_0 = 1$, $a_1 = 0$, we obtain $a_2 = a_0 = 1$, $a_3 = 0$, $a_4 = 0$, etc., and $y_1 = 1 + x^2$. If we set $a_0 = 0$, $a_1 = 1$, we obtain $y_2 = x$. This is a basis of solutions.

To make sure that we did not make a mistake at the beginning, we could write the first few terms explicitly, namely, the constant, linear, and quadratic terms of each series and check our result. This gives

$$(2a_2x^2 + \cdots) - 2a_1x - 4a_2x^2 + 2a_0 + 2a_1x + 2a_2x^2 + \cdots$$
$$= 2a_2 + 6a_3x + 12a_4x^2 + \cdots.$$

We take $a_0 = 1$, $a_1 = 1$. We then get $a_2 = a_0 = 1$ from the constant terms, $a_3 = 0$ from the linear terms, $a_4 = 0$ from the quadratic terms, etc., as before.

20. Indicial equation $r(r - 1) + r - 1 = 0$. Hence $r_1 = 1$, $r_2 = -1$. These roots differ by an integer; this is Case 3. It turns out that no logarithm will appear. A basis of solutions is

$$y_1 = x - \frac{x^5}{3!} + \frac{x^9}{5!} - \frac{x^{13}}{7!} + \cdots$$
$$y_2 = \frac{1}{x} - \frac{x^3}{2!} + \frac{x^7}{4!} - \frac{x^{11}}{6!} + \frac{x^{15}}{8!} - \cdots.$$

We see that $y_1 = x^{-1} \sin x^2$ and $y_2 = x^{-1} \cos x^2$. The coefficients $a_0, \cdots, a_3$ and $A_0, \cdots, A_3$ were arbitrary, and the two solutions were obtained by the choices $a_0 = 1$ and the others zero, and $A_0 = 1$ and the other A_j $(j = 1, 2, 3)$ zero.

22. $y = x^{-2}[c_1J_4(x) + c_2Y_4(x)]$

im05.qxd 9/21/05 11:10 AM Page 116

24. $y = x^{5/2}(c_1 \cos x + c_2 \sin x)$. This is the case in which the Bessel functions reduce to cosine and sine divided or multiplied by a power of x.

26. $y = A \cos kx + B \sin kx$, where $k = \sqrt{\lambda}$. $y(0) = A = 0$ from the first boundary condition. From this and the second boundary condition,

$$y = B \sin kx, \qquad y' = Bk \cos kx, \qquad \cos k\pi = 0, \qquad k\pi = (2m + 1)\pi/2.$$

Hence $k_m = (2m + 1)/2$, $\lambda = {k_m}^2$, $y_m = \sin k_m x$, $m = 0, 1, \cdots$.

28. $x = e^t$, $t = \ln |x|$, $y(x) \equiv \tilde{y}(t)$, $y' = \dot{\tilde{y}}/x$, $\ddot{\tilde{y}} + \lambda\tilde{y} = 0$. For t the boundary conditions are $\tilde{y}(0) = 0$, $\tilde{y}(1) = 0$. A general solution is $\tilde{y} = A \cos kt + B \sin kt$, $k = \sqrt{\lambda}$. Now $A = 0$ from the first boundary condition, and $k = k_m = m\pi$ from the second. Hence the eigenvalues are $\lambda_m = (m\pi)^2$ and eigenfunctions are $y_m = \sin m\pi t = \sin (m\pi \ln |x|)$, $m = 1, 2, \cdots$.

30. $y = A \cos kx + B \sin kx$, $y' = -Ak \sin kx + Bk \cos kx$. From the first boundary condition, $A + Bk = 0$; hence $A = -Bk$. From the second boundary condition, with A replaced by $-Bk$,

$$-Bk \cos 2k\pi + B \sin 2k\pi = 0, \qquad k = \tan 2k\pi, \qquad \lambda_m = {k_m}^2$$

where the k_m's are the infinitely many solutions of $k = \tan 2k\pi$. Eigenfunctions:

$$y_m = \cos k_m x, \qquad \sin k_m x.$$

32. $0.505P_0(x) + 0.377P_2(x) - 0.920P_4(x) + \cdots$

34. $0.637P_0(x) + 0.154P_2(x) + 0.672P_4(x) - 0.663P_6(x) + \cdots$. The approximation by partial sums is poor near the points of discontinuity of the derivative. This is typical.

im06.qxd 9/21/05 12:05 PM Page 117

CHAPTER 6 Laplace Transform

Major Changes

This chapter underwent some major changes regarding the order of the material and the emphasis placed on the various topics.

In particular, Dirac's delta was placed in a separate section. Partial fractions are now considered earlier. Their importance in this chapter has been diminished, and they are explained in terms of practical problems when they are needed, rather than in terms of impractical theoretical formulas. Convolution and nonhomogeneous linear ODEs are now considered earlier, whereas differentiation and integration of *transforms* (not of *functions*!) appears later and in a lesser role.

SECTION 6.1. Laplace Transform. Inverse Transform. Linearity. *s*-Shifting, page 221

Purpose. To explain the basic concepts, to present a short list of basic transforms, and to show how these are derived from the definition.

Main Content, Important Concepts

Transform, inverse transform, linearity

First shifting theorem

Table 6.1

Existence and its practical significance

Comment on Table 6.1

After working for a while in this chapter, the student should be able to memorize these transforms. Further transforms in Sec. 6.9 are derived as we go along, many of them from Table 6.1.

SOLUTIONS TO PROBLEM SET 6.1, page 226

2. $(t^2 - 3)^2 = t^4 - 6t^2 + 9$; transform $\dfrac{24}{s^5} - \dfrac{12}{s^3} + \dfrac{9}{s}$

4. $\sin^2 4t = \dfrac{1}{2} - \dfrac{1}{2}\cos 8t$; transform $\dfrac{1}{2s} - \dfrac{s}{2(s^2 + 64)} = \dfrac{32}{s(s^2 + 64)}$

6. $e^{-t}\sinh 5t = \dfrac{1}{2}(e^{4t} - e^{-6t})$; transform $\dfrac{1}{2}\left(\dfrac{1}{s - 4} - \dfrac{1}{s + 6}\right) = \dfrac{5}{(s + 1)^2 - 25}$.

This can be checked by the first shifting theorem.

8. $\sin(3t - \frac{1}{2}) = \cos\frac{1}{2}\sin 3t - \sin\frac{1}{2}\cos 3t$; transform

$$\frac{3\cos\frac{1}{2} - s\sin\frac{1}{2}}{s^2 + 9}$$

10. $\dfrac{-1.6}{s^2 + 0.04}$

12. $(t + 1)^3 = t^3 + 3t^2 + 3t + 1$; transform $\dfrac{6}{s^4} + \dfrac{6}{s^3} + \dfrac{3}{s^2} + \dfrac{1}{s}$

im06.qxd 9/21/05 12:05 PM Page 118

14. $k\int_a^b e^{-st}\,dt = \dfrac{k}{s}\,(e^{-as} - e^{-bs})$

16. $k(1 - t/b)$; transform

$$k\int_0^b e^{-st}\left(1 - \frac{t}{b}\right)dt = -\frac{k}{s}\,e^{-st}\left(1 - \frac{t}{b}\right)\Big|_0^b + \frac{k}{s}\int_0^b\left(-\frac{1}{b}\right)e^{-st}\,dt$$

$$= \frac{k}{bs^2}\,(bs + e^{-bs} - 1)$$

18. $\dfrac{k}{b}\int_0^b e^{-st}t\,dt = \dfrac{k}{b}\left(\dfrac{1 - e^{-bs}}{s^2} - \dfrac{be^{-bs}}{s}\right)$

20. $\int_0^1 e^{-st}t\,dt + \int_1^2 e^{-st}(2 - t)\,dt$. Integration by parts gives

$$-\frac{e^{-st}t}{s}\Big|_0^1 + \frac{1}{s}\int_0^1 e^{-st}\,dt - \frac{e^{-st}(2 - t)}{s}\Big|_1^2 - \frac{1}{s}\int_1^2 e^{-st}\,dt$$

$$= -\frac{e^{-s}}{s} - \frac{1}{s^2}\,(e^{-s} - 1) + \frac{e^{-s}}{s} + \frac{1}{s^2}\,(e^{-2s} - e^{-s})$$

$$= \frac{1}{s^2}\,(-e^{-s} + 1 + e^{-2s} - e^{-s}) = \frac{(1 - e^{-s})^2}{s^2}\,.$$

22. Let $st = \tau$, $t = \tau/s$, $dt = d\tau/s$. Then

$$\mathcal{L}(1/\sqrt{t}) = \int_0^\infty e^{-st}t^{-1/2}\,dt$$

$$= \int_0^\infty e^{-\tau}(\tau/s)^{-1/2}\,\frac{1}{s}\,d\tau$$

$$= s^{-1/2}\int_0^\infty e^{-\tau}\tau^{-1/2}\,d\tau$$

$$= s^{-1/2}\Gamma(\tfrac{1}{2}) = \sqrt{\pi/s}.$$

24. No matter how large we choose M and k, we have $e^{t^2} > Me^{kt}$ for all t greater than some t_0 because $t^2 > \ln M + kt$ for all sufficiently large t (and fixed positive M and k).

26. Use $e^{at} = \cosh at + \sinh at$.

28. Let $f = \mathcal{L}^{-1}(F)$, $g = \mathcal{L}^{-1}(G)$. Since the *transform* is linear, we obtain

$$aF + bG = a\mathcal{L}(f) + b\mathcal{L}(g) = \mathcal{L}(af + bg).$$

Now apply $\mathcal{L}^{-1}$ on both sides to get the desired result,

$$\mathcal{L}^{-1}(aF + bG) = \mathcal{L}^{-1}\mathcal{L}(af + bg) = af + bg = a\mathcal{L}^{-1}(F) + b\mathcal{L}^{-1}(G).$$

Note that we have proved much more than just the claim, namely, the following.

Theorem. *If a linear transformation has an inverse, the inverse is linear.*

30. $2\cosh 4t + 4\sinh 4t = 3e^{4t} - e^{-4t}$

32. $\dfrac{10}{2s + \sqrt{2}} = \dfrac{5}{s + 1/\sqrt{2}}$. *Answer* $5e^{-t/\sqrt{2}}$

im06.qxd 9/21/05 12:05 PM Page 119

34. $\dfrac{20}{(s-1)(s+4)} = 4\left(\dfrac{1}{s-1} - \dfrac{1}{s+4}\right)$. *Answer* $4(e^t - e^{-4t})$

36. $4e^{-t} + 9e^{-4t} + 16e^{-9t} + 25e^{-16t}$

38. $\dfrac{18s-12}{9s^2-1} = \dfrac{2s-4/3}{s^2-1/9}$. *Answer* $2\cosh \frac{1}{3}t - 4\sinh \frac{1}{3}t$

40. If $a \neq b$, then $\dfrac{1}{b-a}(e^{-at} - e^{-bt})$. If $a = b$, then te^{-bt} by the shifting theorem (or from the first result by l'Hôpital's rule, taking derivatives with respect to a).

42. $\dfrac{-72}{(s+0.5)^5}$

44. $\dfrac{s+3}{(s+3)^2+\pi^2}$

46. $a_0/(s+1) + a_1/(s+1)^2 + \cdots + n!a_n/(s+1)^{n+1}$

48. $\pi te^{-\pi t}$

50. $e^t(\cos 2t - \frac{5}{2}\sin 2t)$

52. $e^{3t}(4\cos 3t + \frac{10}{3}\sin 3t)$

54. $\dfrac{2s-56}{s^2-4s-12} = \dfrac{2(s-2)-52}{(s-2)^2-16}$. *Answer*

$$e^{2t}(2\cosh 4t - 13\sinh 4t) = -\tfrac{11}{2}e^{6t} + \tfrac{15}{2}e^{-2t}$$

SECTION 6.2. Transforms of Derivatives and Integrals. ODEs, page 227

Purpose. To get a first impression of how the Laplace transform solves ODEs and initial value problems, the task for which it is designed.

Main Content, Important Concepts

(1) $\mathscr{L}(f') = s\mathscr{L}(f) - f(0)$

Extension of (1) to higher derivatives [(2), (3)]

Solution of an ODE, subsidiary equation

Transform of the integral of a function (Theorem 3)

Transfer function (6)

Shifted data problems (Example 6)

Comment on ODEs

The last of the three steps of solution is the hardest, but we shall derive many general properties of the Laplace transform (collected in Sec. 6.8) that will help, along with formulas in Table 6.1 and those in Sec. 6.9, so that we can proceed to ODEs for which the present method is superior to the classical one.

SOLUTIONS TO PROBLEM SET 6.2, page 232

Purpose of Probs. 1–8. 1. To familiarize students with (1) and (2) before they apply these formulas to ODEs. 2. Students should become aware that transforms can often be obtained by several methods.

im06.qxd 9/21/05 12:05 PM Page 120

2. $f = t\cos 5t$, $f' = \cos 5t - 5t\sin 5t$, $f'' = -10\sin 5t - 25t\cos 5t$. Hence

$$\mathscr{L}(f'') = \frac{-50}{s^2+25} - 25\mathscr{L}(f) = s^2\mathscr{L}(f) - s\cdot 0 - 1$$

and thus

$$(s^2+25)\mathscr{L}(f) = \frac{-50}{s^2+25} + 1 = \frac{s^2-25}{s^2+25}.$$

Answer

$$\mathscr{L}(f) = \frac{s^2-25}{(s^2+25)^2}.$$

4. $f = \cos^2 \pi t$, $f' = -2\pi\cos \pi t \sin \pi t = -\pi \sin 2\pi t$. Hence

$$\mathscr{L}(f') = \frac{-2\pi^2}{s^2+4\pi^2} = s\mathscr{L}(f) - 1, \qquad s\mathscr{L}(f) = \frac{s^2+4\pi^2-2\pi^2}{s^2+4\pi^2}.$$

This gives the *answer*

$$\mathscr{L}(f) = \frac{s^2+2\pi^2}{s(s^2+4\pi^2)}.$$

6. $f = \cosh^2 \frac{1}{2}t$, $f' = \cosh \frac{1}{2}t \sinh \frac{1}{2}t = \frac{1}{2}\sinh t$. Hence

$$\mathscr{L}(f') = s\mathscr{L}(f) - 1 = \frac{1/2}{s^2-1}, \qquad s\mathscr{L}(f) = \frac{\frac{1}{2}+s^2-1}{s^2-1}.$$

This gives the *answer*

$$\mathscr{L}(f) = \frac{s^2-\frac{1}{2}}{s(s^2-1)}.$$

8. $f = \sin^4 t$, $f' = 4\sin^3 t\cos t$, $f'' = 12\sin^2 t\cos^2 t - 4\sin^4 t$. From this and (2) it follows that

$$\mathscr{L}(f'') = 12\mathscr{L}(\sin^2 t\cos^2 t) - 4\mathscr{L}(f) = s^2\mathscr{L}(f).$$

Collecting terms and using Prob. 3 with $\omega = 2$ and $\sin 2\alpha = 2\sin\alpha\cos\alpha$, we obtain

$$(s^2+4)\mathscr{L}(f) = 3\mathscr{L}(\sin^2 2t) = \frac{3\cdot 8}{s(s^2+16)}.$$

Answer

$$\mathscr{L}(f) = \frac{24}{s(s^2+4)(s^2+16)}.$$

10. $sY - 2.8 + 4Y = 0$, $(s+4)Y = 2.8$, $Y = 2.8/(s+4)$, $y = 2.8e^{-4t}$

12. $(s^2 - s - 6)Y = (s-3)(s+2)Y = 6s + 13 - 6 = 6s + 7$. Hence

$$Y = \frac{6s+7}{(s-3)(s+2)} = \frac{5}{s-3} + \frac{1}{s+2}$$

and

$$y = 5e^{3t} + e^{-2t}.$$

14. $(s-2)^2Y = 2.1s + 3.9 - 4\cdot 2.1$. Hence

$$Y = \frac{2.1s-4.5}{(s-2)^2} = \frac{2.1(s-2)+4.2-4.5}{(s-2)^2}.$$

im06.qxd 9/21/05 12:05 PM Page 121

This gives the solution

$$y = 2.1e^{2t} - 0.3te^{2t}$$

as expected in the case of a double root of the characteristic equation.

16. $(s^2 + ks - 2k^2)Y = 2s + 2k + 2k$, $Y = (2s + 4k)/[(s - k)(s + 2k)] = 2/(s - k)$, $y = 2e^{kt}$

18. We obtain

$$(s^2 + 9)Y = \frac{10}{s + 1}.$$

The solution of this subsidiary equation is

$$Y = \frac{10}{(s + 1)(s^2 + 9)} = \frac{1}{s + 1} - \frac{s - 1}{s^2 + 9}.$$

This gives the solution $y = e^{-t} - \cos 3t + \frac{1}{3}\sin 3t$.

20. The subsidiary equation is

$$(s^2 - 6s + 5)Y = 3.2s + 6.2 - 6 \cdot 3.2 + 29s/(s^2 + 4).$$

The solution Y is

$$Y = \frac{(3.2s - 13)(s^2 + 4) + 29s}{(s - 1)(s - 5)(s^2 + 4)}.$$

In terms of partial fractions, this becomes

$$Y = \frac{1}{s - 1} + \frac{2}{s - 5} + \frac{0.2s - 2.4 \cdot 2}{s^2 + 4}.$$

The inverse transform of this gives the solution

$$y = e^t + 2e^{5t} + 0.2\cos 2t - 2.4\sin 2t.$$

22. $t = \tilde{t} + 1$, so that the "shifted problem" is

$$\tilde{y}'' - 2\tilde{y}' - 3\tilde{y} = 0, \qquad \tilde{y}(0) = -3, \qquad \tilde{y}'(0) = -17.$$

Hence the corresponding subsidiary equation is

$$(s^2 - 2s - 3)\tilde{Y} = -3s - 17 + 6.$$

Its solution is

$$\tilde{Y} = \frac{-3s - 11}{(s + 1)(s - 3)} = \frac{2}{s + 1} - \frac{5}{s - 3}.$$

Inversion gives

$$\tilde{y} = 2e^{-\tilde{t}} - 5e^{3\tilde{t}}.$$

This is the solution of the "shifted problem," and the solution of the given problem is

$$y = 2e^{-(t-1)} - 5e^{3(t-1)}.$$

24. $t = \tilde{t} + 3$, so that the "shifted equation" is

$$\tilde{y}'' + 2\tilde{y}' + 5\tilde{y} = 50\tilde{t}.$$

The corresponding subsidiary equation is

$$[(s + 1)^2 + 4]\tilde{Y} = -4s + 14 - 2 \cdot 4 + 50/s^2.$$

im06.qxd 9/21/05 12:05 PM Page 122

Its solution is

$$\tilde{Y} = \frac{10}{s^2} - \frac{4}{s} + \frac{4}{(s+1)^2 + 4}.$$

The inverse transform is

$$\tilde{y} = 10\tilde{t} - 4 + 2e^{-\tilde{t}} \sin 2\tilde{t}.$$

Hence the given problem has the solution

$$y = 10(t-3) - 4 + 2e^{-(t-3)} \sin 2(t-3).$$

26. Project. We derive (a). We have $f(0) = 0$ and

$$f'(t) = \cos \omega t - \omega t \sin \omega t, \qquad f'(0) = 1$$
$$f''(t) = -2\omega \sin \omega t - \omega^2 f(t).$$

By (2),

$$\mathcal{L}(f'') = -2\omega \frac{\omega}{s^2 + \omega^2} - \omega^2 \mathcal{L}(f) = s^2 \mathcal{L}(f) - 1.$$

Collecting $\mathcal{L}(f)$-terms, we obtain

$$\mathcal{L}(f)(s^2 + \omega^2) = \frac{-2\omega^2}{s^2 + \omega^2} + 1 = \frac{s^2 - \omega^2}{s^2 + \omega^2}.$$

Division by $s^2 + \omega^2$ on both sides gives (a).

In (b) on the right we get from (a)

$$\mathcal{L}(\sin \omega t - \omega t \cos \omega t) = \frac{\omega}{s^2 + \omega^2} - \omega \frac{s^2 - \omega^2}{(s^2 + \omega^2)^2}.$$

Taking the common denominator and simplifying the numerator,

$$\omega(s^2 + \omega^2) - \omega(s^2 - \omega^2) = 2\omega^3$$

we get (b).

(c) is shown in Example 1.

(d) is derived the same way as (b), with + instead of −, so that the numerator is

$$\omega(s^2 + \omega^2) + \omega(s^2 - \omega^2) = 2\omega s^2,$$

which gives (d).

(e) is similar to (a). We have $f(0) = 0$ and obtain

$$f'(t) = \cosh at + at \sinh at, \qquad f'(0) = 1$$
$$f''(t) = 2a \sinh at + a^2 f(t).$$

By (2) we obtain

$$\mathcal{L}(f'') = \frac{2a^2}{s^2 - a^2} + a^2 \mathcal{L}(f) = s^2 \mathcal{L}(f) - 1.$$

Hence

$$\mathcal{L}(f)(s^2 - a^2) = \frac{2a^2}{s^2 - a^2} + 1 = \frac{s^2 + a^2}{s^2 - a^2}.$$

Division by $s^2 - a^2$ gives (e).

im06.qxd 9/21/05 12:05 PM Page 123

(f) follows similarly. We have $f(0) = 0$ and, furthermore,

$$f'(t) = \sinh at + at \cosh at, \qquad f'(0) = 0$$
$$f''(t) = 2a \cosh at + a^2 f(t)$$

$$\mathscr{L}(f''(t)) = 2a \frac{s}{s^2 - a^2} + a^2\mathscr{L}(f) = s^2\mathscr{L}(f)$$

$$\mathscr{L}(f)(s^2 - a^2) = \frac{2as}{s^2 - a^2}.$$

Division by $s^2 - a^2$ gives formula (f).

28. We start from

$$\mathscr{L}^{-1}\left(\frac{1}{s - \pi}\right) = e^{\pi t}$$

and integrate twice. The first integration gives

$$\frac{1}{\pi}(e^{\pi t} - 1).$$

Multiplication by 10 and another integration from 0 to t gives the *answer*

$$\frac{10}{\pi^2}(e^{\pi t} - 1) - \frac{10t}{\pi}.$$

30. The inverse of $1/(s^2 + 1)$ is $\sin t$. A first integration from 0 to t gives $1 - \cos t$, and another integration yields $t - \sin t$.

32. The inverse of $2/(s^2 + 9)$ is $\frac{2}{3}\sin 3t$. Integration from 0 to t gives the *answer*

$$\tfrac{2}{9}(1 - \cos 3t) = \tfrac{4}{9}\sin^2 \tfrac{3}{2}t.$$

34. The inverse of $1/(s^2 + \pi^2)$ is $\frac{1}{\pi}\sin \pi t$. A first integration from 0 to t gives

$$\frac{1}{\pi^2}(1 - \cos \pi t).$$

Another integration gives the *answer*

$$\frac{1}{\pi^2}\left(t - \frac{1}{\pi}\sin \pi t\right).$$

SECTION 6.3. Unit Step Function. *t*-Shifting, page 233

Purpose

1. To introduce the unit step function $u(t - a)$, which together with Dirac's delta (Sec. 6.4) greatly increases the usefulness of the Laplace transform.

2. To find the transform of

$$0 \quad (t < a), \qquad f(t - a) \quad (t > a)$$

if that of $f(t)$ is known (*"t-shifting"*). (*"s-shifting"* was considered in Sec. 6.1.)

im06.qxd 9/21/05 12:05 PM Page 124

Main Content, Important Concepts

Unit step function (1), its transform (2)

Second shifting theorem (Theorem 1)

Comment on the Unit Step Function

Problem Set 6.3 shows that $u(t - a)$ is the basic function for representing discontinuous functions.

SOLUTIONS TO PROBLEM SET 6.3, page 240

2. $t(1 - u(t - 1)) = t - [(t - 1) + 1]u(t - 1)$. Hence the transform is

$$\frac{1}{s^2} - \frac{e^{-s}}{s^2} - \frac{e^{-s}}{s}.$$

4. $(\sin 3t)(1 - u(t - \pi)) = \sin 3t + u(t - \pi) \sin 3(t - \pi)$. Hence the transform is

$$\frac{3}{s^2 + 9}(1 + e^{-\pi s}).$$

6. We obtain

$$t^2u(t - 3) = [(t - 3)^2 + 6(t - 3) + 9]u(t - 3).$$

Hence the transform is

$$\left(\frac{2}{s^3} + \frac{6}{s^2} + \frac{9}{s}\right) e^{-3s}.$$

8. $(1 - e^{-t})(1 - u(t - \pi)) = 1 - e^{-t} - (1 - e^{-(t-\pi)-\pi})u(t - \pi)$. Hence the transform is

$$\frac{1}{s} - \frac{1}{s + 1} - \frac{e^{-\pi s}}{s} + e^{-\pi}\frac{1}{s + 1} e^{-\pi s}.$$

10. $u(t - 6\pi/\omega) \sin \omega t = u(t - 6\pi/\omega) \sin(\omega t - 6\pi)$. Hence the transform is

$$\frac{\omega}{s^2 + \omega^2} e^{-6\pi s/\omega}.$$

12. $\frac{1}{2}(e^t - e^{-t})(1 - u(t - 2)) = \frac{1}{2}(e^t - e^{-t}) - \frac{1}{2}(e^{(t-2)+2} - e^{(-t+2)-2})u(t - 2)$. Hence the transform is

$$\frac{1}{2} \cdot \frac{1}{s - 1} - \frac{1}{2} \cdot \frac{1}{s + 1} - \frac{1}{2}\left(\frac{e^2}{s - 1} - \frac{e^{-2}}{s + 1}\right) e^{-2s}.$$

Alternatively, by using the addition formula (22) in App. 3.1 we obtain the transform in the form

$$\frac{1}{s^2 - 1} - \left(\frac{\cosh 2}{s^2 - 1} + \frac{s \sinh 2}{s^2 - 1}\right) e^{-2s}.$$

14. $s/(s^2 + \omega^2)$ has the inverse $\cos \omega t$. Hence $f(t) = 0$ if $t < 1$ and $\cos \omega(t - 1)$ if $t > 1$.

16. $t - [(t - 1) + 1]u(t - 1) = t - t\,u(t - 1)$; hence $f(t) = t$ if $0 < t < 1$ and 0 if $t > 1$.

18. $1/(s^2 + 2s + 2) = 1/[(s + 1)^2 + 1]$ has the inverse $e^{-t} \sin t$. Hence the given transform has the inverse

$$e^{-(t-\pi)} \sin(t - \pi)u(t - \pi) = -e^{\pi - t} \sin t\, u(t - \pi)$$

which is 0 if $t < \pi$ and $-e^{\pi - t} \sin t$ if $t > \pi$.

im06.qxd 9/21/05 12:05 PM Page 125

20. The inverse transform is

$$e^{kt} - e^{k(t-1)}e^k u(t-1) = \begin{cases} e^{kt} \text{ if } 0 < t < 1 \\ 0 \quad \text{if} \qquad t > 1. \end{cases}$$

22. The inverse transform is $2.5(u(t-2.6) - u(t-3.8))$, that is, 2.5 if $2.6 < t < 3.8$ and 0 elsewhere.

24. $(9s^2 - 6s + 1)Y = 27s + 9 - 18 = 27s - 9$. Hence

$$Y = \frac{27s-9}{9s^2-6s+1} = \frac{3s-1}{(s-\frac{1}{3})^2} = \frac{3}{s-\frac{1}{3}}.$$

Hence the *answer* is $y = 3e^{t/3}$.

26. $(s^2 + 10s + 24)Y = (s+4)(s+6)Y = \dfrac{288}{s^3} + \dfrac{19}{12}s - 5 + \dfrac{190}{12}$. Division by $s^2 + 10s + 24$ and expansion in terms of partial fractions gives

$$Y = \frac{12}{s^3} - \frac{5}{s^2} + \frac{19/12}{s}.$$

Hence the *answer* is $y = 6t^2 - 5t + \frac{19}{12}$. Note that it does not contain a contribution from the general solution of the homogeneous ODE.

28. The subsidiary equation is

$$(s^2 + 3s + 2)Y = \frac{1}{s} - \frac{e^{-s}}{s}.$$

It has the solution

$$Y = \frac{1-e^{-s}}{s(s^2+3s+2)} = \left(\frac{1}{2s} + \frac{1}{2(s+2)} - \frac{1}{s+1}\right)(1-e^{-s}).$$

This gives the *answer*

$$y = \tfrac{1}{2} + \tfrac{1}{2}e^{-2t} - e^{-t} - (\tfrac{1}{2} + \tfrac{1}{2}e^{-2(t-1)} - e^{-(t-1)})u(t-1);$$

that is,

$$y = \begin{cases} \frac{1}{2} + \frac{1}{2}e^{-2t} - e^{-t} & \text{if } 0 < t < 1 \\ \frac{1}{2}e^{-2t}(1-e^2) - e^{-t}(1-e) & \text{if} \qquad t > 1. \end{cases}$$

30. The subsidiary equation is

$$(s^2 - 16)Y = \frac{48}{s-2}(1 - e^{-4s+8}) + 3s - 4.$$

Now

$$\frac{\dfrac{48}{s-2} + 3s - 4}{s^2 - 16} = \frac{3}{s+4} + \frac{4}{s-4} - \frac{4}{s-2}$$

has the inverse transform $y_1 = 3e^{-4t} + 4e^{4t} - 4e^{2t}$. This is the solution for $0 < t < 4$. The solution for $t > 4$ is

$$y = y_2 = e^{-4t}(3 - e^{24}) + e^{4t}(4 - 3e^{-8}).$$

im06.qxd 9/21/05 12:05 PM Page 126

In y_2 the e^{2t}-term has dropped out. The result can be confirmed classically by noting that we must have

$$y_2(4) = y_1(4) = 3e^{-16} + 4e^{16} - 4e^{8}$$
$$y_2'(4) = y_1'(4) = -12e^{-16} + 16e^{16} - 8e^{8}.$$

32. $r = 35e^{2t}(1 - u(t-2))$. The subsidiary equation is

$$(s^2 + 8s + 15)Y = \frac{35}{s-2}(1 - e^{-2(s-2)}) + 3s - 8 + 24.$$

Its solution is

$$Y = \frac{3s^2 + 10s + 3 - 35e^{-2s+4}}{s^3 + 6s^2 - s - 30}.$$

The inverse transform of Y is

$$y = e^{2t} + 2e^{-5t} + u(t-2)(-e^{2t} - \tfrac{5}{2}e^{-5t+14} + \tfrac{7}{2}e^{-3t+10}).$$

Thus,

$$y = \begin{cases} e^{2t} + 2e^{-5t} & \text{if } 0 < t < 2 \\ e^{-5t}(2 - \frac{5}{2}e^{14}) + \frac{7}{2}e^{-3t+10} & \text{if } \quad t > 2. \end{cases}$$

34. $t = \pi + \tilde{t}$, $\tilde{y}'' + 2\tilde{y}' + 5\tilde{y} = \tilde{r}$, $\tilde{r} = 10[-1 + u(\tilde{t} - \pi)]\sin\tilde{t}$, $\tilde{y}(0) = 1$, $\tilde{y}'(0) = -2 + 2e^{-\pi}$. The solution in terms of $\tilde{t}$ is

$$\tilde{y}(\tilde{t}) = e^{-t-\pi}\sin 2\tilde{t} + \cos\tilde{t} - 2\sin\tilde{t}$$
$$+ u(\tilde{t} - \pi)[e^{-\tilde{t}+\pi}(-\cos 2\tilde{t} + \tfrac{1}{2}\sin 2\tilde{t}) - \cos\tilde{t} + 2\sin\tilde{t}].$$

In terms of t,

$$y(t) = e^{-t}\sin 2t - \cos t + 2\sin t$$
$$+ u(t - 2\pi)[e^{-t+2\pi}(-\cos 2t + \tfrac{1}{2}\sin 2t) + \cos t - 2\sin t].$$

36. $10i + 100\int_0^t i(\tau)\,d\tau = 100(u(t-0.5) - u(t-0.6))$. Divide by 10 and take the transform, using Theorem 3 in Sec. 6.2,

$$I + \frac{10}{s}I = \frac{10}{s}(e^{-0.5s} - e^{-0.6s}).$$

Solving for $I = \mathcal{L}(i)$ gives

$$I = \frac{10}{s+10}(e^{-0.5s} - e^{-0.6s}).$$

The inverse transform is

$$i(t) = 10(e^{-10(t-0.5)}u(t-0.5) - e^{-10(t-0.6)}u(t-0.6)).$$

Hence

$$i(t) = 0 \qquad \text{if} \qquad t < 0.5$$
$$i(t) = 10e^{-10(t-0.5)} \qquad \text{if} \qquad 0.5 < t < 0.6$$
$$i(t) = 10(e^{-10(t-0.5)} - e^{-10(t-0.6)})$$
$$= 10e^{-10t}(e^5 - e^6)$$
$$= -2550e^{-10t} \qquad \text{if} \qquad t > 0.6.$$

im06.qxd 9/21/05 12:05 PM Page 127

Jumps occur at $t = 0.5$ (upward) and at $t = 0.6$ (downward) because the right side has those jumps and the term involving the integral (representing the charge on the capacitor) cannot change abruptly; hence the first term, $Ri(t)$, must jump by the amounts of the jumps on the right, which have size 100, and since $R = 10$, the current has jumps of size 10.

38. We obtain

$$I = 14 \cdot 10^5 \frac{se^{-4s-12}}{(s+10)(s+3)} = \left(\frac{2 \cdot 10^6}{s+10} - \frac{6 \cdot 10^5}{s+3}\right) e^{-4s-12}$$

hence

$$i = u(t-4)\,[2 \cdot 10^6 e^{-10(t-4)-12} - 6 \cdot 10^5 e^{-3(t-4)-12}].$$

40. $i' + 1000i = 40 \sin t\, u(t-\pi)$. The subsidiary equation is

$$sI + 1000I = -40 \frac{e^{-\pi s}}{s^2+1}.$$

Its solution is

$$I = \frac{-40e^{-\pi s}}{(s^2+1)(s+1000)} = \frac{-40e^{-\pi s}}{1\,000\,001}\left(\frac{1}{s+1000} - \frac{s-1000}{s^2+1}\right).$$

The inverse transform is

$$i = u(t-\pi)\left[-\frac{40}{1\,000\,001}(\cos t + e^{-1000(t-\pi)}) + \frac{40\,000}{1\,000\,001}\sin t\right];$$

hence $i = 0$ if $t < \pi$, and $i \approx 0.04 \sin t$ if $t > \pi$.

42. $i'' + 4i = 200(1-t^2)(1-u(t-1))$. Observing that

$$t^2 = (t-1)^2 + 2(t-1) + 1,$$

we obtain the subsidiary equation

$$(s^2+4)I = 200\left(\frac{1}{s} - \frac{2}{s^3}\right) + 200e^{-s}\left(\frac{2}{s^2} + \frac{2}{s^3}\right).$$

Its solution is

$$I = 200 \frac{s^2 - 2 + e^{-s}(2s+2)}{s^3(s^2+4)} = 25\left(\frac{3}{s} - \frac{4}{s^3} - \frac{3s}{s^2+4}\right) + 25e^{-s}\left(-\frac{1}{s} + \frac{4}{s^2} + \frac{4}{s^3} + \frac{s-4}{s^2+4}\right).$$

Its inverse transform is

$$i = 75 - 50t^2 - 75\cos 2t + u(t-1)[-75 + 50t^2 + 25\cos(2t-2) - 50\sin(2t-2)].$$

44. $0.5i'' + 20i = 78\cos t\,(1 - u(t-\pi))$. The subsidiary equation is

$$(0.5s^2 + 20)I = \frac{78s}{s^2+1}(1 + e^{-\pi s}).$$

Its solution is

$$I = \frac{156s(1+e^{-\pi s})}{(s^2+1)(s^2+40)} = 4s\left(\frac{1}{s^2+1} - \frac{1}{s^2+40}\right)(1+e^{-\pi s}).$$

im06.qxd 9/21/05 12:05 PM Page 128

Its inverse transform is

$$i = 4\cos t - 4\cos\sqrt{40}t - 4u(t-\pi)\,[\cos t + \cos(\sqrt{40}(t-\pi))].$$

46. $i' + 4i + 20\int_0^t i(\tau)\,d\tau = 34e^{-t}(1-u(t-4))$. The subsidiary equation is

$$\left(s + 4 + \frac{20}{s}\right) I = \frac{34}{s+1}\,(1 - e^{-4s-4}).$$

Its solution is

$$I = \frac{34s}{(s+1)(s^2+4s+20)}\,(1 - e^{-4s-4}).$$

The inverse transform is

$$i = -2e^{-t} + e^{-2t}(2\cos 4t + 9\sin 4t) + u(t-4)\,[2e^{-t+4} + e^{-2(t-2)}(2e^{-t} - 2\cos 4(t-4) - 9\sin 4(t-4)].$$

SECTION 6.4. Short Impulses. Dirac's Delta Function. Partial Fractions, page 241

Purpose. Modeling of short impulses by **Dirac's delta** function (also known as **unit impulse** function). The text includes a remark that this is not a function in the usual sense of calculus but a "generalized function" or "distribution." Details cannot be discussed on the level of this book; they can be found in books on functional analysis or on PDEs. See, e.g., L. Schwartz, *Mathematics for the Physical Sciences,* Paris: Hermann, 1966. The French mathematician LAURENT SCHWARTZ (1915–2002) created and popularized the theory of distributions. See also footnote 2.

Main Content

Definition of Dirac's delta (3)

Sifting property (4)

Transform of delta (5)

Application to mass–spring systems and electric networks

More on partial fractions (Example 4)

For the beginning of the discussion of partial fractions in the present context, see Sec. 6.2.

SOLUTIONS TO PROBLEM SET 6.4, page 247

2. The subsidiary equation is

$$(s^2 + 2s + 2)Y = 1 + \frac{1}{1+s} + 5e^{-2s}$$

where the 1 comes from $y'(0)$. The solution in terms of partial fractions is

$$Y = \frac{1}{(s+1)^2+1} + \frac{1}{1+s} - \frac{s+1}{(s+1)^2+1} + \frac{5e^{-2s}}{(s+1)^2+1}.$$

Hence the inverse transform (the solution of the problem) is

$$y = e^{-t}\sin t + e^{-t} - e^{-t}\cos t + 5e^{-(t-2)}\sin(t-2)\,u(t-2).$$

4. The subsidiary equation is

$$(s^2 + 3s + 2)Y = s - 1 + 3 + \frac{10}{s^2+1} + 10e^{-s}.$$

im06.qxd 9/21/05 12:05 PM Page 129

In terms of partial fractions, its solution is

$$Y = \frac{-2}{s+2} + \frac{6}{s+1} - \frac{3s-1}{s^2+1} + 10\left(\frac{1}{s+1} - \frac{1}{s+2}\right)e^{-s}.$$

Its inverse transform is

$$y = -2e^{-2t} + 6e^{-t} - 3\cos t + \sin t + 10u(t-1)\left[e^{-t+1} - e^{-2(t-1)}\right].$$

Without the δ-term, the solution is $-3\cos t + \sin t - 2e^{-2t} + 6e^{-t}$ and approaches a harmonic oscillation fairly soon. With the δ-term the first half-wave has a maximum amplitude of about 5, but from about $t = 8$ or 10 on its graph coincides practically with the graph of that harmonic oscillation (whose maximum amplitude is $\sqrt{10}$). This is physically understandable, since the system has damping that eventually consumes the additional energy due to the δ-term.

6. The subsidiary equation is

$$(s^2 + 2s - 3)Y = s + 2 + 100(e^{-2s} + e^{-3s}).$$

The solution is

$$Y = \frac{s + 2 + 100(e^{-2s} + e^{-3s})}{(s-1)(s+3)}.$$

Its inverse transform gives the solution of the problem,

$$y = \tfrac{1}{4}(e^{-3t} + 3e^{t}) - 25u(t-2)\,(e^{-3t+6} - e^{t-2}) + 25u(t-3)\,(-e^{-3t+9} + e^{t-3}).$$

Without the factor 100 the cusps of the curve at $t = 2$ and $t = 3$ caused by the delta functions would hardly be visible in the graph, because the solution increases exponentially. Solve the problem without the factor 100.

8. The subsidiary equation is

$$(s^2 + 5s + 6)Y = e^{-\pi s/2} - \frac{s}{s^2+1}e^{-\pi s}.$$

Its solution is

$$Y = \left(\frac{1}{s+2} - \frac{1}{s+3}\right)e^{-\pi s/2} - \left(-\frac{0.4}{s+2} + \frac{0.3}{s+3} + \frac{0.1(s+1)}{s^2+1}\right)e^{-\pi s}.$$

The inverse transform of Y is

$$y = u(t - \tfrac{1}{2}\pi)\left[e^{-2t+\pi} - e^{-3t+3\pi/2}\right] - 0.1u(t-\pi)\left[-4e^{-2t+2\pi} + 3e^{-3t+3\pi} - \cos t - \sin t\right].$$

This solution is zero from 0 to $\frac{1}{2}\pi$ and then increases rapidly. Its first negative half-wave has a smaller maximum amplitude (about 0.1) than the continuation as a harmonic oscillation with maximum amplitude of about 0.15.

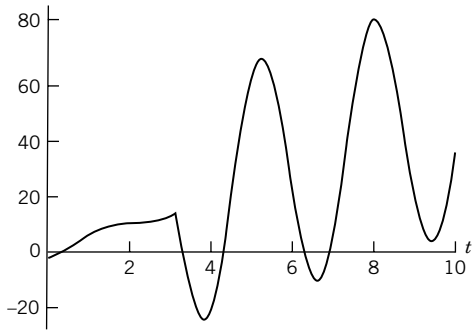
10. This is Prob. 9 without the damping term. The subsidiary equation is

$$(s^2 + 5)Y = -2s + 5 + \frac{25}{s^2} - 100e^{-\pi s}.$$

Its solution is

$$Y = \frac{-2s+5}{s^2+5} + \frac{25}{s^2(s^2+5)} - \frac{100}{s^2+5}e^{-\pi s}.$$

im06.qxd 9/21/05 12:05 PM Page 130



The partial fraction reduction of the second term on the right is

$$5\left(\frac{1}{s^2} - \frac{1}{s^2 + 5}\right).$$

The inverse transform of Y is (note that the sine terms cancel)

$$y = -2\cos t\sqrt{5} + 5t - 20\sqrt{5}\,u(t - \pi)\sin(\sqrt{5}(t - \pi)).$$

The graph begins at $t = 0$ according to $5t - 2\cos t\sqrt{5}$ (the solution without the δ-term) and then starts oscillating with maximum amplitude of about 40 about the straight line given by $5t$. Since there is no damping, the energy corresponding to the δ-term imposed at $t = \pi$ will not disappear from the system; hence we obtain the indicated oscillations. See the figure.

Section 6.4. Problem 10

12. The subsidiary equation is

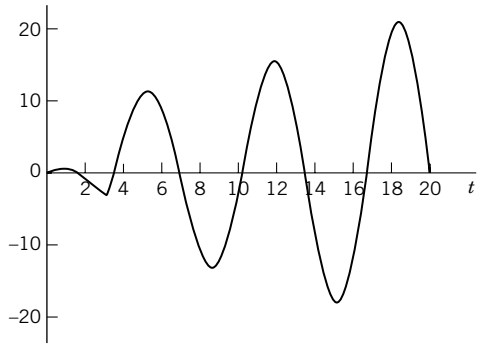
$$(s^2 + 1)Y = 1 - \frac{2}{s^2 + 1} + 10e^{-\pi s}.$$

Its solution is

$$Y = \frac{1}{s^2 + 1} - \frac{2}{(s^2 + 1)^2} + \frac{10}{s^2 + 1}\,e^{-\pi s}.$$

The inverse transform of Y is

$$\begin{aligned} y &= \sin t - (\sin t - t\cos t) - 10\,u(t - \pi)\sin t \\ &= t\cos t - 10\,u(t - \pi)\sin t. \end{aligned}$$



We see that we have a resonance term, $t\cos t$. At $t = \pi$ the graph has a sharp cusp and then shows the oscillations with increasing maximum amplitude to be expected in the case of resonance. See the figure.

14. CAS Project. Students should become aware that careful observation of graphs may lead to discoveries or to more information about conjectures that they may want to prove or disprove. The curves branch from the solution of the homogeneous ODE at the instant at which the impulse is applied, which by choosing, say, $a = 1, 2, 3, \cdots$, gives an interesting joint graph.

16. Team Project. (a) If $f(t)$ is piecewise continuous on an interval of length p, then its Laplace transform exists, and we can write the integral from zero to infinity as the series of integrals over successive periods:

$$\mathscr{L}(f) = \int_0^\infty e^{-st}f(t)\,dt = \int_0^p e^{-st}f\,dt + \int_p^{2p} e^{-st}f\,dt + \int_{2p}^{3p} e^{-st}f\,dt + \cdots.$$

im06.qxd 9/21/05 12:05 PM Page 131

Section 6.4. Problem 12

If we substitute $t = \tau + p$ in the second integral, $t = \tau + 2p$ in the third integral, $\cdots$, $t = \tau + (n - 1)p$ in the nth integral, $\cdots$, then the new limits in every integral are 0 and p. Since

$$f(\tau + p) = f(\tau), \qquad f(\tau + 2p) = f(\tau),$$

etc., we thus obtain

$$\mathscr{L}(f) = \int_0^p e^{-s\tau} f(\tau)\, d\tau + \int_0^p e^{-s(\tau+p)} f(\tau)\, d\tau + \int_0^p e^{-s(\tau+2p)} f(\tau)\, d\tau + \cdots.$$

The factors that do not depend on τ can be taken out from under the integral signs; this gives

$$\mathscr{L}(f) = [1 + e^{-sp} + e^{-2sp} + \cdots] \int_0^p e^{-s\tau} f(\tau)\, d\tau.$$

The series in brackets $[\cdots]$ is a geometric series whose sum is $1/(1 - e^{-ps})$. The theorem now follows.

(b) From (11) we obtain

$$\mathscr{L}(f) = \frac{1}{1 - e^{-2\pi s/\omega}} \int_0^{\pi/\omega} e^{-st} \sin \omega t\, dt.$$

Using $1 - e^{-2\pi s/\omega} = (1 + e^{-\pi s/\omega})(1 - e^{-\pi s/\omega})$ and integrating by parts or noting that the integral is the imaginary part of the integral

$$\int_0^{\pi/\omega} e^{(-s+i\omega)t}\, dt = \frac{1}{-s + i\omega}\, e^{(-s+i\omega)t} \Big|_0^{\pi/\omega} = \frac{-s - i\omega}{s^2 + \omega^2}\, (-e^{-s\pi/\omega} - 1)$$

we obtain the result.

(c) From (11) we obtain the following equation by using $\sin \omega t$ from 0 to π/ω and $-\sin \omega t$ from π/ω to $2\pi/\omega$:

$$\frac{\omega}{s^2 + \omega^2}\, \frac{1 + e^{\pi s/\omega}}{e^{\pi s/\omega} - 1} = \frac{\omega}{s^2 + \omega^2}\, \frac{e^{-\pi s/2\omega} + e^{\pi s/2\omega}}{e^{\pi s/2\omega} - e^{-\pi s/2\omega}}$$

$$= \frac{\omega}{s^2 + \omega^2}\, \frac{\cosh(\pi s/2\omega)}{\sinh(\pi s/2\omega)}.$$

This gives the result.

(d) The sawtooth wave has the representation

$$f(t) = \frac{k}{p}\, t \qquad \text{if } 0 < t < p, \qquad f(t + p) = f(t).$$

im06.qxd 9/21/05 12:05 PM Page 132

Integration by parts gives

$$\int_0^p e^{-st} t\,dt = -\frac{t}{s}\,e^{-st}\Big|_0^p + \frac{1}{s}\int_0^p e^{-st}\,dt$$

$$= -\frac{p}{s}\,e^{-sp} - \frac{1}{s^2}\,(e^{-sp} - 1)$$

and thus from (11) we obtain the result

$$\mathscr{L}(f) = \frac{k}{ps^2} - \frac{ke^{-ps}}{s(1 - e^{-ps})} \qquad (s > 0).$$

(e) Since kt/p has the transform k/ps^2, from (d) we have the result

$$\frac{ke^{-ps}}{s(1 - e^{-ps})} \qquad (s > 0).$$

SECTION 6.5. Convolution. Integral Equations, page 248

Purpose. To find the inverse $h(t)$ of a product $H(s) = F(s)G(s)$ of transforms whose inverses are known.

Main Content, Important Concepts

Convolution $f * g$, its properties

Convolution theorem

Application to ODEs and integral equations

Comment on Occurrence

In an ODE the transform $R(s)$ of the right side $r(t)$ is known from Step 1. Solving the subsidiary equation algebraically for $Y(s)$ causes the transform $R(s)$ to be multiplied by the reciprocal of the factor of $Y(s)$ on the left (the transfer function $Q(s)$; see Sec. 6.2). This calls for the convolution theorem, unless one sees some other way or shortcut.

Very Short Courses. This section can be omitted.

SOLUTIONS TO PROBLEM SET 6.5, page 253

2. $t * t = \int_0^t \tau(t - \tau)\,d\tau = \frac{t^3}{2} - \frac{t^3}{3} = \frac{t^3}{6}$

4. $\int_0^t e^{a\tau}e^{b(t-\tau)}\,d\tau = e^{bt}\int_0^t e^{(a-b)\tau}\,d\tau = \frac{e^{bt}}{a - b}\,(e^{(a-b)t} - 1) = \frac{1}{a - b}\,(e^{at} - e^{bt})$

6. $1 * f(t) = \int_0^t f(\tau)\,d\tau$

8. By the definition and by (11) in App. 3.1 we obtain

$$\int_0^t \sin\tau\cos(t - \tau)\,d\tau = \tfrac{1}{2}\int_0^t \sin t\,d\tau + \tfrac{1}{2}\int_0^t \sin(2\tau - t)\,d\tau.$$

Integration of this gives

$$\tfrac{1}{2}\,t\sin t + \left[\tfrac{1}{4}\,(-\cos(2\tau - t))\right]\Big|_0^t = \tfrac{1}{2}\,t\sin t - \tfrac{1}{4}\,[\cos t - \cos(-t)].$$

Hence the *answer* is $\frac{1}{2}t\sin t$.

im06.qxd 9/21/05 12:05 PM Page 133

10. $\mathscr{L}(1)\mathscr{L}(e^t)$, $1 * e^t = \displaystyle\int_0^t e^\tau\, d\tau = e^t - 1$

12. $t * e^{2t} = \displaystyle\int_0^t e^{2\tau}(t - \tau)\, d\tau = \frac{t}{2}\,(e^{2t} - 1) - \frac{t}{2}\,e^{2t} + \frac{1}{4}\,e^{2t} - \frac{1}{4}$

$= -\dfrac{t}{2} + \dfrac{1}{4}\,e^{2t} - \dfrac{1}{4}$

14. $\frac{1}{4}(\cos 4t) * (\sin 4t) = \frac{1}{4}\displaystyle\int_0^t \cos 4\tau \sin 4(t - \tau)\, d\tau$. Use (11) in App. 3.1 to convert the product in the integrand to a sum and integrate. This gives

$$\frac{1}{4}\int_0^t \frac{1}{2}\,(\sin 4t + \sin(4t - 8\tau))\, d\tau = \frac{t}{8}\sin 4t + \frac{1}{64}\,(\cos 4t - \cos(-4t)).$$

Hence the *answer* is $\dfrac{t}{8}\sin 4t$, in agreement with formula 22 in Sec. 6.9.

16. $(\sin t) * (\sin 5t) = \displaystyle\int_0^t \sin\tau \sin 5(t - \tau)\, d\tau$. Using formula (11) in App. 3.1, convert the product in the integrand to a sum and integrate, obtaining

$$\begin{aligned}
&\tfrac{1}{2}\int_0^t [-\cos(5t - 4\tau) + \cos(\tau - 5t + 5\tau)]\, d\tau \\
&= \tfrac{1}{2}\big[-\tfrac{1}{4}\sin(-5t + 4\tau) + \tfrac{1}{6}\sin(6\tau - 5t)\big]\Big|_0^t \\
&= \tfrac{1}{8}(\sin t - \sin 5t) + \tfrac{1}{12}(\sin t + \sin 5t) \\
&= \tfrac{5}{24}\sin t - \tfrac{1}{24}\sin 5t.
\end{aligned}$$

18. The subsidiary equation is

$$(s^2 + 1)Y = \frac{1}{s^2 + 1}$$

and has the solution

$$Y = \frac{1}{(s^2 + 1)^2}\,.$$

Since the inverse of $1/(s^2 + 1)$ is $\sin t$, the convolution theorem gives the *answer*

$$\begin{aligned}
y = (\sin t) * (\sin t) &= \int_0^t \sin\tau \sin(t - \tau)\, d\tau \\
&= -\tfrac{1}{2}t\cos t + \tfrac{1}{2}\sin t.
\end{aligned}$$

20. The subsidiary equation is

$$(s + 1)(s + 4)Y = \frac{2}{s + 2}\,.$$

Its solution is

$$Y = \frac{2}{(s + 1)(s + 2)(s + 4)}\,.$$

im06.qxd 9/21/05 12:05 PM Page 134

Two applications of the convolution theorem thus give

$$(2e^{-t} * e^{-2t}) * e^{-4t} = \int_0^t \left(2\int_0^p e^{-\tau}e^{-2p+2\tau}\,d\tau\right)e^{-4t+4p}\,dp$$
$$= \int_0^t (2e^{-p} - 2e^{-2p})e^{-4t+4p}\,dp$$
$$= \frac{2}{3}\,e^{-t} - e^{-2t} + \frac{1}{3}\,e^{-4t}.$$

22. The subsidiary equation is

$$(s^2 + 3s + 2)Y = \frac{1 - e^{-as}}{s}\,.$$

Now

$$\frac{1}{s^2 + 3s + 2} = \frac{1}{(s + 1)(s + 2)} = \frac{1}{s + 1} - \frac{1}{s + 2}\,.$$

The inverse transform of this is $e^{-t} - e^{-2t}$. Hence, since $r(t) = 1$ if $t < a$ and 0 thereafter, this gives

$$r(t) * (e^{-t} - e^{-2t}) = \int (e^{-(t-\tau)} - e^{-2(t-\tau)})\,d\tau$$
$$= e^{-(t-\tau)} - \tfrac{1}{2}e^{-2(t-\tau)}.$$

If $t < a$, the limits of integration are 0 and t; this gives

$$y(t) = 1 - e^{-t} - \tfrac{1}{2} + \tfrac{1}{2}e^{-2t} = \tfrac{1}{2} - e^{-t} + \tfrac{1}{2}e^{-2t}.$$

If $t > a$, we integrate from 0 to a, obtaining

$$y(t) = e^{-(t-a)} - e^{-t} - \tfrac{1}{2}e^{-2(t-a)} + \tfrac{1}{2}e^{-2t}.$$

Using the subsidiary equation (above) and a partial fraction expansion, we obtain

$$Y = (1 - e^{-as})\left(\frac{1}{2s} + \frac{1}{2(s + 2)} - \frac{1}{s + 1}\right)$$

and the same expressions for $y(t)$.

24. The subsidiary equation is

$$(s^2 + 5s + 6)Y = s + 5 + e^{-3s}.$$

Its solution is

$$Y = \frac{s + 5 + e^{-3s}}{(s + 2)(s + 3)} = \frac{3}{s + 2} - \frac{2}{s + 3} + \left(\frac{1}{s + 2} - \frac{1}{s + 3}\right)e^{-3s}.$$

The inverse transform of the first two terms on the right is

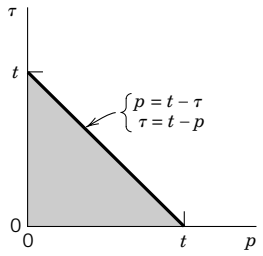
$$3e^{-2t} - 2e^{-3t}.$$

The inverse transform of the last two terms can be obtained by the second shifting theorem or by convolution. By convolution we use the sifting property, formula (4) in Sec. 6.4. We obtain

$$\delta(t - 3) * (e^{-2t} - e^{-3t}) = \int_0^t [e^{-2(t-\tau)} - e^{-3(t-\tau)}]\delta(\tau - 3)\,d\tau.$$

For $t < 3$ this gives 0. For $t > 3$ we obtain

$$e^{-2(t-3)} - e^{-3(t-3)}.$$



im06.qxd 9/21/05 12:05 PM Page 135

26. Team Project. (a) Setting $t - \tau = p$, we have $\tau = t - p$, $d\tau = -dp$, and p runs from t to 0; thus

$$f * g = \int_0^t f(\tau)g(t - \tau)\,d\tau = \int_t^0 g(p)f(t - p)\,(-dp)$$
$$= \int_0^t g(p)f(t - p)\,dp = g * f.$$

(b) Interchanging the order of integration and noting that we integrate over the shaded triangle in the figure, we obtain

$$(f * g) * v = v * (f * g)$$
$$= \int_0^t v(p) \int_0^{t-p} f(\tau)g(t - p - \tau)\,d\tau\,dp$$
$$= \int_0^t f(\tau) \int_0^{t-\tau} g(t - \tau - p)v(p)\,dp\,d\tau$$
$$= f * (g * v).$$

Section 6.5. Team Project 26(b)

(c) This is a simple consequence of the additivity of the integral.

(d) Let $t > k$. Then $(f_k * f)(t) = \int_0^k \frac{1}{k} f(t - \tau)\,d\tau = f(t - \tilde{t})$ for some $\tilde{t}$ between 0 and k. Now let $k \to 0$. Then $\tilde{t} \to 0$ and $f_k(t - \tilde{t}) \to \delta(t)$, so that the formula follows.

(e) $s^2Y - sy(0) - y'(0) + \omega^2 Y = \mathscr{L}(r)$ has the solution

$$Y = \frac{1}{\omega}\left(\frac{\omega}{s^2 + \omega^2}\right)\mathscr{L}(r) + y(0)\frac{s}{s^2 + \omega^2} + \frac{y'(0)}{\omega}\,\frac{\omega}{s^2 + \omega^2}$$

etc.

28. The integral equation can be written

$$y(t) + y(t) * \cosh t = t + e^t.$$

This implies by the convolution theorem that its transform is

$$Y + \frac{s}{s^2 - 1}\,Y = \frac{1}{s^2} + \frac{1}{s - 1}\,.$$

The solution is

$$Y = \frac{s^2 - 1}{s^2 + s - 1}\left(\frac{1}{s^2} + \frac{1}{s - 1}\right) = \frac{1}{s^2} + \frac{1}{s}\,.$$

im06.qxd 9/21/05 12:05 PM Page 136

Hence its inverse transform gives the *answer* $y(t) = t + 1$. This result can easily be checked by substitution into the given equation and integration.

30. $Y + \dfrac{2s}{s^2+1}\,Y = \dfrac{s^2+2s+1}{s^2+1}\,Y = \dfrac{s}{s^2+1}$, hence

$$Y = \frac{1}{s+1} - \frac{1}{(s+1)^2}.$$

This gives the *answer* $y = (1-t)e^{-t}$.

32. $Y\left(1 - \dfrac{1}{s^2}\right) = \dfrac{2}{s} - \dfrac{1}{s^3}$, hence

$$Y = \frac{2s^2-1}{s(s^2-1)} = \frac{1}{s} + \frac{s}{s^2-1}.$$

The *answer* is $y = 1 + \cosh t$.

34. $Y\left(1 + \dfrac{1}{s-2}\right) = \dfrac{2}{s^3} - \dfrac{1}{s^2} - \dfrac{1}{2s} + \dfrac{1}{2(s-2)}$, $Y = \dfrac{4}{s^3}$, $y = 2t^2$

SECTION 6.6. Differentiation and Integration of Transforms. ODEs with Variable Coefficients, page 254

Purpose. To show that, ***roughly,*** differentiation and integration of transforms (not of functions, as before!) corresponds to multiplication and division, respectively, of functions by t, with application to the derivation of further transforms and to the solution of Laguerre's differential equation.

Comment on Application to Variable-Coefficient Equations

This possibility is rather limited; our Example 3 is perhaps the best elementary example of practical interest.

Very Short Courses. This section can be omitted.

SOLUTIONS TO PROBLEM SET 6.6, page 257

2. $\left(\dfrac{s}{s^2-4}\right)' = \dfrac{s^2-4-2s^2}{(s^2-4)^2} = -\dfrac{s^2+4}{(s^2-4)^2}$

4. By the addition formula for the cosine we have

$$\cos(t+k) = \cos t \cos k - \sin t \sin k.$$

The transform of this function is

$$\frac{s\cos k - \sin k}{s^2+1}.$$

The derivative times -1 is

$$-\frac{\cos k\,(s^2+1) - (s\cos k - \sin k)2s}{(s^2+1)^2}.$$

im06.qxd 9/21/05 12:05 PM Page 137

Simplification gives the *answer*

$$\frac{(s^2 - 1)\cos k - 2s \sin k}{(s^2 + 1)^2}.$$

6. We need two differentiations. We can drop the two minus signs. Starting from the transform of $\sin 3t$, we obtain

$$\left(\frac{3}{s^2 + 9}\right)'' = \left(\frac{-6s}{(s^2 + 9)^2}\right)'$$
$$= \frac{-6(s^2 + 9)^2 + 6s \cdot 2(s^2 + 9) \cdot 2s}{(s^2 + 9)^4}$$
$$= \frac{-6s^2 - 54 + 24s^2}{(s^2 + 9)^3}$$
$$= \frac{18(s^2 - 3)}{(s^2 + 9)^3}.$$

8. $\mathscr{L}(t^n e^{kt}) = \dfrac{n!}{(s - k)^{n+1}}$ can be obtained from $\mathscr{L}(e^{kt}) = \dfrac{1}{s - k}$ by n subsequent differentiations,

$$\left(\frac{1}{s - k}\right)^{(n)} = \left(\frac{-1}{(s - k)^2}\right)^{(n-1)} = \cdots = \frac{(-1)^n n!}{(s - k)^{n+1}}$$

and multiplication by $(-1)^n$ (to take care of the minus sign in (1) in each of the n steps), or much more simply, by the first shifting theorem, starting from $\mathscr{L}(t^n) = n!/s^{n+1}$.

10. $$-\left(\frac{s}{s^2 + \omega^2}\right)' = -\frac{s^2 + \omega^2 - 2s^2}{(s^2 + \omega^2)^2} = \frac{s^2 - \omega^2}{(s^2 + \omega^2)^2}$$

12. $$-\left(\frac{1}{(s + k)^2 + 1}\right)' = \frac{2(s + k)}{((s + k)^2 + 1)^2}$$

14. By differentiation we have

$$\left(\frac{4}{s^2 + 16}\right)' = \frac{-8s}{(s^2 + 16)^2}.$$

Hence the *answer* is $\frac{1}{8}t \sin 4t$. By integration we see that

$$\int_s^\infty \frac{\tilde{s}}{(\tilde{s}^2 + 16)^2}\, d\tilde{s} = \frac{\frac{1}{2}}{s^2 + 16}$$

has the inverse transform $\frac{1}{8}\sin 4t$ and gives the same answer. By convolution,

$$(\cos 4t) * (\tfrac{1}{4}\sin 4t) = \int_0^t \cos 4\tau \sin(4t - 4\tau)\, d\tau$$

and gives the same answer.

16. By differentiation

$$\left(\frac{1}{s^2 - 1}\right)' = \frac{-2s}{(s^2 - 1)^2}.$$

This shows that the *answer* is $\frac{1}{2}t \sinh t$.

im06.qxd 9/21/05 12:05 PM Page 138

18. $\ln \dfrac{s+a}{s+b} = \ln(s+a) - \ln(s+b) = -\displaystyle\int_s^\infty \frac{d\sigma}{\sigma+a} + \int_s^\infty \frac{d\sigma}{\sigma+b}$. This shows that the *answer* is $(-e^{-at} + e^{-bt})/t$.

20. $\left(\operatorname{arccot} \dfrac{s}{\omega}\right)' = -\dfrac{1/\omega}{1+\left(\dfrac{s}{\omega}\right)^2} = \dfrac{-\omega}{s^2+\omega^2}$ shows that the *answer* is $(\sin \omega t)/t$.

22. CAS Project. Students should become aware that usually there are several possibilities for calculations, and they should not rush into numerical work before carefully selecting formulas.

(b) Use the usual rule for differentiating a product n times. Some of the polynomials are

$$l_2 = 1 - 2t + \tfrac{1}{2}t^2$$
$$l_3 = 1 - 3t + \tfrac{3}{2}t^2 - \tfrac{1}{6}t^3$$
$$l_4 = 1 - 4t + 3t^2 - \tfrac{2}{3}t^3 + \tfrac{1}{24}t^4$$
$$l_5 = 1 - 5t + 5t^2 - \tfrac{5}{3}t^3 + \tfrac{5}{24}t^4 - \tfrac{1}{120}t^5.$$

SECTION 6.7. Systems of ODEs, page 258

Purpose. This section explains the application of the Laplace transform to systems of ODEs in terms of three typical examples: a mixing problem, an electrical network, and a system of several (two) masses on elastic springs.

SOLUTIONS TO PROBLEM SET 6.7, page 262

2. The subsidiary equations are

$$sY_1 - 1 = 5Y_1 + Y_2$$
$$sY_2 + 3 = Y_1 + 5Y_2.$$

The solution is

$$Y_1 = \frac{s-8}{(s-5)^2-1} = \frac{(s-5)-3}{(s-5)^2-1}$$

$$Y_2 = \frac{-3s+16}{(s-5)^2-1} = \frac{-3(s-5)+1}{(s-5)^2-1}.$$

The inverse transform is

$$y_1 = e^{5t}\cosh t - 3e^{5t}\sinh t = 2e^{4t} - e^{6t}$$
$$y_2 = -3e^{5t}\cosh t + e^{5t}\sinh t = -2e^{4t} - e^{6t}.$$

4. The subsidiary equations are

$$sY_1 + Y_2 = 1$$

$$Y_1 + sY_2 = \frac{2s}{s^2+1}.$$

The solution is

$$Y_1 = \frac{s}{s^2+1}, \qquad Y_2 = \frac{1}{s^2+1}.$$

The inverse transform is $y_1 = \cos t$, $y_2 = \sin t$.

im06.qxd 9/21/05 12:05 PM Page 139

6. The subsidiary equations are

$$sY_1 = 4Y_2 - \frac{8s}{s^2 + 16}$$

$$sY_2 = 3 - 3Y_1 - \frac{36}{s^2 + 16}\,.$$

The solution is

$$Y_1 = \frac{4}{s^2 + 16}\,, \qquad Y_2 = \frac{3s}{s^2 + 16}\,.$$

The inverse transform is $y_1 = \sin 4t$, $y_2 = 3\cos 4t$.

8. The subsidiary equations are

$$sY_1 = -3 + 6Y_1 + Y_2$$
$$sY_2 = -3 + 9Y_1 + 6Y_2.$$

The solution is

$$Y_1 = \frac{-3s + 15}{s^2 - 12s + 27} = -\frac{2}{s - 9} - \frac{1}{s - 3}$$

$$Y_2 = \frac{-3s - 9}{s^2 - 12s + 27} = -\frac{6}{s - 9} + \frac{3}{s - 3}\,.$$

The inverse transform is

$$y_1 = -2e^{9t} - e^{3t}, \qquad y_2 = -6e^{9t} + 3e^{3t}.$$

10. The subsidiary equations are

$$sY_1 = 4 - 2Y_1 + 3Y_2$$
$$sY_2 = 3 + 4Y_1 - Y_2.$$

The solution is

$$Y_1 = \frac{4s + 13}{s^2 + 3s - 10} = \frac{3}{s - 2} + \frac{1}{s + 5}$$

$$Y_2 = \frac{3s + 22}{s^2 + 3s - 10} = \frac{4}{s - 2} - \frac{1}{s + 5}\,.$$

The inverse transform is

$$y_1 = 3e^{2t} + e^{-5t}, \qquad y_2 = 4e^{2t} - e^{-5t}.$$

12. The subsidiary equations are

$$sY_1 = 2 + 2Y_1 + Y_2$$
$$sY_2 = 4Y_1 + 2Y_2 + 64e^{-s}\left(\frac{1}{s^2} + \frac{1}{s}\right).$$

The solution is

$$Y_1 = 2\left[\frac{1}{s - 4} - \frac{2}{s(s - 4)} + \frac{32e^{-s}}{s - 4}\left(\frac{1}{s^2} + \frac{1}{s^3}\right)\right]$$

$$Y_2 = 8\left[\frac{1}{s(s - 4)} + \frac{8e^{-s}}{s - 4}\left(\frac{1}{s} - \frac{1}{s^2} - \frac{2}{s^3}\right)\right].$$

im06.qxd 9/21/05 12:05 PM Page 140

Using partial fraction expansions

$$\frac{1}{s-4} - \frac{2}{s(s-4)} = \frac{1}{2(s-4)} + \frac{1}{2s}$$

and

$$64\left(\frac{1}{s^2(s-4)} + \frac{1}{s^3(s-4)}\right) = -\frac{5}{s} - \frac{20}{s^2} - \frac{16}{s^3} + \frac{5}{s-4}$$

which because of e^{-s} gives the inverse transform

$$-5 - 20(t-1) - 8(t-1)^2 + 5e^{4(t-1)}$$

and similarly for the expressions in Y_2, we obtain the inverse transforms of Y_1 and Y_2 in the form

$$y_1 = 1 + e^{4t} + u(t-1)\left[-8t^2 - 4t + 7 + 5e^{4t-4}\right]$$
$$y_2 = -2 + 2e^{4t} + u(t-1)\left[16t^2 - 8t - 18 + 10e^{4t-4}\right].$$

14. The subsidiary equations are

$$sY_1 = 1 - Y_2$$
$$sY_2 = -Y_1 + \frac{2s}{s^2+1} - \frac{2e^{-2\pi s}s}{s^2+1}.$$

The solution is

$$Y_1 = \frac{s(s^2 - 1 + 2e^{-2\pi s})}{s^4 - 1}$$
$$= \frac{s}{s^2+1} + \frac{2se^{-2\pi s}}{s^4-1}$$
$$= \frac{s}{s^2+1} + e^{-2\pi s}\left(\frac{1/2}{s-1} + \frac{1/2}{s+1} - \frac{s}{s^2+1}\right)$$
$$Y_2 = \frac{s^2 - 1 - 2s^2e^{-2\pi s}}{s^4-1}$$
$$= \frac{1}{s^2+1} + e^{-2\pi s}\left(\frac{1}{2}\left(\frac{1}{s+1} - \frac{1}{s-1}\right) - \frac{1}{s^2+1}\right).$$

The inverse transform is

$$y_1 = \cos t + u(t-2\pi)\left[-\cos t + \tfrac{1}{2}(e^{-t+2\pi} + e^{t-2\pi})\right]$$
$$y_2 = \sin t + u(t-2\pi)\left[-\sin t + \tfrac{1}{2}(e^{-t+2\pi} - e^{t-2\pi})\right].$$

Thus $y_1 = \cos t$ and $y_2 = \sin t$ if $0 < t < 2\pi$; $y_1 = \cosh(t - 2\pi)$, and $y_2 = -\sinh(t-2\pi)$ if $t > 2\pi$.

16. The subsidiary equations are

$$s^2Y_1 = s - 2Y_1 + 2Y_2$$
$$s^2Y_2 = 3s + 2Y_1 - 5Y_2.$$

The solution is

$$Y_1 = \frac{s(s^2+11)}{s^4+7s^2+6} = \frac{2s}{s^2+1} - \frac{s}{s^2+6}$$
$$Y_2 = \frac{s(3s^2+8)}{s^4+7s^2+6} = \frac{s}{s^2+1} + \frac{2s}{s^2+6}.$$

im06.qxd 9/21/05 12:05 PM Page 141

Hence the inverse transform is

$$y_1 = 2\cos t - \cos t\sqrt{6}, \qquad y_2 = \cos t + 2\cos t\sqrt{6}.$$

18. The subsidiary equations are

$$s^2Y_1 = 6 - Y_2 - \frac{1010}{s^2 + 100}$$

$$s^2Y_2 = 8s - 6 - Y_1 + \frac{1010}{s^2 + 100}\,.$$

The solution is, in terms of partial fractions,

$$Y_1 = \frac{-4}{s - 1} + \frac{10}{s^2 + 100} + \frac{4s}{s^2 + 1}$$

$$Y_2 = \frac{4}{s - 1} - \frac{10}{s^2 + 100} + \frac{4s}{s^2 + 1}\,.$$

The inverse transform is

$$y_1 = -4e^t + \sin 10t + 4\cos t$$
$$y_2 = 4e^t - \sin 10t + 4\cos t.$$

20. The subsidiary equations are

$$4sY_1 - 8 + sY_2 - 2sY_3 = 0$$

$$-2sY_1 + 4 \qquad + \quad sY_3 = \frac{1}{s}$$

$$2sY_2 - 4sY_3 = -\frac{16}{s^2}\,.$$

The solution is

$$Y_1 = 2\left(\frac{1}{s} + \frac{1}{s^3}\right), \qquad Y_2 = \frac{2}{s^2}\,, \qquad Y_3 = \frac{1}{s^2} + \frac{4}{s^3}\,.$$

The inverse transform is

$$y_1 = 2 + t^2, \qquad y_2 = 2t, \qquad y_3 = t + 2t^2.$$

22. The subsidiary equations are

$$s^2Y_1 - s - 1 = -8Y_1 + 4Y_2 + \frac{11}{s^2 + 1}$$

$$s^2Y_2 - s + 1 = -8Y_2 + 4Y_1 - \frac{11}{s^2 + 1}\,.$$

The solution, in terms of partial fractions, is

$$Y_1 = \frac{s}{s^2 + 4} + \frac{1}{s^2 + 1}$$

$$Y_2 = \frac{s}{s^2 + 4} - \frac{1}{s^2 + 1}\,.$$

im06.qxd 9/21/05 12:05 PM Page 142

The inverse transform is

$$y_1 = \cos 2t + \sin t$$
$$y_2 = \cos 2t - \sin t.$$

24. The new salt contents are

$$y_1 = 100 - 62.5e^{-0.24t} - 37.5e^{-0.08t}$$
$$y_2 = 100 + 125e^{-0.24t} - 75e^{-0.08t}.$$

Setting $2t = \tau$ gives the old solution, except for notation.

26. For $0 \leqq t \leqq 2\pi$ the solution is as in Prob. 25; for i_1 we have

$$i_1 = -26e^{-2t} - 16e^{-8t} + 42 \cos t + 15 \sin t.$$

For $t > 2\pi$ we have to add to this further terms whose form is determined by this solution and the second shifting theorem,

$$u(t - 2\pi)\,[26e^{-2t+4\pi} + 16e^{-8t+16\pi} - 42 \cos t - 15 \sin t].$$

The cosine and sine terms cancel, so that

$$i_1 = -26(1 - e^{4\pi})e^{-2t} + 16(1 - e^{16\pi})e^{-8t} \qquad \text{if} \quad t > 2\pi.$$

Similarly, for i_2 we obtain

$$i_2 = \begin{cases} -26e^{-2t} + 8e^{-8t} + 18 \cos t + 12 \sin t \\ -26(1 - e^{4\pi})e^{-2t} + 8(1 - e^{16\pi})e^{-8t}. \end{cases}$$

SOLUTIONS TO CHAP. 6 REVIEW QUESTIONS AND PROBLEMS, page 267

12. $\dfrac{2}{(s+1)^2 + 4}$, one of the transforms in Table 6.1

14. $\cos^2 4t = \frac{1}{2} + \frac{1}{2} \cos 8t$. The transform is

$$\frac{1/2}{s} + \frac{s/2}{s^2 + 64} = \frac{s^2 + 32}{s(s^2 + 64)}.$$

16. $u(t - 2\pi) \sin t = u(t - 2\pi) \sin (t - 2\pi)$. Hence the transform is $e^{-2\pi s}/(s^2 + 1)$.

18. $\sin \omega t$ has the transform $\omega/(s^2 + \omega^2)$, and $\cos \omega t$ has the transform $s/(s^2 + \omega^2)$. Hence, by convolution, the given function

$$(\sin \omega t) * (\cos \omega t) = \tfrac{1}{2} t \sin \omega t$$

has the transform

$$\frac{\omega s}{(s^2 + \omega^2)^2}.$$

20. $\dfrac{2s}{s^4 - 1}$. Problems 17–22 illustrate that sums of expressions can often be combined to an expression of a new form. This motivates that, conversely, partial fraction expansions are helpful in finding inverse transforms.

22. $\dfrac{s}{s^2 - 4} - \dfrac{s}{s^2 - 1} = \dfrac{3s}{(s^2 - 4)(s^2 - 1)}$

24. $7.5 \sinh 2t$

im06.qxd 9/21/05 12:05 PM Page 143

26. $\dfrac{3s}{s^2 - 2s + 2} = \dfrac{3(s-1)+3}{(s-1)^2+1}$. Hence the inverse transform is

$$3e^t(\cos t + \sin t).$$

28. $\dfrac{2s-10}{s^3} = \dfrac{2}{s^2} - \dfrac{10}{s^3}$. This shows that the inverse transform is

$$\begin{aligned} &u(t-5)\,[2(t-5) - 5(t-5)^2] \\ &= u(t-5)\,[-5t^2 + 52t - 135]. \end{aligned}$$

30. The given transform suggests the differentiation

$$\left(\frac{s}{s^2+16}\right)' = \frac{s^2 + 16 - s\cdot 2s}{(s^2+16)^2} = -\frac{s^2-16}{(s^2+16)^2}$$

and shows that the *answer* is $t\cos 4t$.

32. $\frac{1}{4}(t^6 + 3t^4 + 6t^2)$

34. $\dfrac{1}{2s^2+2s+1} = \dfrac{1/2}{(s+1/2)^2+1/4}$. Hence $2e^{-t/2}\sin\frac{1}{2}t$.

36. $y = -\cos 4t + u(t-\pi)\sin 4t$. To see the impact of $4\delta(t-\pi)$, graph both the solution and the term $-\cos 4t$, perhaps in a short t-interval with midpoint π.

38. $y = 0$ if $0 < t < 2$ and $1 - \cos(t-2)$ if $t > 2$

40. $y = e^{-2t}(13\cos t + 11\sin t) + 10t - 8$

42. $Y = e^{-s}/(s-1)^2$, $y = e^{t-1}(t-1)u(t-1)$

44. $y = \cos 2t + \frac{1}{2}[u(t-\pi) - u(t-2\pi)]\sin 2t$. The curve has cusps at $t = \pi$ and 2π (abrupt changes of the tangent direction).

46. $y_1 = 8e^t - 5e^{-2t} - 18t - 3$, $\quad y_2 = 32e^t - 5e^{-2t} - 42t - 27$

48. $y_1 = \frac{1}{2}u(t-\pi)\sin 2t$, $\quad y_2 = u(t-\pi)\cos 2t$. Hence y_1 is continuous at π, whereas y_2 has an upward jump of 1 at that point.

50. $y_1 = 3e^{4t} + e^{-4t} - 2\cos 4t + \sin 4t$, $\quad y_2 = 3e^{4t} + e^{-4t} + 2\cos 4t - \sin 4t$

52. $0.5q'' + 50q = 1425(1 - u(t-\pi))\sin 5t$. The subsidiary equation is

$$\tfrac{1}{2}s^2Q + 50Q = 1425\cdot 5\,\frac{1+e^{-\pi s}}{s^2+25}.$$

The solution is

$$Q = 14250\,\frac{1+e^{-\pi s}}{(s^2+25)(s^2+100)} = \frac{14250}{75}\,(1+e^{-\pi s})\left(\frac{1}{s^2+25} - \frac{1}{s^2+100}\right).$$

The inverse transform is

$$q = -19\sin 10t + 38\sin 5t + u(t-\pi)\,(-19\sin 10t - 38\sin 5t).$$

Thus the superposition of two sines terminates at $t = \pi$, and $-38\sin 10t$ continues thereafter.

54. The system is

$$\begin{aligned} 2i_1' + i_1 - i_2 &= 90e^{-t/4} \\ i_2' - i_1' + 2i_2 &= 0. \end{aligned}$$

im06.qxd 9/21/05 12:05 PM Page 144

The subsidiary equations are

$$2sI_1 + I_1 - I_2 = \frac{90}{s + 1/4}$$

$$sI_2 - 2 - sI_1 + 2I_2 = 0.$$

The solution is

$$I_1 = \frac{184s + 361}{4s^3 + 9s^2 + 6s + 1} = -\frac{59}{(s + 1)^2} - \frac{140}{s + 1} + \frac{140}{s + 1/4}$$

$$I_2 = \frac{8s^2 + 186s + 1}{4s^3 + 9s^2 + 6s + 1} = \frac{59}{(s + 1)^2} + \frac{22}{s + 1} - \frac{20}{s + 1/4}\ .$$

The inverse transform is

$$i_1 = -(59t + 140)e^{-t} + 140e^{-t/4}$$

$$i_2 = (59t + 22)e^{-t} - 20e^{-t/4}.$$

im07.qxd 9/21/05 12:09 PM Page 145

Part B LINEAR ALGEBRA. VECTOR CALCULUS

Part B consists of

Chap. 7 Linear Algebra: Matrices, Vectors, Determinants. Linear Systems

Chap. 8 Linear Algebra: Matrix Eigenvalue Problems

Chap. 9 Vector Differential Calculus. Grad, Div, Curl

Chap. 10 Vector Integral Calculus. Integral Theorems.

Hence we have retained the previous subdivision of Part B into four chapters.

Chapter 9 is self-contained and completely independent of Chaps. 7 and 8. Thus, Part B consists of two large **independent** units, namely, Linear Algebra (Chaps. 7, 8) and Vector Calculus (Chaps. 9, 10). Chapter 10 depends on Chap. 9, mainly because of the occurrence of div and curl (defined in Chap. 9) in the Gauss and Stokes theorems in Chap. 10.

CHAPTER 7 Linear Algebra: Matrices, Vectors, Determinants. Linear Systems

Changes

The order of the material in this chapter and its subdivision into sections has been retained, but various local changes have been made to increase the usefulness of this chapter for applications, in particular:

1. The beginning, which was somewhat slow by modern standards, has been streamlined, so that the student will see **applications** to linear systems of equations much earlier.
2. A reference section (Sec. 7.6) on second- and third-order determinants has been included for easier access from other parts of the book.

SECTION 7.1. Matrices, Vectors: Addition and Scalar Multiplication, page 272

Purpose. Explanation of the basic concepts. Explanation of the two basic matrix operations. The latter derive their importance from their use in defining vector spaces, a fact that should perhaps not be mentioned at this early stage. Its systematic discussion follows in Sec. 7.4, where it will fit nicely into the flow of thoughts and ideas.

Main Content, Important Concepts

Matrix, square matrix, main diagonal

Double subscript notation

Row vector, column vector, transposition

Equality of matrices

Matrix addition

Scalar multiplication (multiplication of a matrix by a scalar)

im07.qxd 9/21/05 12:09 PM Page 146

Comments on Important Facts

One should emphasize that vectors are always included as special cases of matrices and that those two operations have properties [formulas (3), (4)] similar to those of operations for numbers, which is a great practical advantage.

SOLUTIONS TO PROBLEM SET 7.1, page 277

2. $\begin{bmatrix} 0 & 8 \\ 8 & 16 \\ 4 & 12 \end{bmatrix}, \begin{bmatrix} 12 & 2 \\ -8 & 14 \\ -16 & 6 \end{bmatrix}, \begin{bmatrix} 12 & 10 \\ 0 & 30 \\ -12 & 18 \end{bmatrix}, \begin{bmatrix} 0 & 16 \\ 16 & 32 \\ 8 & 24 \end{bmatrix}$

4. $\begin{bmatrix} 6 & -10 & 2 \\ -12 & 8 & 12 \\ 6 & 18 & -8 \end{bmatrix}$, same, $\begin{bmatrix} 15 & 2.5 & 21.5 \\ -2.5 & 9 & 8 \\ 31.5 & 23 & -20 \end{bmatrix}$, undefined

6. Undefined, undefined, $\begin{bmatrix} -72 & -20 & -108 \\ 4 & -40 & -32 \\ -156 & -104 & 96 \end{bmatrix}$, same

8. Undefined, $\begin{bmatrix} -21 \\ 8 \\ 0 \end{bmatrix}$, undefined, undefined

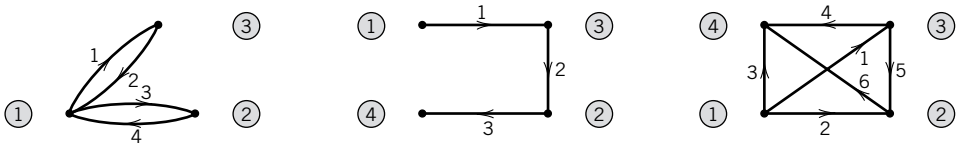
10. $\frac{1}{5}\mathbf{A}$, $\frac{1}{10}\mathbf{A}$. Similar (and more important) instances are the scaling of equations in linear systems, the formation of linear combinations, and the like, as will be shown later.

12. 3, 2, −4 and 0, 2, 0. The concept of a main diagonal is restricted to square matrices.

14. No, no, no. Transposition, which relates row and column vectors, will be discussed in the next section.

16. (b). The incidence matrices are as follows, with nodes corresponding to rows and branches to columns, as in Fig. 152.

$$\begin{bmatrix} 1 & 0 & -1 & 1 \\ 0 & 1 & 1 & -1 \\ -1 & -1 & 0 & 0 \end{bmatrix},$$



$$\begin{bmatrix} 1 & 0 & 1 & 0 & 0 \\ -1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 1 \\ 0 & -1 & -1 & 1 & -1 \end{bmatrix}, \qquad \begin{bmatrix} -1 & 0 & 0 & -1 & 1 & -1 \\ 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & -1 & 1 \\ 0 & 0 & -1 & 1 & 0 & 0 \end{bmatrix}$$

From a figure we may more easily grasp the kind of network. However, in the present context, matrices have two advantages over figures, namely, the computer can handle

im07.qxd 9/21/05 12:09 PM Page 147

them without great difficulties, and a matrix determines a network uniquely, whereas a given network can be drawn as a figure in various ways, so that one does not immediately see that two different figures represent the same network. A nice example is given in Sec. 23.1.

(c) The networks corresponding to the given matrices may be drawn as follows:

(e) The nodal incidence matrix is

$$\mathbf{A} = \begin{bmatrix} 1 & -1 & -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & -1 & -1 \\ -1 & 0 & 0 & -1 & 0 & 1 \end{bmatrix}.$$

SECTION 7.2. Matrix Multiplication, page 278

Purpose. Matrix multiplication, the third and last algebraic operation, is defined and discussed, with emphasis on its "unusual" properties; this also includes its representation by inner products of row and column vectors.

Main Content, Important Facts

Definition of matrix multiplication ("rows times columns")

Properties of matrix multiplication

Matrix products in terms of inner products of vectors

Linear transformations motivating the definition of matrix multiplication

$\mathbf{AB} \neq \mathbf{BA}$ in general, so the order of factors is important.

$\mathbf{AB} = \mathbf{0}$ does not imply $\mathbf{A} = \mathbf{0}$ or $\mathbf{B} = \mathbf{0}$ or $\mathbf{BA} = \mathbf{0}$.

$(\mathbf{AB})^T = \mathbf{B}^T\mathbf{A}^T$

Short Courses. Products in terms of row and column vectors and the discussion of linear transformations could be omitted.

Comment on Notation

For transposition, T seems preferable over a prime, which is often used in the literature but will be needed to indicate differentiation in Chap. 9.

Comments on Content

Most important for the next sections on systems of equations are the multiplication of a matrix times a vector.

Examples 1, 2, and 4 emphasize that matrix multiplication is not commutative and make the student aware of the restrictions of matrix multiplication.

Formula (10d) for the transposition of a product should be memorized.

In motivating matrix multiplication by linear transformations, one may also illustrate the geometric significance of noncommutativity by combining a rotation with a stretch in

im07.qxd 9/21/05 12:09 PM Page 148

x-direction in both orders and show that a circle transforms into an ellipse with main axes in the direction of the coordinate axes or rotated, respectively.

SOLUTIONS TO PROBLEM SET 7.2, page 286

2. $\begin{bmatrix} -3 \\ 50 \\ 54 \end{bmatrix}$, same, $[-62 \quad 34 \quad 2]$, $\mathbf{0}$ (the 3×3 zero matrix)

4. $\begin{bmatrix} 36 & -16 & -16 \\ 20 & -6 & -22 \\ -20 & 10 & 26 \end{bmatrix}$, $\begin{bmatrix} 113 & 64 & -80 \\ 64 & 65 & -16 \\ -80 & -16 & 137 \end{bmatrix}$, $\begin{bmatrix} 36 & 20 & -20 \\ -16 & -6 & 10 \\ -16 & -22 & 26 \end{bmatrix}$, same

6. Undefined, undefined, $\begin{bmatrix} -22 \\ -63 \\ -25 \end{bmatrix}$, $[-22 \quad -63 \quad -25]$

8. Undefined, -868, 868, $\begin{bmatrix} -125 & 300 & 1900 \\ -25 & 60 & 380 \\ -50 & 120 & 760 \end{bmatrix}$

10. $\begin{bmatrix} 3 & -140 & 92 \\ -24 & -119 & 22 \\ 0 & 94 & -143 \end{bmatrix}$, same, $\begin{bmatrix} -77 & -80 & 64 \\ -44 & -71 & -6 \\ 60 & 26 & -111 \end{bmatrix}$

14. 538, undefined, undefined, 1690

16. $\mathbf{M} = \mathbf{AB} - \mathbf{BA}$ must be the 2×2 zero matrix. It has the form

$$\mathbf{M} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} 2 & 3 \\ 3 & 4 \end{bmatrix} - \begin{bmatrix} 2 & 3 \\ 3 & 4 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$$

$$= \begin{bmatrix} 2a_{11} + 3a_{12} - 2a_{11} - 3a_{21} & 3a_{11} + 4a_{12} - 2a_{12} - 3a_{22} \\ 2a_{21} + 3a_{22} - 3a_{11} - 4a_{21} & 3a_{21} + 4a_{22} - 3a_{12} - 4a_{22} \end{bmatrix}.$$

$a_{21} = a_{12}$ from $m_{11} = 0$ (also from $m_{22} = 0$). $a_{22} = a_{11} + \frac{2}{3}a_{12}$ from $m_{12} = 0$ (also from $m_{21} = 0$). *Answer:*

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{12} & a_{11} + \frac{2}{3}a_{12} \end{bmatrix}.$$

im07.qxd 9/21/05 12:09 PM Page 149

18. The calculation for the first column is

$$\begin{bmatrix} 6 & -2 & -2 \\ 10 & -3 & 1 \\ -10 & 5 & 1 \end{bmatrix} \begin{bmatrix} 9 \\ 4 \\ -4 \end{bmatrix} = \begin{bmatrix} 54 \\ 74 \\ -74 \end{bmatrix},$$

and similarly for the other two columns; see the answer to Prob. 1, last matrix given.

20. Idempotent are $\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$, $\begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}$, etc.; nilpotent are $\begin{bmatrix} 0 & a \\ 0 & 0 \end{bmatrix}$, $\begin{bmatrix} 0 & 0 \\ b & 0 \end{bmatrix}$, etc., and $\mathbf{A}^2 = \mathbf{I}$ is true for

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}, \begin{bmatrix} 1 & 0 \\ a & -1 \end{bmatrix}, \begin{bmatrix} -1 & b \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & c \\ 1/c & 0 \end{bmatrix}$$

where a, b, and $c \neq 0$ are arbitrary.

22. The entry c_{kj} of $(\mathbf{AB})^\mathsf{T}$ is c_{jk} of **AB,** which is Row j of **A** times Column k of **B.** On the right, c_{kj} is Row k of $\mathbf{B}^\mathsf{T}$, hence Column k of **B,** times Column j of $\mathbf{A}^\mathsf{T}$, hence Row j of **A.**

24. An annual increase of about 4−5% because the matrix of this Markov process is

$$\mathbf{A} = \begin{bmatrix} 0.9 & 0.001 \\ 0.1 & 0.999 \end{bmatrix}$$

and the initial state is $[2000 \quad 298000]^\mathsf{T}$, so that multiplication by **A** gives the further states (rounded) $[2098 \quad 297902]^\mathsf{T}$, $[2186 \quad 297814]^\mathsf{T}$, $[2265 \quad 297735]^\mathsf{T}$.

26. The transition probabilities can be given in a matrix

$$\begin{matrix} & \text{From } N & \text{From } T & \\ \mathbf{A} = & \begin{bmatrix} 0.9 & 0.5 \\ 0.1 & 0.5 \end{bmatrix} & \begin{matrix} \text{To } N \\ \text{To } T \end{matrix} \end{matrix}$$

and multiplication of $[1 \quad 0]^\mathsf{T}$ by **A,** $\mathbf{A}^2$, $\mathbf{A}^3$ gives $[0.9 \quad 0.1]^\mathsf{T}$, $[0.86 \quad 0.14]^\mathsf{T}$, $[0.844 \quad 0.156]^\mathsf{T}$. *Answer:* 0.86, 0.844.

28. Team Project. (b) Use induction on n. True if $n = 1$. Take the formula in the problem as the induction hypothesis, multiply by **A,** and simplify the entries in the product by the addition formulas for the cosine and sine to get $\mathbf{A}^{n+1}$.

(c) These formulas follow directly from the definition of matrix multiplication.

(d) A scalar matrix would correspond to a stretch or contraction by the same factor in all directions.

(e) Rotations about the x_1-, x_2-, x_3-axes through θ, φ, ψ, respectively.

SECTION 7.3. Linear Systems of Equations. Gauss Elimination, page 287

Purpose. This simple section centers around the Gauss elimination for solving linear systems of m equations in n unknowns $x_1, \cdots, x_n$, its practical use as well as its mathematical justification (leaving the—more demanding—general existence theory to the next sections).

im07.qxd 9/21/05 12:09 PM Page 150

Main Content, Important Concepts

Nonhomogeneous, homogeneous, coefficient matrix, augmented matrix

Gauss elimination in the case of the existence of

I. a unique solution (Example 2)

II. infinitely many solutions (Example 3)

III. no solutions (Example 4).

Pivoting

Elementary row operations, echelon form

Background Material. All one needs here is the multiplication of a matrix and a vector.

Comments on Content

The student should become aware of the following facts:

1. Linear systems of equations provide a major application of matrix algebra and justification of the definitions of its concepts.

2. The Gauss elimination (with pivoting) gives meaningful results in each of the Cases I−III.

3. This method is a *systematic* elimination that does not look for unsystematic "shortcuts" (depending on the size of the numbers involved and still advocated in some older precomputer-age books).

Algorithms for programs of Gauss's and related methods are discussed in Sec. 20.1, which is independent of the rest of Chap. 20 and can thus be taken up along with the present section in case of time and interest.

SOLUTIONS TO PROBLEM SET 7.3, page 295

2. $x = -2$, $y = 1$

4. $x = 5$, y arbitrary, $z = 2y - 1$. Unknowns that remain arbitrary are sometimes denoted by other letters, such as t_1, t_2, etc. In the present case we could thus write the solutions as $x = 5$, $y = t_1$, $z = 2t_1 - 1$.

6. $x = t_1$ arbitrary, $y = 3x = 3t_1$, $z = 2x = 2t_1$

8. No solution

10. $x = t_1$ arbitrary, $y = 2x - 5 = 2t_1 - 5$, $z = 3x + 1 = 3t_1 + 1$

12. $x = 3z - 1 = 3t_1 - 1$, $y = -z + 4 = -t_1 + 4$, $z = t_1$ arbitrary

14. $w = 2x + 1 = 2t_1 + 1$, $x = t_1$ arbitrary, $y = 1$, $z = 2$

16. $w = 1$, $x = t_1$ arbitrary, $y = 2x - 1 = 2t_1 - 1$, $z = 3x + 2 = 3t_1 + 2$

18. Currents at the lower node:

$$-I_1 + I_2 + I_3 = 0$$

(minus because I_1 flows out). Voltage in the left circuit:

$$R_1I_1 + R_2I_2 = E_1 + E_2$$

and in the right circuit:

$$R_2I_2 - R_3I_3 = E_2$$

im07.qxd 9/21/05 12:09 PM Page 151

(minus because I_3 flows against the arrow of E_2). *Answer:*

$$I_1 = \frac{1}{D}\,[(R_2 + R_3)E_1 + R_3E_2]$$

$$I_2 = \frac{1}{D}\,[R_3E_1 + (R_3 + R_1)E_2]$$

$$I_3 = \frac{1}{D}\,[R_2E_1 - R_1E_2]$$

where $D = R_1R_2 + R_2R_3 + R_3R_1$.

22. $P_1 = 9$, $P_2 = 8$, $D_1 = S_1 = 34$, $D_2 = S_2 = 38$

24. Project. (a) **B** and **C** are different. For instance, it makes a difference whether we first multiply a row and then interchange, and then do these operations in reverse order.

$$\mathbf{B} = \begin{bmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \\ a_{21} - 5a_{11} & a_{22} - 5a_{12} \\ 8a_{41} & 8a_{42} \end{bmatrix}, \qquad \mathbf{C} = \begin{bmatrix} a_{11} & a_{12} \\ a_{31} - 5a_{11} & a_{32} - 5a_{12} \\ a_{21} & a_{22} \\ 8a_{41} & 8a_{42} \end{bmatrix}$$

(b) Premultiplying **A** by **E** (that is, multiplying **A** by **E** from the left) makes **E** operate on *rows* of **A.** The assertions then follow almost immediately from the definition of matrix multiplication.

SECTION 7.4. Linear Independence. Rank of a Matrix. Vector Space, page 296

Purpose. This section introduces some theory centered around linear independence and rank, in preparation for the discussion of the existence and uniqueness problem for linear systems of equations (Sec. 7.7).

Main Content, Important Concepts

Linear independence

Real vector space R^n, dimension, basis

Rank defined in terms of row vectors

Rank in terms of column vectors

Invariance of rank under elementary row operations

Short Courses. For the further discussion in the next sections, it suffices to define linear independence and rank.

Comments on Rank and Vector Spaces

Of the three possible equivalent definitions of **rank,**

(i) By row vectors (our definition),

(ii) By column vectors (our Theorem 3),

(iii) By submatrices with nonzero determinant (Sec. 7.7),

the first seems to be most practical in our context.

im07.qxd 9/21/05 12:09 PM Page 152

Introducing **vector spaces** here, rather than in Sec. 7.1, we have the advantage that the student immediately sees an application (row and column spaces). Vector spaces in full generality follow in Sec. 7.9.

SOLUTIONS TO PROBLEM SET 7.4, page 301

2. Row reduction of the matrix and of its transpose gives

$$\begin{bmatrix} 8 & 2 & 5 \\ 0 & 2 & 19 \\ 0 & 0 & 0 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 8 & 16 & 4 \\ 0 & 2 & -1 \\ 0 & 0 & 0 \end{bmatrix}.$$

Hence the rank is 2, and bases are $[8 \quad 2 \quad 5]$, $[0 \quad 2 \quad 19]$ and $[8 \quad 16 \quad 4]^T$, $[0 \quad 2 \quad -1]^T$.

4. Row reduction as in Prob. 2 gives the matrices

$$\begin{bmatrix} a & b & c \\ 0 & \dfrac{a^2 - b^2}{a} & \dfrac{c(a-b)}{a} \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} a & b \\ 0 & \dfrac{c(a-b)}{a} \\ 0 & 0 \end{bmatrix}.$$

Hence for general a, b, c the rank is 2. Bases are $[a \quad b \quad c]$, $[0 \quad a^2 - b^2 \quad c(a-b)]$ and $[a \quad b]^T$, $[0 \quad c(a-b)]^T$.

6. The matrix is symmetric. The reduction gives

$$\begin{bmatrix} 1 & 1 & a \\ 0 & a-1 & 1-a \\ 0 & 0 & 2-a^2-a \end{bmatrix}.$$

Hence a basis is $[1 \quad 1 \quad a]$, $[0 \quad a-1 \quad 1-a]$, $[0 \quad 0 \quad 2-a^2-a]$ and the transposed vectors (column vectors) for the column space. Hence the rank is 1 (if $a = 1$), 2 (if $a = -2$), and 3 if $a \neq 1, -2$.

8. The row reductions as in Prob. 2 give

$$\begin{bmatrix} 1 & -2 & 3 & -4 \\ 0 & 1 & -2 & 7 \\ 0 & 0 & -4 & -4 \\ 0 & 0 & 0 & -40 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 1 & 2 & 3 & 4 \\ 0 & 1 & 2 & 7 \\ 0 & 0 & -4 & 4 \\ 0 & 0 & 0 & -40 \end{bmatrix}.$$

The rank is 4, and bases are

$[1 \quad 0 \quad 0 \quad 0]$, $[0 \quad 1 \quad 0 \quad 0]$, $[0 \quad 0 \quad 1 \quad 0]$, $[0 \quad 0 \quad 0 \quad 1]$

and the same vectors written as column vectors.

im07.qxd 9/21/05 12:09 PM Page 153

10. The matrix is symmetric. Row reduction gives

$$\begin{bmatrix} 1 & 2 & 3 & 4 \\ 0 & -1 & -2 & -3 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

Hence the rank is 2, and bases are [1 2 3 4], [0 1 2 3] and the same vectors transposed (as column vectors).

12. The matrix is symmetric. Row reduction gives

$$\begin{bmatrix} -7 & 5 & 0 & 2 \\ 0 & 5/7 & 2 & 2/7 \\ 0 & 0 & -7 & 1 \\ 0 & 0 & 0 & 5/7 \end{bmatrix}.$$

Hence the ranks is 4, and bases are

[1 0 0 0], [0 1 0 0], [0 0 1 0], [0 0 0 1]

and the same vectors written as column vectors.

14. Yes

16. No, by Theorem 4

18. No. Quite generally, if one of the vectors $\mathbf{v}_{(1)}, \cdots, \mathbf{v}_{(m)}$ is **0,** say, $\mathbf{v}_{(1)} = \mathbf{0}$, then (1) holds with any $c_1 \neq 0$ and $c_2, \cdots, c_m$ all zero.

20. No. It is remarkable that $\mathbf{A} = [a_{jk}]$ with $a_{jk} = j + k - 1$ has rank 2 for any size n of the matrix.

22. **AB** and its transpose $(\mathbf{AB})^\mathsf{T} = \mathbf{B}^\mathsf{T}\mathbf{A}^\mathsf{T}$ have the same rank.

24. This follows directly from Theorem 3.

26. A proof is given in Ref. [B3], Vol. 1, p. 12.

28. Yes if and only if $k = 0$. Then the dimension is 3, and a basis is [1 0 0 0], [0 3 0 2], [0 0 1 0].

30. No. If $\mathbf{v} = [v_1 \quad v_2]$ satisfies the inequality, $-\mathbf{v}$ does not. Draw a sketch to see the geometric meaning of the inequality characterizing the "half-plane" above the sloping straight line $v_2 = v_1$.

32. Yes, dimension 1, basis [1 1 5 0]

34. No, because of the positivity assumption

36. Yes, dimension 2. The two given equations form a homogeneous linear system with the augmented matrix

$$\begin{bmatrix} 3 & 0 & -1 & 0 & 0 \\ 2 & 3 & 0 & -4 & 0 \end{bmatrix}.$$

The solution is

$$v_1 = -\tfrac{3}{2}v_2 + 2v_4, \qquad v_2 \text{ arbitrary}, \qquad v_3 = -\tfrac{9}{2}v_2 + 6v_4, \qquad v_4 \text{ arbitrary}.$$

im07.qxd 9/21/05 12:09 PM Page 154

Taking $v_2 = -\frac{2}{3}$ and $v_4 = 0$, we obtain the basis vector

$$\begin{bmatrix} 1 & -\frac{2}{3} & 3 & 0 \end{bmatrix}.$$

Taking $v_2 = 0$ and $v_4 = 1$, we get

$$[2 \quad 0 \quad 6 \quad 1].$$

Instead of the second vector we could also use

$$\begin{bmatrix} 0 & \frac{4}{3} & 0 & 1 \end{bmatrix}$$

obtained by taking the second vector minus twice the first.

SECTION 7.5. Solutions of Linear Systems: Existence, Uniqueness, page 302

Purpose. The student should see that the totality of solutions (including the existence and uniqueness) can be characterized in terms of the ranks of the coefficient matrix and the augmented matrix.

Main Content, Important Concepts

Augmented matrix

Necessary and sufficient conditions for the existence of solutions

Implications for homogeneous systems

rank $\mathbf{A}$ + nullity $\mathbf{A} = n$

Background Material. Rank (Sec. 7.4)
Short Courses. Brief discussion of the first two theorems, illustrated by some simple examples.

Comments on Content

This section should make the student aware of the great importance of rank. It may be good to have students memorize the condition

$$\text{rank } \mathbf{A} = \text{rank } \widetilde{\mathbf{A}}$$

for the existence of solutions.

Students familiar with ODEs may be reminded of the analog of Theorem 4 (see Sec. 2.7).

This section may also provide a good opportunity to point to the roles of existence and uniqueness problems throughout mathematics (and to the distinction between the two).

SECTION 7.7. Determinants. Cramer's Rule, page 308

Second- and third-order determinants see in the reference Sec. 7.6.

Main Content of This Section

*n*th-order determinants

General properties of determinants

Rank in terms of determinants (Theorem 3)

Cramer's rule for solving linear systems by determinants (Theorem 4)

im07.qxd 9/21/05 12:09 PM Page 155

General Comments on Determinants

Our definition of a determinant seems more practical than that in terms of permutations (because it immediately gives those general properties), at the expense of the proof that our definition is unambiguous (see the proof in App. 4).

General properties are given for order n, from which they can be easily seen for $n = 3$ when needed.

The importance of determinants has decreased with time, but determinants will remain in eigenvalue problems (characteristic determinants), ODEs (Wronskians!), integration and transformations (Jacobians!), and other areas of practical interest.

SOLUTIONS TO PROBLEM SET 7.7, page 314

6. 1 **8.** -728 **10.** -27

12. 0. Together with Prob. 11 this illustrates the theorem that for odd n the determinant of an $n \times n$ skew-symmetric matrix has the value 0. This is not generally true for even n, as Prob. 16 proves.

14. 158

16. 36

18. $x = 4, y = -3$

20. $w = 2, x = 5, y = -1, z = -6$

22. 2

24. Team Project. (a) Use row operation (subtraction of rows) on D to transform the last column of D into the form $[0 \quad 0 \quad 1]^T$ and then develop $D = 0$ by this column.

(b) For a plane the equation is $ax + by + cz + d \cdot 1 = 0$, so that we get the determinantal equation

$$\begin{vmatrix} x & y & z & 1 \\ x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \end{vmatrix} = 0.$$

The plane is $3x + 4y - 2z = 5$.

(c) For a circle the equation is

$$a(x^2 + y^2) + bx + cy + d \cdot 1 = 0,$$

so that we get

$$\begin{vmatrix} x^2 + y^2 & x & y & 1 \\ x_1^2 + y_1^2 & x_1 & y_1 & 1 \\ x_2^2 + y_2^2 & x_2 & y_2 & 1 \\ x_3^2 + y_3^2 & x_3 & y_3 & 1 \end{vmatrix} = 0.$$

The circle is $x^2 + y^2 - 4x - 2y = 20$.

(d) For a sphere the equation is

$$a(x^2 + y^2 + z^2) + bx + cy + dz + e \cdot 1 = 0,$$

im07.qxd 9/21/05 12:09 PM Page 156

so that we obtain

$$\begin{vmatrix} x^2 + y^2 + z^2 & x & y & z & 1 \\ x_1^2 + y_1^2 + z_1^2 & x_1 & y_1 & z_1 & 1 \\ x_2^2 + y_2^2 + z_2^2 & x_2 & y_2 & z_2 & 1 \\ x_3^2 + y_3^2 + z_3^2 & x_3 & y_3 & z_3 & 1 \\ x_4^2 + y_4^2 + z_4^2 & x_4 & y_4 & z_4 & 1 \end{vmatrix} = 0.$$

The sphere through the given points is $x^2 + y^2 + (z - 1)^2 = 16$.

(e) For a general conic section the equation is

$$ax^2 + bxy + cy^2 + dx + ey + f \cdot 1 = 0,$$

so that we get

$$\begin{vmatrix} x^2 & xy & y^2 & x & y & 1 \\ x_1^2 & x_1y_1 & y_1^2 & x_1 & y_1 & 1 \\ x_2^2 & x_2y_2 & y_2^2 & x_2 & y_2 & 1 \\ x_3^2 & x_3y_3 & y_3^2 & x_3 & y_3 & 1 \\ x_4^2 & x_4y_4 & y_4^2 & x_4 & y_4 & 1 \\ x_5^2 & x_5y_5 & y_5^2 & x_5 & y_5 & 1 \end{vmatrix} = 0.$$

26. $\det \mathbf{A}_n = (-1)^{n-1}(n - 1)$. True for $n = 2$, a 2-simplex on R^1, that is, a segment (an interval), because

$$\det \mathbf{A}_2 = (-1)^{2-1}(2 - 1) = -1.$$

Assume true for n as just given. Consider $\mathbf{A}_{n+1}$. To get the first row with all entries 0, except for the first entry, subtract from Row 1 the expression

$$\frac{1}{n - 1} (\text{Row } 2 + \cdots + \text{Row } (n + 1)).$$

The first component of the new row is $-n/(n - 1)$, whereas the other components are all 0. Develop $\det \mathbf{A}_{n+1}$ by this new first row and notice that you can then apply the above induction hypothesis,

$$\det \mathbf{A}_{n+1} = -\frac{n}{n - 1} (-1)^{n-1}(n - 1) = (-1)^n n,$$

as had to be shown.

SECTION 7.8. Inverse of a Matrix. Gauss–Jordan Elimination, page 315

Purpose. To familiarize the student with the concept of the inverse $\mathbf{A}^{-1}$ of a square matrix **A,** its conditions for existence, and its computation.

Main Content, Important Concepts

$\mathbf{A}\mathbf{A}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$

Nonsingular and singular matrices

Existence of $\mathbf{A}^{-1}$ and rank

im07.qxd 9/21/05 12:09 PM Page 157

Gauss–Jordan elimination

$(\mathbf{AC})^{-1} = \mathbf{C}^{-1}\mathbf{A}^{-1}$

Cancellation laws (Theorem 3)

$\det(\mathbf{AB}) = \det(\mathbf{BA}) = \det \mathbf{A} \det \mathbf{B}$

Short Courses. Theorem 1 without proof, Gauss–Jordan elimination, formulas (4*) and (7).

Comments on Content

Although in this chapter we are not concerned with operations count (Chap. 20), it would make no sense to first blindfold the student by using Gauss–Jordan for solving $\mathbf{Ax} = \mathbf{b}$ and then later in numerics correct the false impression by explaining why Gauss elimination is better because back substitution needs fewer operations than the diagonalization of a triangular matrix. Thus Gauss–Jordan should be applied only when $\mathbf{A}^{-1}$ is wanted.

The "unusual" properties of matrix multiplication, briefly mentioned in Sec. 7.2 can now be explored systematically by the use of rank and inverse.

Formula (4*) is worth memorizing.

SOLUTIONS TO PROBLEM SET 7.8, page 322

2. $\begin{bmatrix} 0.6 & 0.8 \\ 0.8 & -0.6 \end{bmatrix}$. This is a symmetric orthogonal matrix. Orthogonal matrices will be discussed in Sec. 8.3, where they will fit much better into the material.

4. The inverse equals the transpose. This is the defining property of orthogonal matrices to be discussed in Sec. 8.3.

6. $\begin{bmatrix} 4 & -1 & -5 \\ 15 & 1 & -5 \\ 5 & 4 & 9 \end{bmatrix}$

8. $\begin{bmatrix} 19 & 2 & -9 \\ -4 & -1 & 2 \\ -2 & 0 & 1 \end{bmatrix}$

10. $\begin{bmatrix} 0 & 0 & \frac{1}{2} \\ \frac{1}{8} & 0 & 0 \\ 0 & \frac{1}{4} & 0 \end{bmatrix}$

12. $\begin{bmatrix} 11 & 5 & 2 \\ 4 & 2 & -1 \\ 2 & 1 & 0 \end{bmatrix}$

14. Rotation through 2θ. The inverse represents the rotation through -2θ. Replacement of 2θ by -2θ in the matrix gives the inverse.

16. $\mathbf{I} = (\mathbf{A}^2)^{-1}\mathbf{A}^2$. Multiply this by $\mathbf{A}^{-1}$ from the right on both sides of the equation. This gives $\mathbf{A}^{-1} = (\mathbf{A}^2)^{-1}\mathbf{A}$. Do the same operation once more to get the formula to be proved.

im07.qxd 9/21/05 12:09 PM Page 158

18. $\mathbf{I} = \mathbf{I}^T = (\mathbf{A}^{-1}\mathbf{A})^T = \mathbf{A}^T(\mathbf{A}^{-1})^T$. Now multiply the first and the last expression by $(\mathbf{A}^T)^{-1}$ from the left, obtaining $(\mathbf{A}^T)^{-1} = (\mathbf{A}^{-1})^T$.

20. Multiplication by $\mathbf{A}$ from the right interchanges Row 1 and Row 2 of $\mathbf{A}$, and the inverse of this interchange is the interchange that gives the original matrix back. Hence the inverse of the given matrix should equal the matrix itself, as is the case.

22. For such a matrix (see the solution to Prob. 4) the determinant has either the value 1 or -1. In the present case it equals -1. The values of the cofactors (determinants of 2×2 matrices times 1 or -1) are obtained by straightforward calculation.

SECTION 7.9. Vector Spaces, Inner Product Spaces, Linear Transformations, *Optional*, page 323

Purpose. In this optional section we extend our earlier discussion of vector spaces R^n and C^n, define inner product spaces, and explain the role of matrices in linear transformations of R^n into R^m.

Main Content, Important Concepts

Real vector space, complex vector space

Linear independence, dimension, basis

Inner product space

Linear transformation of R^n into R^m

Background Material. Vector spaces R^n (Sec. 7.4)

Comments on Content

The student is supposed to see and comprehend how concrete models (R^n and C^n, the inner product for vectors) lead to abstract concepts, defined by axioms resulting from basic properties of those models. Because of the level and general objective of this chapter, we have to restrict our discussion to the illustration and explanation of the abstract concepts in terms of some simple typical examples.

Most essential from the viewpoint of matrices is our discussion of *linear transformations,* which in a more theoretically oriented course of a higher level would occupy a more prominent position.

Comment on Footnote 4

Hilbert's work was fundamental to various areas in mathematics; roughly speaking, he worked on number theory 1893–1898, foundations of geometry 1898–1902, integral equations 1902–1912, physics 1910–1922, and logic and foundations of mathematics 1922–1930. Closest to our interests here is the development in integral equations, as follows. In 1870 Carl Neumann (Sec. 5.6) had the idea of solving the Dirichlet problem for the Laplace equation by converting it to an integral equation. This created general interest in integral equations. In 1896 Vito Volterra (1860–1940) developed a general theory of these equations, followed by Ivar Fredholm (1866–1927) in 1900–1903 (whose papers caused great excitement), and Hilbert since 1902. This gave the impetus to the development of inner product and Hilbert spaces and operators defined on them. These spaces and operators and their spectral theory have found basic applications in quantum mechanics since 1927. Hilbert's great interest in mathematical physics is documented by Ref. [GR3], a classic full of ideas that are of importance to the mathematical work of the engineer. For more details, see G. Birkhoff and E. Kreyszig. The establishment of functional analysis. *Historia Mathematica* **11** (1984), pp. 258−321.

im07.qxd 9/21/05 12:09 PM Page 159

SOLUTIONS TO PROBLEM SET 7.9, page 329

2. Yes, dimension 1. A basis vector is obtained by solving the given linear system consisting of the two given conditions. The solution is $[v_1 \quad 3v_1 \quad 11v_1]$, v_1 arbitrary. $v_1 = 1$ gives the basis vector $[1 \quad 3 \quad 11]^T$.

4. Yes, dimension 6, basis

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix},$$

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

6. No, because of the second condition

8. No because $\det(\mathbf{A} + \mathbf{B}) \neq \det \mathbf{A} + \det \mathbf{B}$ in general

10. Yes, dimension 2, basis $\cos x$, $\sin x$

12. Yes, dimension 4, basis

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 & 0 \\ 4 & 0 & -9 \end{bmatrix}.$$

14. If another such representation with coefficients k_j would also hold, subtraction would give $\Sigma(c_j - k_j)\mathbf{a}_j = \mathbf{0}$; hence $c_j - k_j = 0$ because of the linear independence of the basis vectors. This proves the uniqueness.

16. $x_1 = 0.5y_1 - 0.5y_2$

$x_2 = 1.5y_1 - 2.5y_2$

18. $x_1 = 4y_1 \quad + 2y_3$

$x_2 = \quad y_2 + 4y_3$

$x_3 = \quad 5y_3$

20. $x_1 = \quad 0.50y_2 - 0.25y_3$

$x_2 = 0.50y_1 \quad + 0.25y_3$

$x_3 = -0.25y_1 + 0.25y_2$

22. $\sqrt{44}$ **24.** $\frac{1}{8}\sqrt{285} = 2.110\,243$ **26.** 1

28. $2v_1 + v_3 = 0$, $v_3 = -2v_1$; hence $[v_1 \quad v_2 \quad -2v_1]^T$ with arbitrary v_1 and v_2. These vectors lie in a plane through the origin whose normal vector is the given vector.

30. $\mathbf{a} = [4 \quad 2 \quad -6]^T$, $\mathbf{b} = [16 \quad -32 \quad 0]^T$, $\mathbf{a} + \mathbf{b} = [20 \quad -30 \quad -6]^T$. For the norms we thus obtain

$$\|\mathbf{a} + \mathbf{b}\| = \sqrt{1336} = 36.55 < \|\mathbf{a}\| + \|\mathbf{b}\| = \sqrt{56} + 16\sqrt{5} = 43.26.$$

im07.qxd 9/21/05 12:09 PM Page 160

SOLUTIONS TO CHAP. 7 REVIEW QUESTIONS AND PROBLEMS, page 330

12. $x = 3 - 2y$, y arbitrary, $z = 0$

14. No solution

16. $x = 1$, $y = -3$, $z = 5$

18. $x = -2z$, $y = \frac{1}{4}$, z arbitrary

20. $\mathbf{AB} = \begin{bmatrix} -52 & 42 & 48 \\ -96 & 34 & -42 \\ -110 & 61 & 18 \end{bmatrix}$, $\mathbf{BA} = \begin{bmatrix} 52 & 96 & 110 \\ -42 & -34 & -61 \\ -48 & 42 & -18 \end{bmatrix} = -(\mathbf{AB})^{\mathsf{T}}$

22. $\mathbf{A}^2 + \mathbf{B}^2 = \begin{bmatrix} 149 & 134 & 212 \\ 134 & 428 & 346 \\ 212 & 346 & 389 \end{bmatrix} + \begin{bmatrix} -40 & 18 & -6 \\ 18 & -13 & -12 \\ -6 & -12 & -45 \end{bmatrix} = \begin{bmatrix} 109 & 152 & 206 \\ 152 & 415 & 334 \\ 206 & 334 & 344 \end{bmatrix}$

24. $\mathbf{AA}^{\mathsf{T}} = \mathbf{A}^{\mathsf{T}}\mathbf{A} = \begin{bmatrix} 149 & 134 & 212 \\ 134 & 428 & 346 \\ 212 & 346 & 389 \end{bmatrix}$

26. $\mathbf{Aa} = \begin{bmatrix} 49 \\ 142 \\ 109 \end{bmatrix}$, $\mathbf{a}^{\mathsf{T}}\mathbf{A} = [49 \quad 142 \quad 109]$, $\mathbf{a}^{\mathsf{T}}\mathbf{Aa} = 1250$

28. 0

30. $\begin{bmatrix} -20.8 & 16.8 & 19.2 \\ -38.4 & 13.6 & -16.8 \\ -44.0 & 24.4 & 7.2 \end{bmatrix}$

32. 2, 2. Hence one unknown remains arbitrary.

34. 2, 3. Hence the system has no solution, by Theorem 1 in Sec. 7.5.

36. 2, 2. Hence one unknown remains arbitrary.

38. $\frac{1}{20}\begin{bmatrix} 2 & -1 & 3 \\ -12 & 6 & -8 \\ 18 & -4 & 12 \end{bmatrix}$

40. Singular, rank 2

42. diag $(\frac{1}{3}, \quad -1, \quad \frac{1}{5})$

44. The equations obtained by Kirchhoff's laws are

$$\begin{aligned} -I_1 - I_2 + I_3 &= 0 && \text{(Left node)} \\ 50I_1 + 80I_3 &= 3800 && \text{(Upper loop)} \\ 40I_2 + 80I_3 &= 3400 && \text{(Lower loop).} \end{aligned}$$

This gives the solution $I_1 = 20$ A, $I_2 = 15$ A, $I_3 = 35$ A.

im08.qxd 9/21/05 12:12 PM Page 161

CHAPTER 8 Linear Algebra: Matrix Eigenvalue Problems

Prerequisite for this chapter is some familiarity with the notion of a matrix and with the two algebraic operations for matrices. Otherwise the chapter is independent of Chap. 7, so that it can be used for teaching eigenvalue problems and their applications, without first going through the material in Chap. 7.

SECTION 8.1. Eigenvalues, Eigenvectors, page 334

Purpose. To familiarize the student with the determination of eigenvalues and eigenvectors of real matrices and to give a first impression of what one can expect (multiple eigenvalues, complex eigenvalues, etc.).

Main Content, Important Concepts

Eigenvalue, eigenvector

Determination of eigenvalues from the characteristic equation

Determination of eigenvectors

Algebraic and geometric multiplicity, defect

Comments on Content

To maintain undivided attention on the basic concepts and techniques, all the examples in this section are formal, and typical applications are put into a separate section (Sec. 8.2).

The distinction between the algebraic and geometric multiplicity is mentioned in this early section, and the idea of a *basis of eigenvectors* **("eigenbasis")** could perhaps be mentioned briefly in class, whereas a thorough discussion of this in a later section (Sec. 8.4) will profit from the increased experience with eigenvalue problems, which the student will have gained at that later time.

The possibility of *normalizing* any eigenvector is mentioned in connection with Theorem 2, but this will be of greater interest to us only in connection with orthonormal or unitary systems (Secs. 8.4 and 8.5).

In our present work we find eigen*values* first and are then left with the much simpler task of determining corresponding eigen*vectors.* Numeric work (Secs. 20.6–20.9) may proceed in the opposite order, but to mention this here would perhaps just confuse the student.

SOLUTIONS TO PROBLEM SET 8.1, page 338

2. The characteristic equation is

$$D(\lambda) = (a - \lambda)(c - \lambda) = 0.$$

Hence $\lambda_1 = a$, $\lambda_2 = c$. Components of eigenvectors can now be determined for $\lambda_1 = a$ from

$$0x_1 + bx_2 = 0, \qquad \text{say,} \qquad x_1 = 1, \qquad x_2 = 0$$

so that an eigenvector is $[1 \quad 0]^T$, and for $\lambda_2 = c$ from

$$(a - c)x_1 + bx_2 = 0, \qquad \text{say,} \qquad x_1 = 1, \qquad x_2 = (c - a)/b,$$

so that an eigenvector is

$$\begin{bmatrix} 1 & \dfrac{c - a}{b} \end{bmatrix}^T.$$

im08.qxd 9/21/05 12:12 PM Page 162

Here we must assume that $b \neq 0$. If $b = 0$, we have a diagonal matrix with the same eigenvalues as before and eigenvectors $[1 \quad 0]^T$ and $[0 \quad 1]^T$.

4. This zero matrix, like any square zero matrix, has the eigenvalue 0, whose algebraic multiplicity and geometric multiplicity are both equal to 2, and we can choose any basis, for instance $[1 \quad 0]^T$ and $[0 \quad 1]^T$.

6. The characteristic equation is

$$(a - \lambda)^2 + b^2 = 0. \qquad \text{Solutions are} \qquad \lambda = a \pm ib.$$

Eigenvectors are obtained from

$$(a - \lambda)x_1 + bx_2 = \mp ibx_1 + bx_2 = 0.$$

Hence we can take $x_1 = 1$ and $x_2 = \pm i$. Note that b has dropped out, and the eigenvectors are the same as in Example 4 of the text.

8. $(\lambda - 1)^2 = 0$, $\lambda = 1$, any vector is an eigenvector, and $[1 \quad 0]^T$, $[0 \quad 1]^T$ is a basis of the eigenspace (the x_1x_2-plane).

10. The characteristic equation is

$$(\cos\theta - \lambda)^2 + \sin^2\theta = 0.$$

Solutions (eigenvalues) are $\lambda = \cos\theta \pm i \sin\theta$. Eigenvectors are obtained from

$$(\lambda - \cos\theta)x_1 + (\sin\theta)x_2 = (\sin\theta)(\pm ix_1 + x_2) = 0,$$

say, $x_1 = 1$, $x_2 = \mp i$.

Note that this matrix represents a rotation through an angle θ, and this linear transformation preserves no real direction in the x_1x_2-plane, as would be the case if the eigenvectors were positive real. This explains why these vectors must be complex.

12. $-(\lambda^2 - 72\lambda - 2673)\lambda = 0$; 0, $[0 \quad 1 \quad -1]^T$; -27, $[1 \quad 2 \quad 2]^T$; 99, $[-22 \quad 1 \quad 10]^T$

14. $-(\lambda^3 - 3\lambda^2 - 6\lambda + 8)/(\lambda - 1) = -(\lambda^2 - 2\lambda - 8)$; 4, $[2 \quad 1 \quad -2]^T$; 1, $[2 \quad -2 \quad 1]^T$; -2, $[1 \quad 2 \quad 2]^T$

16. 0.5, $[1 \quad 0 \quad 0]^T$; 1.0, $[0.4 \quad 1.0 \quad 0]^T$; 3.5, $[0.22 \quad 1.80 \quad 3.00]^T$

18. $-(\lambda^3 - 9\lambda^2 - 81\lambda + 729)/(\lambda - 9) = -\lambda^2 + 81$; 9, $[2 \quad -2 \quad 1]^T$, defect 1; -9, $[2 \quad 1 \quad -2]^T$

20. The characteristic equation is

$$\lambda^2(\lambda^2 - 38\lambda + 360) = 0.$$

Eigenvalues and eigenvectors are

$$\lambda_1 = 0, \qquad [0 \quad 1 \quad 0 \quad 0]^T, \qquad [1 \quad 0 \quad 0 \quad 0]^T$$
$$\lambda_2 = 18, \qquad [1 \quad 1 \quad 9 \quad 9]^T$$
$$\lambda_3 = 20, \qquad [-3 \quad 3 \quad 5 \quad -5]^T.$$

22. The indicated division of the characteristic polynomial gives

$$(\lambda^4 - 22\lambda^2 + 24\lambda + 45)/(\lambda - 3)^2 = \lambda^2 + 6\lambda + 5.$$

The eigenvalues and eigenvectors are

$$\lambda_1 = 3, \qquad [1 \quad 1 \quad 1 \quad 1]^T \text{ with a defect of 1}$$
$$\lambda_2 = -1 \qquad [3 \quad -1 \quad 1 \quad 1]^T$$
$$\lambda_3 = -5, \qquad [-11 \quad 1 \quad 5 \quad 1]^T.$$

im08.qxd 9/21/05 12:12 PM Page 163

24. Using the given eigenvectors, we obtain

$$(\lambda^4 - 118\lambda^2 - 168\lambda + 1485)/[(\lambda - 3)(\lambda + 5)] = \lambda^2 - 2\lambda - 99.$$

The eigenvalues and eigenvectors are

$$\lambda_1 = 11, \quad [-9 \quad 7 \quad 11 \quad -13]^T$$

$$\lambda_2 = 3, \quad [1 \quad 1 \quad 1 \quad 1]^T$$

$$\lambda_3 = -5, \quad [-7 \quad -7 \quad 13 \quad 5]^T$$

$$\lambda_4 = -9, \quad [2 \quad -1 \quad 2 \quad -1]^T$$

30. By Theorem 1 in Sec. 7.8 the inverse exists if and only if $\det \mathbf{A} \neq 0$. On the other hand, from the product representation

$$D(\lambda) = \det(\mathbf{A} - \lambda\mathbf{I}) = (-1)^n(\lambda - \lambda_1)(\lambda - \lambda_2) \cdots (\lambda - \lambda_n)$$

of the characteristic polynomial we obtain

$$\det \mathbf{A} = (-1)^n(-\lambda_1)(-\lambda_2) \cdots (-\lambda_n) = \lambda_1\lambda_2 \cdots \lambda_n.$$

Hence $\mathbf{A}^{-1}$ exists if and only if 0 is not an eigenvalue of **A.**

Furthermore, let $\lambda \neq 0$ be an eigenvalue of **A.** Then

$$\mathbf{Ax} = \lambda\mathbf{x}.$$

Multiply this by $\mathbf{A}^{-1}$ from the left:

$$\mathbf{A}^{-1}\mathbf{Ax} = \lambda\mathbf{A}^{-1}\mathbf{x}.$$

Now divide by λ:

$$\frac{1}{\lambda}\,\mathbf{x} = \mathbf{A}^{-1}\mathbf{x}.$$

SECTION 8.2. Some Applications of Eigenvalue Problems, page 340

Purpose. Matrix eigenvalue problems are of greatest importance in physics, engineering, geometry, etc., and the applications in this section and in the problem set are supposed to give the student at least some impression of this fact.

Main Content

Applications of eigenvalue problems in

Elasticity theory (Example 1),

Probability theory (Example 2),

Biology (Example 3),

Mechanical vibrations (Example 4).

Short Courses. Of course, this section can be omitted, for reasons of time, or one or two of the examples can be considered quite briefly.

Comments on Content

The examples in this section have been selected from the viewpoint of modest prerequisites, so that not too much time will be needed to set the scene.

Example 4 illustrates why real matrices can have complex eigenvalues (as mentioned before, in Sec. 8.1), and why these eigenvalues are physically meaningful. (For students familiar with systems of ODEs, one can easily pick further examples from Chap. 4.)

im08.qxd 9/21/05 12:12 PM Page 164

SOLUTIONS TO PROBLEM SET 8.2, page 343

2. (x, y, z) is mapped onto $(x, y, -z)$. Hence $[0 \quad 0 \quad 1]^T$ is an eigenvector corresponding to the eigenvalue -1 of the matrix

$$\mathbf{A} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix}.$$

Furthermore, $\lambda = 1$ is an eigenvalue of $\mathbf{A}$ of algebraic and geometric multiplicity 2. Two linearly independent eigenvectors are

$$\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}.$$

4. Sketch the line $y = x$ in the xy-plane to see that

$$(1, 0, 0) \quad \text{maps onto} \quad (\tfrac{1}{2}, \tfrac{1}{2}, 0),$$
$$(0, 1, 0) \quad \text{maps onto} \quad (\tfrac{1}{2}, \tfrac{1}{2}, 0)$$

and $(0, 0, 1)$ maps onto itself. Hence the matrix is

$$\begin{bmatrix} \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{2} & \frac{1}{2} & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

To the eigenvalue 1 there correspond the eigenvectors

$$\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$$

which span the plane $y = x$. This indicates that every point of this plane is mapped onto itself. For the eigenvalue 0 an eigenvector is $[1 \quad -1 \quad 0]^T$. This shows that any point on the line $y = -x$, $z = 0$ (which is perpendicular to the plane $y = x$) is mapped onto the origin.

6. $(1, 0)$ maps onto $(0, 1)$. Also, $(0, 1)$ maps onto $(-1, 0)$. Hence the matrix is

$$\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}.$$

This is the "rotation matrix" in Prob. 10 of Problem Set 8.1 with $\theta = \pi/2$. The eigenvalues are i and $-i$. Corresponding eigenvectors are complex, in agreement with the fact that under this rotation, no direction is preserved.

8. Extension by a factor 1.2 (the eigenvalue) in the direction of the eigenvector $[1 \quad 1]^T$ (45°). Contraction by -0.4, direction given by $[1 \quad -1]^T$ ($-45°$). It is typical of a symmetric matrix that the principal directions are orthogonal.

10. Extension by a factor 13 in the direction given by $[1 \quad 2]^T$ (63.4°); extension by a factor 3 in the direction given by $[2 \quad -1]^T$ ($-26.6°$).

im08.qxd 9/21/05 12:12 PM Page 165

12. Extension factors $9 + 2\sqrt{5} = 13.47$ and $9 - 2\sqrt{5} = 4.53$ in the directions given by $[1 \quad 2 + \sqrt{5}]^T$ and $[1 \quad 2 - \sqrt{5}]^T$ (76.7° and −13.3°, respectively).

14. Extension factors 11 and 9.5, corresponding to the principal directions $[1 \quad 1/\sqrt{2}]^T$ (35.26°) and $[-1/\sqrt{2} \quad 1]^T$ (144.74°), respectively.

16. **A** has the same eigenvalues as $\mathbf{A}^T$, and $\mathbf{A}^T$ has row sums 1, so that it has the eigenvalue 1 with eigenvector $\mathbf{x} = [1 \cdots 1]^T$.

Leontief was a leader in the development and application of quantitative methods in empirical economical research, using genuine data from the economy of the United States to provide, in addition to the "closed model" of Prob. 15 (where the producers consume the whole production), "open models" of various situations of production and consumption, including import, export, taxes, capital gains and losses, etc. See W. W. Leontief, *The Structure of the American Economy 1919–1939* (Oxford: Oxford University Press, 1951); H. B. Cheney and P. G. Clark, *Interindustry Economics* (New York: Wiley, 1959).

18. $[4 \quad 9]^T$. Since eigenvectors are determined only up to a nonzero multiplicative constant, this limit vector must be multiplied by a constant such that the sum of its two components equals the sum of the components of the vector representing the initial state.

20. An eigenvector corresponding to the eigenvalue 1 is

$$[121 \quad 132 \quad 176]^T.$$

The other eigenvalues are -0.3 with eigenvector $[1 \quad 7 \quad -8]^T$ and 0.4 with eigenvector $[1 \quad 0 \quad -1]^T$. These are not needed here.

22. The growth rate is 3. A corresponding eigenvector is $[40 \quad 10 \quad 1]^T$, but is not needed. Neither are the other two eigenvalues 0 with eigenvector $[0 \quad 0 \quad 1]^T$ and -3 with eigenvector $[40 \quad -10 \quad 1]^T$.

24. **Team Project. (a)** This follows by comparing the coefficient of λ^{n-1} in the expansion of $D(\lambda)$ with that obtained from the product representation.

(b) $\mathbf{A}\mathbf{x}_j = \lambda_j \mathbf{x}_j$ $(\mathbf{x}_j \neq \mathbf{0})$, $(\mathbf{A} - k\mathbf{I})\mathbf{x}_j = \lambda_j \mathbf{x}_j - k\mathbf{x}_j = (\lambda_j - k)\mathbf{x}_j$

(c) The first statement follows from

$$\mathbf{A}\mathbf{x} = \lambda\mathbf{x}, \quad (k\mathbf{A})\mathbf{x} = k(\mathbf{A}\mathbf{x}) = k(\lambda\mathbf{x}) = (k\lambda)\mathbf{x},$$

the second by induction and multiplication of $\mathbf{A}^k\mathbf{x}_j = \lambda_j{}^k\mathbf{x}_j$ by **A** from the left.

(d) From $\mathbf{A}\mathbf{x}_j = \lambda_j\mathbf{x}_j$ $(\mathbf{x}_j \neq \mathbf{0})$ and (e) follows $k_p\mathbf{A}^p\mathbf{x}_j = k_p\lambda_j{}^p\mathbf{x}_j$ and $k_q\mathbf{A}^q\mathbf{x}_j = k_q\lambda_j{}^q\mathbf{x}_j$ $(p \geqq 0,\ q \geqq 0$, integer). Adding on both sides, we see that $k_p\mathbf{A}^p + k_q\mathbf{A}^q$ has the eigenvalue $k_p\lambda_j{}^p + k_q\lambda_j{}^q$. From this the statement follows.

(e) $\det(\mathbf{L} - \lambda\mathbf{I}) = -\lambda^3 + l_{12}l_{21}\lambda + l_{13}l_{21}l_{32} = 0$. Hence $\lambda \neq 0$. If all three eigenvalues are real, at least one is positive since trace $\mathbf{L} = 0$. The only other possibility is $\lambda_1 = a + ib$, $\lambda_2 = a - ib$, λ_3 real (except for the numbering of the eigenvalues). Then $\lambda_3 > 0$ because

$$\lambda_1\lambda_2\lambda_3 = (a^2 + b^2)\lambda_3 = \det\mathbf{L} = l_{13}l_{21}l_{32} > 0.$$

SECTION 8.3. Symmetric, Skew-Symmetric, and Orthogonal Matrices, page 345

Purpose. To introduce the student to the three most important classes of real square matrices and their general properties and eigenvalue theory.

im08.qxd 9/21/05 12:12 PM Page 166

Main Content, Important Concepts

The eigenvalues of a symmetric matrix are real.

The eigenvalues of a skew-symmetric matrix are pure imaginary or zero.

The eigenvalues of an orthogonal matrix have absolute value 1.

Further properties of orthogonal matrices

Comments on Content

The student should memorize the preceding three statements on the locations of eigenvalues as well as the basic properties of orthogonal matrices (orthonormality of row vectors and of column vectors, invariance of inner product, determinant equal to 1 or -1).

Furthermore, it may be good to emphasize that, since the eigenvalues of an orthogonal matrix may be complex, so may be the eigenvectors. Similarly for skew-symmetric matrices. Both cases are simultaneously illustrated by

$$\mathbf{A} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \quad \text{with eigenvectors} \quad \begin{bmatrix} 1 \\ i \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 1 \\ -i \end{bmatrix}$$

corresponding to the eigenvalues i and $-i$, respectively.

SOLUTIONS TO PROBLEM SET 8.3, page 348

4. Let $\mathbf{Ax} = \lambda\mathbf{x}$ ($\mathbf{x} \neq \mathbf{0}$), $\mathbf{Ay} = \mu\mathbf{y}$ ($\mathbf{y} \neq \mathbf{0}$). Then

$$\lambda\mathbf{x}^\mathsf{T} = (\mathbf{Ax})^\mathsf{T} = \mathbf{x}^\mathsf{T}\mathbf{A}^\mathsf{T} = \mathbf{x}^\mathsf{T}\mathbf{A}.$$

Thus

$$\lambda\mathbf{x}^\mathsf{T}\mathbf{y} = \mathbf{x}^\mathsf{T}\mathbf{Ay} = \mathbf{x}^\mathsf{T}\mu\mathbf{y} = \mu\mathbf{x}^\mathsf{T}\mathbf{y}.$$

Hence if $\lambda \neq \mu$, then $\mathbf{x}^\mathsf{T}\mathbf{y} = 0$, which proves orthogonality.

6. $\det \mathbf{A} = \det(\mathbf{A}^\mathsf{T}) = \det(-\mathbf{A}) = (-1)^n \det \mathbf{A} = -\det \mathbf{A} = 0$ if n is odd. Hence the answer is no. For even $n = 2, 4, \cdots$ we have

$$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \quad \begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{bmatrix}, \quad \text{etc.}$$

8. Yes, for instance,

$$\begin{bmatrix} 1/2 & \sqrt{3}/2 & 0 \\ \sqrt{3}/2 & -1/2 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

10. Symmetric when $b = 0$, skew-symmetric when $a = 0$, orthogonal when $a^2 + b^2 = 1$. Eigenvalues $a + ib$ and $a - ib$. Note that this section concerns *real* matrices.

12. Orthogonal, rotation about the z-axis through an angle θ. Eigenvalues 1 and $\cos\theta \pm i \sin\theta$

14. Skew-symmetric, eigenvalues 0 and $\pm 18i$

im08.qxd 9/21/05 12:12 PM Page 167

16. Orthogonal, eigenvalues 1 and

$$\frac{7}{18} \pm \frac{5\sqrt{11}}{18}\, i$$

all three of absolute value 1

18. See the answer to Prob. 12, above.

20. CAS Experiment.

(a) $\mathbf{A}^{\mathsf{T}} = \mathbf{A}^{-1}$, $\mathbf{B}^{\mathsf{T}} = \mathbf{B}^{-1}$, $(\mathbf{AB})^{\mathsf{T}} = \mathbf{B}^{\mathsf{T}}\mathbf{A}^{\mathsf{T}} = \mathbf{B}^{-1}\mathbf{A}^{-1} = (\mathbf{AB})^{-1}$. Also $(\mathbf{A}^{-1})^{\mathsf{T}} = (\mathbf{A}^{\mathsf{T}})^{-1} = (\mathbf{A}^{-1})^{-1}$. In terms of rotations it means that the composite of rotations and the inverse of a rotation are rotations.

(b) The inverse is

$$\begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}.$$

(c) To a rotation of about 16.26°. No limit. For a student unfamiliar with complex numbers this may require some thought.

(d) Limit 0, approach along some spiral.

(e) The matrix is obtained by using familiar values of cosine and sine,

$$\mathbf{A} = \begin{bmatrix} \sqrt{3}/2 & -1/2 \\ 1/2 & \sqrt{3}/2 \end{bmatrix}.$$

SECTION 8.4. Eigenbases. Diagonalization. Quadratic Forms, page 349

Purpose. This section exhibits the role of bases of eigenvectors ("eigenbases") in connection with linear transformations and contains theorems of great practical importance in connection with eigenvalue problems.

Main Content, Important Concepts

Bases of eigenvectors (Theorems 1, 2)

Similar matrices have the same spectrum (Theorem 3)

Diagonalization of matrices (Theorem 4)

Principal axes transformation of forms (Theorem 5)

Short Courses. Complete omission of this section or restriction to a short look at Theorems 1 and 5.

Comments on Content

Theorem 1 on similar matrices has various applications in the design of numeric methods (Chap. 20), which often use subsequent similarity transformations to tridiagonalize or (nearly) diagonalize matrices on the way to approximations of eigenvalues and eigenvectors. The matrix $\mathbf{X}$ of eigenvectors [see (5)] also occurs quite frequently in that context.

Theorem 2 is another result of fundamental importance in many applications, for instance, in those methods for numerically determining eigenvalues and eigenvectors. Its proof is substantially more difficult than the proofs given in this chapter.

im08.qxd 9/21/05 12:12 PM Page 168

SOLUTIONS TO PROBLEM SET 8.4, page 355

2. The eigenvalues are -8 and 8. Corresponding eigenvectors are $[2 \quad -1]^T$ and $[2 \quad 1]^T$, respectively. Thus,

$$\mathbf{X} = \begin{bmatrix} 2 & 2 \\ -1 & 1 \end{bmatrix}.$$

This gives the diagonal matrix $\mathbf{D} = \text{diag}\,(-8, 8)$.

4. The eigenvalues are -2 and 1. Corresponding eigenvectors are $[2 \quad -5]^T$ and $[1 \quad -1]^T$, respectively. Hence

$$\mathbf{X} = \begin{bmatrix} 2 & 1 \\ -5 & -1 \end{bmatrix}.$$

This gives the diagonal matrix $\mathbf{D} = \text{diag}\,(-2, 1)$.

6. The eigenvalues are -12 and 5. Corresponding eigenvectors are $[1 \quad -2]^T$ and $[7 \quad 3]^T$, respectively. The diagonal matrix is $\mathbf{D} = \text{diag}\,(-12, 5)$.

8. The eigenvalues are 4, 0, -2. Eigenvectors are $[1 \quad 0 \quad 1]^T$, $[1 \quad -1 \quad 0]^T$, $[0 \quad 5 \quad 3]^T$, respectively. Hence

$$\mathbf{X} = \begin{bmatrix} 1 & 1 & 0 \\ 0 & -1 & 5 \\ 1 & 0 & 3 \end{bmatrix}.$$

The diagonal matrix is diag (4, 0 -2).

12. Project. (a) This follows immediately from the product representation of the characteristic polynomial of **A.**

(b) $\mathbf{C} = \mathbf{AB}$, $c_{11} = \sum_{l=1}^{n} a_{1l}b_{l1}$, $c_{22} = \sum_{l=1}^{n} a_{2l}b_{l2}$, etc. Now take the sum of these n sums. Furthermore, trace **BA** is the sum of

$$\tilde{c}_{11} = \sum_{m=1}^{n} b_{1m}a_{m1}, \cdots, \tilde{c}_{nn} = \sum_{m=1}^{n} b_{nm}a_{mn},$$

involving the same n^2 terms as those in the double sum of trace **AB.**

(c) By multiplications from the right and from the left we readily obtain

$$\tilde{\mathbf{A}} = \mathbf{P}^2\hat{\mathbf{A}}\mathbf{P}^{-2}.$$

(d) Interchange the corresponding eigenvectors (columns) in the matrix **X** in (5).

14. We obtain

$$\hat{\mathbf{A}} = \begin{bmatrix} -5 & 0 \\ 24 & 5 \end{bmatrix}.$$

The eigenvalues of $\hat{\mathbf{A}}$ are 5 and -5. Corresponding eigenvectors are $[0 \quad 1]^T$ and $[5 \quad -12]^T$, respectively. From this we obtain the eigenvectors $[2 \quad 1]^T$ and $[1 \quad -2]^T$, respectively, of **A.**

16. We obtain

$$\hat{\mathbf{A}} = \begin{bmatrix} -\frac{2}{5} & \frac{2}{5} \\ \frac{68}{5} & \frac{7}{5} \end{bmatrix}.$$

im08.qxd 9/21/05 12:12 PM Page 169

The eigenvalues of $\hat{\mathbf{A}}$ are -2 and 3. Corresponding eigenvectors are $[1 \quad -4]^T$ and $[2 \quad 17]^T$, respectively. From this we obtain the eigenvectors $[0 \quad -15]^T$ and $[50 \quad 70]^T$, respectively, of **A.**

18. We obtain

$$\hat{\mathbf{A}} = \begin{bmatrix} 4 & 3 & -9 \\ 0 & -5 & 15 \\ 0 & -5 & 15 \end{bmatrix}.$$

The eigenvalues are 0, 4, 10. Corresponding eigenvectors of $\hat{\mathbf{A}}$ are $[0 \quad 3 \quad 1]^T$, $[1 \quad 0 \quad 0]^T$, $[1 \quad -1 \quad -1]^T$, respectively. From these we obtain the eigenvectors $[3 \quad 0 \quad 1]^T$, $[0 \quad 1 \quad 0]^T$, $[-1 \quad 1 \quad -1]^T$, respectively, of **A.** These differ from those of $\hat{\mathbf{A}}$ by an interchange of the first two components. Indeed, this is the effect of **P** under multiplication from the left.

20. The symmetric coefficient matrix is

$$\mathbf{C} = \begin{bmatrix} 3 & 2\sqrt{3} \\ 2\sqrt{3} & 7 \end{bmatrix}.$$

It has the eigenvalues 9 and 1. Hence the transformed form is

$$9y_1^2 + y_2^2 = 9.$$

This is an ellipse with semiaxes 1 and 3.

The matrix **X** whose columns are normalized eigenvectors of **C** gives the relation between **y** and **x** in the form

$$\mathbf{x} = \begin{bmatrix} 1/2 & -\sqrt{3}/2 \\ \sqrt{3}/2 & 1/2 \end{bmatrix} \mathbf{y}.$$

22. The symmetric coefficient matrix is

$$\mathbf{C} = \begin{bmatrix} 6 & 8 \\ 8 & -6 \end{bmatrix}.$$

It has the eigenvalues 10 and -10. Hence the transformed form is

$$10y_1^2 - 10y_2^2 = 20; \qquad \text{thus,} \qquad y_1^2 - y_2^2 = 2.$$

This is a hyperbola. The matrix **X** whose columns are normalized eigenvectors of **C** gives the relation between **y** and **x** in the form

$$\mathbf{x} = \begin{bmatrix} 2/\sqrt{5} & 1/\sqrt{5} \\ 1/\sqrt{5} & -2/\sqrt{5} \end{bmatrix} \mathbf{y}.$$

24. The symmetric coefficient matrix of the form is

$$\mathbf{C} = \begin{bmatrix} 7 & -12 \\ -12 & 0 \end{bmatrix}.$$

It has the eigenvalues 16 and -9. Hence the transformed form is

$$16y_1^2 - 9y_2^2 = 144; \qquad \text{thus,} \qquad y_1^2/9 - y_2^2/16 = 1.$$

im08.qxd 9/21/05 12:12 PM Page 170

This is a hyperbola. The matrix **X** whose columns are normalized eigenvectors of **C** gives the relation between **y** and **x** in the form

$$\mathbf{x} = \begin{bmatrix} 0.8 & 0.6 \\ -0.6 & 0.8 \end{bmatrix} \mathbf{y}.$$

26. The symmetric coefficient matrix is

$$\mathbf{C} = \begin{bmatrix} 3 & 11 \\ 11 & 3 \end{bmatrix}.$$

It has the eigenvalues 14 and -8. Hence the transformed form is

$$14y_1^2 - 8y_2^2 = 0; \qquad \text{thus,} \qquad y_2 = \pm(\sqrt{7}/2)y_1.$$

This is a pair of straight lines through the origin. The matrix **X** whose columns are normalized eigenvectors of **C** gives the relation between **y** and **x** in the form

$$\mathbf{x} = \begin{bmatrix} 1/\sqrt{2} & 1/\sqrt{2} \\ 1/\sqrt{2} & -1/\sqrt{2} \end{bmatrix} \mathbf{y}.$$

28. The symmetric coefficient matrix is

$$\mathbf{C} = \begin{bmatrix} 6.5 & 2.5 \\ 2.5 & 6.5 \end{bmatrix}.$$

It has the eigenvalues 9 and 4. Hence the transformed form is

$$9y_1^2 + 4y_2^2 = 36; \qquad \text{thus,} \qquad y_1^2/4 + y_2^2/9 = 1.$$

This is an ellipse with semiaxes 2 and 3. The matrix **X** whose columns are normalized eigenvectors of **C** gives the relation between **y** and **x** in the form

$$\mathbf{x} = \begin{bmatrix} 1/\sqrt{2} & 1/\sqrt{2} \\ 1/\sqrt{2} & -1/\sqrt{2} \end{bmatrix} \mathbf{y}.$$

30. Transform $Q(\mathbf{x})$ by (9) to the canonical form (10). Since the inverse transform $\mathbf{y} = \mathbf{X}^{-1}\mathbf{x}$ of (9) exists, there is a one-to-one correspondence between all $\mathbf{x} \neq \mathbf{0}$ and $\mathbf{y} \neq \mathbf{0}$. Hence the values of $Q(\mathbf{x})$ for $\mathbf{x} \neq \mathbf{0}$ concide with the values of (10) on the right. But the latter are obviously controlled by the signs of the eigenvalues in the three ways stated in the theorem. This completes the proof.

SECTION 8.5. Complex Matrices and Forms. *Optional,* page 356

Purpose. This section is devoted to the three most important classes of complex matrices and corresponding forms and eigenvalue theory.

Main Content, Important Concepts

Hermitian and skew-Hermitian matrices

Unitary matrices, unitary systems

Location of eigenvalues (Fig. 161)

Quadratic forms, their symmetric coefficient matrix

Hermitian and skew-Hermitian forms

im08.qxd 9/21/05 12:12 PM Page 171

Background Material. Section 8.3, which the present section generalizes. The prerequisites on complex numbers are very modest, so that students will need hardly any extra help in that respect.

Short Courses. This section can be omitted.

The importance of these matrices results from quantum mechanics as well as from mathematics itself (e.g., from unitary transformations, product representations of nonsingular matrices $\mathbf{A} = \mathbf{UH}$, $\mathbf{U}$ unitary, $\mathbf{H}$ Hermitian, etc.).

The determinant of a unitary matrix (see Theorem 4) may be complex. For example, the matrix

$$\mathbf{A} = \frac{1+i}{\sqrt{2}} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

is unitary and has

$$\det \mathbf{A} = i.$$

SOLUTIONS TO PROBLEM SET 8.5, page 361

2. $(\overline{\mathbf{BA}})^{\mathsf{T}} = (\overline{\mathbf{B}}\,\overline{\mathbf{A}})^{\mathsf{T}} = \overline{\mathbf{A}}^{\mathsf{T}}\overline{\mathbf{B}}^{\mathsf{T}} = \mathbf{A}(-\mathbf{B}) = -\mathbf{AB}$. For the matrices in Example 2,

$$\mathbf{AB} = \begin{bmatrix} 1+19i & 5+3i \\ -23+10i & -1 \end{bmatrix}.$$

4. Eigenvectors are as follows. (Multiplication by a complex constant may change them drastically!)

For $\mathbf{A}$ $\quad [1-3i \quad 5]^{\mathsf{T}}, \quad [1-3i \quad -2]^{\mathsf{T}}$

For $\mathbf{B}$ $\quad [2+i \quad i]^{\mathsf{T}}, \quad [2+i \quad -5i]^{\mathsf{T}}$

For $\mathbf{C}$ $\quad [1 \quad 1]^{\mathsf{T}}, \quad [1 \quad -1]^{\mathsf{T}}.$

6. Skew-Hermitian, eigenvalue $-2i$ with eigenvector $[1 \quad -1]^{\mathsf{T}}$; eigenvalue $2i$ with eigenvector $[1 \quad 1]^{\mathsf{T}}$.

8. Skew-Hermitian, unitary, eigenvalues i and $-i$; corresponding eigenvectors $[1 \quad 1]^{\mathsf{T}}$ and $[1 \quad -1]^{\mathsf{T}}$, respectively.

10. Hermitian. The eigenvalues and eigenvectors are

$-2, \quad [i \quad -1-i \quad 1]^{\mathsf{T}}$

$0, \quad [-i \quad 0 \quad 1]^{\mathsf{T}}$

$2, \quad [i \quad 1+i \quad 1]^{\mathsf{T}}.$

12. Project. (a) $\mathbf{A} = \mathbf{H} + \mathbf{S}$, $\mathbf{H} = \frac{1}{2}(\mathbf{A} + \overline{\mathbf{A}}^{\mathsf{T}})$, $\mathbf{S} = \frac{1}{2}(\mathbf{A} - \overline{\mathbf{A}}^{\mathsf{T}})$ ($\mathbf{H}$ Hermitian, $\mathbf{S}$ skew-Hermitian)

(b) $\overline{\mathbf{A}}^{\mathsf{T}}\mathbf{A} = \mathbf{A}^2 = \mathbf{A}\overline{\mathbf{A}}^{\mathsf{T}}$ if $\mathbf{A}$ is Hermitian, $\overline{\mathbf{A}}^{\mathsf{T}}\mathbf{A} = -\mathbf{A}^2 = \mathbf{A}(-\mathbf{A}) = \mathbf{A}\overline{\mathbf{A}}^{\mathsf{T}}$ if $\mathbf{A}$ is skew-Hermitian, $\overline{\mathbf{A}}^{\mathsf{T}}\mathbf{A} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I} = \mathbf{A}\mathbf{A}^{-1} = \mathbf{A}\overline{\mathbf{A}}^{\mathsf{T}}$ if $\mathbf{A}$ is unitary.

(c) We have $\mathbf{A} = \mathbf{H} + \mathbf{S}$, $\overline{\mathbf{A}}^{\mathsf{T}} = \overline{\mathbf{H}}^{\mathsf{T}} + \overline{\mathbf{S}}^{\mathsf{T}} = \mathbf{H} - \mathbf{S}$; hence

$$\mathbf{A}\overline{\mathbf{A}}^{\mathsf{T}} = (\mathbf{H}+\mathbf{S})(\mathbf{H}-\mathbf{S}) = \mathbf{H}^2 - \mathbf{HS} + \mathbf{SH} - \mathbf{S}^2$$

and

$$\overline{\mathbf{A}}^{\mathsf{T}}\mathbf{A} = (\mathbf{H}-\mathbf{S})(\mathbf{H}+\mathbf{S}) = \mathbf{H}^2 + \mathbf{HS} - \mathbf{SH} - \mathbf{S}^2.$$

These two expressions are equal if and only if

$$-\mathbf{HS} + \mathbf{SH} = \mathbf{HS} - \mathbf{SH}; \qquad \text{thus,} \qquad 2\mathbf{SH} = 2\mathbf{HS},$$

and $\mathbf{HS} = \mathbf{SH}$, as claimed.

im08.qxd 9/21/05 12:12 PM Page 172

(d) For instance,

$$\begin{bmatrix} 0 & 0 \\ i & 0 \end{bmatrix}$$

is not normal. A normal matrix that is not Hermitian, skew-Hermitian, or unitary is obtained if we take a unitary matrix and multiply it by 2 or some other real factor different from ± 1.

(e) The inverse of a product $\mathbf{UV}$ of unitary matrices is

$$(\mathbf{UV})^{-1} = \mathbf{V}^{-1}\mathbf{U}^{-1} = \overline{\mathbf{V}}^{\mathsf{T}}\overline{\mathbf{U}}^{\mathsf{T}} = (\overline{\mathbf{UV}})^{\mathsf{T}}.$$

This proves that $\mathbf{UV}$ is unitary.

We show that the inverse $\mathbf{A}^{-1} = \mathbf{B}$ of a unitary matrix $\mathbf{A}$ is unitary. We obtain

$$\mathbf{B}^{-1} = (\mathbf{A}^{-1})^{-1} = (\overline{\mathbf{A}}^{\mathsf{T}})^{-1} = (\overline{\mathbf{A}^{-1}})^{\mathsf{T}} = \overline{\mathbf{B}}^{\mathsf{T}},$$

as had to be shown.

14. This form is Hermitian. Its value can be obtained directly by looking at the matrix, namely,

$$\begin{aligned} \overline{\mathbf{x}}^{\mathsf{T}}\mathbf{A}\mathbf{x} &= a\bar{x}_1x_1 + (b + ic)\bar{x}_1x_2 + (b - ic)\bar{x}_2x_1 + k\bar{x}_2x_2 \\ &= a|x_1|^2 + 2\mathrm{Re}\,[b + ic)\bar{x}_1x_2] + k|x_2|^2. \end{aligned}$$

Here we have used that $\mathrm{Re}\, z = \frac{1}{2}(z + \bar{z})$. Indeed, the two middle terms in the first line on the right are complex conjugates of each other. We also note that the value of the form is real, as it should be for a Hermitian form.

16. Eigenvalues and eigenvectors are

$$\begin{aligned} S_x: &\quad -1, \quad \begin{bmatrix} 1 \\ -1 \end{bmatrix}; \quad 1, \quad \begin{bmatrix} 1 \\ 1 \end{bmatrix} \\ S_y: &\quad -1, \quad \begin{bmatrix} 1 \\ -i \end{bmatrix}; \quad 1, \quad \begin{bmatrix} 1 \\ i \end{bmatrix} \\ S_z: &\quad -1, \quad \begin{bmatrix} 0 \\ 1 \end{bmatrix}; \quad 1, \quad \begin{bmatrix} 1 \\ 0 \end{bmatrix}. \end{aligned}$$

SOLUTIONS TO CHAP. 8 REVIEW QUESTIONS AND PROBLEMS, page 362

10. $\mathbf{X}^{-1}\mathbf{A}\mathbf{X} = \begin{bmatrix} 8/65 & 1/65 \\ 1/65 & -8/65 \end{bmatrix} \mathbf{A} \begin{bmatrix} 8 & 1 \\ 1 & -8 \end{bmatrix} = \begin{bmatrix} 13 & 0 \\ 0 & 104 \end{bmatrix}$

12. $\mathbf{X}^{-1}\mathbf{A}\mathbf{X} = \frac{1}{9}\begin{bmatrix} 2 & 1 & 0 \\ 0 & -2 & -1 \\ 1 & 0 & 2 \end{bmatrix} \mathbf{A} \begin{bmatrix} 4 & 2 & 1 \\ 1 & -4 & -2 \\ -2 & -1 & 4 \end{bmatrix} = \begin{bmatrix} 18 & 0 & 0 \\ 0 & 9 & 0 \\ 0 & 0 & -9 \end{bmatrix}$

14. $\mathbf{X}^{-1}\mathbf{A}\mathbf{X} = \frac{1}{3}\begin{bmatrix} 1 & 1 & -1 \\ 0 & 1 & 1 \\ 1 & -1 & 0 \end{bmatrix} \mathbf{A} \begin{bmatrix} 1 & 1 & 2 \\ 1 & 1 & -1 \\ -1 & 2 & 1 \end{bmatrix} = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 11 & 0 \\ 0 & 0 & -10 \end{bmatrix}$

im08.qxd 9/21/05 12:12 PM Page 173

16. $\mathbf{P}^{-1} = \dfrac{1}{20}\begin{bmatrix} 16 & -8 & 2 \\ -4 & 2 & 2 \\ 2 & 4 & -1 \end{bmatrix}$, $\hat{\mathbf{A}} = \begin{bmatrix} 15 & 126 & 0 \\ 7 & -6 & 0 \\ -8.5 & -3 & 18 \end{bmatrix}$, $\lambda = 18, 36, -27$

From the form of $\hat{\mathbf{A}}$ it can be seen that one of the eigenvalues is 18, so that the determination of the other two eigenvalues amounts to solving a quadratic equation.

18. The symmetric coefficient matrix is

$$\mathbf{A} = \begin{bmatrix} 11.56 & 10.08 \\ 10.08 & 17.44 \end{bmatrix}.$$

It has the eigenvalues 25 and 4. Hence the form represents the ellipse

$$25y_1^2 + 4y_2^2 = 100; \qquad \text{thus,} \qquad y_1^2/4 + y_2^2/25 = 1$$

with semiaxes 2 and 5.

20. The symmetric coefficient matrix is

$$\mathbf{A} = \begin{bmatrix} 14 & 12 \\ 12 & -4 \end{bmatrix}.$$

It has the eigenvalues 20 and -10. Hence the form represents the hyperbola

$$20y_1^2 - 10y_2^2 = 20; \qquad \text{thus,} \qquad y_1^2 - \tfrac{1}{2}y_2^2 = 1.$$

im09.qxd 9/21/05 12:15 PM Page 174

CHAPTER 9 Vector Differential Calculus. Grad, Div, Curl

This chapter is independent of the previous two chapters (7 and 8).

Changes

The differential–geometric theory of curves in space and in the plane, which in the previous edition was distributed over three consecutive sections, along with its application in mechanics, is now streamlined and shortened and presented in a single section, with a discussion of tangential and normal acceleration in a more concrete fashion.

Formulas for grad, div, and curl in **curvilinear coordinates** are placed for reference in App. A3.4.

SECTION 9.1. Vector in 2-Space and 3-Space, page 364

Purpose. We introduce vectors in 3-space given geometrically by (families of parallel) directed segments or algebraically by ordered triples of real numbers, and we define addition of vectors and scalar multiplication (multiplication of vectors by numbers).

Main Content, Important Concepts

Vector, norm (length), unit vector, components

Addition of vectors, scalar multiplication

Vector space R^3, linear independence, basis

Comments on Content

Our discussions in the whole chapter will be independent of Chaps. 7 and 8, and there will be no more need for writing vectors as columns and for distinguishing between row and column vectors. Our notation $\mathbf{a} = [a_1, a_2, a_3]$ is compatible with that in Chap. 7. Engineers seem to like both notations

$$\mathbf{a} = [a_1, a_2, a_3] = a_1\mathbf{i} + a_2\mathbf{j} + a_3\mathbf{k},$$

preferring the first for "short" components and the second in the case of longer expressions.

The student is supposed to understand that the whole vector algebra (and vector calculus) has resulted from applications, with concepts that are practical, that is, they are "made to measure" for standard needs and situations; thus, in this section, the two algebraic operations resulted from forces (forming resultants and changing magnitudes of forces); similarly in the next sections. The restriction to three dimensions (as opposed to n dimensions in the previous two chapters) allows us to "visualize" concepts, relations, and results and to give geometrical explanations and interpretations.

On a higher level, the equivalence of the geometric and the algebraic approach (Theorem 1) would require a consideration of how the various triples of numbers for the various choices of coordinate systems must be related (in terms of coordinate transformations) for a vector to have a norm and direction independent of the choice of coordinate systems.

Teaching experience makes it advisable to cover the material in this first section rather slowly and to assign relatively many problems, so that the student gets a feel for vectors in R^3 (and R^2) and the interrelation between algebraic and geometric aspects.

im09.qxd 9/21/05 12:15 PM Page 175

SOLUTION TO PROBLEM SET 9.1, page 370

2. The components are -5, -5, -5. The length is $5\sqrt{3}$. Hence the unit vector in the direction of $\mathbf{v}$ is $[-1/\sqrt{3}, \quad -1/\sqrt{3}, \quad -1/\sqrt{3}]$.

4. $v_1 = -2$, $v_2 = 6$, $v_3 = 6$; $|\mathbf{v}| = \sqrt{76}$. Hence the unit vector in the direction of $\mathbf{v}$ is $[-1/\sqrt{19}, \quad 3/\sqrt{19}, \quad 3/\sqrt{19}]$.

6. Components 6, 8, 10; length $10\sqrt{2}$. Unit vector $[0.6/\sqrt{2}, \quad 0.8/\sqrt{2}, \quad 1/\sqrt{2}]$.

8. *Q:* (0, 0, 0); $|\mathbf{v}| = \sqrt{84}$

10. *Q:* (3, 2, 6), $|\mathbf{v}| = 7$. Note that the given vector is the position vector of *Q*.

12. *Q:* (4, 0, 0); $|\mathbf{v}| = 3\sqrt{3}$

14. $[-6, 3, 10]$. This illustrates (4a).

16. $[26, -13, -19]$. This illustrates (4b).

18. $[2/\sqrt{5}, -1/\sqrt{5}, 0]$, $[0, 0, 1]$. These are unit vectors.

20. $5.48 \approx \sqrt{30} < \sqrt{5} + \sqrt{45} \approx 8.94$

24. $[11, 8, 0]$ is the resultant, $\sqrt{185} = 13.6$ its magnitude

26. The resultant is **0.** The forces are in equilibrium.

28. Resultant $[13, 25, 3]$, magnitude $\sqrt{803} = 28.3$

30. The z-component of the resultant is 0 for $c = -12$.

32. $1 \leqq |\mathbf{p} + \mathbf{q}| \leqq 3$, nothing about the direction. If this were the arm of some machine or robot, it could not reach the origin but could reach every point of the annulus (ring) indicated. In the next problem the origin can be reached.

34. $\mathbf{v}_B - \mathbf{v}_A = [-400/\sqrt{2}, 400/\sqrt{2}] - [-500/\sqrt{2}, -500/\sqrt{2}] = [100/\sqrt{2}, 900/\sqrt{2}]$

36. Choose a coordinate system whose axes contain the mirrors. Let $\mathbf{u} = [u_1, u_2]$ be incident. Then the first reflection gives, say, $\mathbf{v} = [u_1, -u_2]$, and the second $\mathbf{w} = [-u_1, -u_2] = \mathbf{-u}$. The reflected ray is parallel to the incoming ray, with the direction reversed.

38. Team Project. (a) The idea is to write the position vector of the point of intersection *P* in two ways and then to compare them, using that $\mathbf{a}$ and $\mathbf{b}$ are linearly independent vectors. Thus

$$\lambda(\mathbf{a} + \mathbf{b}) = \mathbf{a} + \mu(\mathbf{b} - \mathbf{a}).$$

$\lambda = 1 - \mu$ are the coefficients of $\mathbf{a}$ and $\lambda = \mu$ those of $\mathbf{b}$. Together, $\lambda = \mu = \frac{1}{2}$, expressing bisection.

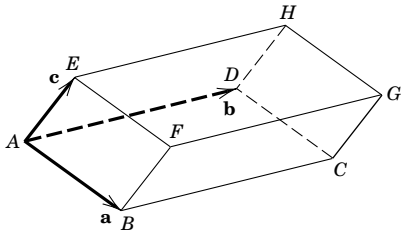
(b) The idea is similar to that in part (a). It gives

$$\lambda(\mathbf{a} + \mathbf{b}) = \tfrac{1}{2}\mathbf{a} + \mu\,\tfrac{1}{2}(\mathbf{b} - \mathbf{a}).$$

$\lambda = \frac{1}{2} - \frac{1}{2}\mu$ from $\mathbf{a}$ and $\lambda = \frac{1}{2}\mu$ from $\mathbf{b}$, resulting in $\lambda = \frac{1}{4}$, thus giving a ratio $(3/4):(1/4) = 3:1$.

(c) Partition the parallelogram into four congruent parallelograms. Part (a) gives $1:1$ for a small parallelogram, hence $1:(1 + 2)$ for the large parallelogram.

(d) $\mathbf{v}(P) = \frac{1}{2}\mathbf{a} + \lambda(\mathbf{b} - \frac{1}{2}\mathbf{a}) = \frac{1}{2}\mathbf{b} + \mu(\mathbf{a} - \frac{1}{2}\mathbf{b})$ has the solution $\lambda = \mu = \frac{1}{3}$, which gives by substitution $\mathbf{v}(P) = \frac{1}{3}(\mathbf{a} + \mathbf{b})$ and shows that the third median OQ passes through P and OP equals $\frac{2}{3}$ of $|\mathbf{v}(Q)| = \frac{1}{2}|\mathbf{a} + \mathbf{b}|$, dividing OQ in the ratio $2:1$, too.



(e) In the figure in the problem set, $\mathbf{a} + \mathbf{b} + \mathbf{c} + \mathbf{d} = \mathbf{0}$; hence $\mathbf{c} + \mathbf{d} = -(\mathbf{a} + \mathbf{b})$. Also, $AB = \frac{1}{2}(\mathbf{a} + \mathbf{b})$, $CD = \frac{1}{2}(\mathbf{c} + \mathbf{d}) = -\frac{1}{2}(\mathbf{a} + \mathbf{b})$, and for DC we get $+\frac{1}{2}(\mathbf{a} + \mathbf{b})$, which shows that one pair of sides is parallel and of the same length. Similarly for the other pair.

im09.qxd 9/21/05 12:15 PM Page 176

(f) Let **a, b, c** be edge vectors with a common initial point (see the figure). Then the four (space) diagonals have the midpoints

$$AG: \quad \tfrac{1}{2}(\mathbf{a} + \mathbf{b} + \mathbf{c})$$
$$BH: \quad \mathbf{a} + \tfrac{1}{2}(\mathbf{b} + \mathbf{c} - \mathbf{a})$$
$$EC: \quad \mathbf{c} + \tfrac{1}{2}(\mathbf{a} + \mathbf{b} - \mathbf{c})$$
$$DF: \quad \mathbf{b} + \tfrac{1}{2}(\mathbf{a} + \mathbf{c} - \mathbf{b}),$$

and these four position vectors are equal.

Section 9.1. Parallelepiped in Team Project 38(f)

(g) Let $\mathbf{v}_1, \cdots, \mathbf{v}_n$ be the vectors. Their angle is $\alpha = 2\pi/n$. The interior angle at each vertex is $\beta = \pi - (2\pi/n)$. Put $\mathbf{v}_2$ at the terminal point of $\mathbf{v}_1$, then $\mathbf{v}_3$ at the terminal point of $\mathbf{v}_2$, etc. Then the figure thus obtained is an n-sided regular polygon, because the angle between two sides equals $\pi - \alpha = \beta$. Hence

$$\mathbf{v}_1 + \mathbf{v}_2 + \cdots + \mathbf{v}_n = \mathbf{0}.$$

(Of course, for *even* n the truth of the statement is immediately obvious.)

SECTION 9.2. Inner Product (Dot Product), page 371

Purpose. We define, explain, and apply a first kind of product of vectors, the dot product $\mathbf{a} \cdot \mathbf{b}$, whose value is a scalar.

Main Content, Important Concepts

Definition (1)

Dot product in terms of components

Orthogonality

Length and angle between vectors in terms of dot products

Cauchy–Schwarz and triangle inequalities

Comment on Dot Product

This product is motivated by work done by a force (Example 2), by the calculation of components of forces (Example 3), and by geometric applications such as those given in Examples 5 and 6.

"Inner product" is more modern than "dot product" and is also used in more general settings (see Sec. 7.9).

im09.qxd 9/21/05 12:15 PM Page 177

SOLUTIONS TO PROBLEM SET 9.2, page 376

2. $\sqrt{21}$, 5, $\sqrt{14}$ **4.** 12 **6.** 3 **8.** 96 **10.** $\sqrt{21} < 5 + \sqrt{14}$

12. $8 < \sqrt{21}\sqrt{14} = 7\sqrt{6} = 17.15$

14. $\mathbf{u}\bullet(\mathbf{v} - \mathbf{w}) = 0$; that is, $\mathbf{v} - \mathbf{w}$ is orthogonal to **u.** So it does *not* imply that $\mathbf{v} - \mathbf{w} = \mathbf{0}$, that is, $\mathbf{v} = \mathbf{w}$.

16. $\mathbf{a}\bullet\mathbf{b} = 4 < 5\sqrt{21}$, $\sqrt{54} = 7.35 < \sqrt{21} + 5 = 9.58$, $54 + 38 = 2(21 + 25) = 92$

18. $|\mathbf{a} + \mathbf{b}|^2 = (\mathbf{a} + \mathbf{b})\bullet(\mathbf{a} + \mathbf{b}) \leqq |\mathbf{a}|^2 + 2|\mathbf{a}||\mathbf{b}| + |\mathbf{b}|^2 = (|\mathbf{a}| + |\mathbf{b}|)^2$

20. $[2, 7, -4]\bullet[-3, 1, 0] = 1$

22. $[4, 3, 6]\bullet[-4, 1, -9] = -67$

24. Let $\overrightarrow{AB} = \mathbf{a}$. Then $W = (\mathbf{p} + \mathbf{q})\bullet\mathbf{a} = \mathbf{p}\bullet\mathbf{a} + \mathbf{q}\bullet\mathbf{a}$.

26. $6/\sqrt{42} = 0.9258 = \cos\gamma$, $\gamma = 22.2°$

28. $7/\sqrt{70} = 0.837 = \cos\gamma$, $\gamma = 33.2°$

30. $6/\sqrt{54} = 0.6165 = \cos\gamma$, $\gamma = 35.26°$

32. $|\mathbf{c}|^2 = |\mathbf{a} - \mathbf{b}|^2 = (\mathbf{a} - \mathbf{b})\bullet(\mathbf{a} - \mathbf{b}) = |\mathbf{a}|^2 + |\mathbf{b}|^2 - 2|\mathbf{a}||\mathbf{b}|\cos\gamma$

34. $\beta - \alpha$ is the angle between the unit vectors **a** and **b.** Hence (2) gives the result.

36. Hesse's normal form gives $10/|[5, 2, 1]| = 10/\sqrt{30} = \sqrt{10/3}$.

38. 0. The vectors are orthogonal.

40. $-\sqrt{5}$

42. Team Project. (b) $a_1 = -8/3$

(c) $[4, 2]\bullet[5, -10] = 0$

(d) $\pm[0.6, -0.8]$

(e) $\mathbf{v}\bullet\mathbf{a} = 2v_1 + v_2 = 0$; hence $\mathbf{v} = [v_1, -2v_1, v_3]$. Yes, of dimension 2.

(f) $c = -11.5$

(g) $(\mathbf{a} + \mathbf{b})\bullet(\mathbf{a} - \mathbf{b}) = |\mathbf{a}|^2 - |\mathbf{b}|^2 = 0$, $|\mathbf{a}| = |\mathbf{b}|$. A square

(h) Let the mirrors correspond to the coordinate planes. If the ray $[v_1, v_2, v_3]$ first hits the *yz*-plane, then the *xz*-plane, and then the *xy*-plane, it will be reflected to $[-v_1, v_2, v_3]$, $[-v_1, -v_2, v_3]$, $[-v_1, -v_2, -v_3]$; hence the angle is 180°, the reflected ray will be parallel to the incident ray but will have the opposite direction.

Corner reflectors have been used in connection with missiles; their aperture changes if the axis of the missile deviates from the tangent direction of the path. See E. Kreyszig, On the theory of corner reflectors with unequal faces. Ohio State University: *Antenna Lab Report* 601/19, 1957.

SECTION 9.3. Vector Product (Cross Product), page 377

Purpose. We define and explain a second kind of product of vectors, the cross product $\mathbf{a} \times \mathbf{b}$, which is a vector perpendicular to both given vectors (or the zero vector in some cases).

Main Content, Important Concepts

Definition of cross product, its components (2), (2**)

Right- and left-handed coordinate systems

Properties (anticommutative, not associative)

Scalar triple product

im09.qxd 9/21/05 12:15 PM Page 178

Prerequisites. Elementary use of second- and third-order determinants (see Sec. 7.6)

Comment on Motivations

Cross products were suggested by the observation that in certain applications, one associates with two given vectors a third vector perpendicular to the given vectors (illustrations in Examples 4–6). Scalar triple products can be motivated by volumes and linear independence (Theorem 2 and Example 6).

SOLUTIONS TO PROBLEM SET 9.3, page 383

2. $[4, -2, -1]$, $\sqrt{21}$, 13

4. $[-19, 21, -24]$, since $\mathbf{d} \times \mathbf{d} = \mathbf{0}$, $[-19, 21, -24]$

6. $\mathbf{0}$ because of anticommutativity

8. $\mathbf{0}$ because the two factors are parallel, even equal.

10. $[50, -30, 0] \neq [54, -27, 10]$, illustrating nonassociativity

12. $[2, 4, 46]$

14. $1, -1$

16. -141

18. -108

20. $-480, -480$

22. Straightforward calculation. In the first formula, each of the three components is multiplied by ℓ.

24. Team Project. (12) is obtained by noting that

$$|\mathbf{a} \times \mathbf{b}|^2 = |\mathbf{a}|^2|\mathbf{b}|^2 \sin^2 \gamma = |\mathbf{a}|^2|\mathbf{b}|^2(1 - \cos^2 \gamma) = (\mathbf{a} \cdot \mathbf{a})(\mathbf{b} \cdot \mathbf{b}) - (\mathbf{a} \cdot \mathbf{b})^2.$$

To prove (13), we choose a right-handed Cartesian coordinate system such that the x-axis has the direction of $\mathbf{d}$ and the xy-plane contains $\mathbf{c}$. Then the vectors in (13) are of the form

$$\mathbf{b} = [b_1, b_2, b_3], \qquad \mathbf{c} = [c_1, c_2, 0], \qquad \mathbf{d} = [d_1, 0, 0].$$

Hence by (2**),

$$\mathbf{c} \times \mathbf{d} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ c_1 & c_2 & 0 \\ d_1 & 0 & 0 \end{vmatrix} = -c_2 d_1 \mathbf{k}, \qquad \mathbf{b} \times (\mathbf{c} \times \mathbf{d}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ b_1 & b_2 & b_3 \\ 0 & 0 & -c_2 d_1 \end{vmatrix}.$$

The "determinant" on the right equals $[-b_2 c_2 d_1, \quad b_1 c_2 d_1, \quad 0]$. Also,

$$\begin{aligned} (\mathbf{b} \cdot \mathbf{d})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{d} &= b_1 d_1 [c_1, c_2, 0] - (b_1 c_1 + b_2 c_2)[d_1, 0, 0] \\ &= [-b_2 c_2 d_1, \quad b_1 d_1 c_2, \quad 0]. \end{aligned}$$

This proves (13) for our special coordinate system. Now the length and direction of a vector and a vector product, and the value of an inner product, are independent of the choice of the coordinates. Furthermore, the representation of $\mathbf{b} \times (\mathbf{c} \times \mathbf{d})$ in terms of $\mathbf{i}, \mathbf{j}, \mathbf{k}$ will be the same for right-handed and left-handed systems, because of the double cross multiplication. Hence, (13) holds in any Cartesian coordinate system, and the proof is complete.

(14) follows from (13) with $\mathbf{b}$ replaced by $\mathbf{a} \times \mathbf{b}$.

im09.qxd 9/21/05 12:15 PM Page 179

To prove (15), we note that $\mathbf{a} \bullet [\mathbf{b} \times (\mathbf{c} \times \mathbf{d})]$ equals

$$(\mathbf{a} \quad \mathbf{b} \quad [\mathbf{c} \times \mathbf{d}]) = (\mathbf{a} \times \mathbf{b}) \bullet (\mathbf{c} \times \mathbf{d})$$

by the definition of the triple product, as well as $(\mathbf{a} \bullet \mathbf{c})(\mathbf{b} \bullet \mathbf{d}) - (\mathbf{a} \bullet \mathbf{d})(\mathbf{b} \bullet \mathbf{c})$ by (13) (take the dot product by **a**).

The last formula, (16), follows from familiar rules of interchanging the rows of a determinant.

26. $[-3, -3, 0] \times [0, 0, 5] = [-15, 15, 0]; \quad 15\sqrt{2}$

28. **0,** 0. Q lies on the line of action of **p.**

30. $\mathbf{w} \times \mathbf{r} = [5/\sqrt{2}, 5/\sqrt{2}, 0] \times [4, 2, -2] = [-5\sqrt{2}, 5\sqrt{2}, -5\sqrt{2}]$, $|\mathbf{v}| = \sqrt{150}$

32. $|[-3, -4, -7] \times [-1, -8, -4]| = |[-40, -5, 20]| = 45$

34. $\frac{1}{2}|[0, 3, 0] \times [4, 0, 2]| = \frac{1}{2}|[6, 0, -12]| = \sqrt{45}$

36. $[2, 3, 2] \times [-1, 5, -3] = [-19, 4, 13]$,
hence

$$-19x + 4y + 13z = c = -19 \cdot 2 + 4 \cdot 1 + 13 \cdot 3 = 5.$$

38. From the given points we get three edge vectors whose scalar triple product is

$$\begin{vmatrix} 4 & 1 & -1 \\ 6 & 4 & 4 \\ 4 & 5 & 7 \end{vmatrix} = -8.$$

Hence the *answer* is 8/6 = 4/3.

SECTION 9.4. Vector and Scalar Functions and Fields. Derivatives, page 384

Purpose. To get started on vector differential calculus, we discuss vector functions and their continuity and differentiability.

Main Content, Important Concepts

Vector and scalar functions and fields

Continuity, derivative of vector functions (9), (10)

Differentiation of dot, cross, and triple products, (11)–(13)

Partial derivatives

Comment on Content

This parallels calculus of functions of one variable and can be surveyed quickly.

SOLUTIONS TO PROBLEM SET 9.4, page 389

2. Parallel straight lines

4. Circles $\left(x - \dfrac{1}{2c}\right)^2 + y^2 = \dfrac{1}{4c^2}$ passing through the origin

6. Hyperbolas $x^2 - (y - 4)^2 = const$

im09.qxd 9/21/05 12:15 PM Page 180

8. CAS Project. A CAS can graphically handle these more complicated functions, whereas the paper-and-pencil method is relatively limited. This is the point of the project.

Note that all these functions occur in connection with Laplace's equation, so they are real or imaginary parts of complex analytic functions.

10. Elliptic cylinders with vertical generating straight lines

12. Cylinders with cross section $z = 4y^2 + c$ and generating straight lines parallel to the x-axis

14. Elliptic paraboloids $z = x^2 + 4y^2 + c$

16. On horizontal lines $y = const$ the **i**-component of **v** is constant, and on vertical lines $x = const$ the **j**-component of **v** is constant.

18. At each point the vector **v** equals the corresponding position vector, so that sketching is easy.

20. On $y = x$ the vector **v** is vertical and on $y = -x$ it is horizontal.

22. As a curve this is a helix. The first derivative $[-4 \sin t, 4 \cos t, 2]$ is tangent to this curve, as we shall discuss in the next section, and the second derivative $[-4 \cos t, -4 \sin t, 0]$ is parallel to the xy-plane and perpendicular to that tangent.

24. $[\cos x \cosh y, \quad -\sin x \sinh y]$, $[\sin x \sinh y, \quad \cos x \cosh y]$; $[e^x \cos y, e^x \sin y]$, $[-e^x \sin y, e^x \cos y]$

SECTION 9.5. Curves. Arc Length. Curvature. Torsion, page 389

Purpose. Discussion of space curves as an application of vector functions of one variable, the use of curves as paths in mechanics (and as paths of integration of line integrals in Chapter 10). Role of parametric representations, interpretation of derivatives in mechanics, completion of the discussion of the foundations of differential–geometric curve theory.

Main Content, Important Concepts

Parametric representation (1)

Orientation of a curve

Circle, ellipse, straight line, helix

Tangent vector (7), unit tangent vector (8), tangent (9)

Length (10), arc length (11)

Arc length as parameter [cf. (14)]

Velocity, acceleration (16)–(19)

Centripetal acceleration, Coriolis acceleration

Curvature, torsion, Frenet formulas (Prob. 50)

Short Courses. This section can be omitted.

Comment on Problems 26–28

These involve only integrals that are simple (which is generally not the case in connection with lengths of curves).

im09.qxd 9/21/05 12:15 PM Page 181

SOLUTIONS TO PROBLEM SET 9.5, page 398

2. $\mathbf{r}(t) = [5 + 3t, \quad 1 + t, \quad 2 - t]$

4. $\mathbf{r}(t) = [t, \quad 3 + 2t, \quad 7t]$

6. $\mathbf{r}(t) = [\cos t, \quad \sin t, \quad \sin t]$

8. Direction of the line of intersection $[1, 1, -1] \times [2, -5, 1] = [-4, -3, -7]$. Point of intersection with the xy-plane $z = 0$ from $x + y = 2$, $2x - 5y = 3$; thus $x = 13/7$, $y = 1/7$. Hence a parametric representation is

$$\mathbf{r}(t) = \left[\tfrac{13}{7} - 4t, \quad \tfrac{1}{7} - 3t, \quad -7t\right].$$

10. Helix $[3 \cos t, \quad 3 \sin t, \quad 4t]$

12. Straight line through $(4, 0, -3)$ in the direction of $[-2, \quad 8, \quad 5]$

14. Space curve with projections $y = x^2$, $z = x^3$ into the xy- and xz-coordinate planes, similar to the curve in Fig. 210.

16. Hyperbola $x^2 - y^2 = 1$, $z = 0$

18. $x = 1$, $(y - 5)(z + 5) = 1$; hyperbola

20. No, because the exponential function $e^{\tilde{t}}$ is nonnegative.

22. $\mathbf{r}' = [1, 2t, 0]$, $\mathbf{u} = (1 + 4t^2)^{-1/2}[1, 2t, 0]$, $\mathbf{q} = [2 + w, \quad 4 + 4w, \quad 0]$

24. $\mathbf{r}'(t) = [-3 \sin t, \quad 3 \cos t, \quad 4]$, $\mathbf{u} = [-0.6 \sin t, \quad 0.6 \cos t, \quad 0.8]$, $\mathbf{q} = [3, \quad 3w, \quad 8\pi + 4w]$

26. $t = 4\pi$, $\mathbf{r}' = [-2 \sin t, \quad 2 \cos t, \quad 6]$, $\sqrt{\mathbf{r}' \bullet \mathbf{r}'} = \sqrt{40}$, $\ell = 4\pi\sqrt{40}$

28. $\mathbf{r}' = [-3a \cos^2 t \sin t, \quad 3a \sin^2 t \cos t]$. Taking the dot product and applying trigonometric simplification gives

$$\begin{aligned}\mathbf{r}' \bullet \mathbf{r}' &= 9a^2 \cos^4 t \sin^2 t + 9a^2 \sin^4 t \cos^2 t \\ &= 9a^2 \cos^2 t \sin^2 t \\ &= \frac{9a^2}{4} \sin^2 2t.\end{aligned}$$

From this we obtain as the length in the first quadrant

$$\ell = \frac{3}{2} a \int_0^{\pi/2} \sin 2t \, dt = -\frac{3a}{4} (\cos \pi - \cos 0) = \frac{3a}{2}. \qquad \textit{Answer: } 6a$$

30. We obtain

$$\begin{aligned}ds^2 &= dx^2 + dy^2 \\ &= (d\rho \cos \theta - \rho \sin \theta \, d\theta)^2 + (d\rho \sin \theta + \rho \cos \theta \, d\theta)^2 \\ &= d\rho^2 + \rho^2 \, d\theta^2 \\ &= (\rho'^2 + \rho^2) \, d\theta^2.\end{aligned}$$

For the cardioid,

$$\begin{aligned}\rho^2 + \rho'^2 &= a^2(1 - \cos \theta)^2 + a^2 \sin^2 \theta \\ &= 2a^2(1 - \cos \theta) \\ &= 4a^2 \sin^2 \tfrac{1}{2}\theta\end{aligned}$$

so that

$$\ell = 2a \int_0^{2\pi} \sin \tfrac{1}{2}\theta \, d\theta = 8a.$$

im09.qxd 9/21/05 12:15 PM Page 182

32. $\mathbf{v} = \mathbf{r}' = [4, \quad -3, \quad 0]$, $|\mathbf{v}| = 5$, $\mathbf{a} = \mathbf{0}$

34. $\mathbf{v} = \mathbf{r}' = [-\sin t, \quad 2\cos t, \quad 0]$, $|\mathbf{v}| = (\sin^2 t + 4\cos^2 t)^{1/2}$, $\mathbf{a} = [-\cos t, \quad -2\sin t, \quad 0]$. Hence the tangential acceleration is

$$\mathbf{a}_{\tan} = \frac{-3 \sin t \cos t}{\sin^2 t + 4 \cos^2 t} [-\sin t, \quad 2\cos t, \quad 0]$$

and has the magnitude $|\mathbf{a}_{\tan}|$, where

$$|\mathbf{a}_{\tan}|^2 = \frac{9 \sin^2 t \cos^2 t}{\sin^2 t + 4 \cos^2 t}.$$

36. CAS Project. (a) $\mathbf{v} = [-2\sin t - 2\sin 2t, \quad 2\cos t - 2\cos 2t]$. From this we obtain $|\mathbf{v}|^2 = \mathbf{v} \bullet \mathbf{v} = (-2\sin t - 2\sin 2t)^2 + (2\cos t - 2\cos 2t)^2$. Performing the squares and simplifying gives

$$\begin{aligned} |\mathbf{v}|^2 &= 8(1 + \sin t \sin 2t - \cos t \cos 2t) \\ &= 8(1 - \cos 3t) \\ &= 16 \sin^2 \frac{3t}{2}. \end{aligned}$$

Hence

$$|\mathbf{v}| = 4 \sin \frac{3t}{2}.$$

$$\mathbf{a} = [-2\cos t - 4\cos 2t, \quad -2\sin t + 4\sin 2t].$$

We use (18*). By straightforward simplification (four terms cancel),

$$\begin{aligned} \mathbf{a} \bullet \mathbf{v} &= 12(\cos t \sin 2t + \sin t \cos 2t) \\ &= 12 \sin 3t. \end{aligned}$$

Hence (18*) gives

$$\mathbf{a}_{\tan} = \frac{12 \sin 3t}{16 \sin^2 (3t/2)} \mathbf{v}$$

$$\mathbf{a}_{\text{norm}} = \mathbf{a} - \mathbf{a}_{\tan}.$$

(b) $\mathbf{v} = [-\sin t - 2\sin 2t, \quad \cos t - 2\cos 2t]$

$$|\mathbf{v}|^2 = 5 - 4\cos 3t$$

$$\mathbf{a} = [-\cos t - 4\cos 2t, \quad -\sin t + 4\sin 2t]$$

$$\mathbf{a}_{\tan} = \frac{6 \sin 3t}{5 - 4\cos 3t} [-\sin t - 2\sin 2t, \quad \cos t - 2\cos 2t]$$

$$\mathbf{a}_{\text{norm}} = \mathbf{a} - \mathbf{a}_{\tan}$$

(c) $\mathbf{v} = [-\sin t, \quad 2\cos 2t, \quad -2\sin 2t]$

$$|\mathbf{v}|^2 = 4 + \sin^2 t$$

$$\mathbf{a} = [-\cos t, \quad -4\sin 2t, \quad -4\cos 2t]$$

$$\mathbf{a}_{\tan} = \frac{\frac{1}{2} \sin 2t}{4 + \sin^2 t} [-\sin t, \quad 2\cos 2t, \quad -2\sin 2t]$$

$$\mathbf{a}_{\text{norm}} = \mathbf{a} - \mathbf{a}_{\tan}$$

im09.qxd 9/21/05 12:15 PM Page 183

(d) $\mathbf{v} = [c\cos t - ct\sin t, \quad c\sin t + ct\cos t, \quad c]$

$$|\mathbf{v}|^2 = c^2(t^2+2)$$

$$\mathbf{a} = [-2c\sin t - ct\cos t, \quad 2c\cos t - ct\sin t, \quad 0]$$

$$\mathbf{a}_{\tan} = \frac{ct}{t^2+2}\,[\cos t - t\sin t, \quad \sin t + t\cos t, \quad 1]$$

$$\mathbf{a}_{\text{norm}} = \mathbf{a} - \mathbf{a}_{\tan}$$

This is a spiral on a cone.

38. $\mathbf{R} = 3.85\cdot 10^8$ m, $|\mathbf{v}| = 2\pi R/(2.36\cdot 10^6) = 1025$ [m/sec], $|\mathbf{v}| = \omega R$, $|\mathbf{a}| = \omega^2 R = |\mathbf{v}|^2/R = 0.0027$ [m/sec^2], which is only $2.8\cdot 10^{-4}\,g$, where g is the acceleration due to gravity at the earth's surface.

40. $R = 3960 + 450 = 4410$ [mi], $2\pi R = 100|\mathbf{v}|$, $|\mathbf{v}| = 277.1$ mi/min,

$$g = |\mathbf{a}| = \omega^2 R = |\mathbf{v}|^2/R = 17.41 \text{ [mi/min}^2\text{]} = 25.53 \text{ [ft/sec}^2\text{]} = 7.78 \text{ [m/sec}^2\text{]}.$$

Here we used $|\mathbf{v}| = \omega R$.

42. We denote derivatives with respect to t by primes. In (22),

$$\mathbf{u} = \frac{d\mathbf{r}}{ds} = \mathbf{r}'\,\frac{dt}{ds}, \qquad \frac{dt}{ds} = \frac{1}{s'} = (\mathbf{r}'\bullet\mathbf{r}')^{-1/2}. \qquad \text{[See (12).]}$$

Thus in (22),

$$\frac{d\mathbf{u}}{ds} = \mathbf{r}''\left(\frac{dt}{ds}\right)^2 + \mathbf{r}'\,\frac{d^2t}{ds^2} = \mathbf{r}''(\mathbf{r}'\bullet\mathbf{r}')^{-1} + \mathbf{r}'\,\frac{d^2t}{ds^2}$$

where

$$\frac{d^2t}{ds^2} = \frac{d}{dt}\left(\frac{dt}{ds}\right)\frac{dt}{ds} = -\tfrac{1}{2}(\mathbf{r}'\bullet\mathbf{r}')^{-3/2}\,2(\mathbf{r}''\bullet\mathbf{r}')(\mathbf{r}'\bullet\mathbf{r}')^{-1/2}$$

$$= -(\mathbf{r}''\bullet\mathbf{r}')(\mathbf{r}'\bullet\mathbf{r}')^{-2}.$$

Hence

$$\frac{d\mathbf{u}}{ds} = \mathbf{r}''(\mathbf{r}'\bullet\mathbf{r}')^{-1} - \mathbf{r}'(\mathbf{r}''\bullet\mathbf{r}')(\mathbf{r}'\bullet\mathbf{r}')^{-2}$$

$$\frac{d\mathbf{u}}{ds}\bullet\frac{d\mathbf{u}}{ds} = (\mathbf{r}''\bullet\mathbf{r}'')(\mathbf{r}'\bullet\mathbf{r}')^{-2} - 2(\mathbf{r}''\bullet\mathbf{r}')^2(\mathbf{r}'\bullet\mathbf{r}')^{-3} + (\mathbf{r}'\bullet\mathbf{r}')^{-3}(\mathbf{r}''\bullet\mathbf{r}')^2$$

$$= (\mathbf{r}''\bullet\mathbf{r}'')(\mathbf{r}'\bullet\mathbf{r}')^{-2} - (\mathbf{r}''\bullet\mathbf{r}')^2(\mathbf{r}'\bullet\mathbf{r}')^{-3}.$$

Taking square roots, we get (22*).

44. $\tau = -\mathbf{p}\bullet(\mathbf{u}\times\mathbf{p})' = -\mathbf{p}\bullet(\mathbf{u}'\times\mathbf{p} + \mathbf{u}\times\mathbf{p}') = 0 - (\mathbf{p}\ \ \mathbf{u}\ \ \mathbf{p}') = +(\mathbf{u}\ \ \mathbf{p}\ \ \mathbf{p}')$**.** Now $\mathbf{u} = \mathbf{r}'$**,** $\mathbf{p} = (1/\kappa)\mathbf{r}''$**;** hence $\mathbf{p}' = (1/\kappa)\mathbf{r}''' + (1/\kappa)'\mathbf{r}''$. Inserting this into the triple product (the determinant), we can simplify the determinant by familiar rules and let the last term in $\mathbf{p}'$ disappear. Pulling out $1/\kappa$ from both $\mathbf{p}$ and $\mathbf{p}'$, we obtain the second formula in (23**).

46. $$\frac{d\mathbf{r}}{ds} = \frac{d\mathbf{r}}{dt}\Big/\frac{ds}{dt}, \qquad \frac{d^2\mathbf{r}}{ds^2} = \frac{d^2\mathbf{r}}{dt^2}\Big/\left(\frac{ds}{dt}\right)^2 + \cdots,$$

$$\frac{d^3\mathbf{r}}{ds^3} = \frac{d^3\mathbf{r}}{dt^3}\Big/\left(\frac{ds}{dt}\right)^3 + \cdots$$

im09.qxd 9/21/05 12:15 PM Page 184

where the dots denote terms that vanish by applying familiar rules for simplifying determinants; thus

$$\tau = \frac{1}{\kappa^2}\left(\frac{d\mathbf{r}}{ds} \quad \frac{d^2\mathbf{r}}{ds^2} \quad \frac{d^3\mathbf{r}}{ds^3}\right) = \frac{1}{\kappa^2(ds/dt)^6}\left(\frac{d\mathbf{r}}{dt} \quad \frac{d^2\mathbf{r}}{dt^2} \quad \frac{d^3\mathbf{r}}{dt^3}\right).$$

Now use (22*) and (12).

48. From $\mathbf{r}(t) = [a\cos t, \quad a\sin t, \quad ct]$ we obtain

$$\mathbf{r}' = [-a\sin t, \quad a\cos t, \quad c], \qquad \mathbf{r}'\bullet\mathbf{r}' = a^2 + c^2 = K^2.$$

Hence by integration, $s = Kt$. Consequently, $t = s/K$. This gives the indicated representation of the helix with arc length s as parameter. Denoting derivatives with respect to s also by primes, we obtain

$$\mathbf{r}(s) = \left[a\cos\frac{s}{K}, \quad a\sin\frac{s}{K}, \quad \frac{cs}{K}\right], \qquad K^2 = a^2 + c^2$$

$$\mathbf{u}(s) = \mathbf{r}'(s) = \left[-\frac{a}{K}\sin\frac{s}{K}, \quad \frac{a}{K}\cos\frac{s}{K}, \quad \frac{c}{K}\right]$$

$$\mathbf{r}''(s) = \left[-\frac{a}{K^2}\cos\frac{s}{K}, \quad -\frac{a}{K^2}\sin\frac{s}{K}, \quad 0\right]$$

$$\kappa(s) = |\mathbf{r}''| = \sqrt{\mathbf{r}''\bullet\mathbf{r}''} = \frac{a}{K^2} = \frac{a}{a^2 + c^2}$$

$$\mathbf{p}(s) = \frac{1}{\kappa(s)}\mathbf{r}''(s) = \left[-\cos\frac{s}{K}, \quad -\sin\frac{s}{K}, \quad 0\right]$$

$$\mathbf{b}(s) = \mathbf{u}(s) \times \mathbf{p}(s) = \left[\frac{c}{K}\sin\frac{s}{K}, \quad -\frac{c}{K}\cos\frac{s}{K}, \quad \frac{a}{K}\right]$$

$$\mathbf{b}'(s) = \left[\frac{c}{K^2}\cos\frac{s}{K}, \quad \frac{c}{K^2}\sin\frac{s}{K}, \quad 0\right]$$

$$\tau(s) = -\mathbf{p}(s)\bullet\mathbf{b}'(s) = \frac{c}{K^2} = \frac{c}{a^2 + c^2}.$$

Positive c gives a right-handed helix and positive torsion; negative c gives a left-handed helix and negative torsion.

50. $\mathbf{p}' = (1/\kappa)\mathbf{u}'$ implies the first formula, $\mathbf{u}' = \kappa\mathbf{p}$**.** The third Frenet formula was given in the text before (23). To obtain the second Frenet formula, use

$$\mathbf{p}' = (\mathbf{b} \times \mathbf{u})' = \mathbf{b}' \times \mathbf{u} + \mathbf{b} \times \mathbf{u}' = -\tau\,\mathbf{p} \times \mathbf{u} + \mathbf{b} \times \kappa\mathbf{p} = +\tau\mathbf{b} - \kappa\mathbf{u}.$$

In differential geometry (see Ref. [GR8] in App. 1) it is shown that the whole differential–geometric theory of curves can be obtained from the Frenet formulas, whose solution shows that the **"natural equations"** $\kappa = \kappa(s)$, $\tau = \tau(s)$ determine a curve uniquely, except for its position in space.

SECTION 9.6. Calculus Review: Functions of Several Variables. *Optional,* page 400

Purpose. To give students a handy reference and some help on material known from calculus that they will need in their further work.

im09.qxd 9/21/05 12:15 PM Page 185

SOLUTIONS TO PROBLEM SET 9.6, page 403

2. $w' = (h/g)' = (h'g - g'h)/g^2$

4. $x' = -2 \sin t, \quad y' = 2 \cos t, z' = 5$, so that by the chain rule

$$\begin{aligned} w' &= (y + z)(-2 \sin t) + (z + x)\, 2 \cos t + (x + y) \cdot 5 \\ &= (2 \sin t + 5t)(-2 \sin t) + (2 \cos t + 5t)\, 2 \cos t \\ &\qquad + (2 \cos t + 2 \sin t) \cdot 5 \\ &= 4 \cos 2t + 10[(t + 1) \cos t + (-t + 1) \sin t]. \end{aligned}$$

6. $\partial w/\partial u = -24u + 32v, \quad \partial w/\partial v = 32u + 24v$

8. $\partial w/\partial u = 4u^3(v^4 - 4 + v^{-4}), \quad \partial w/\partial v = 4u^4(v^3 - v^{-5})$

10. This follows from (1). *Answer:*

$$\partial \tilde{w}/\partial x = 3x^2 + 2(x^2 + y^2)2x, \qquad \partial \tilde{w}/\partial y = 3y^2 + 2(x^2 + y^2)2y.$$

SECTION 9.7. Gradient of a Scalar Field. Directional Derivative, page 403

Purpose. To discuss gradients and their role in connection with directional derivatives, surface normals, and the generation of vector fields from scalar fields (potentials).

Main Content, Important Concepts

Gradient, nabla operator

Directional derivative, maximum increase, surface normal

Vector fields as gradients of potentials

Laplace's equation

Comments on Content

This is probably the first section in which one should no longer rely on knowledge from calculus, although relatively elementary calculus books usually include a passage on gradients.

Potentials are important; they will occur at a number of places in our further work.

SOLUTIONS TO PROBLEM SET 9.7, page 409

2. $\nabla f = \left[2x, \quad \frac{2}{9}y\right]$

4. $\nabla f = \left[4x^3, \quad 4y^3\right]$

6. $\nabla f = [2x - 6, \quad 2y - 2]$

8. $\mathbf{v} = \nabla f = (x^2 + y^2)^{-1}[2x, \quad 2y], \quad \mathbf{v}(P) = [0.32, \quad 0.24]$

10. $\mathbf{v} = \nabla f = [2x, \quad 8y, \quad 18z], \quad \mathbf{v}(P) = [6, \quad 16, \quad 18]$

12. $\mathbf{v} = \nabla f = (x^2 + y^2 + z^2)^{-3/2}[-x, \quad -y, \quad -z], \quad \mathbf{v}(P) = [-2/27, \quad -1/27, \quad -2/27]$

14. $\nabla T = (x^2 + y^2)^{-1}[-y, \quad x], -\nabla T(P) = [0.25, \quad -0.25]$

16. $\nabla T = (x^2 + y^2)^{-2}[y^2 - x^2, \quad -2xy], -\nabla T(P) = [1/16, \quad 0]$

18. $\nabla T = [\cos x \cosh y, \quad \sin x \sinh y], -\nabla T(P) = \left[-2.6/\sqrt{2}, \quad -2.4/\sqrt{2}\right]$

20. $\nabla f = (x^2 + y^2)^{-2}\left[-2xy, \quad x^2 - y^2\right], \nabla f(P) = [-15/578, \quad 4/289]$

22. $\nabla f = (x^2 + y^2)^{-1}[2x, \quad 2y], \nabla f(P) = [1/3, \quad 1/3]$

24. $\nabla f = \left[2xy, \quad x^2 - y^2\right], \nabla f(P) = [12, \quad -5]$

26. $\nabla z = [-8x, \quad -2y], \nabla z(P) = [-24, \quad 12]$. Hence a vector in the direction of steepest ascent is $[-2, \quad 1]$, for instance.

im09.qxd 9/21/05 12:15 PM Page 186

28. A normal vector is $[2x, \quad 6y, \quad 2z]$. Its value at P is $[8, \quad 6, \quad 6]$.

30. A normal vector is $[2x, \quad -2y, \quad 8z]$. Its value at P is $[-4, \quad -2, \quad 32]$.

32. A normal vector is $[-2x, \quad -2y, \quad 1]$. Its value at P is $[-6, \quad -8, \quad 1]$.

34. $\nabla f = [2x, \quad 2y, \quad 2z]$, $\nabla f(P) = [4, \quad -4, \quad 2]$, $\nabla f(P) \bullet \mathbf{a} = 0$. This shows that $\mathbf{a}$ is tangent to the level surface $f(x, y, z) = 9$ through P.

36. $\nabla f = -(x^2 + y^2 + z^2)^{-3/2}[x, \quad y, \quad z]$, $\nabla f(P) = -(1/216)[4, \quad 2, \quad -4]$. Hence the directional derivative is

$$-(1/216)[1, \quad 2, \quad -2] \bullet [4, \quad 2, \quad -4]/3 = -2/81 = -0.02469.$$

38. $\nabla f = [8x, \quad 2y, \quad 18z]$, $\nabla f(P) = [16, \quad 8, \quad 0]$. Hence the directional derivative is

$$[16, \quad 8, \quad 0] \bullet [-2, \quad -4, \quad 3]/\sqrt{29} = -64/\sqrt{29} = -11.88.$$

40. $f = ye^x + z^2$

42. Project. The first formula follows from

$$[(fg)_x, \quad (fg)_y, \quad (fg)_z] = [f_x g, \quad f_y g, \quad f_z g] + [fg_x, \quad fg_y, \quad fg_z].$$

The second formula follows by the chain rule, and the third follows by applying the quotient rule to each of the components $(f/g)_x$, $(f/g)_y$, $(f/g)_z$ and suitably collecting terms. The last formula follows by two applications of the product rule to each of the three terms of ∇^2.

SECTION 9.8. Divergence of a Vector Field, page 410

Purpose. To explain the divergence (the second of the three concepts grad, div, curl) and its physical meaning in fluid flows.

Main Content, Important Concepts

Divergence of a vector field

Continuity equations (5), (6)

Incompressibility condition (7)

Comment on Content

The interpretation of the divergence in Example 2 depends essentially on our assumption that there are no sources or sinks in the box. From our calculations it becomes plausible that in the case of sources or sinks the divergence may be related to the net flow across the boundary surfaces of the box. To confirm this and to make it precise we need integrals; we shall do this in Sec. 10.8 (in connection with Gauss's divergence theorem).

Moving div and curl to Chap. 10?

Experimentation has shown that this would perhaps not be a good idea, simply because it would combine two substantial difficulties, that of understanding div and curl themselves, and that of understanding the nature and role of the two basic integral theorems by Gauss and Stokes, in which div and curl play the key role.

SOLUTIONS TO PROBLEM SET 9.8, page 413

2. $\operatorname{div} \mathbf{v} = 4e^{2x} \cos 2y + 10e^{2z}$

4. $\operatorname{div} \mathbf{v} = 0$

6. $\operatorname{div} \mathbf{v} = 0$. This follows immediately by noting that v_1, v_2, v_3 does not depend on x, y, z, respectively.

im09.qxd 9/21/05 12:15 PM Page 187

8. div $\mathbf{v} = 2 + \dfrac{\partial v_3}{\partial z}$. Of course, there are many ways of satisfying the conditions. For instance, (a) $v_3 = 0$, (b) $v_3 = -z - \frac{1}{3}z^3$. The point of the problem is that the student gets used to the definition of the divergence and recognizes that div $\mathbf{v}$ can have different values and also the sign can differ in different regions of space.

10. $\mathbf{v} = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k} = \dfrac{dx}{dt}\,\mathbf{i} + \dfrac{dy}{dt}\,\mathbf{j} + \dfrac{dz}{dt}\,\mathbf{k} = x\mathbf{i}$**.** Hence div $\mathbf{v} = 1$, and

$$\frac{dx}{dt} = x, \qquad \frac{dy}{dt} = 0, \qquad \frac{dz}{dt} = 0.$$

By integration, $x = c_1e^t$, $y = c_2$, $z = c_3$, and $\mathbf{r} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$**.** Hence

$$\mathbf{r}(0) = c_1\mathbf{i} + c_2\mathbf{j} + c_3\mathbf{k} \qquad \text{and} \qquad \mathbf{r}(1) = c_1e\mathbf{i} + c_2\mathbf{j} + c_3\mathbf{k}.$$

This shows that the cube in Prob. 9 is now transformed into the rectangular parallelepiped bounded by $x = 0$, $x = e$, $y = 0$, $y = 1$, $z = 0$, $z = 1$, whose volume is e.

12. **(a)** Parallel flow

(b) Outflow on the left and right, no flow across the other sides; hence div $\mathbf{v} > 0$.

(c) Outflow left and right, inflow from above and below, balance perhaps zero; by calculation, div $\mathbf{v} = 0$. Etc.

14. $6xy/z^4$

16. $-4/\sqrt{x^2 + y^2}$ by straightforward simplification

18. 0

20. $2(\sin^2 x - \cos^2 x - \cos^2 y + \sin^2 y) = -2(\cos 2x + \cos 2y)$

SECTION 9.9. Curl of Vector Field, page 414

Purpose

We introduce the curl of a vector field (the last of the three concepts grad, div, curl) and interpret it in connection with rotations (Example 2 and Theorem 1). A main application of the curl follows in Sec. 10.9 in Stokes's integral theorem.

Experience has shown that it is generally didactically preferable to defer Stokes's theorem to a later section and first to give the student a feel for the curl independent of an integral theorem.

Main Content

Definition of the curl (1)

Curl and rotations (Theorem 1)

Gradient fields are irrotational (Theorem 2)

Irrotational fields, conservative fields

SOLUTIONS TO PROBLEM SET 9.9, page 416

2. $-n\left[z^{n-1}, \quad x^{n-1}, \quad y^{n-1}\right]$

4. curl $\mathbf{v} = \mathbf{0}$**.** Recall from Theorem 3 in Sec. 9.7 with $\mathbf{r}_0 = \mathbf{0}$ and $x^2 + y^2 + z^2 = r^2$ that the present vector field is a gradient field, so that we must have curl $\mathbf{v} = \mathbf{0}$**.**

im09.qxd 9/21/05 12:15 PM Page 188

6. curl $\mathbf{v} = [\sin z, \quad \tan^2 x + 1, \quad -\cos y]$

8. A proof follows by calculation directly from the definitions.

10. curl $\mathbf{v} = [0, 0, 2y]$, div $\mathbf{v} = 0$, incompressible; paths are obtained as follows. We have

$$\mathbf{v} = \mathbf{r}' = [x', \quad y', \quad z'] = [-y^2, \quad 4, \quad 0].$$

Equating components gives

$$z' = 0, \qquad z = c_3, \qquad y' = 4, \qquad y = 4t + c_2, \qquad x' = -y^2$$

and by substitution of y

$$x' = -(4t + c_2)^2; \qquad \text{hence} \qquad x = -\tfrac{1}{12}(4t + c_2)^3 + c_1.$$

12. curl $\mathbf{v} = [0, \quad 0, \quad \sec x \tan x]$, div $\mathbf{v} = -\csc x \cot x$. The paths are obtained from

$$\mathbf{v} = [x', \quad y', \quad z'] = [\csc x, \quad \sec x, \quad 0].$$

Equating the first components gives

$$x' = \csc x, \qquad \sin x\, dx = dt, \qquad -\cos x = t - c_1;$$

hence $x = -\arccos(t - c_1)$.

By comparing the second components we obtain

$$y' = \sec x = \frac{1}{\cos x} = \frac{1}{c_1 - t}, \qquad y = -\ln(c_1 - t) + c_2.$$

Finally, for the third components we have $z' = 0$, $z = c_3$. Our solution contains enough arbitrary constants to accommodate individual particles with a corresponding path.

14. curl $\mathbf{v} = [0, \quad 0, \quad -3x^2 - 3y^2]$, div $\mathbf{v} = 0$, incompressible. The paths are obtained by the following calculation.

$$x' = y^3, \qquad y' = -x^3, \qquad x^3\, dx + y^3\, dy = 0,$$
$$x^4 + y^4 = c, \qquad z = c_3.$$

Each of these closed curves lies in the plane $z = c_3$ between the square of side $2c^{1/4}$ symmetrically located with respect to the origin and the circle of radius $c^{1/4}$ and center $[0, \quad 0, \quad c_3]$.

16. Project. Parts (b) and (d) are basic. They follow from the definitions by direct calculation. Part (a) follows by decomposing each component accordingly.

(c) In the first component in (1) we now have fv_3 instead of v_3, etc. Product differentiation gives $(fv_3)_y = f_y v_3 + f \cdot (v_3)_y$. Similarly for the other five terms in the components. $f_y v_3$ and the corresponding five terms give (grad f) $\times$ $\mathbf{v}$ and the other six terms $f \cdot (v_3)_y$, etc. give f curl **v.**

(d) For twice continuously differentiable f the mixed second derivatives are equal, so that the result follows from $\nabla f = f_x\mathbf{i} + f_y\mathbf{j} + f_z\mathbf{k}$ and (1), which gives

$$\text{curl}(\nabla f) = [(f_z)_y - (f_y)_z]\mathbf{i} + [(f_x)_z - (f_z)_x]\mathbf{j} + [(f_y)_x - (f_x)_y]\mathbf{k}.$$

(e) Write out and compare the twelve terms on either side.

18. curl $(f\mathbf{u}) = [x^3z - 3xyz^2, \quad xy^3 - 3x^2yz, \quad yz^3 - 3xy^2z]$

curl $(g\mathbf{u}) = [x^2 - 3z^2 - 2zx - 2yz, \quad y^2 - 3x^2 - 2xy - 2zx,$
$z^2 - 3y^2 - 2xy - 2yz]$

20. curl $(\mathbf{u} \times \mathbf{v}) = [2xyz - z^3 - x^2y, \quad 2xyz - x^3 - y^2z, \quad 2xyz - y^3 - z^2x]$. Furthermore,

curl $(\mathbf{v} \times \mathbf{u}) = -$curl $(\mathbf{u} \times \mathbf{v})$.

im09.qxd 9/21/05 12:15 PM Page 189

SOLUTIONS TO CHAP. 9 REVIEW QUESTIONS AND PROBLEMS, page 416

12. 0 (orthogonal), 19, $[-56, 7, 22]$

14. 744, 744, 744, 77

16. 389, 389, 389. Of course, the third expression is just the usual notation for the scalar triple product, and the first two expressions justify such a notation that does not indicate where the dot and the cross is being used because it does not matter.

18. Unit vectors $(1/\sqrt{62})[3, \quad 2, \quad 7]$, $(1/\sqrt{65})[1, \quad 8, \quad 0]$

20. $0.90 = \left|\sqrt{62} - \sqrt{77}\right| < 11.79 = \sqrt{139} < 16.65 = \sqrt{62} + \sqrt{77}$. This illustrates the triangle inequality (Sec. 9.2) and consequences of it.

22. $\cos \gamma = [4, \quad 3, \quad -1] \bullet [1, \quad 1, \quad 1]/\sqrt{26 \cdot 3} = 6/\sqrt{26 \cdot 3} = 0.6794$, $\gamma = 47.2°$

24. $[-19, \quad -13, \quad -3]$, the negative of the sum of those vectors

26. $\mathbf{q} \bullet [2, \quad -5, \quad 0] = 5$

28. See Prob. 41 in Problem Set 9.2.

30. $\mathbf{m} = \mathbf{r} \times \mathbf{p} = [-4, 3, 0] \times [4, 2, 0] = [0, 0, -20]$. The moment has the tendency to produce a clockwise rotation.

32. $\mathbf{v} = \mathbf{r}' = [-5 \sin t, \quad \cos t, \quad 2]$, where $t = \frac{1}{4}\pi$, so that

$$\mathbf{v}(P) = \mathbf{r}'(P) = \left[-5/\sqrt{2}, \quad 1/\sqrt{2}, \quad 2\right], \qquad \left|\mathbf{v}(P)\right| = \sqrt{17},$$

and for the acceleration we obtain

$$\mathbf{a} = \mathbf{v}' = [-5 \cos t, \quad -\sin t, \quad 0]$$
$$\mathbf{a}(P) = \left[-5/\sqrt{2}, \quad -1/\sqrt{2}, \quad 0\right].$$

The curve is a helix on an elliptic cylinder.

34. Vectors in the plane are

$$[2 - 1, \quad 3 - 0, \quad 5 - 2] = [1, \quad 3, \quad 3]$$

and

$$[3 - 1, \quad 5 - 0, \quad 7 - 2] = [2, \quad 5, \quad 5].$$

Their vector product is $[0, 1, -1]$. This is a normal vector of the plane. Hence an equation of the plane is $y - z = c$, and by substituting the coordinates of any of the three points we see that $c = -2$. *Answer:* $z = y + 2$

36. grad $f = [y, z + x, y]$. At P it has the value $[4, 3, 4]$. Hence f grad f has at P the value $[48, \quad 36, \quad 48]$.

38. 4, 0

40. **0,** 0

42. We obtain

$$\frac{1}{\sqrt{x^4 + y^4 + z^4}} \left[y^2, z^2, x^2\right] \bullet [y, \quad z + x, \quad y]$$

$$= \frac{1}{\sqrt{x^4 + y^4 + z^4}} (y^3 + z^3 + z^2x + x^2y).$$

At $(1, 2, 0)$ this gives the value $10/\sqrt{17}$.

44. We obtain

$$\begin{aligned} \operatorname{div}(\mathbf{v} \times \mathbf{w}) &= \operatorname{div}\left(\left[zx^2 - (4z - x)z^2, \qquad (4z - x)y^2 - yx^2, \qquad yz^2 - zy^2\right]\right) \\ &= 2zx + z^2 + 8yz + 2zy - 2xy - x^2 - y^2. \end{aligned}$$

im10.qxd 9/21/05 12:49 PM Page 190

CHAPTER 10 Vector Integral Calculus. Integral Theorems

SECTION 10.1. Line Integrals, page 420

Purpose. To explain line integrals in space and in the plane conceptually and technically with regard to their evaluation by using the representation of the path of integration.

Main Content, Important Concepts

Line integral (3), (3′), its evaluation

Its motivation by work done by a force ("work integral")

General properties (5)

Dependence on path (Theorem 2)

Background Material. Parametric representation of curves (Sec. 9.5); a couple of review problems may be useful.

Comments on Content

The integral (3) is more practical than (8) (more direct in view of subsequent material), and work done by a force motivates it sufficiently well.

Independence of path is settled in the next section.

SOLUTIONS TO PROBLEM SET 10.1, page 425

2. $\mathbf{r}(t) = [t, \quad 10t, \quad 0]$, $0 \leqq t \leqq 2$, $\mathbf{r}' = [1, \quad 10, \quad 0]$, $\mathbf{F}(\mathbf{r}(t)) = [1000t^3, \quad t^3, \quad 0]$. Hence the integral is

$$\int_0^2 1010t^3 \, dt = 4040.$$

The path of integration is shorter than that in Prob. 1, but the value of the integral is greater. This is not unusual.

4. $\mathbf{r} = [2 \cos t, \quad 2 \sin t, \quad 0]$, $0 \leqq t \leqq \pi$, $\mathbf{r}' = [-2 \sin t, \quad 2 \cos t]$. Hence $\mathbf{F}(\mathbf{r}(t)) = [4 \cos^2 t, \quad 4 \sin^2 t, \quad 0]$. This gives the integral

$$\int_0^\pi (-8 \cos^2 t \sin t + 8 \sin^2 t \cos t) \, dt = -\tfrac{16}{3} + 0.$$

6. Clockwise integration is requested, so that we take, say, $\mathbf{r} = [\cos t, \quad -\sin t]$, $0 \leqq t \leqq \frac{1}{2}\pi$. By differentiation, $\mathbf{r}' = [-\sin t, \quad -\cos t]$. Hence

$$\mathbf{F}(\mathbf{r}(t)) = \left[e^{\cos t}, \quad e^{-\sin t}\right],$$

and the integral is

$$\int_0^{\pi/2} (-e^{\cos t} \sin t - e^{-\sin t} \cos t) \, dt = \left[e^{\cos t} + e^{-\sin t}\right]_0^{\pi/2}.$$

This gives the *answer* $-2 \sinh 1$.

8. $\mathbf{r} = \left[t, \quad t^2, \quad t^3\right]$, $0 \leqq t \leqq \frac{1}{2}$, $\mathbf{r}' = \left[1, \quad 2t, \quad 3t^2\right]$. Hence

$$\mathbf{F}(\mathbf{r}(t)) = \left[\cosh t, \quad \sinh t^2, \quad e^{t^3}\right].$$

im10.qxd 9/21/05 12:49 PM Page 191

This gives the integral

$$\int_0^{1/2} (\cosh t + 2t \sinh t^2 + 3t^2 e^{t^3})\, dt = \sinh \tfrac{1}{2} + \cosh \tfrac{1}{4} + e^{1/8} - 2 = 0.6857.$$

10. Here we integrate around a triangle in space. For the three sides and corresponding integrals we obtain

$$\mathbf{r}_1 = [t, \quad t, \quad 0], \quad \mathbf{r}_1' = [1, \quad 1, \quad 0], \quad \mathbf{F}(\mathbf{r}_1(t)) = [t, \quad 0, \quad 2t], \quad \int_0^1 t\, dt = \tfrac{1}{2}$$

$$\mathbf{r}_2 = [1, \quad 1, \quad t], \quad \mathbf{r}_2' = [0, \quad 0, \quad 1], \quad \mathbf{F}(\mathbf{r}_2(t)) = [1, \quad -t, \quad 2], \quad \int_0^1 2\, dt = 2$$

$$\mathbf{r}_3 = [1 - t, \quad 1 - t, \quad 1 - t], \quad \mathbf{r}_3' = [-1, -1, -1],$$

$$\mathbf{F}(\mathbf{r}_3(t)) = [1 - t, \quad -1 + t, \quad 2 - 2t], \quad \int_0^1 (-2 + 2t)\, dt = -2 + 1.$$

Hence the *answer* is 3/2.

12. $\mathbf{r} = [\cos t, \quad \sin t, \quad t]$, $\mathbf{r}' = [-\sin t, \quad \cos t, \quad 1]$. From $\mathbf{F} = \left[y^2, \quad x^2, \quad \cos^2 z\right]$ we obtain $\mathbf{F}(\mathbf{r}(t)) = \left[\sin^2 t, \quad \cos^2 t, \quad \cos^2 t\right]$. Hence the integral is

$$\int_0^{4\pi} (-\sin^3 t + \cos^3 t + \cos^2 t)\, dt = 0 + 0 + 2\pi = 2\pi.$$

14. Project. (a) $\mathbf{r} = [\cos t, \quad \sin t]$, $\mathbf{r}' = [-\sin t, \quad \cos t]$. From $\mathbf{F} = \left[xy, \quad -y^2\right]$ we obtain $\mathbf{F}(\mathbf{r}(t)) = \left[\cos t \sin t, \quad -\sin^2 t\right]$. Hence the integral is

$$-2 \int_0^{\pi/2} \cos t \sin^2 t\, dt = -\frac{2}{3}.$$

Setting $t = p^2$, we have $\mathbf{r} = \left[\cos p^2, \quad \sin p^2\right]$ and

$$\mathbf{F}(\mathbf{r}(p)) = \left[\cos p^2 \sin p^2, \quad -\sin^2 p^2\right].$$

Now $\mathbf{r}' = \left[-2p \sin p^2, \quad 2p \cos p^2\right]$, so that the integral is

$$\int_0^{\sqrt{\pi/2}} (-2p \cos p^2 \sin^2 p^2 - 2p \cos p^2 \sin^2 p^2)\, dp = -\tfrac{2}{3}.$$

(b) $\mathbf{r} = [t, \quad t^n]$, $\mathbf{F}(\mathbf{r}(t)) = [t^{n+1}, \quad -t^{2n}]$, $\mathbf{r}' = [1, \quad nt^{n-1}]$. The integral is

$$\int_0^1 (t^{n+1} - nt^{3n-1})\, dt = \frac{1}{n+2} - \frac{1}{3}.$$

(c) The limit is $-1/3$. The first portion of the path gives 0, since $y = 0$. The second portion is $\mathbf{r}_2 = [1, \quad t]$, so that $F(\mathbf{r}_2(t)) = [t, \quad -t^2]$, $\mathbf{r}' = [0, \quad 1]$. Hence the integrand is $-t^2$, which upon integration gives $-1/3$.

16. By integration,

$$\int_0^2 (1 - \sinh^2 t)\, dt = 2 - \int_0^2 \tfrac{1}{2}(\cosh 2t - 1)\, dt = 3 - \tfrac{1}{4} \sinh 4.$$

18. $\mathbf{F}(\mathbf{r}(t)) = [\cos t \sin t, \quad \tan t, \quad 0]$. Integration from 0 to $\pi/4$ gives the vector

$$\left[-\tfrac{1}{2} \cos^2 t, \quad -\ln \cos t, \quad 0\right]_0^{\pi/4} = \left[\tfrac{1}{4}, \quad \tfrac{1}{2} \ln 2, \quad 0\right].$$

im10.qxd 9/21/05 12:49 PM Page 192

20. $\mathbf{r} = \left[t, \frac{4}{3}t\right]$, $0 \leqq t \leqq 3$, $L = 5$, $|\mathbf{F}| = \sqrt{t^4 + \frac{16}{9}t^2}$. The derivative is

$$\tfrac{1}{2}\left[t^4 + \tfrac{16}{9}t^2\right]^{-1/2}(4t^3 + \tfrac{32}{9}t).$$

The expression in parentheses $(\cdots)$ has the root $t = 0$, but no further real roots. Hence the maximum of $|\mathbf{F}|$ is taken at (3, 4), so that we obtain the bound

$$L|\mathbf{F}| \leqq 5\sqrt{81 + 16} = 5\sqrt{97} < 50.$$

Calculation gives $\mathbf{r}' = \left[1, \frac{4}{3}\right]$, $\mathbf{F}(\mathbf{r}(t)) = \left[t^2, \frac{4}{3}t\right]$. The integral is

$$\int_0^3 (t^2 + \tfrac{16}{9}t)\, dt = 9 + 8 = 17.$$

SECTION 10.2. Path Independence of Line Integrals, page 426

Purpose. Independence of path is a basic issue on line integrals, and we discuss it here in full.

Main Content, Important Concepts

Definition of independence of path

Relation to gradient (Theorem 1), potential theory

Integration around closed curves

Work, conservative systems

Relation to exactness of differential forms

Comment on Content

We see that our text pursues three ideas by relating path independence to (i) gradients (potentials), (ii) closed paths, and (iii) exactness of the form under the integral sign. The complete proof of the latter needs Stokes's theorem, so here we leave a small gap to be easily filled in Sec. 10.9.

It would not be a good idea to delay introducing the important concept of path independence until Stokes's theorem is available.

SOLUTIONS TO PROBLEM SET 10.2, page 432

2. The exactness test for path independence gives $2ye^{2x} = 2ye^{2x}$. $f(x, y) = \frac{1}{2}y^2e^{2x}$ and $f(0, 5) - f(5, 0) = 12.5 - 0$.

4. The exactness test for path independence gives $-2 \cos y \sin y = -2 \cos y \sin y$. $f = x \cos^2 y$, $f(6, \pi) - f(2, 0) = 6 \cdot 1 - 2 \cdot 1 = 4$.

6. For the dx-term and the dy-term the exactness test gives

$$2xye^{x^2+y^2-2z} = 2xye^{x^2+y^2-2z}.$$

Etc. $f = \frac{1}{2}e^{x^2+y^2-2z}$. Evaluation at the limits gives $\frac{1}{2}e^2 - \frac{1}{2}$.

8. For the dx-term and the dy-term the exactness test for path independence gives $-6xy^2 = -6xy^2$, etc. $f = x^2(y^3 - z^3)$. Evaluation at the limits of integration gives $16 \cdot 64 - 4 \cdot (-1) = 1028$.

10. Project. (a) $2y^2 \neq x^2$ from (6″).

(b) $\mathbf{r} = [t, \quad bt]$, $0 \leqq t \leqq 1$, represents the first part of the path. By integration, $b/4 + b^3/2$. On the second part, $\mathbf{r} = [1, t]$, $b \leqq t \leqq 1$. Integration gives $2(1 - b^3)/3$.

im10.qxd 9/21/05 12:49 PM Page 193

Equating the derivative of the sum of the two expressions to zero gives $b = 1/\sqrt{2} = 0.70711$. The corresponding maximum value of I is $1/(6\sqrt{2}) + 2/3 = 0.78452$.

(c) The first part is $y = x/c$ or $\mathbf{r} = [t, \quad t/c]$, $0 \leqq t \leqq c$. The integral over this portion is $c^3/4 + c/2$. For the second portion $\mathbf{r} = [t, \quad 1]$, $c \leqq t \leqq 1$, the integral is $(1 - c^3)/3$. For $c = 1$ we get $I = 0.75$, the same as in (b) for $b = 1$. This is the maximum value of I for the present paths through $(c, 1)$ because the derivative of I with respect to c is positive for $0 \leqq c \leqq 1$.

12. Path independent. The test gives $6x^2e^{2y} = 6x^2e^{2y}$, etc. We find

$$f = x^3e^{2y} + \tfrac{1}{2}x^2.$$

The integral has the value $a^3e^{2b} + \frac{1}{2}a^2$.

14. Path dependent. The test for path independence is

$$\begin{aligned} 2x\cos y &= 2x\cos y && \text{(for } x, y\text{)} \\ 0 &= 0 && \text{(for } z, x\text{)} \\ 0 &\neq 2y && \text{(for } z, y\text{).} \end{aligned}$$

16. Path dependent. The test is

$$\begin{aligned} -2e^x\sin 2y &= -2e^x\sin 2y && \text{(for } x, y\text{)} \\ 0 &\neq -z && \text{(for } x, z\text{)} \end{aligned}$$

and we can terminate here.

18. Path independent. $f = yz\sinh x$. The value of the integral is $bc\sinh a$.

SECTION 10.3. Calculus Review: Double Integrals. *Optional,* page 433

Purpose. We need double integrals (and line integrals) in the next section and review them here for completeness, suggesting that the student go on to the next section.

Content

Definition, evaluation, and properties of double integrals

Some standard applications

Change of variables, Jacobians (6), (7)

Polar coordinates (8)

Historical Comment

The two ways of evaluating double integrals explained in the text give the same result. For continuous functions this was known at least to Cauchy. Some calculus books call this **Fubini's theorem,** after the Italian mathematician GUIDO FUBINI (1879–1943; 1939–1943 professor at New York University), who in 1907 proved the result for arbitrary Lebesgue-integrable functions (published in *Atti Accad. Naz. Lincei, Rend.*, $\mathbf{16}_1$, 608–614).

SOLUTIONS TO PROBLEM SET 10.3, page 438

2. $\displaystyle\int_0^1 \left[x^2y + xy^2 + \tfrac{1}{3}y^3\right]\Big|_{y=x}^{2x} dx = \int_0^1 \left[2x^3 + 4x^3 + \tfrac{8}{3}x^3 - (x^3 + x^3 + \tfrac{1}{3}x^3)\right] dx = \tfrac{19}{12}$

im10.qxd 9/21/05 12:49 PM Page 194

4. $$\int_0^1\int_y^{\sqrt{y}} (1 - 2xy)\,dx\,dy = \int_0^1 \left[x - x^2y\right]\Big|_y^{\sqrt{y}}\,dy$$
$$= \int_0^1 \left[\sqrt{y} - y^2 - (y - y^3)\right]dy = \tfrac{1}{12}$$

6. $$\int_0^3\int_x^3 \cosh(x + y)\,dy\,dx = \int_0^3 [\sinh(x + y)]\Big|_x^3\,dx$$
$$= \int_0^3 (\sinh(x + 3) - \sinh 2x)\,dx$$
$$= \left[\cosh(x + 3) - \tfrac{1}{2}\cosh 2x\right]\Big|_{x=0}^3$$
$$= \tfrac{1}{2}\cosh 6 - \cosh 3 + \tfrac{1}{2}$$

8. $$\int_0^1 \tfrac{1}{2}x^2y^2\Big|_{1-x}^{1-x^2}\,dx = \int_0^1 \tfrac{1}{2}x^2\left[(1 - x^2)^2 - (1 - x)^2\right]dx$$
$$= \int_0^1 \tfrac{1}{2}x^2(x^4 - 3x^2 + 2x)\,dx = \tfrac{3}{140}$$

10. Integrating first over y and then over x is simpler than integrating in the opposite order, because of the form of the region of integration, which is the same triangle as in Prob. 2. We obtain

$$\int_0^1\int_x^{2x} xye^{x^2-y^2}\,dy\,dx = \int_0^1 \left[x(-\tfrac{1}{2})e^{x^2-y^2}\right]\Big|_x^{2x}\,dx$$
$$= \int_0^1 (-\tfrac{1}{2}x)(x^{-3x^2} - 1)\,dx = \tfrac{1}{12}e^{-3} + \tfrac{1}{6}.$$

12. For $z = 0$ we have $3x + 4y = 12$, thus $y = 3 - \frac{3}{4}x$; this is the upper limit of the y-integration. We then integrate over x from 0 to 4. The main point of the problem is to see how one can determine limits of integration from the given data. The integral of $z = 6 - \frac{3}{2}x - 2y$ is now as follows.

$$\int_0^4\int_0^{3-3x/4} (6 - \tfrac{3}{2}x - 2y)\,dy\,dx = \int_0^4 \left[6y - \tfrac{3}{2}xy - y^2\right]\Big|_0^{3-3x/4}\,dx$$
$$= \int_0^4 \left[(6 - \tfrac{3}{2}x)(3 - \tfrac{3}{4}x) - (3 - \tfrac{3}{4}x)^2\right]dx$$
$$= \int_0^4 (9 - \tfrac{9}{2}x + \tfrac{9}{16}x^2)\,dx$$
$$= 36 - 36 + 12$$
$$= 12.$$

We confirm this by the scalar triple product of the edge vectors,

$$\tfrac{1}{6}\begin{vmatrix} 4 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 6 \end{vmatrix} = 12.$$

im10.qxd 9/21/05 12:49 PM Page 195

14. $\bar{x} = 0$ because of symmetry. $M = \frac{1}{2}\pi a^2$. For $\bar{y}$, using polar coordinates defined by $x = r\cos\theta$, $y = r\sin\theta$, we obtain

$$\bar{y} = \frac{1}{M}\int_0^{\pi}\int_0^{a}(r\sin\theta)\,r\,dr\,d\theta = \frac{1}{M}\int_0^{\pi}\frac{a^3}{3}\sin\theta\,d\theta$$
$$= \frac{2}{\pi a^2}\cdot\frac{a^3}{3}\cdot 2$$
$$= \frac{4a}{3\pi}$$
$$= 0.4244a.$$

For $a = 1$ we get $4/(3\pi)$, as in Example 2. It is obvious that the present semidisk and the quarterdisk in the example have the same $\bar{y}$.

16. $\bar{x} = b/2$ for reasons of symmetry. Since the given R and its left half (the triangle with vertices (0, 0), $(b/2, 0)$, $(b/2, h)$) have the same $\bar{y}$, we can consider that half, for which $M = \frac{1}{4}bh$. We obtain

$$\bar{y} = \frac{4}{bh}\int_0^{b/2}\int_0^{2hx/b} y\,dy\,dx = \frac{4}{bh}\int_0^{b/2}\frac{1}{2}\left(\frac{2hx}{b}\right)^2 dx$$
$$= \frac{4}{bh}\cdot\frac{1}{2}\left(\frac{2h}{b}\right)^2\cdot\frac{1}{3}\left(\frac{b}{2}\right)^3 = \frac{h}{3}.$$

This is the same value as in Prob. 15. This equality of the $\bar{y}$-values seems obvious.

18. We obtain

$$I_x = \int_0^{b/2}\int_0^{2hx/b} y^2\,dy\,dx + \int_{b/2}^{b}\int_0^{2h-2hx/b} y^2\,dy\,dx$$
$$= \int_0^{b/2}\frac{1}{3}\left(\frac{2hx}{b}\right)^3 dx + \int_{b/2}^{b}\frac{1}{3}\left[2h\left(1-\frac{x}{b}\right)\right]^3 dx$$
$$= \frac{1}{24}bh^3 + \frac{1}{24}bh^3 = \frac{1}{12}bh^3.$$

Each of those two halves of R contributes half to the moment I_x about the x-axis. Hence we could have simplified our calculation and saved half the work. Of course, this ***does not hold*** for I_y. We obtain

$$I_y = \int_0^{b/2}\int_0^{2hx/b} x^2\,dy\,dx + \int_{b/2}^{b}\int_0^{2h-2hx/b} x^2\,dy\,dx$$
$$= \int_0^{b/2} x^2\left(\frac{2hx}{b}\right)dx + \int_{b/2}^{b} x^2\left(2h-\frac{2hx}{b}\right)dx$$
$$= \frac{1}{32}b^3h + \frac{11}{96}b^3h = \frac{7}{48}b^3h.$$

20. We denote the right half of R by $R_1 \cup R_2$, where R_1 is the rectangular part and R_2 the triangular. The moment of inertia I_{x1} of R_1 with respect to the x-axis is

$$I_{x1} = \int_0^{b/2}\int_0^{h} y^2\,dy\,dx = \int_0^{b/2}\frac{h^3}{3}\,dx = \frac{1}{6}bh^3.$$

im10.qxd 9/21/05 12:49 PM Page 196

Similarly for the triangle R_2 we obtain

$$I_{x2} = \int_{b/2}^{a/2} \int_{0}^{h(2x-a)/(b-a)} y^2 \, dy \, dx$$

$$= \int_{b/2}^{a/2} \frac{1}{3} \frac{h^3(2x - a)^3}{(b - a)^3} \, dx$$

$$= \frac{1}{24} h^3(a - b).$$

Together,

$$\frac{1}{2} I_x = \frac{h^3}{24} (3b + a) \qquad \text{and} \qquad I_x = \frac{1}{12} h^3(3b + a).$$

I_y is the same as in Prob. 19; that is,

$$I_y = \frac{h(a^4 - b^4)}{48(a - b)} .$$

This can be derived as follows, where we integrate first over x and then over y, which is simpler than integrating in the opposite order, where we would have to add the two contributions, one over the square and the other over the triangle, which would be somewhat cumbersome. Solving the equation for the right boundary

$$y = \frac{h}{a - b} (a - 2x)$$

for x, we have

$$x = \frac{1}{2h} (ah - (a - b)y)$$

and thus

$$\frac{1}{2} I_y = \int_{0}^{h} \int_{0}^{(ah-(a-b)y)/2h} x^2 \, dx \, dy$$

$$= \int_{0}^{h} \frac{1}{24h^3} (ah - (a - b)y)^3 \, dy$$

$$= \frac{h}{96} (a^3 + a^2b + ab^2 + b^3) = \frac{h(a^4 - b^4)}{96(a - b)} .$$

Now we multiply by 2, because we considered only the right half of the profile.

SECTION 10.4. Green's Theorem in the Plane, page 439

Purpose. To state, prove, and apply Green's theorem in the plane, relating line and double integrals.

Comment on the Role of Green's Theorem in the Plane

This theorem is a special case of each of the two "big" integral theorems in this chapter, Gauss's and Stokes's theorems (Secs. 10.7, 10.9), but we need it as the essential tool in the proof of Stokes's theorem.

The present theorem must not be confused with *Green's first and second theorems* in Sec. 10.8.

im10.qxd 9/21/05 12:49 PM Page 197

SOLUTIONS TO PROBLEM SET 10.4, page 444

2. $\int_0^{\pi/2}\int_0^{\pi/2} (2\cos y - \sin x)\,dx\,dy = 2\cdot\tfrac{1}{2}\cdot\pi\cdot 1 - \tfrac{1}{2}\pi\cdot 1 = \tfrac{1}{2}\pi$

4. $\int_0^{2}\int_0^{x/2} (e^x + e^y)\,dy\,dx = \int_0^{2}(\tfrac{1}{2}xe^x + e^{x/2} - 1)\,dx = -\tfrac{7}{2} + 2e + \tfrac{1}{2}e^2$

6. $\int_0^{1}\int_{x^2}^{x} x\sinh y\,dy\,dx = \int_0^{1}[x\cosh y]\Big|_{x^2}^{x} dx = \int_0^{1}(x\cosh x - x\cosh x^2)\,dx.$

Integration over x now gives $\tfrac{1}{2}\sinh 1 - \cosh 1 + 1$.

8. $\mathbf{F} = \operatorname{grad}(e^x\cos y)$, so that the integral around a closed curve is zero. Also the integrand in (1) on the left is identically zero.

10. $$\int_0^{3}\int_1^{2}\left(ye^x - \frac{x}{y}\right)dy\,dx = \int_0^{3}\left[\frac{1}{2}y^2e^x - x\ln y\right]_1^{2} dx = \int_0^{3}\left(\frac{3}{2}e^x - x\ln 2\right)dx.$$

Integration over x gives

$$\left[\tfrac{3}{2}e^x - \tfrac{1}{2}x^2\ln 2\right]_0^{3} = \tfrac{3}{2}e^3 - \tfrac{3}{2} - \tfrac{9}{2}\ln 2 = 25.51.$$

12. This is a portion of a circular ring (annulus) bounded by the circles of radii 1 and 2 centered at the origin, in the first quadrant bounded by $y = x$ and the y-axis. The integrand is $-1/y^2 - 2x^2y$. We use polar coordinates, obtaining

$$\begin{aligned}
&\int_{\pi/4}^{\pi/2}\int_1^{2}\left(-\frac{1}{r^2\sin^2\theta} - 2r^3\cos^2\theta\sin\theta\right) r\,dr\,d\theta \\
&\quad = \int_{\pi/4}^{\pi/2}\left[-\frac{\ln 2}{\sin^2\theta} - \frac{2}{5}(32-1)\cos^2\theta\sin\theta\right]d\theta \\
&\quad = (\ln 2)\left(\cot\frac{\pi}{2} - \cot\frac{\pi}{4}\right) + \frac{62}{15}\left(\cos^3\frac{\pi}{2} - \cos^2\frac{\pi}{4}\right) \\
&\quad = -\ln 2 - \frac{31}{15\sqrt{2}} \\
&\quad = -2.155.
\end{aligned}$$

14. $\nabla^2 w = 2 + 2 = 4$. *Answer:* 4π. *Confirmation.* $\mathbf{r} = [\cos s, \quad \sin s]$,

$\mathbf{r}' = [-\sin s, \quad \cos s]$. Outer unit normal vector $\mathbf{n} = [\cos s, \quad \sin s]$,

grad $w = [2x, \quad 2y] = [2\cos s, \quad 2\sin s]$, $(\operatorname{grad} w)\bullet\mathbf{n} = 2\cos s\cos s + 2\sin s\sin s$.

Integration gives $2\pi\cdot 2 = 4\pi$.

16. $\nabla^2 w = 30(x^4y + xy^4) = 30r^5(\cos^4\theta\sin\theta + \cos\theta\sin^4\theta)$. Integration gives

$$\begin{aligned}
\int_0^{\pi}\int_0^{2}\nabla^2 w\, r\,dr\,d\theta &= 30\,\frac{r^7}{7}\Big|_0^{2}\int_0^{\pi}(\cos^4\theta\sin\theta + \cos\theta\sin^4\theta)\,d\theta \\
&= 30\cdot\frac{128}{7}\left[-\frac{1}{5}\cos^5\theta + \frac{1}{5}\sin^5\theta\right]_0^{\pi} \\
&= 6\cdot\frac{128}{7}\cdot 2 = \frac{1536}{7} = 219.43.
\end{aligned}$$

im10.qxd 9/21/05 12:49 PM Page 198

18. Set $F_1 = -ww_y$ and $F_2 = ww_x$ in Green's theorem, where subscripts x and y denote partial derivatives. Then $(F_2)_x - (F_1)_y = {w_x}^2 + {w_y}^2$ because $\nabla^2 w = 0$, and

$$\begin{aligned} F_1\,dx + F_2\,dy &= (-ww_y x' + ww_x y')\,ds \\ &= w(\text{grad } w)\cdot(y'\mathbf{i} - x'\mathbf{j})\,ds \\ &= w(\text{grad } w)\cdot\mathbf{n}\,ds = w\,\frac{\partial w}{\partial n}\,ds \end{aligned}$$

where primes denote derivatives with respect to s.

20. Project. We obtain div $\mathbf{F}$ in (11) from (1) if we take $\mathbf{F} = [F_2, \quad -F_1]$. Taking $\mathbf{n} = [y', \quad -x']$ as in Example 4, we get from (1) the right side in (11),

$$(\mathbf{F}\cdot\mathbf{n})\,ds = \left(F_2\,\frac{dy}{ds} + F_1\,\frac{dx}{ds}\right)ds = F_2\,dy + F_1\,dx.$$

Formula (12) follows from the explanation of (1′).

Furthermore, div $\mathbf{F} = 7 - 3 = 4$ times the area of the disk of radius 2 gives 16π.

For the line integral in (11) we need

$$\mathbf{r} = \left[2\cos\frac{s}{2}, \quad 2\sin\frac{s}{2}\right], \qquad \mathbf{r}' = \left[-\sin\frac{s}{2}, \quad \cos\frac{s}{2}\right], \qquad \mathbf{n} = [y', \quad -x']$$

where s varies from 0 to 4π. This gives

$$\oint_C \mathbf{F}\cdot\mathbf{n}\,ds = \oint_C (7xy' + 3yx')\,ds = \int_0^{4\pi}\left(14\cos^2\frac{s}{2} - 6\sin^2\frac{s}{2}\right)ds = 16\pi.$$

In (12) we have curl $\mathbf{F} = \mathbf{0}$ and

$$\mathbf{F}\cdot\mathbf{r}' = -14\cos\frac{s}{2}\sin\frac{s}{2} - 6\cos\frac{s}{2}\sin\frac{s}{2} = -10\sin s$$

which gives zero upon integration from 0 to 4π.

SECTION 10.5. Surfaces for Surface Integrals, page 445

Purpose. The section heading indicates that we are dealing with a tool in surface integrals, and we concentrate our discussion accordingly.

Main Content, Important Concepts

Parametric surface representation (2) (see also Fig. 239)

Tangent plane

Surface normal vector **N,** unit surface normal vector **n**

Short Courses. Discuss (2) and (4) and a simple example.

Comments on Text and Problems

The student should realize and understand that the present parametric representations are the two-dimensional analog of parametric curve representations.

Examples 1–3 and Probs. 1–10 concern some standard surfaces of interest in applications. We shall need only a few of these surfaces, but these problems should help students grasp the idea of a parametric representation and see the relation to representations (1). Moreover, it may be good to collect surfaces of practical interest in one place for possible reference.

im10.qxd 9/21/05 12:49 PM Page 199

SOLUTIONS TO PROBLEM SET 10.5, page 448

2. Circles, straight lines through the origin. A normal vector is

$$\mathbf{N} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \cos v & \sin v & 0 \\ -u \sin v & u \cos v & 0 \end{vmatrix} = [0, \quad 0, \quad u] = u\mathbf{k}.$$

At the origin this normal vector is the zero vector, so that (4) is violated at (0, 0). This can also be seen from the fact that all the lines $v = const$ pass through the origin, and the curves $u = const$ (the circles) shrink to a point at the origin. ***This is a consequence of the choice of the representation, not of the geometric shape of the present surface*** (in contrast with the cone, where the apex has a similar property, but for ***geometric*** reasons).

4. $x^2 + y^2 = z$, circles, parabolas with the z-axis as axis; a normal vector is

$$[-2u^2 \cos v, \quad -2u^2 \sin v, \quad u].$$

6. $\frac{1}{4}x^2 - y^2 = z$, hyperbolas, parabolas. A normal vector is

$$[-2u^2 \cosh v, \quad 8u^2 \sinh v, \quad 4u].$$

8. $z = \arctan(y/x)$, helices (hence the name!), horizontal straight lines. This surface is similar to a spiral staircase, without steps (as in the Guggenheim Museum in New York). A normal vector is

$$[\sin v, \quad -\cos v, \quad u].$$

10. $x^2/a^2 + y^2/b^2 + z^2/c^2 = 1$. Both families of parameter curves consist of ellipses. A normal vector is

$$[bc \cos^2 v \cos u, \quad ac \cos^2 v \sin u, \quad ab \sin v \cos v].$$

12. $z = \frac{5}{3}x + \frac{1}{3}y - 10$; hence $\left[u, \quad v, \quad \frac{5}{3}u + \frac{1}{3}v - 10\right]$, or if we multiply by 3,

$$\mathbf{r}(u, v) = [3u, \quad 3v, \quad 5u + v - 30].$$

A normal vector is

$$\mathbf{N} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & 0 & 5 \\ 0 & 3 & 1 \end{vmatrix} = [-15, \quad -3, \quad 9].$$

More simply, $[5, \quad 1, \quad -3]$ by applying grad to the given representation. The two vectors are proportional, as expected.

14. In (3) the center is (0, 0, 0). Here it is (1, −2, 0). Hence we obtain

$$\mathbf{r}(u, v) = [1 + 5 \cos v \cos u, \quad -2 + 5 \cos v \sin u, \quad 5 \sin v].$$

From this and (4) we obtain the normal vector

$$\mathbf{N} = [25 \cos^2 v \cos u, \quad 25 \cos^2 v \sin u, \quad 25 \cos v \sin v].$$

16. A parametric representation is

$$\mathbf{r}(u, v) = [u \cos v, \quad 2u \sin v, \quad 4u^2].$$

A normal vector is

$$\mathbf{N} = [-16u^2 \cos v, \quad -8u^2 \sin v, \quad 2u].$$

im10.qxd 9/21/05 12:49 PM Page 200

Another one is

$$\text{grad}\,(z - 4x^2 - y^2) = [-8x, \quad -2y, \quad 1]$$
$$= [-8u\cos v, \quad -4u\sin v, \quad 1].$$

Multiplication by $2u$ gives the previous normal vector.

18. A representation is

$$\mathbf{r}(u, v) = [2\cosh u, 3\sinh u, v].$$

A normal vector is

$$\mathbf{N} = [3\cosh u, \quad -2\sinh u, \quad 0].$$

Note that **N** is parallel to the xy-plane. Another normal vector is

$$\text{grad}\,(9x^2 - 4y^2) = [18x, \quad -8y, \quad 0] = [36\cosh u, \quad -24\sinh u, \quad 0].$$

Division by 12 gives the previous normal vector.

20. Set $x = u$ and $y = v$.

22. $\mathbf{N}(0, 0) = \mathbf{0}$ in Prob. 2 (polar coordinates); see the answer to Prob. 2. In Probs. 4 and 7 (paraboloids) the situation is similar to that of the polar coordinates. In Prob. 6 the origin is a saddle point. In each of these cases one can find a representation for which $\mathbf{N}(0, 0) \neq \mathbf{0}$; see Prob. 23 for the paraboloid. In Prob. 5 the reason is the form of the surface (the apex of the cone, where no tangent plane and hence no normal exists).

24. Project. (a) $\mathbf{r}_u(P)$ and $\mathbf{r}_v(P)$ span $T(P)$. $\mathbf{r}^*$ varies over $T(P)$. The vanishing of the scalar triple product implies that $\mathbf{r}^* - \mathbf{r}(P)$ lies in the tangent plane $T(P)$.

(b) Geometrically, the vanishing of the dot product means that $\mathbf{r}^* - \mathbf{r}(P)$ must be perpendicular to ∇g, which is a normal vector of S at P.

(c) Geometrically, $f_x(P)$ and $f_y(P)$ span $T(P)$, so that for any choice of x^*, y^* the point (x^*, y^*, z^*) lies in $T(P)$. Also, $x^* = x$, $y^* = y$ gives $z^* = z$, so that $T(P)$ passes through P, as it should.

SECTION 10.6. Surface Integrals, page 449

Purpose. We define and discuss surface integrals with and without taking into account surface orientations.

Main Content

Surface integrals (3) ≡ (4) ≡ (5)

Change of orientation (Theorem 1)

Integrals (6) without regard to orientation; also (11)

Comments on Content

The right side of (3) shows that we need only **N** but not the corresponding unit vector **n.**

An orientation results automatically from the choice of a surface representation, which determines $\mathbf{r}_u$ and $\mathbf{r}_v$ and thus **N.**

The existence of nonorientable surfaces is interesting but is not needed in our further work.

SOLUTIONS TO PROBLEM SET 10.6, page 456

2. $\mathbf{r} = [u, \quad v, \quad 4 - u - v]$, $\quad 0 \leqq u \leqq 4 - v, \quad 0 \leqq v \leqq 4$,
$\mathbf{F} = [u^2, \quad v^2, \quad (4 - u - v)^2]$, $\quad \mathbf{N} = [1, \quad 1, \quad 1]$. From this we obtain

$$\int_0^4 \int_0^{4-v} \mathbf{F}\cdot\mathbf{N}\, du\, dv = \int_0^4 \left[\tfrac{1}{3}u^3 + v^2u - \tfrac{1}{3}(4 - u - v)^3\right]\Big|_0^{4-v} dv = 64.$$

im10.qxd 9/21/05 12:49 PM Page 201

4. Quarter of a circular cylinder of radius 3 and height 2 in the first octant with the z-axis as axis. A parametric representation is

$$\mathbf{r} = [3\cos u, \quad 3\sin u, \quad v], \qquad 0 \leqq u \leqq \tfrac{1}{2}\pi, \quad 0 \leqq v \leqq 2.$$

From this we obtain

$$\mathbf{N} = [3\cos u, \quad 3\sin u, \quad 0]$$

$$\mathbf{F}\cdot\mathbf{N} = 3e^{3\sin u}\cos u - 3e^{v}\sin u.$$

Integration over u from 0 to $\frac{1}{2}\pi$ gives $e^3 - 1 - 3e^v$. Integration of this over v from 0 to 2 gives the *answer*

$$2(e^3 - 1) - 3(e^2 - 1) = 2e^3 - 3e^2 + 1 = 19.0039.$$

6. $\mathbf{r} = [u, \quad \cos v, \quad \sin v]$, $0 \leqq u \leqq 20$, $0 \leqq v \leqq \pi$, $\mathbf{N} = [0, \quad -\cos v, \quad -\sin v]$; hence

$$\mathbf{F}\cdot\mathbf{N} = -\cos^4 v \sin v.$$

Integration over v from 0 to π gives $-2/5$. Integration of this over u from 0 to 20 gives the *answer* -8.

8. $\mathbf{r} = [u, \quad \cos v, \quad 3\sin v]$, $\mathbf{N} = [0, \quad -3\cos v, \quad -\sin v]$; hence

$$\mathbf{F} = [\tan(u\cos v), \quad u^2\cos v, \quad -3\sin v].$$

This gives

$$\mathbf{F}\cdot\mathbf{n} = -3u^2\cos^2 v + 3\sin^2 v.$$

Integration over u from 1 to 4 gives

$$-63\cos^2 v + 9\sin^2 v.$$

Integration of this over v from 0 to 2π gives the *answer*

$$-63\pi + 9\pi = -54\pi.$$

10. Portion of a circular cone with the z-axis as axis. A parametric representation is

$$\mathbf{r} = [u\cos v, \quad u\sin v, \quad 4u] \qquad (0 \leqq u \leqq 2,\ 0 \leqq v \leqq \pi).$$

From this,

$$\mathbf{N} = [-4u\cos v, \quad -4u\sin v, \quad u], \qquad \mathbf{F} = [u^2\sin^2 v, \quad u^2\cos^2 v, \quad 256u^4].$$

The integrand is

$$\mathbf{F}\cdot\mathbf{n} = -4u^3\sin^2 v\cos v - 4u^3\cos^2 v\sin v + 256u^5.$$

Integration over u from 0 to 2 gives

$$-16\sin^2 v\cos v - 16\cos^2 v\sin v + \frac{8192}{3}.$$

Integration of this over v from 0 to π gives

$$\left[-\frac{16}{3}\sin^3 v + \frac{16}{3}\cos^3 v + \frac{8192}{3}v\right]_0^{\pi} = -\frac{32}{3} + \frac{8192}{3}\pi = 8568.$$

12. $\mathbf{r} = [u, \quad v, \quad u + v^2]$, $\mathbf{N} = [-1, \quad -2v, \quad 1]$, $\mathbf{F} = [\cosh v, \quad 0, \quad \sinh u]$. Hence the integrand is

$$\mathbf{F}\cdot\mathbf{N} = -\cosh v + \sinh u.$$

im10.qxd 9/21/05 12:49 PM Page 202

Integration over v from 0 to u gives $-\sinh u + u \sinh u$. Integration of this over u from 0 to 1 gives

$$[-\cosh u + u \cosh u - \sinh u]\Big|_0^1 = 1 - \sinh 1.$$

14. $\mathbf{r} = [u, \quad v, \quad 2 - u - v]$, $0 \leqq u \leqq 2$, $0 \leqq v \leqq 2 - u$, $\mathbf{N} = [1, \quad 1, \quad 1]$, $|\mathbf{N}| = \sqrt{3}$, $G = \cos v + \sin u$; hence

$$\int_0^{2-u} G|\mathbf{N}|\, dv = \sqrt{3}[\sin v + v \sin u]\Big|_0^{2-u} = \sqrt{3}[\sin (2 - u) + (2 - u) \sin u].$$

Integration over u from 0 to 2 gives

$$\sqrt{3}[\cos (2 - u) - 2 \cos u - \sin u + u \cos u]\Big|_0^2$$
$$= \sqrt{3}[3 - \cos 2 - \sin 2] = 4.342.$$

16. $\mathbf{r} = [4 \cos u, \quad 4 \sin u, \quad v]$, $\mathbf{N} = [4 \cos u, \quad 4 \sin u, \quad 0]$, $|\mathbf{N}| = 4$. Furthermore,

$$G = 4 \sin u\, e^{4 \cos u} + 4 \cos u\, e^{4 \sin u} + e^v.$$

Also, $G|\mathbf{N}|$ is the same times 4. Integration over u from 0 to π gives

$$4[-e^{4 \cos u} + e^{4 \sin u} + ue^v]\Big|_0^\pi$$
$$= 4(-e^{-4} + e^4 + e^0 - e^0 + \pi e^v).$$

Integration of this over v from 0 to 4 gives

$$16(-e^{-4} + e^4) + 4\pi(e^4 - 1) = 1547.$$

18. $\mathbf{r} = [\cos v \cos u, \quad \cos v \sin u, \quad \sin v]$, $0 \leqq u \leqq \pi$, $0 \leqq v \leqq \pi/2$. A normal vector is

$$\mathbf{N} = [\cos^2 v \cos u, \quad \cos^2 v \sin u, \quad \cos v \sin v] \qquad \text{and} \qquad |\mathbf{N}| = \cos v.$$

On S,

$$G = a \cos v \cos u + b \cos v \sin u + c \sin v.$$

The integrand is this expression times $\cos v$. Integration over u from 0 to π gives

$$0 + 2b \cos^2 v + \pi c \sin v \cos v.$$

Integration of this over v from 0 to $\pi/2$ gives the *answer*

$$\tfrac{1}{2}\pi(b + c).$$

20. $\mathbf{r} = [u, \quad v, \quad uv]$, $0 \leqq u \leqq 1$, $0 \leqq v \leqq 1$, $\mathbf{N} = [-v, \quad -u, \quad 1]$, so that

$$|\mathbf{N}| = \sqrt{u^2 + v^2 + 1}.$$

On S we have

$$G = 3uv, \qquad G|\mathbf{N}| = 3uv\sqrt{u^2 + v^2 + 1}.$$

Integration over u from 0 to 1 gives

$$[v(v^2 + u^2 + 1)^{3/2}]\Big|_0^1 = v(v^2 + 2)^{3/2} - v(v^2 + 1)^{3/2}.$$

Integration of this over v from 0 to 1 gives

$$\tfrac{1}{5}[(v^2 + 2)^{5/2} - (v^2 + 1)^{5/2}]\Big|_0^1 = \tfrac{1}{5}(3^{5/2} - 2^{5/2} - (2^{5/2} - 1)) = 1.055.$$

im10.qxd 9/21/05 12:49 PM Page 203

24. $I_{x=y} = \iint_S \left[\frac{1}{2}(x - y)^2 + z^2 \right] \sigma \, dA$

26. $h\pi(1 + h^2/6)$

28. Proof for a lamina S of density σ. Choose coordinates so that A is the z-axis and B is the line $x = k$ in the xz-plane. Then

$$\begin{aligned} I_B &= \iint_S [(x - k)^2 + y^2]\sigma \, dA = \iint_S (x^2 - 2kx + k^2 + y^2)\sigma \, dA \\ &= \iint_S (x^2 + y^2)\sigma \, dA - 2k \iint_S x\sigma \, dA + k^2 \iint_S \sigma \, dA \\ &= I_A - 2k \cdot 0 + k^2 M, \end{aligned}$$

the second integral being zero because it is the first moment of the mass about an axis through the center of gravity.

For a mass distributed in a region in space the idea of proof is the same.

30. Team Project. (a) Use $d\mathbf{r} = \mathbf{r}_u \, du + \mathbf{r}_v \, dv$. This gives (13) and (14) because

$$d\mathbf{r} \bullet d\mathbf{r} = \mathbf{r}_u \bullet \mathbf{r}_u \, du^2 + 2\mathbf{r}_u \bullet \mathbf{r}_v \, du \, dv + \mathbf{r}_v \bullet \mathbf{r}_v \, dv^2.$$

(b) *E, F, G* appear if you express everything in terms of dot products. In the numerator,

$$\mathbf{a} \bullet \mathbf{b} = (\mathbf{r}_u g' + \mathbf{r}_v h') \bullet (\mathbf{r}_u p' + \mathbf{r}_v q') = Eg'p' + F(g'q' + h'p') + Gh'q'$$

and similarly in the denominator.

(c) This follows by Lagrange's identity (Problem Set 9.3),

$$\begin{aligned} |\mathbf{r}_u \times \mathbf{r}_v|^2 = (\mathbf{r}_u \times \mathbf{r}_v) \bullet (\mathbf{r}_u \times \mathbf{r}_v) &= (\mathbf{r}_u \bullet \mathbf{r}_u)(\mathbf{r}_v \bullet \mathbf{r}_v) - (\mathbf{r}_u \bullet \mathbf{r}_v)^2 \\ &= EG - F^2. \end{aligned}$$

(d) $\mathbf{r} = [u \cos v, \quad u \sin v], \quad \mathbf{r}_u = [\cos v, \quad \sin v], \quad \mathbf{r}_u \bullet \mathbf{r}_u = \cos^2 v + \sin^2 v = 1$, etc.

(e) By straightforward calculation, $E = (a + b \cos v)^2$, and $F = 0$ (the coordinate curves on the torus are orthogonal!), and $G = b^2$. Hence, as expected,

$$\sqrt{EG - F^2} = b(a + b \cos v).$$

SECTION 10.7. Triple Integrals. Divergence Theorem of Gauss, page 458

Purpose, Content

Proof and application of the first "big" integral theorem in this chapter, Gauss's theorem, preceded by a short discussion of triple integrals (probably known to most students from calculus).

Comment on Proof

The proof is simple:

1. Cut (2) into three components. Take the third, (5).

2. On the left, integrate $\iiint \frac{\partial F^3}{\partial z} \, dz \, dx \, dy$ over z to get

(8) $$\iint [F_3(\text{upper surface}) - F_3(\text{lower surface})] \, dx \, dy$$

integrated over the projection R of the region in the xy-plane (Fig. 250).

im10.qxd 9/21/05 12:49 PM Page 204

3. Show that the right side of (5) equals (8). Since the third component of **n** is cos γ, the right side is

$$\iint F_3 \cos\gamma \, dA = \iint F_3 \, dx\, dy$$
$$= \iint F_3(\text{upper}) \, dx\, dy - \iint F_3(\text{lower}) \, dx\, dy,$$

where minus comes from cos $\gamma < 0$ in Fig. 250, lower surface. This is the proof. Everything else is (necessary) accessory.

SOLUTIONS TO PROBLEM SET 10.7, page 463

2. Integration over x from 0 to 4 gives $\frac{64}{3} + 4y^2 + 4z^2$. Integration of this over y from 0 to 9 gives $1164 + 36z^2$. Integration of this over z from 0 to 1 gives 1176.

Alternatively, integration of x^2, y^2, z^2 over T gives

$$\frac{4^3}{3} \cdot 9 \cdot 1 = 192, \qquad \frac{9^3}{3} \cdot 4 \cdot 1 = 972, \qquad \frac{1^3}{3} \cdot 4 \cdot 9 = 12$$

respectively. The sum is 1176.

4. Limits of integration $0 \leqq x \leqq 2 - y - z$, $0 \leqq y \leqq 2 - z$, $0 \leqq z \leqq 2$. Integration over x gives $-e^{-2} + e^{-y-z}$. Integration of this over y gives $-3e^{-2} + ze^{-2} + e^{-z}$. Integration of this over z gives the *answer* $-5e^{-2} + 1$.

6. Integration over y from 0 to $1 - x^2$ gives $30z(1 - x^2)$. Integration of this over z from 0 to x gives $15(x^2 - x^4)$. Integration of this over x from 0 to 1 gives the *answer* 2.

8. From (3) in Sec. 10.5 with variable r instead of constant a we have

$$x = r\cos v \cos u, \qquad y = r\cos v \sin u, \qquad z = r \sin v.$$

Hence $x^2 + y^2 = r^2 \cos^2 v$. The volume element is $dV = r^2 \cos v \; dr\, du\, dv$. The limits of integration are $0 \leqq r \leqq a$, $0 \leqq u \leqq 2\pi$, $-\frac{1}{2}\pi \leqq v \leqq \frac{1}{2}\pi$. The integrand is $r^4 \cos^3 v$. Integration over r, u, and v gives $a^5/5$, 2π, and 4/3, respectively. The product of these is the *answer* $8\pi a^5/15$.

10. Integration over x, y, and z gives successively

$$a(y^2 + z^2), \qquad \tfrac{1}{12}ab^3 + z^2ab, \qquad \tfrac{1}{12}abc(b^2 + c^2).$$

12. $8\pi a^5/15$, as follows from Prob. 8.

14. $r^2 = y^2 + z^2$. Integration over r from 0 to $\sqrt{x}$ gives $x^2/4$. Integration of this over x from 0 to h gives $h^3/12$. *Answer:* $h^3\pi/6$.

16. $\pi h^5/10 = \pi h^3/6$ gives $h = \sqrt{5/3}$. For $h > \sqrt{5/3}$ the moment I_x is larger for the cone because the mass of the cone is spread out farther than that of the paraboloid when $x > 1$.

18. div **F** = 4. *Answer:* 4 times the volume $\pi r^2 h/3$ of a cone of base radius $r = 2$ and height $h = 2$. *Answer:* $4\pi \cdot 4 \cdot 2/3 = 32\pi/3$.

20. div **F** $= 4x^2$. Set $x = r\cos u$, $y = r \sin u$. The integrand times the volume element is

$$(4r^2 \cos^2 u)r \, dr\, du\, dz.$$

Integration over r from 0 to 5 gives $5^4 \cos^2 u$, integration over u from 0 to 2π then gives 625π, and integration over z finally gives 1250π.

im10.qxd 9/21/05 12:49 PM Page 205

22. div $\mathbf{F} = 3x^2 + 3y^2 + 3z^2 = 3r^2$, $dV = r^2 \cos v \; dr \; du \; dv$. Intervals of integration $0 \leqq r \leqq 5$, $0 \leqq u \leqq 2\pi$, $0 \leqq v \leqq \frac{1}{2}\pi$. The integrand is $3r^4 \cos v$. Integration over r, v, and u gives successively

$$1875 \cos v, \quad 1875, \quad 3750\pi.$$

24. div $\mathbf{F} = 8x + 2y + 2\pi \sin \pi z$. Integration over z from 0 to $1 - x - y$ gives

$$2 + (1 - x - y)(8x + 2y) - 2 \cos [\pi(1 - x - y)].$$

Integration of this over y from 0 to $1 - x$ gives

$$\frac{7}{3} + x - 7x^2 + \frac{11}{3} x^3 - \frac{2}{\pi} \sin [\pi(1 - x)].$$

Integration of this over x from 0 to 1 now gives the *answer* $17/12 - 4/\pi^2$.

SECTION 10.8. Further Applications of the Divergence Theorem, page 463

Purpose. To represent the divergence free of coordinates and to show that it measures the source intensity (Example 1); to use Gauss's theorem for deriving the **heat equation** governing heat flow in a region (Example 2); to obtain basic properties of harmonic functions.

Main Content, Important Concepts

Total flow (1) out of a region

Divergence as the limit of a surface integral; see (2)

Heat equation (5) (to be discussed further in Chap. 12)

Properties of harmonic functions (Theorems 1–3)

Green's formulas (8), (9)

Short Courses. This section can be omitted.

Comments on (2)

Equation (2) is sometimes used as a *definition* of the divergence, giving independence of the choice of coordinates immediately. Also, Gauss's theorem follows more readily from this definition, but since its proof is simple (see Sec. 10.7. in this Manual), that savings is marginal. Also, it seems that to the student our Example 2 in Sec. 9.8 motivates the divergence at least as well (and without integrals) as (2) in the present section does for a beginner.

SOLUTIONS TO PROBLEM SET 10.8, page 468

2. $\mathbf{r} = [\cos \theta, \quad \sin \theta] = \mathbf{N} = \mathbf{n}$, $f = \sin^2 \theta - \cos^2 \theta = -2 \cos 2\theta$ gives the integral 0. The integrals over the disks ($z = 0$ and $z = 5$) are 0, too, because ∇f has no component in the z-direction (the normal direction of those disks).

4. $\nabla^2 g = 4$, grad $f \cdot$ grad $g = [1, \quad 0, \quad 0] \cdot [0, \quad 2y, \quad 2z] = 0$. Integration of $4x$ over the box gives 12. Also, $f \partial g/\partial n$ for the six surfaces gives

$(x = 0)$	$0[-1, \quad 0, \quad 0] \cdot [0, \quad 2y, \quad 2z]$,	integral 0
$(x = 1)$	$1[1, \quad 0, \quad 0] \cdot [0, \quad 2y, \quad 2z]$,	integral 0
$(y = 0)$	$x[0, \quad -1, \quad 0] \cdot [0, \quad 0, \quad 2z]$,	integral 0

im10.qxd 9/21/05 12:49 PM Page 206

$(y = 2)$	$x[0, \quad 1, \quad 0] \bullet [0, \quad 4, \quad 2z]$,	integral of $4x$ gives $2 \cdot 3 = 6$
$(z = 0)$	$x[0, \quad 0, \quad -1] \bullet [0, \quad 2y, \quad 0]$	integral 0
$(z = 3)$	$x[0, \quad 0, \quad 1] \bullet [0, \quad 2y, \quad 6]$	integral of $6x$ gives $3 \cdot 2 = 6$.

6. The volume integral of $2x^4 - 12x^2y^2$ is $2/5 - 4/3$. The surface integral of

$$x^4\mathbf{n} \bullet [0, \quad 2y, \quad 0] - y^2\mathbf{n} \bullet [4x^3, \quad 0, \quad 0] = \mathbf{n} \bullet \left[-4y^2x^3, \quad 2yx^4, \quad 0\right]$$

is $-4/3$ $(x = 1)$ and $2/5$ $(y = 1)$ and 0 for the other faces.

8. $r = a$, $\cos \phi = 1$, $V = \frac{1}{3}a(4\pi a^2)$

10. Team Project. (a) Put $f = g$ in (8).

(b) Use (a).

(c) Use (9).

(d) $h = f - g$ is harmonic and $\partial h/\partial n = 0$ on S. Thus $h = const$ in T by (b).

(e) Use div (grad f) $= \nabla^2 f$ and (2).

SECTION 10.9. Stokes's Theorem, page 468

Purpose. To prove, explain, and apply Stokes's theorem, relating line integrals over closed curves and surface integrals.

Main Content

Formula (2) $\equiv$ (2*)

Further interpretation of the curl (see also Sec. 9.9)

Path independence of line integrals (leftover from Sec. 10.2)

Comment on Orientation

Since the choice of right-handed or left-handed coordinates is essential to the curl (Sec. 9.9), surface orientation becomes essential here (Fig. 251).

Comment on Proof

The proof is simple:

1. Cut (2*) into components. Take the first, (3).
2. Using N_1 and N_3, cast the left side of (3) into the form (7).
3. Transform the right side of (3) by Green's theorem in the plane into a double integral and show equality with the integral obtained on the left.

SOLUTIONS TO PROBLEM SET 10.9, page 473

2. $\mathbf{r} = [2 \cos u, \quad 2 \sin u, \quad v]$, $\quad \text{curl } \mathbf{F} = [0, \quad -5 \cos z, \quad 0] = [0, \quad -5 \cos v, \quad 0]$. Also

$$\mathbf{N} = [2 \cos u, \quad 2 \sin u, \quad 0].$$

Hence

$$(\text{curl } \mathbf{F}) \bullet \mathbf{N} = -5(\cos v)\ 2 \sin u.$$

Integretion over u from 0 to π gives $-20 \cos v$. Integration of this over v from 0 to $\frac{1}{2}\pi$ gives -20. *Answer:* ± 20.

4. $\text{curl } \mathbf{F} = [-\sinh z, \quad -1, \quad 3 \sin y]$, $\quad \mathbf{N} = [0, \quad 0, \quad 1]$. Hence

$$(\text{curl } \mathbf{F}) \bullet \mathbf{N} = 3 \sin y.$$

im10.qxd 9/21/05 12:49 PM Page 207

Integration over y from 0 to 2 and then over x from 0 to 2 gives

$$-3(\cos 2 - 1)\cdot 2 = -6(\cos 2 - 1).$$

The *answer* is $\pm 6(\cos 2 - 1) = \mp 8.497$.

6. $\mathbf{r} = [u\cos v, \quad u\sin v, \quad u]$, curl $\mathbf{F} = [2y, \quad 2z, \quad 2x] = [2u\sin v, \quad 2u, \quad 2u\cos v]$. Furthermore,

$$\mathbf{n}\, dA = \mathbf{N}\, du\, dv = [-u\cos v, \quad -u\sin v, \quad u]\, du\, dv.$$

Hence the integrand is

$$-2u^2\cos v\sin v - 2u^2\sin v + 2u^2\cos v.$$

Integration over u from 0 to 2 gives

$$\tfrac{16}{3}(-\cos v\sin v - \sin v + \cos v).$$

Integration of this from 0 to π gives $\frac{16}{3}(-2) = -32/3$. The *answer* is $\pm 32/3$.

8. (curl $\mathbf{F}$)$\cdot\mathbf{N} = [0, \quad 0, \quad -3x^2 - 3y^2]\cdot[0, \quad 0, \quad 1] = -3x^2 - 3y^2 = -3r^2$. The integral is

$$-3\int_S\int (x^2 + y^2)\, dx\, dy = -3\int_S\int r^3\, dr\, d\theta = -\tfrac{3}{4}r^4\cdot 2\pi\Big|_0^1 = -\tfrac{3}{2}\pi.$$

The *answer* is $\pm 3\pi/2$.

10. $\mathbf{r} = [\cos\theta, \quad \sin\theta]$, $\mathbf{F}\cdot\mathbf{r}' = [\sin^3\theta, -\cos^3\theta]\cdot[-\sin\theta, \quad \cos\theta]$. Integration over θ from 0 to 2π gives $-3\pi/2$.

12. $\mathbf{r} = [u, \quad v, \quad v + 1]$, $\mathbf{N} = [0, \quad -1, \quad 1]$, curl $\mathbf{F} = [0, \quad 2, \quad -2]$. Hence (curl $\mathbf{F}$)$\cdot\mathbf{N} = 0 - 2 - 2 = -4$. The area of the projection $x^2 + y^2 \leqq 1$ is π. This gives the *answer* -4π.

14. $\mathbf{F} = \left[y, \quad xy^3, \quad -zy^3\right]$, curl $\mathbf{F} = \left[-3zy^2, \quad 0, \quad y^3 - 1\right]$, $\mathbf{r} = [u\cos v, \quad u\sin v, \quad b]$, $\mathbf{N} = [0, \quad 0, \quad u]$; hence

$$(\text{curl }\mathbf{F})\cdot\mathbf{N} = (u^3\sin^3 v - 1)u.$$

Integration over u from 0 to a gives

$$\tfrac{1}{5}a^5\sin^3 v - \tfrac{1}{2}a^2.$$

Integration of this over v from 0 to 2π gives the *answer*

$$0 - \pi a^2.$$

To check this directly, we can take

$$\mathbf{r} = \left[a\cos\frac{s}{a}, \quad a\sin\frac{s}{a}, \quad b\right]$$

$$\mathbf{r}' = \left[-\sin\frac{s}{a}, \quad \cos\frac{s}{a}, \quad 0\right]$$

$$\mathbf{F} = \left[a\sin\frac{s}{a}, \quad a^4\cos\frac{s}{a}\sin^3\frac{s}{a}, \quad -a^3\sin^3\frac{s}{a}\right]$$

$$\mathbf{F}\cdot\mathbf{r}' = -a\sin^2\frac{s}{a} + a^4\cos^2\frac{s}{a}\sin^3\frac{s}{a}.$$

Integration of this over s from 0 to $2\pi a$ gives $-\pi a^2$, as before.

im10.qxd 9/21/05 12:49 PM Page 208

16. curl $\mathbf{F} = \mathbf{0}$ gives the *answer* 0.

18. curl $\mathbf{F} = [1, \quad 1, \quad 1]$, $\mathbf{N} = [0, \quad 0, \quad 1]$ (curl $\mathbf{F}$)$\bullet\mathbf{N} = 1$. The area of the projection of the given triangle into the xy-plane is 1/2. This gives the *answer* 1/2.

SOLUTIONS TO CHAP. 10 REVIEW QUESTIONS AND PROBLEMS, page 473

12. Exact, $\mathbf{F} = \text{grad } f(x, y, z)$, $f(x, y, z) = x \cos z - y \sin z$. Hence the integral has the value

$$f(4, 3, 0) - f(-2, 0, \tfrac{1}{2}\pi) = 4 - 0 = 4.$$

14. Not exact. $\mathbf{r} = [3 \cos t, \quad 3 \sin t, \quad 1]$. Hence

$$\begin{aligned}\mathbf{F}(\mathbf{r})\bullet\mathbf{r}' &= [3 \sin t, \quad 6 \cos t, \quad 9 \cos t \sin t]\bullet[-3 \sin t, \quad 3 \cos t, \quad 0] \\ &= -9 \sin^2 t + 18 \cos^2 t.\end{aligned}$$

Integration over t from 0 to 2π gives $-9\pi + 18\pi = 9\pi$.

16. By Stokes's theorem. $\mathbf{r} = [u, \quad v, \quad 2u]$, $\mathbf{N} = [-2, \quad 0, \quad 1]$. Furthermore,

$$\begin{aligned}\text{curl } \mathbf{F} &= [0, \quad -\pi \cos \pi x, \quad -\pi(\sin \pi x + \cos \pi y)] \\ &= [0, \quad -\pi \cos \pi u, \quad -\pi(\sin \pi u + \cos \pi v)].\end{aligned}$$

The inner product is

$$(\text{curl } \mathbf{F}(\mathbf{r}))\bullet\mathbf{N} = -\pi(\sin \pi u + \cos \pi v).$$

Integration over u from 0 to 1/2 gives $-\frac{1}{2}\pi \cos \pi v - 1$. Integration of this over v from 0 to 2 gives -2. *Answer:* ∓ 2.

18. By Stokes's theorem. curl $\mathbf{F} = \mathbf{0}$. Hence the *answer* is 0.

20. Not exact. We obtain

$$\mathbf{r}' = [-2 \sin t, \quad 2 \cos t, \quad 6]$$

and

$$\mathbf{F}(\mathbf{r}) = [4 \cos^2 t, \quad 4 \sin^2 t, \quad 8 \sin^2 t \cos t].$$

The inner product is

$$\mathbf{F}\bullet\mathbf{r}' = -8 \cos^2 t \sin t + 56 \sin^2 t \cos t.$$

Integration gives

$$\frac{8}{3} \cos^3 t + \frac{56}{3} \sin^3 t \Big|_0^{\pi/2} = 16.$$

22. $\bar{x} = 0$ by symmetry. The total mass is

$$M = \int_{-1}^{1} (1 - x^2)\, dx = \frac{4}{3}.$$

Hence

$$\bar{y} = \frac{1}{M} \int_{-1}^{1} \int_{0}^{1-x^2} y\, dy\, dx = \int_{-1}^{1} \frac{3}{8} (1 - x^2)^2\, dx = \frac{2}{5}.$$

24. $x^2 + y^2 = r^2$. The total mass is

$$M = \int_0^{\pi/2} \int_0^1 r^2 \cdot r\, dr\, d\theta = \frac{\pi}{8}.$$

im10.qxd 9/21/05 12:49 PM Page 209

This gives

$$\bar{x} = \frac{1}{M}\int_0^{\pi/2}\int_0^1 (r\cos\theta)r^2 \cdot r\,dr\,d\theta = \frac{8}{5\pi}$$

and $\bar{y} = \bar{x}$ by symmetry.

26. $\mathbf{N} = [1, \quad 1, \quad 1]$, $\mathbf{F}\cdot\mathbf{N} = 2x^2 + 4y$. Integration over y from 0 to $1 - x$ gives

$$2x^2(1 - x) + 2(1 - x)^2.$$

Integration of this over x from 0 to 1 gives 5/6.

28. By Gauss's theorem. div $\mathbf{F} = 3$. The volume of the sphere is $\frac{4}{3}\cdot 5^3\pi$. This gives the *answer* 500π.

30. By direct integration. We can represent the paraboloid in the form

$$\mathbf{r} = [u\cos v, \quad u\sin v, \quad u^2].$$

A normal vector is

$$\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v = [-2u^2\cos v, \quad -2u^2\sin v, \quad u].$$

On the paraboloid,

$$\mathbf{F} = [u^3\sin^3 v, \quad u^3\cos^3 v, \quad 3u^4].$$

The inner product is

$$\begin{aligned}\mathbf{F}\cdot\mathbf{N} &= -2u^5\cos v\sin^3 v - 2u^5\cos^3 v\sin v + 3u^5\\ &= -2u^5\cos v\sin v(\sin^2 v + \cos^2 v) + 3u^5.\end{aligned}$$

Integration of this over v from 0 to 2π gives $0 + 6\pi u^5$. Integration of this over u from 0 to 2 (note that $z = u^2$ varies from 0 to 4) gives $6\pi 2^6/6 = 64\pi$.

32. Direct integration. We have

$$\mathbf{r} = [2\cos u\cos v, \quad 2\cos u\sin v, \quad \sin u] \qquad (0 \leqq u \leqq \tfrac{1}{2}\pi, \quad 0 \leqq v \leqq 2\pi).$$

From this,

$$\begin{aligned}\mathbf{r}_u &= [-2\sin u\cos v, \quad -2\sin u\sin v, \quad \cos u]\\ \mathbf{r}_v &= [-2\cos u\sin v, \quad 2\cos u\cos v, \quad 0]\\ \mathbf{N} &= [-2\cos^2 u\cos v, \quad -2\cos^2 u\sin v, \quad -4\cos u\sin u].\end{aligned}$$

The inner product is

$$\mathbf{F}\cdot\mathbf{N} = (-2\cos^2 u)(\cos v + \sin v) - 4a\cos u\sin u.$$

Integration of $\cos v + \sin v$ over v from 0 to 2π gives 0. Integration of $-4a\cos u\sin u$ over u from 0 to $\pi/2$ gives $-2a$. Integration of this constant over v from 0 to 2π gives $-4\pi a$ (or $+4\pi a$ if we change the orientation by interchanging u and v).

34. By Gauss's theorem. T can be represented by

$$\mathbf{r} = [r\cos u, \quad r\sin u, \quad v], \qquad \text{where} \qquad 0 \leqq r \leqq 1, \quad 0 \leqq u \leqq 2\pi, \quad 0 \leqq v \leqq h.$$

The divergence of $\mathbf{F}$ is

$$\text{div}\,\mathbf{F} = 1 + x + 1 = 2 + x = 2 + r\cos u.$$

The integrand is $(2 + r\cos u)r$. Integration over r from 0 to 1 gives $1 + \frac{1}{3}\cos u$. Integration of this over u from 0 to 2π gives 2π. Integration of this over v from 0 to h gives the *answer* $2\pi h$. Note that this is the integral of the term 2 in div $\mathbf{F}$, whereas $r\cos u$ gives 0.

im10.qxd 9/21/05 12:49 PM Page 210

To check this against Prob. 33, add to the answer πh of Prob. 33 the contributions of the disks D_h: $x^2 + y^2 \leqq 1$, $z = h$, and D_0: $x^2 + y^2 \leqq 1$, $z = 0$.

For D_h we have

$$\mathbf{r} = [r\cos u, \quad r\sin u, \quad h], \qquad \mathbf{N} = [0, \quad 0, \quad 1]$$

and furthermore,

$$\mathbf{F} = [r\cos u, \quad r^2\cos u\sin u, \quad h].$$

Hence $\mathbf{F}\bullet\mathbf{N} = h$. Integration of this constant over $x^2 + y^2 \leqq 1$ gives πh. For D_0 we obtain

$$\mathbf{r} = [r\cos u, \quad r\sin u, \quad 0], \qquad \mathbf{N} = [0, \quad 0, \quad -1].$$

Hence

$$\mathbf{F}\bullet\mathbf{N} = [r\cos u, \quad r^2\cos u\sin u, \quad 0]\bullet[0, \quad 0, \quad -1] = 0$$

and we obtain the contribution 0. Together, $\pi h + \pi h = 2\pi h$, in agreement with the answer to Prob. 34.

im11.qxd 9/21/05 12:33 PM Page 211

Part C. FOURIER ANALYSIS. PARTIAL DIFFERENTIAL EQUATIONS (PDEs)

CHAPTER 11 Fourier Series, Integrals, and Transforms

Change

The first two sections are now combined into a single section, giving a better and somewhat faster start, with more emphasis on the essential ideas and facts.

SECTION 11.1. Fourier Series, page 478

Purpose. To derive the Euler formulas (6) for the coefficients of a Fourier series (5) of a given function of period 2π, using as the key property the orthogonality of the trigonometric system.

Main Content, Important Concepts

Periodic function

Trigonometric system, its orthogonality (Theorem 1)

Fourier series (5) with Fourier coefficients (6)

Representation by a Fourier series (Theorem 2)

Comment on Notation

If we write $a_0/2$ instead of a_0 in (1), we must do the same in (6a) and see that (6a) then becomes (6b) with $n = 0$. This is merely a small notational convenience (but may be a source of confusion to poorer students).

Comment on Fourier Series

Whereas their theory is quite involved, practical applications are simple, once the student has become used to evaluating integrals in (6) that depend on n.

Figure 257 should help students understand why and how a series of continuous terms can have a discontinuous sum.

Comment on the History of Fourier Series

Fourier series were already used in special problems by Daniel Bernoulli (1700–1782) in 1748 (vibrating string, Sec. 12.3) and Euler (Sec. 2.5) in 1754. Fourier's book of 1822 became the source of many mathematical methods in classical mathematical physics. Furthermore, the surprising fact that Fourier series, whose terms are *continuous* functions, may represent *discontinuous* functions led to a reflection on, and generalization of, the concept of a function in general. Hence the book is a landmark in both pure and applied mathematics. [That surprising fact also led to a controversy between Euler and D. Bernoulli over the question of whether the two types of solution of the vibrating string problem (Secs. 12.3 and 12.4) are identical; for details, see E. T. Bell, *The Development of Mathematics,* New York: McGraw-Hill, 1940, p. 482.] A mathematical theory of Fourier series was started by Peter Gustav Lejeune Dirichlet (1805–1859) of Berlin in 1829. The concept of the Riemann integral also resulted from work on Fourier series. Later on, these series became the model case in the theory of orthogonal functions (Sec. 5.7). An English translation of Fourier's book was published by Dover Publications in 1955.

im11.qxd 9/21/05 12:33 PM Page 212

SOLUTIONS TO PROBLEM SET 11.1, page 485

2. 2π, 2π, π, π, 2, 2, 1, 1

4. There is no *smallest* $p > 0$.

6. $f(x + p) = f(x)$ implies

$$f(ax + p) = f(a[x + (p/a)]) = f(ax) \text{ or } g[x + (p/a)] = g(x),$$

where

$$g(x) = f(ax).$$

Thus $g(x)$ has the period p/a. This proves the first statement. The other statement follows by setting $a = 1/b$.

8.–12. These problems should familiarize the student with the kind of periodic functions, some of them discontinuous, that occur in applications as driving forces in mechanics, as boundary potentials in electrostatics or heat conduction, in high-frequency problems in connection with filters, and so on. Functions of this type will occur throughout this chapter and the next one.

14. $\frac{1}{2} + \dfrac{2}{\pi}(\sin x + \frac{1}{3}\sin 3x + \frac{1}{5}\sin 5x + \cdots)$. $\quad f(x) - \frac{1}{2}$ is odd.

16. $\dfrac{2}{\pi}(\sin x - \frac{1}{9}\sin 3x + \frac{1}{25}\sin 5x - + \cdots) + \frac{1}{2}\sin 2x - \frac{1}{4}\sin 4x + \frac{1}{6}\sin 6x - + \cdots$

18. $\dfrac{\pi}{2} - \dfrac{4}{\pi}(\cos x + \frac{1}{9}\cos 3x + \frac{1}{25}\cos 5x + \cdots)$. See also Prob. 15.

20. $\dfrac{1}{\pi}[(2 + \pi)\sin x + \frac{1}{9}(-2 + 3\pi)\sin 3x + \frac{1}{25}(2 + 5\pi)\sin 5x + \cdots]$
$- \frac{1}{2}\sin 2x - \frac{1}{4}\sin 4x - \frac{1}{6}\sin 6x - \cdots$

22. $\frac{4}{3}\pi^2 + 4(\cos x + \frac{1}{4}\cos 2x + \frac{1}{9}\cos 3x + \cdots)$
$- 4\pi(\sin x + \frac{1}{2}\sin 2x + \frac{1}{3}\sin 3x + \cdots)$

24. $2\pi - \dfrac{16}{\pi}(\cos x + \frac{1}{9}\cos 3x + \frac{1}{25}\cos 5x + \cdots)$

26. CAS Experiment. Experimental approach to Fourier series. This should help the student obtain a feel for the kind of series to expect in practice, and for the kind and quality of convergence, depending on continuity properties of the sum of the series.

(a) $f(x) = x$ has discontinuities at $\pm\pi$. The instructor will notice the beginning of the **Gibbs phenomenon** (to be discussed in Problem Set 11.2) at the points of discontinuity.

(b) $f(x) = 1 + x/\pi$ if $-\pi < x < 0$ and $1 - x/\pi$ if $0 < x < \pi$, is continuous throughout, and the accuracy is much better than in (a).

(c) $f(x) = \pi^2 - x^2$ has about the same continuity as (b), and the approximation is good.

The coefficients in (a) involve $1/n$, whereas those in (b) and (c) involve $1/n^2$. This is typical. See also CAS Experiment 27.

28. Project. Integrate by parts. a_0 is obtained as before. The formulas extend to any function for which the derivatives are identically zero from some derivative on. Jumps may occur at points where the representation of $f(x)$ changes, and at the ends $\pm\pi$ of the interval. Accordingly, we write the integral in the Euler formula for a_n as a sum of integrals,

$$\pi a_n = \int_{-\pi}^{\pi} f\cos nx\,dx = \int_{x_0}^{x_1} + \int_{x_1}^{x_2} + \cdots + \int_{x_{m-1}}^{x_m} = \sum_{s=1}^{m}\int_{x_{s-1}}^{x_s} f\cos nx\,dx$$

im11.qxd 9/21/05 12:33 PM Page 213

where $x_0 = -\pi$ and $x_m = \pi$. Integration by parts gives

$$\int_{x_{s-1}}^{x_s} f \cos nx \, dx = \frac{f}{n} \sin nx \Big|_{x_{s-1}}^{x_s} - \frac{1}{n} \int_{x_{s-1}}^{x_s} f' \sin nx \, dx.$$

Now comes an important point: the evaluation of the first expression on the right. $f(x)$ may be discontinuous at x_s and we have to take the left-hand limit $f(x_s - 0)$ of f at x_s. Similarly, at x_{s-1} we have to take the right-hand limit $f(x_{s-1} + 0)$. Hence the first expression on the right equals

$$\frac{1}{n} [f(x_s - 0) \sin nx_s - f(x_{s-1} + 0) \sin nx_{s-1}].$$

Consequently, by inserting this into a_m and using the short notations $S_0 = \sin nx_0$, $S_1 = \sin nx_1$, etc., we obtain

$$\begin{aligned} \pi a_n = \frac{1}{n} [&f(x_1 - 0)S_1 - f(x_0 + 0)S_0 + f(x_2 - 0)S_2 - f(x_1 + 0)S_1 \\ &+ \cdots + f(x_m - 0)S_m - f(x_{m-1} + 0)S_{m-1}] \\ &- \frac{1}{n} \sum_{s=1}^{m} \int_{x_{s-1}}^{x_s} f' \sin nx \, dx. \end{aligned}$$

Collecting terms with the same S the expression in brackets becomes

$$\begin{aligned} &-f(x_0 + 0)S_0 + [f(x_1 - 0) - f(x_1 + 0)]S_1 \\ &\quad + [f(x_2 - 0) - f(x_2 + 0)]S_2 + \cdots + f(x_m - 0)S_m. \end{aligned}$$

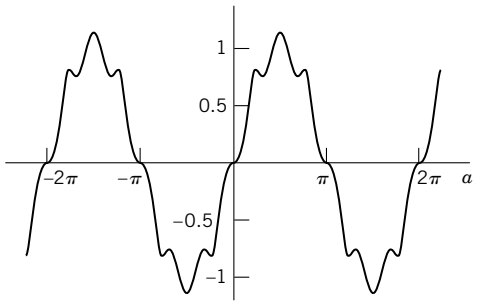
The expressions in the brackets are the jumps of f, multiplied by -1. Furthermore, because of periodicity, $S_0 = S_m$ and $f(x_0) = f(x_m)$, so that we may combine the first and the last term,

$$-j_1 S_1 - j_2 S_2 - \cdots - j_m S_m,$$

and we therefore have the intermediate result

$$\pi a_n = -\frac{1}{n} \sum_{s=1}^{m} j_s \sin nx_s - \frac{1}{n} \sum_{s=1}^{m} \int_{x_{s-1}}^{x_s} f' \sin nx \, dx.$$

By applying the same procedure to the integrals on the right we find



$$\sum_{s=1}^{m} \int_{x_{s-1}}^{x_s} f' \sin nx \, dx = \frac{1}{n} \sum_{s=1}^{m} j_s' \cos nx_s + \frac{1}{n} \sum_{s=1}^{m} \int_{x_{s-1}}^{x_s} f'' \cos nx \, dx.$$

By applying the procedure once more, namely, to the integral on the right, we obtain the "jump formula" for a_n. For the b_n the process is the same. If a derivative of f higher than the second is not identically zero, we have to do additional steps. The number of steps is finite as long as $f(x)$ is piecewise polynomial. For other functions, since partial integration brings in increasingly higher powers of $1/n$, it may be worthwhile to investigate what happens if one terminates the process prematurely, after finitely many steps.

30. CAS Experiment. The student should recognize the importance of the interval in connection with orthogonality, which is the basic concept in the derivation of the Euler formulas.

For instance, for $\sin 3x \sin 4x$ the integral equals $\sin a - \frac{1}{7} \sin 7a$, and the graph suggests orthogonality for $a = \pi$, as expected.

im11.qxd 9/21/05 12:33 PM Page 214

Section 11.1. Integral in Problem 30 as a function of *a*

SECTION 11.2. Functions of Any Period $p = 2L$, page 487

Purpose. It is practical to start with functions of period 2π, as we have done, because in this case the Euler formulas and Fourier series look much simpler. And this is practically no detour because the general case of $p = 2L$ is obtained simply by a linear transformation on the x-axis, giving the Fourier series (5) with coefficients (6).

The notation $p = 2L$ is suggested by the fact that we shall later use **half-range expansions,** with the series used "physically" only on an interval from $x = 0$ to L (the extension of a vibrating string or a beam in heat conduction problems, etc.).

SOLUTIONS TO PROBLEM SET 11.2, page 490

2. $2 + \dfrac{8}{\pi}\left(\sin\dfrac{\pi x}{2} + \dfrac{1}{3}\sin\dfrac{3\pi x}{2} + \dfrac{1}{5}\sin\dfrac{5\pi x}{2} + \cdots\right)$

4. $\left(1 - \dfrac{6}{\pi^2}\right)\sin\pi x - \left(\dfrac{1}{2} - \dfrac{6}{2^3\pi^2}\right)\sin 2\pi x + \left(\dfrac{1}{3} - \dfrac{6}{3^3\pi^2}\right)\sin 3\pi x - + \cdots$

6. Full-wave rectification of a cosine current,

$$\frac{2}{\pi} + \frac{4}{\pi}\left(\frac{1}{1\cdot 3}\cos 2\pi x - \frac{1}{3\cdot 5}\cos 4\pi x + \frac{1}{5\cdot 7}\cos 6\pi x - + \cdots\right)$$

8. $\dfrac{1}{2} + \dfrac{4}{\pi^2}\left(\cos\pi x + \dfrac{1}{9}\cos 3\pi x + \dfrac{1}{25}\cos 5\pi x + \cdots\right)$

10. $\dfrac{1}{2} - \dfrac{4}{\pi^2}\left(\cos\dfrac{\pi x}{2} + \dfrac{1}{9}\cos\dfrac{3\pi x}{2} + \dfrac{1}{25}\cos\dfrac{5\pi x}{2} + \cdots\right)$

$$+ \frac{2}{\pi}\left(\sin\frac{\pi x}{2} - \frac{1}{2}\sin\frac{2\pi x}{2} + \frac{1}{3}\sin\frac{3\pi x}{2} - \frac{1}{4}\sin\frac{4\pi x}{2} + - \cdots\right)$$

12. $b_n = 0$, $a_0 = \dfrac{V_0}{\pi}$,

$$a_n = 100V_0\int_{-1/200}^{1/200}\cos 100\pi t\cos 100n\pi t\,dt$$

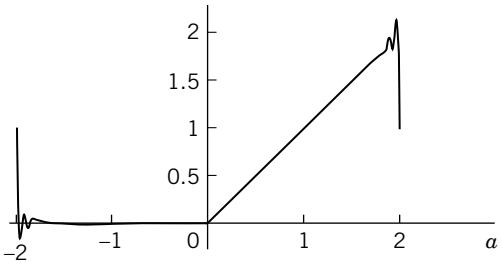
$$= 50V_0\int_{-1/200}^{1/200}\cos 100(n+1)\pi t\,dt + 50V_0\int_{-1/200}^{1/200}\cos 100(n-1)\pi t\,dt,$$

im11.qxd 9/21/05 12:33 PM Page 215

$$\frac{V_0}{\pi} + \frac{V_0}{2}\cos 100\pi t + \frac{2V_0}{\pi}\left(\frac{1}{1\cdot 3}\cos 200\pi t - \frac{1}{3\cdot 5}\cos 400\pi t + \frac{1}{5\cdot 7}\cos 600\pi t - + \cdots\right)$$

14. Multiply by -1 and add 1.

16. In Prob. 21 of Sec. 11.1, write t for x; then



$$\tilde{f}(t) = t^2 = \frac{\pi^2}{3} - 4\left(\cos t - \frac{1}{4}\cos 2t + - \cdots\right).$$

Now set $t = \pi x$ to get $\tilde{f}(t) = \pi^2 x^2$, which shows that the series should be multiplied by $1/\pi^2$ to get that of

$$f(x) = x^2 = \frac{1}{3} - \frac{4}{\pi^2}\left(\cos \pi x - \frac{1}{4}\cos 2\pi x + - \cdots\right).$$

18. Set $x = 1$ in Prob. 3 to get $1 = \frac{1}{3} - \frac{4}{\pi^2}\left(-1 - \frac{1}{4} - \frac{1}{9} - \cdots\right)$, etc.

20. CAS Experiment. The figure shows s_{50} in Prob. 10.

Section 11.2. Gibbs phenomenon in CAS Experiment 20

SECTION 11.3. Even and Odd Functions. Half-Range Expansions, page 490

Purpose. 1. To show that a Fourier series of an even function (an odd function) has only cosine terms (only sine terms), so that unnecesary work and sources of errors are avoided.

2. To represent a function $f(x)$ by a Fourier cosine series or by a Fourier sine series (of period $2L$) if $f(x)$ is given on an interval $0 \leqq x \leqq L$ only, which is half the interval of periodicity—hence the name "half-range."

Comment

Such half-range expansions occur in vibrational problems, heat problems, etc., as will be shown in Chap. 12.

SOLUTIONS TO PROBLEM SET 11.3, page 496

2. Even, even, even, even, neither even nor odd, neither even nor odd, odd, odd

4. Neither even nor odd

6. Even

im11.qxd 9/21/05 12:33 PM Page 216

8. Neither even nor odd

10. Project. (a) Sums and products of even functions are even. Sums of odd functions are odd. Products of odd functions are odd (even) if the number of their factors is odd (even). Products of an even times an odd function are odd. This is important in connection with the integrands in the Euler formulas for the Fourier coefficients. Absolute values of odd functions are even. $f(x) + f(-x)$ is even, $f(x) - f(-x)$ is odd.

(b) $e^{kx} = \cosh kx + \sinh kx$, $\dfrac{1}{1-x} = \dfrac{1}{1-x^2} + \dfrac{x}{1-x^2}$; furthermore,

$$\sin(x+k) = \sin k \cos x + \cos k \sin x,$$
$$\cosh(x+k) = \cosh k \cosh x + \sinh k \sinh x.$$

(c) $f(-x) = -f(x)$ and $f(-x) = f(x)$ together imply $f = 0$.

(d) $\cos^3 x$ is even, $\sin^3 x$ is odd. The Fourier series are the familiar identities

$$\cos^3 x = \tfrac{3}{4}\cos x + \tfrac{1}{4}\cos 3x \qquad \text{and} \qquad \sin^3 x = \tfrac{3}{4}\sin x - \tfrac{1}{4}\sin 3x.$$

See also Prob. 13 in Sec. 11.2.

12. $$\frac{4}{\pi^3}\left((\pi^2-4)\sin \pi x + \frac{1}{27}(9\pi^2-4)\sin 3\pi x + \frac{1}{125}(25\pi^2-4)\sin 5\pi x + \cdots\right)$$
$$-\frac{2}{\pi}\left(\sin 2\pi x + \frac{1}{2}\sin 4\pi x + \frac{1}{3}\sin 6\pi x + \cdots\right)$$

14. $$e^\pi - 1 - (e^\pi + 1)\cos x + \frac{2}{5}(e^\pi - 1)\cos 2x - \frac{1}{5}(e^\pi + 1)\cos 3x$$
$$+ \frac{2}{17}(e^\pi - 1)\cos 4x - + \cdots$$

16. $$\frac{1}{4} + \frac{4}{\pi^2}\left(\cos\frac{\pi x}{4} + \frac{1}{2}\cos\frac{2\pi x}{4} + \frac{1}{9}\cos\frac{3\pi x}{4} + \frac{1}{25}\cos\frac{5\pi x}{4}\right.$$
$$\left. + \frac{1}{18}\cos\frac{6\pi x}{4} + \frac{1}{49}\cos\frac{7\pi x}{4} + \cdots\right)$$

18. (a) $$\frac{1}{4} - \frac{2}{\pi^2}\left(\cos 2\pi x + \frac{1}{9}\cos 6\pi x + \frac{1}{25}\cos 10\pi x + \frac{1}{49}\cos 14\pi x + \cdots\right)$$

(b) $$\frac{1}{\pi}\left(\sin 2\pi x - \frac{1}{2}\sin 4\pi x + \frac{1}{3}\sin 6\pi x - \frac{1}{4}\sin 8\pi x + - \cdots\right)$$

20. (a) $$\frac{1}{2} - \frac{2}{\pi}\left(\cos\frac{\pi x}{4} - \frac{1}{3}\cos\frac{3\pi x}{4} + \frac{1}{5}\cos\frac{5\pi x}{4} - + \cdots\right)$$

(b) $$\frac{2}{\pi}\left(\sin\frac{\pi x}{4} - \sin\frac{\pi x}{2} + \frac{1}{3}\sin\frac{3\pi x}{4} + \frac{1}{5}\sin\frac{5\pi x}{4} - \frac{1}{3}\sin\frac{3\pi x}{2}\right.$$
$$\left. + \frac{1}{7}\sin\frac{7\pi x}{4} + \frac{1}{9}\sin\frac{9\pi x}{4} - \frac{1}{5}\sin\frac{5\pi x}{2} + \frac{1}{11}\sin\frac{11\pi x}{4} + \cdots\right)$$

22. (a) $$\frac{3\pi}{8} - \frac{2}{\pi}\left(\cos x + \frac{1}{2}\cos 2x + \frac{1}{9}\cos 3x + \frac{1}{25}\cos 5x + \frac{1}{18}\cos 6x\right.$$
$$\left. + \frac{1}{49}\cos 7x + \frac{1}{81}\cos 9x + \frac{1}{50}\cos 10x + \frac{1}{121}\cos 11x + \cdots\right)$$

im11.qxd 9/21/05 12:33 PM Page 217

(b) $\left(1 + \frac{2}{\pi}\right) \sin x - \frac{1}{2} \sin 2x + \left(\frac{1}{3} - \frac{2}{9\pi}\right) \sin 3x - \frac{1}{4} \sin 4x$
$+ \left(\frac{1}{5} + \frac{2}{25\pi}\right) \sin 5x - \frac{1}{6} \sin 6x + \left(\frac{1}{7} - \frac{2}{49\pi}\right) \sin 7x + \cdots$

The student should be invited to find the two functions that the sum of the series represents. This can be done by graphing $\sin x - \frac{1}{2} \sin 2x + \frac{1}{3} \sin 3x + - \cdots = x/2$ and then $(2/\pi)(\sin x - 3^{-2} \sin 3x + - \cdots) = f_2$, where

$$f_2(x) = \begin{cases} x/2 & \text{if} \quad -\pi/2 < x < \pi/2 \\ \pi/2 - x/2 & \text{if} \quad \pi/2 < x < 3\pi/2. \end{cases}$$

The first of these functions is discontinuous, the coefficients being proportional to $1/n$, whereas f_2 is continuous, its Fourier coefficients being proportional to $1/n^2$, so that they go to zero much faster than the others.

24. (a) $\frac{L^2}{3} - \frac{4L^2}{\pi^2} \left(\cos \frac{\pi x}{L} - \frac{1}{4} \cos \frac{2\pi x}{L} + \frac{1}{9} \cos \frac{3\pi x}{L} - \frac{1}{16} \cos \frac{4\pi x}{L} + - \cdots\right).$

(b) $\frac{2L^2}{\pi} \left[\left(1 - \frac{4}{\pi^2}\right) \sin \frac{\pi x}{L} - \frac{1}{2} \sin \frac{2\pi x}{L} + \left(\frac{1}{3} - \frac{4}{3^3\pi^2}\right) \sin \frac{3\pi x}{L} - \frac{1}{4} \sin \frac{4\pi x}{L} + \cdots\right]$

The coefficients of the cosine series are proportional to n^{-2}, reflecting the fact that the sum is continuous. The coefficients of the sine series are proportional to n^{-1}, so that they go to zero more slowly, reflecting the fact that the sum of the series is discontinuous.

26. $\int_{-L}^{L} g(x)\,dx = \int_{-L}^{0} g(t)\,dt + \int_{0}^{L} g(x)\,dx = -\int_{L}^{0} g(-x)\,dx + \int_{0}^{L} g(x)\,dx$. Here $t = -x$. Using that $g(x)$ is even, we obtain

$$\int_{0}^{L} g(-x)\,dx + \int_{0}^{L} g(x)\,dx = 2\int_{0}^{L} g(x)\,dx.$$

SECTION 11.4. Complex Fourier Series. *Optional,* page 496

Purpose. To show that the formula for $e^{i\theta}$ or direct derivation leads to the complex Fourier series in which complex exponential functions (instead of cosine and sine) appear. This is interesting, but will not be needed in our further work, so that we can leave it optional.
Short Courses. Sections 11.4–11.9 can be omitted.

SOLUTIONS TO PROBLEM SET 11.4, page 499

2. Direct consequence of (5).

8. Combine the terms pairwise ($n = 0$, $n = -1$), ($n = 1$, $n = -2$), etc. to obtain

$$-\frac{2i}{\pi}\left(2i \sin x + \frac{2i}{3} \sin 3x + \cdots\right) = \frac{4}{\pi}\left(\sin x + \frac{1}{3} \sin 3x + \cdots\right)$$

as in Sec. 11.1, Example 1, with $k = 1$.

im11.qxd 9/21/05 12:33 PM Page 218

10. $i(e^{inx} - e^{-inx}) = -2 \sin nx$, and $(-1)^n$ gives the signs as expected,

$$2(\sin x - \tfrac{1}{2} \sin 2x + \tfrac{1}{3} \sin 3x - + \cdots).$$

12. $e^{inx} + e^{-inx} = 2 \cos nx$, and $2 \cdot 2$ gives the factor 4 in

$$\frac{\pi^2}{3} - 4\left(\cos x - \frac{1}{4} \cos 2x + \frac{1}{9} \cos 3x - \frac{1}{16} \cos 4x + - \cdots\right).$$

14. Project. When $n = m$, the integrand of the integral on the right is $e^0 = 1$, so that the integral equals 2π. This gives

$$\int_{-\pi}^{\pi} f(x) e^{-imx}\, dx = 2\pi c_m$$

provided the other integrals are zero, which is true by (3b),

$$\int_{-\pi}^{\pi} e^{i(n-m)x}\, dx = \frac{1}{i(n-m)} (e^{i(n-m)\pi} - e^{-(n-m)\pi})$$

$$= \frac{1}{i(n-m)} 2i \sin (n-m)\pi = 0.$$

Now writing n for m in (A) gives the coefficient formula in (6).

SECTION 11.5. Forced Oscillations, page 499

Purpose. To show that mechanical or electrical systems with periodic but nonsinusoidal input may respond predominantly to one of the infinitely many terms in the Fourier series of the input, giving an unexpected output; see Fig. 274, where the output frequency is essentially five times that of the input.

Short Courses. Sections 11.4–11.9 can be omitted.

SOLUTIONS TO PROBLEM SET 11.5, page 501

2. For $k = 9$ the amplitude $C_3 = 0.943$ is largest, larger than C_1 by a factor 6. For $k = 81$ the amplitude $C_9 = 0.0349$ is largest; second is $C_1 = 0.0159$.

4. $r'(t)$ is given by the sine series in Example 1 of Sec. 11.1 with $k = -1$. The new C_n is n times the old one, so that C_5 is so large that the output is practically a cosine vibration having five times the input frequency.

6. $y = c_1 \cos \omega t + c_2 \sin \omega t + \dfrac{1}{\omega^2 - {\omega_1}^2} \cos \omega_1 t + \dfrac{1}{\omega^2 - {\omega_2}^2} \cos \omega_2 t$

8. $y = c_1 \cos \omega t + c_2 \sin \omega t + \dfrac{1}{\omega^2 - 1} \sin t + \dfrac{1/3}{\omega^2 - 9} \sin 3t + \dfrac{1/5}{\omega^2 - 25} \sin 5t + \dfrac{1/7}{\omega^2 - 49} \sin 7t$

10. $y = c_1 \cos \omega t + c_2 \sin \omega t + \dfrac{4}{\pi}\left(\dfrac{1}{\omega^2 - 1} \sin t - \dfrac{1/9}{\omega^2 - 9} \sin 3t + \dfrac{1/25}{\omega^2 - 25} \sin 5t - + \cdots\right)$

im11.qxd 9/21/05 12:33 PM Page 219

14. $y = \dfrac{1 - n^2}{D_n}\, a_n \cos nt + \dfrac{nc}{D_n}\, a_n \sin nt, \quad D_n = (1 - n^2)^2 + n^2c^2$

16. $y = A_1 \cos t + B_1 \sin t + A_3 \cos 3t + B_3 \sin 3t + \cdots$, where

$$A_n = -4ncb_n/D_n, \qquad B_n = 4(1 - n^2)b_n/D_n, \qquad D_n = (1 - n^2)^2 + n^2c^2$$

$b_1 = 1, b_2 = 0, b_3 = -1/9, b_4 = 0, b_5 = 1/25, \cdots$. The damping constant c appears in the cosine terms, causing a phase shift, which is 0 if $c = 0$. Also, c increases D_n; hence it decreases the amplitudes, which is physically understandable.

18. $C_n = \sqrt{A_n^2 + B_n^2} = 4/(n^2\pi\sqrt{D_n})$, $D_n = (n^2 - k)^2 + n^2c^2$ with A_n and B_n obtained as solutions of

$$(k - n^2)A_n + \quad ncB_n = 4/n^2\pi$$
$$-ncA_n + (k - n^2)B_n = 0.$$

20. $I = \displaystyle\sum_{n=1}^{\infty} (A_n \cos nt + B_n \sin nt)$,

$$A_n = \frac{80(10 - n^2)}{\pi n^2 D_n}, \quad B_n = \frac{800}{n\pi D_n} \quad (n \text{ odd}),$$

$A_n = 0, B_n = 0$ (n even), $D_n = (10 - n^2)^2 + 100\, n^2$; hence

$$I = 1.266 \cos t + 1.406 \sin t + 0.003 \cos 3t + 0.094 \sin 3t$$
$$- 0.006 \cos 5t + 0.019 \sin 5t - 0.003 \cos 7t + 0.006 \sin 7t$$
$$- 0.002 \cos 9t + 0.002 \sin 9t - 0.001 \cos 11t + 0.001 \sin 11t + \cdots$$

SECTION 11.6. Approximation by Trigonometric Polynomials, page 502

Purpose. We show how to find "best" approximations of a given function by trigonometric polynomials of a given degree N.

Important Concepts

Trigonometric polynomial

Square error, its minimum (6)

Bessel's inequality, Parseval's identity

Short Courses. Sections 11.4–11.9 can be omitted.

Comment on Quality of Approximation

This quality can be measured in many ways. Particularly important are (i) the absolute value of the maximum deviation over a given interval, and (ii) the mean square error considered here. See Ref. [GR7] in App. 1.

SOLUTIONS TO PROBLEM SET 11.6, page 505

2. $F = \dfrac{\pi^2}{3} - 4\left(\cos x - \dfrac{1}{4}\cos 2x + \dfrac{1}{9}\cos 3x - + \cdots + \dfrac{(-1)^{N+1}}{N^2}\cos Nx\right)$;

$E^* = 4.14, 1.00, 0.38, 0.18, 0.10$

4. $F = 2[(\pi^2 - 6)\sin x - \frac{1}{8}(4\pi^2 - 6)\sin 2x + \frac{1}{27}(9\pi^2 - 6)\sin 3x - + \cdots]$; $E^* = 674.8$, 454.7, 336.4, 265.6, 219.0. The coefficients are proportional to $1/n$. Accordingly, E^* decreases slowly; it is 59.64 ($N = 20$), 30.22 ($N = 40$), etc.

im11.qxd 9/21/05 12:33 PM Page 220

6. $F = A + B\cos x + \frac{2}{5}A\cos 2x + \frac{1}{5}B\cos 3x + \frac{2}{17}A\cos 4x + \cdots$, where $A = (1 - e^{-\pi})/\pi$, $B = (1 + e^{-\pi})/\pi$, $E^* = 0.06893, 0.02231, 0.00845, 0.00442, 0.00237$. For $N = 20$ we have $4.9 \cdot 10^{-5}$.

8. We obtain

$$F = \frac{2}{\pi}\sin x + \frac{1}{2}\sin 2x - \frac{2}{9\pi}\sin 3x - \frac{1}{4}\sin 4x + \frac{2}{25\pi}\sin 5x + \frac{1}{6}\sin 6x + \cdots.$$

The values of E^* are

1.3106, 0.5252, 0.5095, 0.3132, 0.3111, 0.2238, 0.2233, 0.1742, 0.1740, $\cdots$.

Their interesting way of decreasing reflects that some of the Fourier coefficients involve $1/n^2$ and others involve $1/n$.

10. CAS Experiment. Factors are the continuity or discontinuity and the speed with which the coefficients go to zero, $1/n$, $1/n^2$.

For $f(x)$ given on $-\pi < x < \pi$ some data are as follows (f, decrease of the coefficients, continuity or not, smallest N such that $E^* < 0.1$).

$f = x$, $1/n$, discontinuous, $N = 126$

$f = x^2$, $1/n^2$, continuous, $N = 5$

$f = x^3$, $1/n^2$, discontinuous. $E^* = 6.105$ for $N = 200$

$f = x^4$, $1/n$, continuous, $N = 40$

$f = x^6$, $1/n$, continuous. For $N = 200$ we still have $E^* = 0.1769$.

For f in Prob. 5 we have $1/n^2$, continuity, $N = 2$. In Prob. 9 we have $1/n^3$, continuity, and $N = 1$.

The functions

$$f(x) = \begin{cases} (x + \frac{1}{2}\pi)^{2k} - (\frac{1}{2}\pi)^{2k} & \text{if} \quad -\pi < x < 0 \\ -(-x - \frac{1}{2}\pi)^{2k} + (\frac{1}{2}\pi)^{2k} & \text{if} \quad 0 < x < \pi \end{cases}$$

with $k = 1, 2, 3, 4$ have coefficients proportional to $1/n^2$ and $E^* < 0.1$ when $N \geqq 1$ ($k = 1$), 5 ($k = 2$), 11 ($k = 3$), 21 ($k = 4$).

These data indicate that the whole situation is more complex than one would at first assume. So the student may need your help and guidance.

SECTION 11.7. Fourier Integral, page 506

Purpose. Beginning in this section, we show how ideas from Fourier series can be extended to nonperiodic functions defined on the real line, leading to integrals instead of series.

Main Content, Important Concepts

Fourier integral (5)

Existence Theorem 1

Fourier cosine integral, Fourier sine integral, (10)–(13)

Application to integration

Short Courses. Sections 11.4–11.9 can be omitted.

im11.qxd 9/21/05 12:33 PM Page 221

SOLUTIONS TO PROBLEM SET 11.7, page 512

2. The integral suggests to use (13). Its value suggests to consider $f(x) = \pi x/2$ $(0 < x < 1)$. Thus $A(w) = 0$, and by integration by parts, $(2/\pi$ cancels),

$$B(w) = \int_0^1 v \sin wv \, dv = \frac{\sin w - w \cos w}{w^2}.$$

At the jump $x = 1$ the mean of the limits is $\pi/4$.

4. The result suggests to consider $f(x) = \pi/2$ $(0 \leqq x < 1)$ and to use (11). Then (10) gives

$$A(w) = \int_0^1 \cos wv \, dv = \frac{\sin w}{w}.$$

Note that for $x = 0$ the integral gives (8*).

6. Use (13) and $f(x) = (\pi/2) \sin x$ $(0 \leqq x \leqq \pi)$ to get from (12) with the help of (11) in App. 3.1

$$B(w) = \int_0^\pi \sin v \sin wv \, dv = \frac{\sin \pi w}{1 - w^2}.$$

8. $A = \dfrac{2}{\pi} \displaystyle\int_0^a v^2 \cos wv \, dv = \frac{2}{\pi w} \left(a^2 \sin aw - \frac{2}{w^2} \sin aw + \frac{2a}{w} \cos aw \right)$, so that the *answer* is

$$\frac{2}{\pi} \int_0^\infty \left[\left(a^2 - \frac{2}{w^2} \right) \sin aw + \frac{2a}{w} \cos aw \right] \frac{\cos xw}{w} \, dw.$$

Although many students will do the actual integration by their CAS, problems of the present type have the merit of illustrating the ideas of integral representations and transforms, a rather deep and versatile creation, and the techniques involved, such as the proper choice of integration variables and integration limits. Moreover, graphics will help in understanding the transformation process and its properties, for instance, with the help of Prob. 18 or similar experiments.

10. $A = \dfrac{2}{\pi} \left(\displaystyle\int_0^1 \frac{v}{2} \cos wv \, dv + \int_1^2 \left(1 - \frac{v}{2} \right) \cos wv \, dv \right) = \frac{2}{\pi w^2} (\cos w - \cos^2 w)$, so that the *answer* is

$$\frac{2}{\pi} \int_0^\infty \frac{\cos w - \cos^2 w}{w^2} \cos xw \, dw.$$

12. $A = \dfrac{2}{\pi} \displaystyle\int_0^a e^{-v} \cos wv \, dv = \frac{2}{\pi} \left(\frac{1 - e^{-a} (\cos wa - w \sin wa)}{1 + w^2} \right)$, so that the integral representation is

$$\frac{2}{\pi} \int_0^\infty \frac{1 - e^{-a}(\cos wa - w \sin wa)}{1 + w^2} \cos xw \, dw.$$

14. $B = \dfrac{2}{\pi} \displaystyle\int_0^a \sin wv \, dv = \frac{2}{\pi} \left(\frac{1 - \cos aw}{w} \right)$. Hence the integral representation is

$$\frac{2}{\pi} \int_0^\infty \frac{1 - \cos aw}{w} \sin xw \, dw.$$

im11.qxd 9/21/05 12:33 PM Page 222

16. $B = \dfrac{2}{\pi}\displaystyle\int_0^1 (1 - v^2)\sin wv\, dv = \dfrac{2}{\pi}\cdot\dfrac{w^2 - 2w\sin w - 2\cos w + 2}{w^3}$ gives the integral representation

$$\frac{2}{\pi}\int_0^\infty \frac{w^2 - 2w\sin w - 2\cos w + 2}{w^3}\sin xw\, dw.$$

18. $B = \dfrac{2}{\pi}\displaystyle\int_0^\pi \cos v \sin wv\, dv = \dfrac{2}{\pi}\,\dfrac{w(1 + \cos \pi w)}{w^2 - 1}$ gives the integral representation

$$\frac{2}{\pi}\int_0^\infty \frac{w(1 + \cos \pi w)}{w^2 - 1}\sin xw\, dw.$$

Note that the Fourier sine series of the odd periodic extension of $f(x)$ of period 2π has the Fourier coefficients $b_n = (2/\pi)n(1 + \cos n\pi)/(n^2 - 1)$. Compare this with B.

20. Project. (a) Formula (a1): Setting $wa = p$, we have from (11)

$$f(ax) = \int_0^\infty A(w)\cos axw\, dw = \int_0^\infty A\left(\frac{p}{a}\right)\cos xp\,\frac{dp}{a}\,.$$

If we again write w instead of p, we obtain (a1).

Formula (a2): From (12) with $f(v)$ replaced by $vf(v)$ we have

$$B^*(w) = \frac{2}{\pi}\int_0^\infty vf(v)\sin wv\, dv = -\frac{dA}{dw}$$

where the last equality follows from (10).

Formula (a3) follows by differentiating (10) twice with respect to w,

$$\frac{d^2A}{dw^2} = -\frac{2}{\pi}\int_0^\infty f^*(v)\cos wv\, dv, \qquad f^*(v) = v^2 f(v).$$

(b) In Prob. 7 we have

$$A = \frac{2}{\pi}\,w^{-1}\sin aw.$$

Hence by differentiating twice we obtain

$$A'' = \frac{2}{\pi}\,(2w^{-3}\sin aw - 2aw^{-2}\cos aw - a^2w^{-1}\sin aw).$$

By (a3) we now get the result, as before,

$$x^2 f(x) = \frac{2}{\pi}\int_0^\infty\left[\left(-\frac{2}{w^3} + \frac{a^2}{w}\right)\sin aw + \frac{2a}{w^2}\cos aw\right]\cos xw\, dw.$$

(c) $A(w) = (2\sin aw)/(\pi w)$; see Prob. 7. By differentiation,

$$B^*(w) = -\frac{dA}{dw} = -\frac{2}{\pi}\left(\frac{a\cos aw}{w} - \frac{\sin aw}{w^2}\right).$$

This agrees with the result obtained by using (12). Note well that here we are dealing with a relation between the *two* Fourier transforms under consideration.

(d) The derivation of the following formulas is similar to that of (a1)–(a3).

(d1) $\quad f(bx) = \dfrac{1}{b}\displaystyle\int_0^\infty B\left(\frac{w}{b}\right)\sin xw\, dw \qquad (b > 0)$

im11.qxd 9/21/05 12:33 PM Page 223

(d2) $$xf(x) = \int_0^\infty C^*(w) \cos xw \, dw, \qquad C^*(w) = \frac{dB}{dw}, \qquad B \text{ as in (12)}$$

(d3) $$x^2 f(x) = \int_0^\infty D^*(w) \sin xw \, dw, \qquad D^*(w) = -\frac{d^2B}{dw^2}.$$

SECTION 11.8. Fourier Cosine and Sine Transforms, page 513

Purpose. Fourier cosine and sine transforms are obtained immediately from Fourier cosine and sine integrals, respectively, and we investigate some of their properties.

Content

Fourier cosine and sine transforms

Transforms of derivatives (8), (9)

Comment on Purpose of Transforms

Just as the Laplace transform (Chap. 6), these transforms are designed for solving differential equations. We show this for PDEs in Sec. 12.6.

Short Courses. Sections 11.4–11.9 can be omitted.

SOLUTIONS TO PROBLEM SET 11.8, page 517

2. Integration by parts gives

$$\hat{f}_c(w) = \sqrt{\frac{2}{\pi}} \int_0^k x \cos wx \, dx = \sqrt{\frac{2}{\pi}} \, \frac{\cos kw + kw \sin kw - 1}{w^2}.$$

4. From (3) and the answer to Prob. 1 we obtain

$$f(x) = \sqrt{\frac{2}{\pi}} \sqrt{\frac{2}{\pi}} \left(\int_0^\infty \frac{\sin 2w}{w} \cos wx \, dw - 2 \int_0^\infty \frac{\sin w}{w} \cos wx \, dw \right).$$

In the first term set $2w = v$ to get (a factor 2 cancels and $(2/\pi)(\pi/2) = 1$)

$$\frac{2}{\pi} \int_0^\infty \frac{\sin v}{v} \cos\left(\frac{vx}{2}\right) dv = \begin{cases} 1 & \text{if } x/2 < 1, \text{ thus } x < 2 \\ 0 & \text{if } x/2 > 1, \text{ thus } x > 2. \end{cases}$$

The second term gives

$$-2 \cdot \frac{2}{\pi} \int_0^\infty \frac{\sin w}{w} \cos wx \, dw = \begin{cases} -2 & \text{if } x < 1 \\ 0 & \text{if } x > 1. \end{cases}$$

Adding the two results, we have -1 if $0 < x < 1$, 1 if $1 < x < 2$, 0 if $x > 2$.

6. By integration by parts we obtain

$$f(x) = \sqrt{\frac{2}{\pi}} \int_0^\infty e^{-w} \cos wx \, dw = \sqrt{\frac{2}{\pi}} \cdot \frac{1}{1 + x^2}.$$

8. Integration by parts gives the *answer*

$$\sqrt{\frac{2}{\pi}} \, \frac{2w \cos w + (w^2 - 2) \sin w}{w^3}.$$

10. The defining integrals (2) and (5) have no limit as $x \to \infty$.

im11.qxd 9/21/05 12:33 PM Page 224

12. $f(x) = e^{-\pi x}$, $f''(x) = \pi^2 f$, $f(0) = 1$. Hence (9b) gives

$$\mathcal{F}_s(f'') = \pi^2 \mathcal{F}_s(f) = -w^2 \mathcal{F}_s(f) + \sqrt{\frac{2}{\pi}}\, w.$$

Ordering terms and solving for $\mathcal{F}_s(f)$ gives

$$(w^2 + \pi^2)\mathcal{F}_s(f) = \sqrt{\frac{2}{\pi}}\, w, \qquad \mathcal{F}_s(f) = \sqrt{\frac{2}{\pi}} \cdot \frac{w}{w^2 + \pi^2}.$$

14. $$\sqrt{\frac{2}{\pi}} \int_0^\pi \sin x \sin wx \, dx = \sqrt{\frac{2}{\pi}} \frac{\sin \pi w}{1 - w^2}$$

16. The integrals in this problem and the next one can be reduced to **Fresnel integrals.** This suggests the transformation $wx = t^2$. Of course, if one does not see this, one would start with, say, $wx = v$ and then perhaps remember that the integral of $v^{-1/2} \sin v$ can be reduced to a Fresnel integral (38) in App. 3.1 by setting $v = t^2$. The present calculation is

$$\begin{aligned}\sqrt{\frac{2}{\pi}} \int_0^\infty x^{-1/2} \sin wx \, dx &= \sqrt{\frac{2}{\pi}} \int_0^\infty w^{1/2} t^{-1} (\sin t^2) 2t \, dt \, w^{-1} \\ &= w^{-1/2} \sqrt{\frac{8}{\pi}} \int_0^\infty \sin t^2 \, dt = w^{-1/2}.\end{aligned}$$

18. The calculation is similar to that in Prob. 16 but requires an additional integration by parts,

$$\begin{aligned}\sqrt{\frac{2}{\pi}} \int_0^\infty x^{-3/2} \sin wx \, dx &= \sqrt{\frac{2}{\pi}} \int_0^\infty w^{3/2} t^{-3} (\sin t^2) w^{-1} 2t \, dt \\ &= \sqrt{\frac{8}{\pi}}\, w^{1/2} \int_0^\infty t^{-2} \sin t^2 \, dt \\ &= \sqrt{\frac{8}{\pi}}\, w^{1/2} \left(-t^{-1} \sin t^2 \Big|_0^\infty + \int_0^\infty t^{-1} (\cos t^2) 2t \, dt \right) \\ &= \sqrt{\frac{8}{\pi}}\, w^{1/2} 2 \sqrt{\frac{\pi}{8}} = 2w^{1/2}.\end{aligned}$$

SECTION 11.9. Fourier Transform. Discrete and Fast Fourier Transforms, page 518

Purpose. Derivation of the Fourier transform from the complex form of the Fourier integral; explanation of its physical meaning and its basic properties.

Main Content, Important Concepts

Complex Fourier integral (4)

Fourier transform (6), its inverse (7)

Spectral representation, spectral density

Transforms of derivatives (9), (10)

Convolution $f * g$

Comments on Content

The complex Fourier integral is relatively easily obtained from the real Fourier integral in Sec. 11.7, and the definition of the Fourier transform is then immediate.

im11.qxd 9/21/05 12:33 PM Page 225

Note that convolution $f * g$ differs from that in Chapter 6, and so does the formula (12) in the convolution theorem (we now have a factor $\sqrt{2\pi}$).

Short Courses. Sections 11.4–11.9 can be omitted.

SOLUTIONS TO PROBLEM SET 11.9, page 528

2. By integration of the defining integral we obtain

$$\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{0} e^{(k-iw)x}\,dx = \frac{1}{\sqrt{2\pi}}\cdot\frac{e^{(k-iw)x}}{k-iw}\,\Bigg|_{-\infty}^{0}$$
$$= \frac{1}{\sqrt{2\pi}}\cdot\frac{1}{k-iw}.$$

4. Integration of the defining integral gives

$$\frac{1}{\sqrt{2\pi}}\int_{-1}^{1} e^{(2-w)ix}\,dx = \frac{-i}{\sqrt{2\pi}(2-w)}\,(e^{(2-w)i} - e^{-(2-w)i})$$
$$= \frac{-i}{\sqrt{2\pi}(2-w)}\,2i\sin(2-w)$$
$$= \sqrt{\frac{2}{\pi}}\,\frac{\sin(w-2)}{w-2}.$$

6. By integration by parts,

$$\frac{1}{\sqrt{2\pi}}\int_{-1}^{1} xe^{-iwx}\,dx = \frac{1}{\sqrt{2\pi}}\left(\frac{xe^{-iwx}}{-iw}\,\Bigg|_{-1}^{1} - \frac{1}{-iw}\int_{-1}^{1} e^{-iwx}\,dx\right)$$
$$= \frac{1}{\sqrt{2\pi}}\left(\frac{e^{-iw}}{-iw} + \frac{e^{iw}}{-iw} - \frac{1}{(-iw)^2}\,e^{-iwx}\Big|_{-1}^{1}\right)$$
$$= \frac{1}{\sqrt{2\pi}}\left(\frac{2\cos w}{-iw} + \frac{1}{w^2}\,(e^{-iw} - e^{iw})\right)$$
$$= \sqrt{\frac{2}{\pi}}\left(\frac{i\cos w}{w} - \frac{i\sin w}{w^2}\right)$$
$$= \sqrt{\frac{2}{\pi}}\cdot\frac{i}{w^2}\,(w\cos w - \sin w).$$

8. By integration by parts we obtain

$$\frac{1}{\sqrt{2\pi}}\int_{-1}^{0} xe^{-x-iwx}\,dx = \frac{1}{\sqrt{2\pi}}\left(\frac{xe^{-(1+iw)x}}{-(1+iw)}\,\Bigg|_{-1}^{0} + \frac{1}{1+iw}\int_{-1}^{0} e^{-(1+iw)x}\,dx\right)$$
$$= \frac{1}{\sqrt{2\pi}}\left(-(-1)\,\frac{e^{1+iw}}{-(1+iw)} + \frac{e^{-(1+iw)x}}{-(1+iw)(1+iw)}\,\Bigg|_{-1}^{0}\right)$$
$$= \frac{1}{\sqrt{2\pi}}\left(\frac{-e^{1+iw}}{1+iw} - \frac{1-e^{1+iw}}{(1+iw)^2}\right)$$
$$= \frac{1}{\sqrt{2\pi}(-w+i)^2}\,(1 + e^{1+iw}(-1 - i(-w+i)))$$
$$= \frac{1}{\sqrt{2\pi}(-w+i)^2}\,(1 + iwe^{1+iw}).$$

im11.qxd 9/21/05 12:33 PM Page 226

Problems 1 to 9 should help the student get a feel for integrating complex exponential functions and for their transformation into cosine and sine, as needed in this context. Here, it is taken for granted that complex exponential functions can be handled in the same fashion as real ones, which will be justified in Part D on complex analysis. The problems show that the technicalities are rather formidable for someone who faces these exponential functions for the first time. This is so for relatively simple $f(x)$, and since a CAS will give all the results without difficulty, it would make little sense to deal with more complicated $f(x)$, which would involve increased technical difficulties but no new ideas.

10. $f(x) = xe^{-x}$ $(x > 0)$, $g(x) = e^{-x}$ $(x > 0)$. Then $f' = e^{-x} - xe^{-x} = g - f$, and by (9),

$$iw\mathcal{F}(f) = \mathcal{F}(f') = \mathcal{F}(g) - \mathcal{F}(f)$$

hence

$$(iw + 1)\mathcal{F}(f) = \mathcal{F}(g) = \frac{1}{\sqrt{2\pi}(1 + iw)}, \qquad \mathcal{F}(f) = \frac{1}{\sqrt{2\pi}(1 + iw)^2}.$$

12. We obtain

$$\frac{i}{\sqrt{2\pi}} \cdot \frac{e^{-ib(a-w)} - e^{ib(a-w)}}{a - w} = \frac{i}{\sqrt{2\pi}} \cdot \frac{-2i \sin b(a - w)}{a - w}$$

$$= \sqrt{\frac{2}{\pi}} \cdot \frac{\sin b(w - a)}{w - a}.$$

14. Team Project. (a) Use $t = x - a$ as a new variable of integration.

(b) Use $c = 3b$. Then (a) gives

$$e^{2ibw}\mathcal{F}(f(x)) = \frac{e^{ibw} - e^{-ibw}}{iw\sqrt{2\pi}} = \frac{2i \sin bw}{iw\sqrt{2\pi}} = \sqrt{\frac{2}{\pi}} \cdot \frac{\sin bw}{w}.$$

(c) Replace w with $w - a$. This gives a new factor e^{iax}.

(d) We see that $\hat{f}(w)$ in formula 7 is obtained from $\hat{f}(w)$ in formula 1 by replacing w with $w - a$. Hence by (c), $f(x)$ in formula 1 times e^{iax} should give $f(x)$ in formula 7, which is true. Similarly for formulas 2 and 8.

SOLUTIONS TO CHAP. 11 REVIEW QUESTIONS AND PROBLEMS, page 532

12. $\frac{1}{2} - \frac{2}{\pi}\left(\cos x - \frac{1}{3}\cos 3x + \frac{1}{5}\cos 5x - + \cdots\right)$

14. $1 - \frac{8}{\pi^2}\left(\cos\frac{\pi x}{2} + \frac{1}{9}\cos\frac{3\pi x}{2} + \frac{1}{25}\cos\frac{5\pi x}{2} + \cdots\right)$

16. $\frac{2}{\pi}\left(\sin \pi x + \frac{1}{2}\sin 2\pi x + \frac{1}{3}\sin 3\pi x + \cdots\right)$

18. $\frac{\sinh \pi}{\pi}\left(1 - \cos x + \sin x + \frac{2}{5}\cos 2x - \frac{4}{5}\sin 2x + \cdots\right)$

20. $\pi - 2(\sin x + \frac{1}{2}\sin 2x + \frac{1}{3}\sin 3x + \frac{1}{4}\sin 4x + \cdots)$

22. 1/2 by Prob. 17. Convergence is slow.

im11.qxd 9/21/05 12:33 PM Page 227

24. From the solution to Prob. 12 we obtain

$$\frac{1}{2} + \frac{4}{\pi^2}\left(1 + \frac{1}{9} + \frac{1}{25} + \cdots\right) = \frac{1}{\pi}\int_{-\pi/2}^{\pi/2} dx = 1.$$

Hence the *answer* is $\pi^2/8$.

26. $\dfrac{2}{\pi}\left(\sin x - \sin 2x + \dfrac{1}{3}\sin 3x + \dfrac{1}{5}\sin 5x - \dfrac{1}{3}\sin 6x + \dfrac{1}{7}\sin 7x + \dfrac{1}{9}\sin 9x - \dfrac{1}{5}\sin 10x + \cdots\right)$.

The sum of

$$-\frac{2}{\pi}\left(\sin 2x + \frac{1}{3}\sin 6x + \frac{1}{5}\sin 10x + \cdots\right)$$

is $-1/2$ if $0 < x < \pi/2$ and $1/2$ if $\pi/2 < x < \pi$ and periodic with π. The sum of the other terms is the rectangular wave discussed in Sec. 11.1. A sketch of the two functions will explain the connection.

28. 0.2976, 0.2976, 0.1561, 0.1561, 0.1052, 0.1052, 0.0792, 0.0792

30. $y = 12 \cdot \dfrac{\sin t}{\omega^2 - 1} - \dfrac{3}{2} \cdot \dfrac{\sin 2t}{\omega^2 - 4} + \dfrac{4}{9} \cdot \dfrac{\sin 3t}{\omega^2 - 9} - \dfrac{3}{16} \cdot \dfrac{\sin 4t}{\omega^2 - 16} + - \cdots + C_1 \cos \omega t + C_2 \sin \omega t$

32. $\dfrac{1}{\pi}\displaystyle\int_0^\infty \frac{(\sin 2w - \sin w)\cos wx + (\cos w - \cos 2w)\sin wx}{w}\, dw$

34. $\dfrac{1}{\pi}\displaystyle\int_0^\infty \frac{1 - \cos 2w}{w^2}\cos wx\, dw$

36. $\dfrac{4}{\pi}\displaystyle\int_0^\infty \frac{2w^2 + 1 - \cos 2w - 2w \sin 2w}{w^3}\sin wx\, dw$

38. $\dfrac{k}{\sqrt{2\pi}}\displaystyle\int_a^b e^{-iwx}\, dx = \frac{k}{\sqrt{2\pi}} \cdot \frac{e^{-iwx}}{-iw}\bigg|_{x=a}^{b} = \frac{ik}{\sqrt{2\pi}} \cdot \frac{e^{-ibw} - e^{-iaw}}{w}$

40. $\mathcal{F}_c(f'') = 4\mathcal{F}_c(f) = -w^2\mathcal{F}_c(f) - \sqrt{\dfrac{2}{\pi}}\, f'(0), \quad f'(0) = -2.$ Hence

$$\mathcal{F}_c(f)(w^2 + 4) = \sqrt{\frac{8}{\pi}}.$$

Now solve for $\mathcal{F}_c(f)$.

Similarly, again by two differentiations,

$$\mathcal{F}_s(f'') = 4\mathcal{F}_s(f) = -w^2\mathcal{F}_s(f) + \sqrt{\frac{2}{\pi}}\, wf(0), \qquad f(0) = 1.$$

Hence

$$\mathcal{F}_s(f)(w^2 + 4) = \sqrt{\frac{2}{\pi}}\, w \qquad \text{and} \qquad \mathcal{F}_s(f) = \sqrt{\frac{2}{\pi}} \cdot \frac{w}{w^2 + 4}.$$

im12.qxd 9/21/05 5:16 PM Page 228

CHAPTER 12 Partial Differential Equations (PDEs)

SECTION 12.1 Basic Concepts, page 535

Purpose. To familiarize the student with the following:

Concept of solution, verification of solutions

Superposition principle for homogeneous linear PDEs

PDEs solvable by methods for ODEs

SOLUTIONS TO PROBLEM SET 12.1, page 537

2. $u = c_1(y)e^{x} + c_2(y)e^{-x}$.

Problems 1–12 will help the student get used to the notations in this chapter; in particular, y will now occur as an *independent* variable. Second-order PDEs in this set will also help review the solution methods in Chap. 2, which will play a role in separating variables.

4. $u = c(x)e^{-y^2}$

6. $u = c_1(y)e^{-2xy} + c_2(y)e^{2xy}$

8. $\ln u = 2x \int y\, dy = xy^2 + \tilde{c}(x)$, $u = c(x)e^{xy^2}$

10. Set $u_y = v$. Then $v_y = 4xv$, $v = \tilde{c}_1(x)e^{4xy}$; hence

$$u = \int v\, dy = c_1(x)e^{4xy} + c_2(x).$$

12. $u = (c_1(x) + c_2(x)y)e^{-5y} + \frac{1}{2}y^2e^{-5y}$. The function on the right is a solution of the homogeneous ODE, corresponding to a double root, so that the last term in the solution involves the factor y^2.

14. $c = 1/2$.

Problems 14–25 should give the student a first impression of what kind of solutions to expect, and of the great variety of solutions compared with those of ODEs. It should be emphasized that although the wave and the heat equations look so similar, their solutions are basically different. It could be mentioned that the boundary and initial conditions are basically different, too. Of course, this will be seen in great detail in later sections, so one should perhaps be cautious not to overload students with such details before they have seen a problem being solved.

16. $c = 6$

18. $c = \sqrt{k/32}$

20. $c = 2$, ω arbitrary

22. Solutions of the Laplace equation in two dimensions will be derived systematically in complex analysis. Nevertheless, it may be useful to see an unsystematic selection of typical solutions, as given in (7) and in Probs. 23–25.

26. Team Project. (a) Denoting derivatives with respect to the entire argument $x + ct$ and $x - ct$, respectively, by a prime, we obtain by differentiating twice

$$u_{xx} = v'' + w'', \qquad u_{tt} = v''c^2 + w''c^2$$

and from this the desired result.

im12.qxd 9/21/05 5:16 PM Page 229

(c) The student should realize that $u = 1/\sqrt{x^2 + y^2}$ is not a solution of Laplace's equation in two variables. It satisfies the Poisson equation with $f = (x^2 + y^2)^{-3/2}$, which seems remarkable.

28. A function whose first partial derivatives are zero is a constant, $u(x, y) = c = const.$ Integrate the first PDE and then use the second.

30. Integrating the first PDE and the second PDE gives

$$u = c_1(y)x + c_2(y) \qquad \text{and} \qquad u = c_3(x)y + c_4(x),$$

respectively. Equating these two functions gives

$$u = axy + bx + cy + k.$$

Alternatively, $u_{xx} = 0$ gives $u = c_1(y)x + c_2(y)$. Then from $u_{yy} = 0$ we get $u_{yy} = c_1''x + c_2'' = 0$; hence $c_1'' = 0$, $c_2'' = 0$, and by integration

$$c_1 = \alpha y + \beta, \qquad c_2 = \gamma y + \delta$$

and by substitution in the previous expression

$$u = c_1x + c_2 = \alpha yx + \beta x + \gamma y + \delta.$$

SECTION 12.2. Modeling: Vibrating String, Wave Equation, page 538

Purpose. A careful derivation of the one-dimensional wave equation (more careful than in most other texts, where some of the essential physical assumptions are usually missing).
Short Courses. One may perhaps omit the derivation and just state the wave equation and mention of what c^2 is composed.

SECTION 12.3. Solution by Separating Variables. Use of Fourier Series, page 540

Purpose. This first section in which we solve a "big" problem has several purposes:

1. To familiarize the student with the wave equation and with the typical initial and boundary conditions that physically meaningful solutions must satisfy.
2. To explain and apply the important method of separation of variables, by which the PDE is reduced to two ODEs.
3. To show how Fourier series help to get the final answer, thus seeing the reward of our great and long effort in Chap. 11.
4. To discuss the eigenfunctions of the problem, the basic building blocks of the solution, which lead to a deeper understanding of the whole problem.

Steps of Solution

1. Setting $u = F(x)G(t)$ gives two ODEs for F and G.
2. The boundary conditions lead to sine and cosine solutions of the ODEs.
3. A series of those solutions with coefficients determined from the Fourier series of the initial conditions gives the final answer.

im12.qxd 9/21/05 5:16 PM Page 230

SOLUTIONS TO PROBLEM SET 12.3, page 546

2. $k(\cos \pi t \sin \pi x - \frac{1}{3} \cos 3\pi t \sin 3\pi x)$

4. $\dfrac{12k}{\pi^3}\left(\cos \pi t \sin \pi x - \dfrac{1}{8} \cos 2\pi t \sin 2\pi x + \dfrac{1}{27} \cos 3\pi t \sin 3\pi x - + \cdots\right)$

6. $\dfrac{\sqrt{8}}{\pi^2}\left(\cos \pi t \sin \pi x + \dfrac{1}{9} \cos 3\pi t \sin 3\pi x - \dfrac{1}{25} \cos 5\pi t \sin 5\pi x - + \cdots\right)$

8. $\dfrac{8}{\pi^2}\left(\dfrac{1}{4} \cos 2\pi t \sin 2\pi x - \dfrac{1}{36} \cos 6\pi t \sin 6\pi x + \dfrac{1}{100} \cos 10\pi t \sin 10\pi x - \cdots\right)$

There are more graphically posed problems (Probs. 5–10) than in previous editions, so that CAS-using students will have to make at least *some* additional effort in solving these problems.

10. $\dfrac{25}{2\pi^2}\left(\sin \dfrac{\pi}{5} \cos \pi t \sin \pi x - \dfrac{1}{4} \sin \dfrac{2\pi}{5} \cos 2\pi t \sin 2\pi x\right.$

$\left. + \dfrac{1}{9} \sin \dfrac{2\pi}{5} \cos 3\pi t \sin\ 3\pi x - \dfrac{1}{16} \sin \dfrac{\pi}{5} \cos 4\pi t \sin 4\pi x + - \cdots\right)$

12. $u = \sum_{n=1}^{\infty} B_n^* \sin nt \sin nx, \quad B_n^* = \dfrac{0.04}{\pi n^3} \sin \dfrac{n\pi}{2}$

14. Team Project. (c) From the given initial conditions we obtain

$$G_n(0) = B_n = \frac{2}{L}\int_0^L f(x) \sin \frac{n\pi x}{L}\, dx,$$

$$\dot{G}_n(0) = \lambda_n B_n^* + \frac{2A\omega(1 - \cos \omega\pi)}{n\pi(\lambda_n{}^2 - \omega^2)} = 0.$$

(e) $u(0, t) = 0$, $w(0, t) = 0$, $u(L, t) = h(t)$, $w(L, t) = h(t)$. The simplest w satisfying these conditions is $w(x, t) = xh(t)/L$. Then

$$v(x, 0) = f(x) - xh(0)/L = f_1(x)$$
$$v_t(x, 0) = g(x) - xh'(0)/L = g_1(x)$$
$$v_{tt} - c^2 v_{xx} = -xh''/L.$$

16. $F_n = \sin(n\pi x/L)$, $G_n = a_n \cos(cn^2\pi^2 t/L^2)$

18. For the string the frequency of the nth mode is proportional to n, whereas for the beam it is proportional to n^2.

20. $F(0) = A + C = 0$, $C = -A$, $F'(0) = \beta(B + D) = 0$, $D = -B$. Then

$$F(x) = A(\cos \beta x - \cosh \beta x) + B(\sin \beta x - \sinh \beta x)$$
$$F''(L) = \beta^2[-A(\cos \beta L + \cosh \beta L) - B(\sin \beta L + \sinh \beta L)] = 0$$
$$F'''(L) = \beta^3[A(\sin \beta L - \sinh \beta L) - B(\cos \beta L + \cosh \beta L)] = 0.$$

The determinant $(\cos \beta L + \cosh \beta L)^2 + \sin^2 \beta L - \sinh^2 \beta L$ of this system in the unknowns A and B must be zero, and from this the result follows.

From (23) we have

$$\cos \beta L = \frac{-1}{\cosh \beta L} \approx 0$$

im12.qxd 9/21/05 5:16 PM Page 231

because cosh βL is very large. This gives the approximate solutions

$$\beta L \approx \tfrac{1}{2}\pi, \tfrac{3}{2}\pi, \tfrac{5}{2}\pi, \cdots \text{ (more exactly, 1.875, 4.694, 7.855, } \cdots).$$

SECTION 12.4. D'Alembert's Solution of the Wave Equation. Characteristics, page 548

Purpose. To show a simpler method of solving the wave equation, which, unfortunately, is not so universal as separation of variables.

Comment on Order of Sections

Section 12.11 on the solution of the wave equation by the Laplace transform may be studied directly after this section. We have placed that material at the end of this chapter because some students may not have studied Chap. 6 on the Laplace transform, which is not a prerequisite for Chap. 12.

Comment on Footnote 1

D'Alembert's *Traité de dynamique* appeared in 1743 and his solution of the vibrating string problem in 1747; the latter makes him, together with Daniel Bernoulli (1700–1782), the founder of the theory of PDEs. In 1754 d'Alembert became Secretary of the French Academy of Science and as such the most influential man of science in France.

SOLUTIONS TO PROBLEM SET 12.4, page 552

2. $u(0, t) = \frac{1}{2}[f(ct) + f(-ct)] = 0$, $f(-ct) = -f(ct)$, so that f is odd. Also

$$u(L, t) = \tfrac{1}{2}[f(ct + L) + f(-ct + L)] = 0$$

hence

$$f(ct + L) = -f(-ct + L) = f(ct - L).$$

This proves the periodicity.

4. $(1/2\pi)(n\pi/2) \cdot 80.83 = 20.21n$

10. The Tricomi equation is elliptic in the upper half-plane and hyperbolic in the lower, because of the coefficient y.

$u = F(x)G(y)$ gives

$$yF''G = -FG'', \qquad \frac{F''}{F} = -\frac{G''}{yG} = -k$$

and $k = 1$ gives Airy's equation.

12. Parabolic. Characteristic equation

$$y'^2 + 2y' + 1 = (y' + 1)^2 = 0.$$

New variables $v = \Phi = x$, $w = \Psi = x + y$. By the chain rule,

$$\begin{aligned} u_x &= u_v + u_w \\ u_{xx} &= u_{vv} + 2u_{vw} + u_{ww} \\ u_{xy} &= u_{vw} + u_{ww} \\ u_{yy} &= u_{ww}. \end{aligned}$$

Substitution of this into the PDE gives the expected normal form

$$u_{vv} = 0.$$

im12.qxd 9/21/05 5:16 PM Page 232

By integration,

$$u_v = \tilde{c}(w), \quad u = \tilde{c}(w)v + c(w).$$

In the original variables this becomes

$$u = xf_1(x + y) + f_2(x + y).$$

14. Hyperbolic. Characteristic equation

$$y'^2 - y' - 2 = (y' + 1)(y' - 2) = 0.$$

Hence new variables are $v = y + x$, $w = y - 2x$. Solution:

$$u = f_1(x + y) + f_2(2x - y).$$

16. Hyperbolic. New variables $x = v$ and $xy = w$. The latter is obtained from

$$-xy' - y = 0, \qquad \frac{y'}{y} = -\frac{1}{x}, \qquad \ln|y| = -\ln|x| + c.$$

By the chain rule we obtain in these new variables from the given PDE by cancellation of $-yu_{yy}$ against a term in xu_{xy} and division of the remaining PDE by x the PDE

$$u_w + xu_{vw} = 0.$$

(The normal form is $u_{vw} = -u_w/x = -u_w/v$.) We set $u_w = z$ and obtain

$$z_v = -\frac{1}{v}\, z, \qquad z = \frac{c(w)}{v}.$$

By integration with respect to w we obtain the solution

$$u = \frac{1}{v}\, f_1(w) + f_2(v) = \frac{1}{x}\, f_1(xy) + f_2(x).$$

18. Elliptic. The characteristic equation is

$$y'^2 - 2y' + 5 = \big[y' - (1 - 2i)\big]\big[y' - (1 + 2i)\big] = 0.$$

Complex solutions are

$$\Phi = y - (1 - 2i)x = const, \qquad \Psi = y - (1 + 2i)x = const.$$

This gives the solutions of the PDE:

$$u = f_1(y - (1 - 2i)x) + f_2(y - (1 + 2i)x).$$

Since the PDE is linear and homogeneous, real solutions are the real and the imaginary parts of u.

20. Hyperbolic. Characteristic equation

$$y'^2 + 4y' + 3 = (y' + 1)(y' + 3) = 0.$$

The solution of the given PDE is

$$u = f_1(x + y) + f_2(3x + y).$$

im12.qxd 9/21/05 5:16 PM Page 233

SECTION 12.5. Heat Equation: Solution by Fourier Series, page 552

Purpose. This section has two purposes:

1. To solve a typical heat problem by steps similar to those for the wave equation, pointing to the two main differences: only *one* initial condition (instead of two) and u_t (instead of u_{tt}), resulting in exponential functions in t (instead of cosine and sine in the wave equation).
2. Solution of Laplace's equation (which can be interpreted as a time-independent heat equation in two dimensions).

Comments on Content

Additional points to emphasize are

More rapid decay with increasing n,

Difference in time evolution in Figs. 292 and 288,

Zero can be an eigenvalue (see Example 4),

Three standard types of boundary value problems,

Analogy of electrostatic and (steady-state) heat problems.

Problem Set 12.5 includes additional heat problems and types of boundary conditions.

SOLUTIONS TO PROBLEM SET 12.5, page 560

2. $u_1 = \sin x\, e^{-t}$, $u_2 = \sin 2x\, e^{-4t}$, $u_3 = \sin 3x\, e^{-9t}$. A main difference is the rapidity of decay, so that series solutions (9) will be well approximated by partial sums of few terms.

4. $(c^2\pi^2/L^2)10 = \ln 2$, $c^2 = 0.00702L^2$

6. $u = \sin 0.1\pi x\, e^{-1.752\pi^2 t/100} + \frac{1}{2} \sin 0.2\pi x\, e^{-1.752\cdot 4\pi^2 t/100}$

8. $$u = \frac{8}{\pi^2}\left(\sin 0.1\pi x\, e^{-0.01752\pi^2 t} - \frac{1}{9}\sin 0.3\pi x\, e^{-0.01752(3\pi)^2 t} + \frac{1}{25}\sin 0.5\pi x\, e^{-0.01752(5\pi)^2 t} - + \cdots\right)$$

10. $u_I = U_1 + (U_2 - U_1)x/L$; this is the solution of (1) with $\partial u/\partial t = 0$ satisfying the boundary conditions.

12. $u(x, 0) = f(x) = 100$, $U_1 = 100$, $U_2 = 0$, $u_I = 100 - 10x$. Hence

$$\begin{aligned} B_n &= \frac{2}{10}\int_0^{10} [100 - (100 - 10x)] \sin\frac{n\pi x}{10}\, dx \\ &= \frac{2}{10}\int_0^{10} 10x \sin\frac{n\pi x}{10}\, dx \\ &= -\frac{200}{n\pi}\cos n\pi \\ &= \frac{(-1)^{n+1}}{n}\cdot 63.66. \end{aligned}$$

im12.qxd 9/21/05 5:16 PM Page 234

This gives the solution

$$u(x, t) = 100 - 10x + 63.66 \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin \frac{n\pi x}{10}\, e^{-1.752(n\pi/10)^2 t}.$$

For $x = 5$ this becomes

$$u(5, t) = 50 + 63.66[e^{-0.1729t} - \tfrac{1}{3}e^{-1.556t} + \tfrac{1}{5}e^{-4.323t} - + \cdots].$$

Obviously, the sum of the first few terms is a good approximation of the true value at any $t > 0$. We find:

t	1	2	3	10	50
$u(5, t)$	99	94	88	61	50

14. $u = \dfrac{\pi}{2} - \dfrac{4}{\pi}\left(\cos x\, e^{-t} + \dfrac{1}{9}\cos 3x\, e^{-9t} + \dfrac{1}{25}\cos 5x\, e^{-25t} + \cdots\right)$

16. $u = 0.5 \cos 4x\, e^{-16t}$

18. $u = \dfrac{\pi}{4} - \dfrac{2}{\pi}\left(\cos 2x\, e^{-4t} + \dfrac{1}{9}\cos 6x\, e^{-36t} + \dfrac{1}{25}\cos 10x\, e^{-100t} + \cdots\right)$

20. $F = A \cos px + B \sin px$, $F(0) = A = 0$, $F'(L) = Bp \cos pL = 0$, $pL = (2n - 1)\pi/2$; hence

$$u = \sum_{n=1}^{\infty} B_{2n-1} \sin \frac{(2n-1)\pi x}{2L} \exp\left\{-\left[\frac{(2n-1)\pi c}{2L}\right]^2 t\right\}$$

where

$$B_{2n-1} = \frac{2}{L}\int_0^L U_0 \sin \frac{(2n-1)\pi x}{2L}\, dx = \frac{4U_0}{\pi(2n-1)}.$$

22. $u = \dfrac{4U_0}{\pi}\displaystyle\sum_{n=1}^{\infty} \frac{1}{n} \sin^2 \frac{n\pi}{4} \sin nx\, e^{-c^2n^2t}$

$= \dfrac{4U_0}{\pi}\left(\dfrac{1}{2}\sin x\, e^{-c^2t} + \dfrac{1}{2}\sin 2x\, e^{-4c^2t} + \cdots\right)$

24. $c^2v_{xx} = v_t$, $v(0, t) = 0$, $v(\pi, t) = 0$, $v(x, 0) = f(x) + Hx(x - \pi)/(2c^2)$, so that, as in (9) and (10),

$$u(x, t) = -\frac{Hx(x-\pi)}{2c^2} + \sum_{n=1}^{\infty} B_n \sin nx\, e^{-c^2n^2t}$$

where

$$B_n = \frac{2}{\pi}\int_0^{\pi}\left(f(x) + \frac{Hx(x-\pi)}{2c^2}\right)\sin nx\, dx.$$

26. $v(x, t) = u(x, t)w(t)$. Substitution into the given PDE gives

$$u_t w + uw' = c^2u_{xx}w - uw.$$

Division by w gives

$$u_t + uw'/w = c^2u_{xx} - u.$$

This reduces to $u_t = c^2u_{xx}$ if $w'/w = -1$, hence $w = e^{-t}$. Also, $u(0, t) = 0$, $u(L, t) = 0$, $u(x, 0) = f(x)$, so that the solution is $v = e^{-t}u$ with u given by (9) and (10).

im12.qxd 9/21/05 5:16 PM Page 235

28. $u = \dfrac{880}{\pi} \displaystyle\sum_{n=1}^{\infty} \dfrac{1}{(2n+1)\sinh(2n+1)\pi} \sin\dfrac{(2n+1)\pi x}{20} \sinh\dfrac{(2n+1)\pi y}{20}$

30. CAS Project. (a) $u = (\sin \pi x \sinh \pi y)/\sinh 2\pi$

(b) $u_y(x, 0, t) = 0, \quad u_y(x, 2, t) = 0, \quad u = \sin m\pi x \cos n\pi y$

32. $u = u_{\mathrm{I}} + u_{\mathrm{II}}$, where

$$u_{\mathrm{I}} = \frac{4U_1}{\pi} \sum_{n=1}^{\infty} \frac{1}{2n-1} \sin\frac{(2n-1)\pi x}{24} \frac{\sinh[(2n-1)\pi y/24]}{\sinh(2n-1)\pi}$$

$$u_{\mathrm{II}} = \frac{4U_0}{\pi} \sum_{n=1}^{\infty} \frac{1}{2n-1} \sin\frac{(2n-1)\pi x}{24} \frac{\sinh[(2n-1)\pi(1-y/24)]}{\sinh(2n-1)\pi}.$$

34. $u = F(x)G(y)$, $F = A\cos px + B\sin px$, $u_x(0, y) = F'(0)G(y) = 0$, $B = 0$, $G = C\cosh py + D\sinh py$, $u_y(x, b) = F(x)G'(b) = 0$, $C = \cosh pb$, $D = -\sinh pb$, $G = \cosh(pb - py)$. For $u = \cos px \cosh p(b - y)$ we get

$$u_x(a, y) + hu(a, y) = (-p\sin pa + h\cosh pa)\cosh p(b - y) = 0.$$

Hence p must satisfy $\tan ap = h/p$, which has infintely many positive real solutions $p = \gamma_1, \gamma_2, \cdots$, as you can illustrate by a simple sketch. *Answer:*

$$u_n = \cos \gamma_n x \cosh \gamma_n(b - y),$$

where $\gamma = \gamma_n$ satisfies $\gamma \tan \gamma a = h$.

To determine coefficients of series of u_n's from a boundary condition at the lower side is difficult because that would not be a Fourier series, the γ_n's being only approximately regularly spaced. See [C3], pp. 114–119, 167.

SECTION 12.6. Heat Equation: Solution by Fourier Integrals and Transforms, page 562

Purpose. Whereas we solved the problem of a finite bar in the last section by using Fourier series, we show that for an infinite bar (practically, a long insulated wire) we can use the Fourier integral for the same purpose. Figure 296 shows the time evolution for a "rectangular" initial temperature (100°C between $x = -1$ and $+1$, zero elsewhere), giving bell-shaped curves as for the density of the normal distribution.

We also show typical applications of the Fourier transform and the Fourier sine transform to the heat equation.

Short Courses. This section can be omitted.

SOLUTIONS TO PROBLEM SET 12.6, page 568

2. $A = \dfrac{2k}{\pi(p^2 + k^2)}$, $B = 0$, $\quad u = \dfrac{2k}{\pi} \displaystyle\int_0^{\infty} \frac{\cos px}{p^2 + k^2} e^{-c^2p^2t}\, dp$

4. $A = \dfrac{2}{\pi} \displaystyle\int_0^{\infty} \frac{\sin v}{v} \cos pv\, dv = \frac{2}{\pi} \cdot \frac{\pi}{2} = 1$ if $0 < p < 1$ and 0 if $p > 1$. Hence

$$u = \int_0^1 \cos px\, e^{-c^2p^2t}\, dp.$$

im12.qxd 9/21/05 5:16 PM Page 236

6. $A = 0$, $B = \dfrac{1}{\pi}\displaystyle\int_{-1}^{1} v \sin pv \, dv = \dfrac{2}{\pi}\,\dfrac{\sin p - p\cos p}{p^2}$; hence

$$u = \frac{2}{\pi}\int_0^{\infty} \frac{\sin p - p\cos p}{p^2} \sin px\, e^{-c^2p^2t}\, dp.$$

8. By integration, $\displaystyle\int_0^{\pi} \cos px \, dp = \frac{\sin \pi x}{x}$.

10. CAS Project. (a) Set $w = -v$ in (21) to get $\operatorname{erf}(-x) = -\operatorname{erf} x$.

(b) See (36) in App. 3.1.

(e) In (12) the argument $x + 2cz\sqrt{t}$ is 0 (the point where f jumps) when $z = -x/(2c\sqrt{t})$. This gives the lower limit of integration.

(f) $u(x, t) = \dfrac{U_0}{2}\left[\operatorname{erf}\dfrac{1-x}{2c\sqrt{t}} + \operatorname{erf}\dfrac{1+x}{2c\sqrt{t}}\right]$, where $t > 0$.

(g) Set $w = s/\sqrt{2}$ in (21).

SECTION 12.7. Modeling: Membrane, Two-Dimensional Wave Equation, page 569

Purpose. A careful derivation of the two-dimensional wave equation governing the motions of a drumhead, from physical assumptions (the analog of the modeling in Sec. 12.2).

SECTION 12.8. Rectangular Membrane. Double Fourier Series, page 571

Purpose. To solve the two-dimensional wave equation in a rectangle $0 \leqq x \leqq a$, $0 \leqq y \leqq b$ ("rectangular membrane") by separation of variables and double Fourier series.

Comment on Content

New features as compared with the one-dimensional case (Sec. 12.3) are as follows:

1. We have to separate twice, first by $u = F(x, y)G(t)$, then the Helmholtz equation for F by $F = H(x)Q(y)$.
2. We get a double sequence of infinitely many eigenvalues λ_{mn} and eigenfunctions u_{mn}; see (9), (10).
3. We need double Fourier series (easily obtainable from the usual Fourier series) to get a solution that also satisfies the initial conditions.

SOLUTIONS TO PROBLEM SET 12.8, page 578

4. $B_{mn} = (-1)^{m+1}8/(mn\pi^2)$ if n odd, $B_{mn} = 0$ if n even. Thus

$$f(x, y) = \frac{8}{\pi^2}\left(\sin \pi x \sin \pi y + \frac{1}{3}\sin \pi x \sin 3\pi y - \frac{1}{2}\sin 2\pi x \sin \pi y - \frac{1}{6}\sin 2\pi x \sin 3\pi y + \frac{1}{3}\sin 3\pi x \sin \pi y + \frac{1}{9}\sin 3\pi x \sin 3\pi y + \cdots\right).$$

im12.qxd 9/21/05 5:16 PM Page 237

6. $B_{mn} = (-1)^{m+n}K_{mn}/(mn\pi^2)$, where

$$K_{mn} = \begin{cases} 0 & \text{if } m, n \text{ even} \\ 16 & \text{if } m, n \text{ odd} \\ 8 & \text{otherwise} \end{cases}$$

8. $B_{mn} = 64/(m^3n^3\pi^6)$ if m, n odd, 0 otherwise

10. The program will give you

$$\begin{aligned} 85 &= 5 \cdot 17 = 2^2 + 9^2 = 6^2 + 7^2 \\ 145 &= 5 \cdot 29 = 1^1 + 12^2 = 8^2 + 9^2 \\ 185 &= 5 \cdot 37 = 4^2 + 13^2 = 8^2 + 11^2 \\ 221 &= 13 \cdot 17 = 5^2 + 14^2 = 10^2 + 11^2 \\ 377 &= 13 \cdot 29 = 4^2 + 19^2 = 11^2 + 16^2 \\ 493 &= 17 \cdot 29 = 3^2 + 22^2 = 13^2 + 18^2 \end{aligned}$$

etc.

12. $0.1 \sin \sqrt{2}t \sin x \sin y$

18. $A = ab$, $b = A/a$, so that from (9) with $m = n = 1$ by differentiating with respect to a and equating the derivative to zero, we obtain

$$\left(\frac{{\lambda_{11}}^2}{c^2\pi^2}\right)' = \left(\frac{1}{a^2} + \frac{1}{b^2}\right)' = \left(\frac{1}{a^2} + \frac{a^2}{A^2}\right)' = \frac{-2}{a^3} + \frac{2a}{A^2} = 0;$$

hence $a^4 = A^2$, $a^2 = A$, $b = A/a = a$.

20. $B_{mn} = (-1)^{m+n}ab/(mn\pi^2)$

22. $B_{mn} = 0$ (m or n even), $\quad B_{mn} = \dfrac{64a^2b^2}{\pi^6m^3n^3}$ (m, n odd)

24. $$\frac{64a^2b^2}{\pi^6} \sum_{\substack{m=1 \\ m,\, n \text{ odd}}}^{\infty} \sum_{n=1}^{\infty} \frac{1}{m^3n^3} \cos\left(\pi t \sqrt{\frac{m^2}{a^2} + \frac{n^2}{b^2}}\right) \sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b}$$

SECTION 12.9. Laplacian in Polar Coordinates. Circular Membrane Fourier–Bessel Series, page 579

Purpose. Detailed derivation of the transformation of the Laplacian into polar coordinates. Derivation of the function that models vibrations of a circular membrane.

Comment on Content

The transformation is a typical case of a task often required in applications. It is done by two applications of the chain rule.

In solving the wave equation we concentrate on the simpler case of radially symmetric vibrations, that is, vibrations independent of the angle. (For eigenfunctions depending on the angle, see Probs. 27–30.). We do three steps:

1. $u = W(r)G(t)$ gives for W Bessel's equation with $\nu = 0$, hence solutions $W(r) = J_0(kr)$.
2. We satisfy the boundary condition $W(R) = 0$ by choosing suitable values of k.
3. A Fourier–Bessel series (18) helps to get the solution (17) of the entire problem.

Short Courses. This section can be omitted.

im12.qxd 9/21/05 5:16 PM Page 238

SOLUTIONS TO PROBLEMS SET 12.9, page 585

6. Team Project. (a) $r^2 \cos 2\theta = r^2(\cos^2\theta - \sin^2\theta) = x^2 - y^2$, $r^2 \sin 2\theta = 2xy$, etc.

(c) $u = \dfrac{400}{\pi}\left(r \sin\theta + \dfrac{1}{3}\, r^3 \sin 3\theta + \dfrac{1}{5}\, r^5 \sin 5\theta + \cdots\right)$

(d) The form of the series results as in (b), and the formulas for the coefficients follow from

$$u_r(R, \theta) = \sum_{n=1}^{\infty} nR^{n-1}(A_n \cos n\theta + B_n \sin n\theta) = f(\theta).$$

(f) $u = -(r + 9/r)(\sin\theta)/8$ by separating variables

8. $600\, r \sin\theta - 200r^3 \sin 3\theta$

10. $\dfrac{2}{\pi}\, r \sin\theta + \dfrac{1}{2}\, r^2 \sin 2\theta - \dfrac{2}{9\pi}\, r^3 \sin 3\theta - \dfrac{1}{4}\, r^4 \sin 4\theta + \cdots$

Except for the presence of the variable r, this is just another important application of Fourier series, and we concentrate on a few simple practically important types of boundary values. Of course, earlier problems on Fourier series can now be modified by introducing the powers of r and considered from the present point of view.

12. $\dfrac{\pi^2}{3} - 4\left(r \cos\theta - \dfrac{1}{4}\, r^2 \cos 2\theta + \dfrac{1}{9}\, r^3 \cos 3\theta - \dfrac{1}{16}\, r^4 \cos 4\theta + - \cdots\right)$

14. To get $u = 0$ on the x-axis, the idea is to extend the given potential from $0 < \theta < \pi$ skew-symmetrically to the whole boundary circle $r = 1$; that is,

$$u(1, \theta) = \begin{cases} 110\,\theta(\pi - \theta) & \text{if } 0 < \theta < \pi \quad \text{(given)} \\ 110\,\theta(\pi + \theta) & \text{if } -\pi < \theta < 0. \end{cases}$$

Then you obtain (valid in the whole disk and thus in the semidisk)

$$u(r, \theta) = \frac{880}{\pi}\left(r \sin\theta + \frac{1}{3^3}\, r^3 \sin 3\theta + \frac{1}{5^3}\, r^5 \sin 5\theta + \cdots\right).$$

16. $\nabla^2 u = u_{x^*x^*} + u_{y^*y^*}$ follows by the chain rule with simplifications similar to those in the text in the derivation of $\nabla^2 u$ in polar coordinates.

18. $\lambda_m/2\pi = c\alpha_m/(2\pi R)$ increases with decreasing R.

20. CAS Project. (b) Error 0.04864 ($m = 1$), 0.02229, 0.01435, 0.01056, 0.00835, 0.00691, 0.00589, 0.00513, 0.00454, 0.00408 ($m = 10$)

(c) The approximation of the partial sums is poorest for $r = 0$.

(d) The radii of the nodal circles are

u_2:	$\alpha_1/\alpha_2 = 0.43565$	Comparison $0.435/0.500 = 0.87$
u_3:	$\alpha_1/\alpha_3 = 0.27789$	$0.278/0.333 = 0.83$
	$\alpha_2/\alpha_3 = 0.63788$	$0.638/0.667 = 0.96$
u_4:	$\alpha_1/\alpha_4 = 0.2039$	$0.204/0.250 = 0.82$
	$\alpha_2/\alpha_4 = 0.4681$	$0.468/0.500 = 0.94$
	$\alpha_3/\alpha_4 = 0.7339$	$0.734/0.750 = 0.98$.

im12.qxd 9/21/05 5:16 PM Page 239

We see that the larger radii are better approximations of the values of the nodes of the string than the smaller ones. The smallest quotient does not seem to improve (to get closer to 1); on the contrary, e.g., for u_6 it is 0.80. The other ratios seem to approach 1 and so does the sum of all of them divided by $m - 1$.

22. The reason is that $f(0) = 1$. The partial sums equal

1.10801 0.96823 1.01371 0.99272 1.00436 · · ·

the last value having 3-digit accuracy. Musically the values indicate substantial contributions of overtones to the overall sound.

30. $\alpha_{11}/2\pi = 0.6098$ (see Table A1 in App. 5)

SECTION 12.10. Laplace's Equation in Cylindrical and Spherical Coordinates. Potential, page 587

Purpose. 1. Transformation of the Laplacian into cylindrical coordinates (which is trivial because of Sec. 12.9) and spherical coordinates; some remarks on areas in which Laplace's equation is basic.

2. Separation of the Laplace equation in spherical coordinates and application to a typical boundary value problem. For simplicity we consider a boundary value problem for a sphere with boundary values depending only on ϕ. We do three steps:

1. $u = G(r)H(\phi)$ and separation gives for H Legendre's equation.
2. Continuity requirements restrict H to Legendre polynomials.
3. A Fourier–Legendre series (18) helps to get the solution (17) of the interior problem. Similarly for the exterior problem, whose solution is (20).

Short Courses. Omit the derivation of the Laplacian in cylindrical and spherical coordinates.

SOLUTIONS TO PROBLEM SET 12.10, page 593

2. By (11′) in Sec. 5.3 we have

$$u_1 = A_1 r \cos\phi = 0 \qquad \text{if} \qquad \phi = \tfrac{1}{2}\pi.$$

This is the xy-plane. Similarly,

$$u_2 = A_2 \frac{r^2}{2}(3\cos^2\phi - 1) = 0 \qquad \text{if} \qquad \cos\phi = \frac{1}{\sqrt{3}}$$

and

$$u_3 = A_3 \frac{r^3}{2}(5\cos^3\phi - 3\cos\phi) = 0 \qquad \text{if} \qquad \cos\phi = 0 \quad \text{and} \quad \sqrt{\frac{3}{5}}\,.$$

6. Substituting $u = u(r)$ into (7) gives

$$\nabla^2 u = u'' + \frac{2}{r}u' = 0, \qquad \frac{u''}{u'} = -\frac{2}{r}, \qquad \ln|u'| = -2\ln|r| + c_1$$

so that $u' = \tilde{c}/r^2$ and $u = c/r + k$.

8. $u = 3000/r - 40$

10. $u = 758.3 - 216.4 \ln r$. The curve in Prob. 8 lies below the present one. This is physically plausible.

im12.qxd 9/21/05 5:16 PM Page 240

14. $\tilde{f}(w) = w$, $A_n = \dfrac{2n+1}{2}\displaystyle\int_{-1}^{1} wP_n(w)\,dw$. Since $w = P_1(w)$ and the $P_n(w)$ are orthogonal on the interval $-1 \leqq w \leqq 1$, we obtain $A_1 = 1$, $A_n = 0$ ($n = 0, 2, 3, \cdots$). *Answer:* $u = r\cos\phi$. Of course, this is at once seen by integration.

16. $A_n = \dfrac{2n+1}{2}\displaystyle\int_0^{\pi} (\sin^2\phi)P_n(\cos\phi)\sin\phi\,d\phi$, $\{A_n\} = \{\frac{2}{3}, 0, -\frac{2}{3}, 0, \cdots\}$. Hence the potential in the interior of S is

$$u = \frac{1}{2} - \frac{1}{2}\left(\frac{4}{3}\,r^2P_2(\cos\phi) - \frac{1}{3}\right) = \frac{2}{3} - \frac{2}{3}\,r^2P_2(\cos\phi).$$

20. $\dfrac{4}{3r^3}\,P_2(\cos\phi) - \dfrac{1}{3r}$, $\quad \dfrac{8}{5r^4}\,P_3(\cos\phi) - \dfrac{3}{5r^2}\,P_1(\cos\phi)$

22. Set $\dfrac{1}{r} = \rho$ and consider $u(\rho, \theta, \phi) = rv(r, \theta, \phi)$. By differentiation,

$$u_\rho = (v + rv_r)\left(-\frac{1}{\rho^2}\right), \quad u_{\rho\rho} = (2v_r + rv_{rr})\,\frac{1}{\rho^4} + \frac{2}{\rho^3}\,(v + rv_r).$$

Thus

$$u_{\rho\rho} + \frac{2}{\rho}\,u_\rho = \frac{1}{\rho^4}\,(2v_r + rv_{rr}) = r^5\left(v_{rr} + \frac{2}{r}\,v_r\right).$$

By substituting this and $u_{\phi\phi} = rv_{\phi\phi}$, etc., into (7) [written in terms of ρ] and dividing by r^5 we obtain the result.

24. Team Project (a) The two drops over a portion of the cable of length Δx are $-Ri\Delta x$ and $-L(\partial i/\partial t)\Delta x$, respectively. Their sum equals the difference $u_{x+\Delta x} - u_x$. Divide by Δx and let $\Delta x \to 0$.

(c) To get the first PDE, differentiate the first transmission line equation with respect to x and use the second equation to replace i_x and i_{xt}:

$$\begin{aligned} -u_{xx} &= Ri_x + Li_{xt} \\ &= R(-Gu - Cu_t) + L(-Gu_t - Cu_{tt}). \end{aligned}$$

Now collect terms. Similarly for the second PDE.

(d) Set $\dfrac{1}{RC} = c^2$. Then $u_t = c^2u_{xx}$, the heat equation. By (9), (10), Sec. 12.5,

$$u = \frac{4U_0}{\pi}\left(\sin\frac{\pi x}{l}\,e^{-\lambda_1^2 t} + \frac{1}{3}\sin\frac{3\pi x}{l}\,e^{-\lambda_3^2 t} + \cdots\right), \qquad \lambda_n{}^2 = \frac{n^2\pi^2}{l^2RC}.$$

(e) $u = U_0\cos(\pi t/(l\sqrt{LC}))\sin(\pi x/l)$

SECTION 12.11. Solutions of PDEs by Laplace Transforms, page 594

Purpose. For students familiar with Chap. 6 we show that the Laplace transform also applies to certain PDEs. In such an application the subsidiary equation will generally be an ODE.

Short Courses. This section can be omitted.

im12.qxd 9/21/05 5:16 PM Page 241

SOLUTIONS TO PROBLEM SET 12.11, page 596

4. $w = w(x, t)$, $W = \mathcal{L}\{w(x, t)\} = W(x, s)$. The subsidiary equation is

$$\frac{\partial W}{\partial x} + x\mathcal{L}\{w_t(x, t)\} = \frac{\partial W}{\partial x} + x(sW - w(x, 0)) = x\mathcal{L}(1) = \frac{x}{s} \text{ and } w(x, 0) = 1.$$

By simplification,

$$\frac{\partial W}{\partial x} + xsW = x + \frac{x}{s}.$$

By integration of this first-order ODE with respect to x we obtain

$$W = c(s)e^{-sx^2/2} + \frac{1}{s^2} + \frac{1}{s}.$$

For $x = 0$ we have $w(0, t) = 1$ and

$$W(0, s) = \mathcal{L}\{w(0, t)\} = \mathcal{L}\{1\} = \frac{1}{s} = c(s) + \frac{1}{s^2} + \frac{1}{s}.$$

Hence $c(s) = -1/s^2$, so that

$$W = -\frac{1}{s^2}e^{-sx^2/2} + \frac{1}{s^2} + \frac{1}{s}.$$

The inverse Laplace transform of this solution of the subsidiary equation is

$$w(x, t) = -(t - \tfrac{1}{2}x^2)\,u(t - \tfrac{1}{2}x^2) + t + 1 = \begin{cases} t + 1 & \text{if} \quad t < \frac{1}{2}x^2 \\ \frac{1}{2}x^2 + 1 & \text{if} \quad t > \frac{1}{2}x^2. \end{cases}$$

6. $W = \mathcal{L}\{w\}$, $W_{xx} = (100s^2 + 100s + 25)W = (10s + 5)^2W$. The solution of this ODE is

$$W = c_1(s)e^{-(10s+5)x} + c_2(s)e^{(10s+5)x}$$

with $c_2(s) = 0$, so that the solution is bounded. $c_1(s)$ follows from

$$W(0, s) = \mathcal{L}\{w(0, t)\} = \mathcal{L}\{\sin t\} = \frac{1}{s^2 + 1} = c_1(s).$$

Hence

$$W = \frac{1}{s^2 + 1}e^{-(10s+5)x}.$$

The inverse Laplace transform (the solution of our problem) is

$$w = \mathcal{L}^{-1}\{W\} = e^{-5x}u(t - 10x)\sin(t - 10x),$$

a traveling wave decaying with x. Here u is the unit step function (the Heaviside function).

8. From $W = F(s)e^{-(x/c)\sqrt{s}}$ and the convolution theorem we have

$$w = f * \mathcal{L}^{-1}\{e^{-k\sqrt{s}}\}, \qquad k = \frac{x}{c}.$$

im12.qxd 9/21/05 5:16 PM Page 242

From this and formula 39 in Sec. 6.9 we get, as asserted,

$$w = \int_0^t f(t - \tau)\, \frac{k}{2\sqrt{\pi\tau^3}}\, e^{-k^2/(4\tau)}\, d\tau.$$

10. $W_0(x, s) = s^{-1}e^{-\sqrt{s}x/c}$, $\mathcal{L}\{u(t)\} = 1/s$, and since $w(x, 0) = 0$,

$$\begin{aligned} W(x, s) &= F(s)sW_0(x, s) \\ &= F(s)[sW_0(x, s) - w(x, 0)] \\ &= F(s)\, \mathcal{L}\left\{\frac{\partial w_0}{\partial t}\right\}. \end{aligned}$$

Now apply the convolution theorem.

SOLUTIONS TO CHAP. 12 REVIEW QUESTIONS AND PROBLEMS, page 597

16. $k = -6$, $m = \pm 1$

18. $u = A(x) \cos 4y + B(x) \sin 4y$

20. $u_y = v$, $v_x + v + x + y + 1 = 0$, $v = c(y)e^{-x} - x - y$. By integration,

$$u = \int v\, dy = c_1(y)e^{-x} - xy - \tfrac{1}{2}y^2 + c_2(x).$$

22. Depending on the sign of the separation constant, we obtain

$$u = (Ae^{kx} + Be^{-kx})(C \cos ky + D \sin ky)$$
$$u = (ax + b)(cy + d)$$
$$u = (A \cos kx + B \sin kx)(Ce^{ky} + De^{-ky}).$$

24. $u = \dfrac{4}{\pi}\left(\cos t \sin x - \dfrac{1}{9} \cos 3t \sin 3x + \dfrac{1}{25} \cos 5t \sin 5x - + \cdots\right)$

26. $u = \dfrac{8}{\pi}\left(\cos t \sin x + \dfrac{1}{3^3} \cos 3t \sin 3x + \dfrac{1}{5^3} \cos 5t \sin 5x + \cdots\right)$

28. $u = \dfrac{20000}{\pi^3}\left(\sin \dfrac{\pi x}{50}\, e^{-0.004572t} + \dfrac{1}{27} \sin \dfrac{3\pi x}{50}\, e^{-0.04115t} + \dfrac{1}{125} \sin \dfrac{5\pi x}{50}\, e^{-0.1143t} + \cdots\right)$

30. $u = 3 \sin \dfrac{\pi x}{10}\, e^{-0.1143t} - \sin \dfrac{3\pi x}{10}\, e^{-1.029t}$

32. $u = \pi^2 - 12\left[(\cos x)e^{-t} - \tfrac{1}{4}(\cos 2x)e^{-4t} + \tfrac{1}{9}(\cos 3x)e^{-9t} - + \cdots\right]$

36. $u = \dfrac{64}{\pi^2} \sum_{\substack{m=1 \\ m,\, n \text{ odd}}}^{\infty} \sum_{n=1}^{\infty} \dfrac{1}{m^3n^3} \sin mx \sin ny\, e^{-c^2(m^2+n^2)t}$

38. Parabolic, $y'^2 - 4y' = (y' - 2)^2 = 0$, $v = x$, $w = y - 2x$; hence

$$u = xf_1(y - 2x) + f_2(y - 2x).$$

im12.qxd 9/21/05 5:16 PM Page 243

40. $u_{xx} + \frac{5}{2}u_{xy} + u_{yy} = 0$, hyperbolic. The characteristic equation is

$$y'^2 - \tfrac{5}{2}y' + 1 = (y' - \tfrac{1}{2})(y' - 2) = 0.$$

Hence the solution is

$$u = f_1(y - \tfrac{1}{2}x) + f_2(y - 2x).$$

42. $u_{xx} - \frac{1}{2}u_{xy} - \frac{1}{2}u_{yy} = 0$, hyperbolic. The characteristic equation is

$$y'^2 + \tfrac{1}{2}y' - \tfrac{1}{2} = (y' - \tfrac{1}{2})(y' + 1) = 0.$$

Hence the solution is

$$u = f_1(y - \tfrac{1}{2}x) + f_2(y + x).$$

44. $\lambda_{11}/2\pi = c\pi(\sqrt{1 + 1})/2\pi = 1/\sqrt{2}$

46. Area $\pi R^2/2 = 1$, $R = \sqrt{2/\pi}$, and

$$ck_{11}/(2\pi) = k_{11}/(2\pi) = \alpha_{11}/(2\pi R) = 3.832/(2\pi\sqrt{2/\pi}) = 3.832/\sqrt{8\pi}.$$

48. $u = \dfrac{(u_0 - u_1)r_0 r_1}{(r_1 - r_0)r} + \dfrac{u_1 r_1 - u_0 r_0}{r_1 - r_0}$, where r is the distance from the center of the spheres

50. $f(\phi) = 4\cos^3\phi$. Now, by (11′), Sec. 5.3,

$$\cos^3\phi = \tfrac{2}{5}P_3(\cos\phi) + \tfrac{3}{5}P_1(\cos\phi).$$

Answer:

$$u = \tfrac{8}{5}r^3P_3(\cos\phi) + \tfrac{12}{5}rP_1(\cos\phi).$$

im13.qxd 9/21/05 12:35 PM Page 244

Part D. COMPLEX ANALYSIS

Major Changes

In the previous edition, conformal mapping was distributed over several sections in the first chapter on complex analysis. It has now been given greater emphasis by consolidation of that material in a separate chapter (Chap. 17), which can be used independently of a CAS (just as any other chapter) or in part supported by the graphic capabilities of a CAS. Thus in this respect one has complete freedom.

Recent teaching experience has shown that the present arrangement seems to be preferable over that of the 8th edition.

CHAPTER 13 Complex Numbers and Functions

SECTION 13.1. Complex Numbers. Complex Plane, page 602

Purpose. To discuss the algebraic operations for complex numbers and the representation of complex numbers as points in the plane.

Main Content, Important Concepts

Complex number, real part, imaginary part, imaginary unit

The four algebraic operations in complex

Complex plane, real axis, imaginary axis

Complex conjugates

Two Suggestions on Content

1. Of course, at the expense of a small conceptual concession, one can also start immediately from (4), (5),

$$z = x + iy, \qquad i^2 = -1$$

and go on from there.

2. If students have some knowledge of complex numbers, the practical division rule (7) and perhaps (8) and (9) may be the only items to be recalled in this section. (But I personally would do more in any case.)

SOLUTIONS TO PROBLEM SET 13.1, page 606

2. Note that $z = 2 + 2i$ and $iz = -2 + 2i$ lie on the bisecting lines of the first and second quadrants.

4. $z_1 z_2 = 0$ if and only if

$$\text{Re}\,(z_1 z_2) = x_2 x_1 - y_2 y_1 = 0 \qquad \text{and} \qquad \text{Im}\,(z_1 z_2) = y_2 x_1 + x_2 y_1 = 0.$$

Let $z_2 \neq 0$, so that $x_2^2 + y_2^2 \neq 0$. Now $x_2^2 + y_2^2$ is the coefficient determinant of our homogeneous system of equations in the "unknowns" x_1 and y_1, so that this system has only the trivial solution; hence $z_1 = 0$.

8. $23 - 2i$

10. $-9, 16$

im13.qxd 9/21/05 12:35 PM Page 245

12. $z_1/z_2 = -7/41 + (22/41)i, \quad \bar{z}_1/\bar{z}_2 = \overline{(z_1/z_2)} = -7/41 - (22/41)i$

14. $-5/13 - (12/13)i, \quad -5/13 + (12/13)i$

16. $3x^2y - y^3,\ y^3$

18. $\text{Im}\left[(1+i)^8 z^2\right] = \text{Im}\left[(2i)^4 z^2\right] = \text{Im}\left[2^4 z^2\right] = 32xy$

SECTION 13.2. Polar Form of Complex Numbers. Powers and Roots, page 607

Purpose. To give the student a firm grasp of the polar form, including the principal value Arg z, and its application in multiplication and division.

Main Content, Important Concepts

Absolute value $|z|$, argument θ, principal value Arg θ

Triangle inequality (6)

Multiplication and division in polar form

nth root, nth roots of unity (16)

SOLUTIONS TO PROBLEM SET 13.2, page 611

2. $2(\cos \frac{1}{2}\pi + i \sin \frac{1}{2}\pi)$, $2(\cos(-\frac{1}{2}\pi) + i \sin(-\frac{1}{2}\pi))$

4. $\sqrt{\frac{1}{4} + \frac{1}{16}\pi^2}\,(\cos \arctan \frac{1}{2}\pi + i \sin \arctan \frac{1}{2}\pi)$

6. Simplification shows that the quotient equals -3. *Answer:* $3(\cos \pi + i \sin \pi)$.

8. Division shows that the given quotient equals

$$\frac{22}{41} + \frac{7}{41}i.$$

Hence the polar form is

$$\frac{1}{41}\sqrt{22^2 + 7^2}\,(\cos \arctan \frac{7}{22} + i \sin \arctan \frac{7}{22}).$$

10. 3.09163, -3.09163. Of course, the problem should be a reminder that the principal value of the argument is discontinuous along the negative real axis, where it jumps by 2π.

12. π since the given value is negative real.

14. $(1+i)^{12} = (2i)^6 = 2^6 i^6 = 2^6 i^2 = -2^6$. Hence the principal value of the argument is π.

Alternatively, Arg $(1+i) = \frac{1}{4}\pi$. Times 12 gives 3π, so that the principal value of the argument is π, as before.

16. $\pm i$

18. $2 \pm 2\sqrt{3}\,i$

20. $-12i$

22. $\pm 1, \pm i, \pm(1 \pm i)/\sqrt{2}$

24. The three values are

$$\sqrt[3]{5}\,(\cos\theta + i \sin\theta)$$
$$\sqrt[3]{5}\,(\cos(\theta + \tfrac{2}{3}\pi) + i \sin(\theta + \tfrac{2}{3}\pi))$$
$$\sqrt[3]{5}\,(\cos(\theta + \tfrac{4}{3}\pi) + i \sin(\theta + \tfrac{4}{3}\pi))$$

where $\theta = \frac{1}{3} \arctan \frac{4}{3}$.

im13.qxd 9/21/05 12:35 PM Page 246

26. Team Project. (a) Use (15).

(b) Use (10) in App. 3.1 in the form

$$\cos\tfrac{1}{2}\theta = \sqrt{\tfrac{1}{2}(1 + \cos\theta)}, \qquad \sin\tfrac{1}{2}\theta = \sqrt{\tfrac{1}{2}(1 - \cos\theta)},$$

multiply them by $\sqrt{r}$,

$$\sqrt{r}\cos\tfrac{1}{2}\theta = \sqrt{\tfrac{1}{2}(r + r\cos\theta)}, \qquad \sqrt{r}\sin\tfrac{1}{2}\theta = \sqrt{\tfrac{1}{2}(r - r\cos\theta)},$$

use $r\cos\theta = x$, and finally choose the sign of $\operatorname{Im}\sqrt{z}$ in such a way that $\operatorname{sign}\left[(\operatorname{Re}\sqrt{z})(\operatorname{Im}\sqrt{z})\right] = \operatorname{sign} y$.

(c) $\pm\sqrt{2}(1 + i)$, $\pm(5 - 3i)$, $\pm(4 + \sqrt{7}\,i)$

28. $z^2 = 2i$, $-5 + 12i$, $z = \pm(1 + i)$, $\pm(2 + 3i)$ by (19)

30. $z^2 = \pm 4i$, $z = \pm(1 \pm i)\sqrt{2}$. One of the two factors is

$$(z - (1 + i)\sqrt{2})(z - (1 - i)\sqrt{2}) = z^2 - 2\sqrt{2}z + 4$$

and the other is

$$(z - (-1 + i)\sqrt{2})(z - (-1 - i)\sqrt{2}) = z^2 + 2\sqrt{2}z + 4.$$

The product equals $z^4 + 16$.

32. $|z| = \sqrt{x^2 + y^2} \geqq |x|$, etc.

SECTION 13.3. Derivative. Analytic Function, page 612

Purpose. To define (complex) analytic functions—the class of functions complex analysis is concerned with—and the concepts needed for that definition, in particular, derivatives.

This is preceded by a collection of a few standard concepts on sets in the complex plane that we shall need from time to time in the chapters on complex analysis.

Main Content, Important Concepts

Unit circle, unit disk, open and closed disks

Domain, region

Complex function

Limit, continuity

Derivative

Analytic function

Comment on Content

The most important concept in this section is that of an **analytic function.** The other concepts resemble those of real calculus. The most important new *idea* is connected with the **limit:** the approach in infinitely many possible directions. This yields the negative result in Example 4 and—much more importantly—the **Cauchy–Riemann equations** in the next section.

SOLUTIONS TO PROBLEM SET 13.3, page 617

2. Closed annulus bounded by circles of radii 1 and 5 centered at $1 - 4i$

4. Open vertical strip of width 2π

6. Open half-plane extending from the vertical line $x = -1$ to the right

im13.qxd 9/21/05 12:35 PM Page 247

8. Angular region of angle $\pi/2$ symmetric to the positive x-axis

10. We obtain

$$\text{Re}\,\frac{1}{z} = \frac{x}{x^2 + y^2} < 1, \qquad x < x^2 + y^2, \qquad \frac{1}{4} < \left(x - \frac{1}{2}\right)^2 + y^2.$$

This is the exterior of the circle of radius $\frac{1}{2}$ centered at $\frac{1}{2}$.

12. $3x^2 - 3y^2 - 6x + i(6xy - 6y + 3)$; the value is $-3 + 9i$.

14. The given function is (multiply by $1 - \bar{z}$)

$$f = \frac{1 - x + iy}{(1 - x)^2 + y^2}$$

which shows Re f and Im f. The value at the given z is $1.6 + 0.8i$.

16. No, since $r^2(\cos 2\theta)/r^2 = \cos 2\theta$

18. Yes, since $(r^2/r)\cos\theta \to 0$ as $r \to 0$.

20. $\left(1 - \dfrac{10}{z^2 + 1}\right)' = \dfrac{20z}{(z^2 + 1)^2}$

22. 0. This is the case in which a linear fractional transformation (Möbius transformation) has derivative identically zero. We shall discuss this in Sec. 17.2. The given function equals $-2i$.

24. $\dfrac{2z}{(z + i)^2} - \dfrac{2z^2}{(z + i)^3} = \dfrac{2iz}{(z + i)^3}$

26. Team Project. (a) Use Re $f(z) = \left[f(z) + \overline{f(z)}\right]/2$, Im $f(z) = \left[f(z) - \overline{f(z)}\right]/2i$.

(b) Assume that $\lim_{z\to z_0} f(z) = l_1$, $\lim_{z\to z_0} f(z) = l_2$, $l_1 \neq l_2$. For every $\epsilon > 0$ there are $\delta_1 > 0$ and $\delta_2 > 0$ such that

$$|f(z) - l_j| < \epsilon \qquad \text{when} \qquad 0 < |z - z_0| < \delta_j, \qquad j = 1, 2.$$

Hence for $\epsilon = |l_1 - l_2|/2$ and $0 < |z - z_0| < \delta$, where $\delta \leqq \delta_1$, $\delta \leqq \delta_2$, we have

$$\begin{aligned} |l_1 - l_2| &= |[f(z) - l_2] - [f(z) - l_1]| \\ &\leqq |f(z) - l_2| + |f(z) - l_1| < 2\epsilon = |l_1 - l_2|. \end{aligned}$$

(c) By continuity, for any $\epsilon > 0$ there is a $\delta > 0$ such that $|f(z) - f(a)| < \epsilon$ when $|z - a| < \delta$. Now $|z_n - a| < \delta$ for all sufficiently large n since $\lim z_n = a$. Thus $|f(z_n) - f(a)| < \epsilon$ for these n.

(d) The proof is as in calculus. We write

$$\frac{f(z) - f(z_0)}{z - z_0} - f'(z_0) = \eta.$$

Then from the definition of a limit it follows that for any given $\epsilon > 0$ there is a $\delta > 0$ such that $|\eta| < \epsilon$ when $|z - z_0| < \delta$. From this and the triangle inequality,

$$|f(z) - f(z_0)| = |z - z_0||f'(z_0) + \eta| \leqq |z - z_0||f'(z_0)| + |z - z_0|\epsilon,$$

which approaches 0 as $|z - z_0| \to 0$.

(e) The quotient in (4) is $\Delta x/\Delta z$, which is 0 if $\Delta x = 0$ but 1 if $\Delta y = 0$, so that it has no limit as $\Delta z \to 0$.

(f) $$\frac{f(z + \Delta z) - f(z)}{\Delta z} = \frac{(z + \Delta z)(\bar{z} + \overline{\Delta z}) - z\bar{z}}{\Delta z} = z\,\frac{\overline{\Delta z}}{\Delta z} + \bar{z} + \overline{\Delta z}.$$

im13.qxd 9/21/05 12:35 PM Page 248

When $z = 0$ the expression on the right approaches zero as $\Delta z \to 0$. When $z \neq 0$ and $\Delta z = \Delta x$, then $\overline{\Delta z} = \Delta x$ and that expression approaches $z + \bar{z}$. When $z \neq 0$ and $\Delta z = i\Delta y$, then $\overline{\Delta z} = -i\Delta y$ and that expression approaches $-z + \bar{z}$. This proves the statement.

SECTION 13.4. Cauchy–Riemann Equations. Laplace's Equation, page 618

Purpose. To derive and explain the most important equations in this chapter, the Cauchy–Riemann equations, a system of two PDEs, which constitute the basic criterion for analyticity.

Main Content, Important Concepts

Cauchy–Riemann equations (1)

These equations as a criterion for analyticity (Theorems 1 and 2)

Derivative in terms of partial derivatives, (4), (5)

Relation of analytic functions to Laplace's equation

Harmonic function, harmonic conjugate

Comment on Content

(4), (5), and Example 3 will be needed occasionally.

The relation to Laplace's equation is basic, as mentioned in the text.

SOLUTIONS TO PROBLEM SET 13.4, page 623

2. No

4. Yes when $z \neq \pm 1, \pm i$

6. No

8. Yes

10. Yes when $z \neq 0$

12. $f(z) = -iz^2/2$

14. $f(z) = 1/z$

16. $f(z) = -\text{Arg } z + i \ln |z|$

18. No

20. $f(z) = \cos x \cosh y - i \sin x \sinh y = \cos z$ (to be introduced in Sec. 13.6)

22. $a = 3$, $e^{3x} \sin 3y$

24. $a = b = 0$, $v = const$

26. Team Project. (a) $u = const$, $u_x = u_y = 0$, $v_x = v_y = 0$ by (1), $v = const$, and $f = u + iv = const$.

(b) Same idea as in (a).

(c) $f' = u_x + iv_x = 0$ by (4). Hence $v_y = 0$, $u_y = 0$ by (1), $f = u + iv = const$.

SECTION 13.5. Exponential Function, page 623

Purpose. Sections 13.5–13.7 are devoted to the most important elementary functions in complex, which generalize the corresponding real functions, and we emphasize properties that are not apparent in real.

im13.qxd 9/21/05 12:35 PM Page 249

Basic Properties of the Exponential Function

Derivative and functional relation as in real

Euler formula, polar form of z

Periodicity with $2\pi i$, fundamental region

$e^z \neq 0$ for all z

SOLUTIONS TO PROBLEM SET 13.5, page 626

2. -20.086, 20.086

4. $-ie^{\sqrt{2}} = -4.11325i$, 4.11325

6. $-e^{\pi} = -23.1407$, 23.1407

8. i, 1

10. $\exp(x^3 - 3xy^2)(\cos(3x^2y - y^3) + i(\sin(3x^2y - y^3))$

12. $e^{1/z} = \exp\left(\dfrac{x}{x^2 + y^2}\right)\left(\cos\dfrac{y}{x^2 + y^2} - i\sin\dfrac{y}{x^2 + y^2}\right)$

14. $\sqrt{2}\, e^{\pi i/4}$

16. $5\exp(i \arctan\frac{4}{3})$

18. $z = \frac{1}{3}(\ln 4 \pm 2n\pi i)$, $n = 0, 1, \cdots$

20. No solutions

22. Team Project. (a) $e^{1/z}$ is analytic for all $z \neq 0$. $e^{\bar{z}}$ is not analytic for any z. The last function is analytic if and only if $k = 1$.

(b) (i) $e^x \sin y = 0$, $\sin y = 0$. *Answer:* On the horizontal lines $y = \pm n\pi$, $n = 0, 1, \cdots$. (ii) $e^{-x} < 1$, $x > 0$ (the right half-plane).

(iii) $e^{\bar{z}} = e^{x-iy} = e^x(\cos y - i\sin y) = \overline{e^x(\cos y + i\sin y)} = \overline{e^z}$. *Answer:* All z.

(d) $f' = u_x + iv_x = f = u + iv$, hence $u_x = u$, $v_x = v$. By integration,

$$u = c_1(y)e^x, \qquad v = c_2(y)e^x.$$

By the first Cauchy–Riemann equation,

$$u_x = v_y = c_2'e^x, \qquad \text{thus} \qquad c_1 = c_2' \qquad (' = d/dy).$$

By the second Cauchy–Riemann equation,

$$u_y = c_1'e^x = -v_x = -c_2e^x, \qquad \text{thus} \qquad c_1' = -c_2.$$

Differentiating the last equation with respect to y, we get

$$c_1'' = -c_2' = -c_1, \qquad \text{hence} \qquad c_1 = a\cos y + b\sin y.$$

Now for $y = 0$ we must have

$$u(x, 0) = c_1(0)e^x = e^x, \qquad c_1(0) = 1, \qquad a = 1,$$
$$v(x, 0) = c_2(0)e^x = 0, \qquad c_2(0) = 0.$$

Also, $b = c_1'(0) = -c_2(0) = 0$. Together $c_1(y) = \cos y$. From this,

$$c_2(y) = -c_1'(y) = \sin y.$$

This gives $f(z) = e^x(\cos y + i\sin y)$.

im13.qxd 9/21/05 12:35 PM Page 250

SECTION 13.6. Trigonometric and Hyperbolic Functions, page 626

Purpose. Discussion of basic properties of trigonometric and hyperbolic functions, with emphasis on the relations between these two classes of functions as well as between them and the exponential function; here we see on an elementary level that investigation of special functions in complex can add substantially to their understanding.

Main Content

Definitions of $\cos z$ and $\sin z$ (1)

Euler's formula in complex (5)

Definitions of $\cosh z$ and $\sinh z$ (11)

Relations between trigonometric and hyperbolic functions

Real and imaginary parts (6) and Prob. 3

SOLUTIONS TO PROBLEM SET 13.6, page 629

4. The right side is

$$\cosh z_1 \cosh z_2 + \sinh z_1 \sinh z_2$$
$$= \frac{1}{4}\,(e^{z_1} + e^{-z_1})(e^{z_2} + e^{-z_2}) + \frac{1}{4}\,(e^{z_1} - e^{-z_1})(e^{z_2} - e^{-z_2}).$$

If we multiply out, then because of the minus signs the products $e^{z_1}e^{-z_2}$ and $e^{-z_1}e^{z_2}$ cancel in pairs. There remains, as asserted,

$$2 \cdot \tfrac{1}{4}(e^{z_1+z_2} + e^{-z_1-z_2}) = \cosh (z_1 + z_2).$$

Similarly for the other formula.

6. Special case of the first formula in Prob. 4.

8. $\sin 1 \cosh 1 + i \cos 1 \sinh 1 = 1.2985 + 0.63496i$

10. $\cosh 3\pi = 6195.8$

12. The two expressions are equal because of (14) or (15). We thus obtain, for instance,

$$\sin (2 + \pi i) = \sin 2 \cosh \pi + i \cos 2 \sinh \pi = 10.541 - 4.8060i.$$

14. $\sinh 4 \cos 3 - i \cosh 4 \sin 3 = -27.017 - 3.8537i$

16. We obtain

$$\tan z = \frac{\sin z}{\cos z} = \frac{\sin z \,\overline{\cos z}}{|\cos z|^2}\,.$$

Hence the denominator is (use $\cosh^2 y = \sinh^2 y + 1$ to simplify)

$$\cos^2 x \cosh^2 y + \sin^2 x \sinh^2 y = \cos^2 x + \sinh^2 y.$$

Insert $\sin z$ and $\cos z$ into the numerator and multiply out. Then for the real part of the product you get

$$\sin x \cos x \cosh^2 y - \cos x \sin x \sinh^2 y = \sin x \cos x$$

and for the imaginary part, using $\sin^2 x + \cos^2 x = 1$, you get

$$\sin^2 x \cosh y \sinh y + \cos^2 x \cosh y \sinh y = \cosh y \sinh y.$$

im13.qxd 9/21/05 12:35 PM Page 251

18. $\cos x \sinh y = 0$, $x = \frac{1}{2}\pi \pm 2n\pi$, $\cosh y = 100$, $\cosh y \approx \frac{1}{2}e^y$ for large y, $e^y \approx 200$, $y \approx 5.29832$ (agrees to 4D with the solution of $\cosh y = 100$).
Answer: $z = \frac{1}{2}\pi \pm 2n\pi \pm 5.29832i$.

20. (a) $\cosh x \cos y = -1$, (b) $\sinh x \sin y = 0$. From (b) we have $x = 0$ or $y = \pm n\pi$. Then $y = (2n + 1)\pi$ and $x = 0$ from (a). *Answer:* $z = (2n + 1)\pi i$.

22. (a) $\sin x \sinh y = 0$, $y = 0$ or $x = n\pi$ (parallels to the y-axis)
(b) $\cos x \sinh y = 0$, $y = 0$ or $x = \frac{1}{2}(2n + 1)\pi$, where $n = 0, \pm 1, \pm 2, \cdots$

24. From (7a) we obtain

$$|\cos z|^2 = \cos^2 x + \sinh^2 y = \cos^2 x + \cosh^2 y - 1.$$

Hence $|\cos z|^2 \geqq \sinh^2 y$ from the first equality, and $|\cos z|^2 \leqq \cosh^2 y$ from the second equality. Now take the square root.

The inequality for $|\sin z|$ is obtained similarly.

SECTION 13.7. Logarithm. General Power, page 630

Purpose. Discussion of the complex logarithm, which extends the real logarithm $\ln x$ (defined for positive x) to an infinitely many-valued relation (3) defined for all $z \neq 0$; definition of general powers z^c.

Comment on Notation

$\ln z$ is also denoted by $\log z$, but for the engineer, who also needs logarithms $\log x$ of base 10, the notation ln is more practical; this notation is widely used in mathematics.

Important Formulas

Real and imaginary parts (1)

Relation of the principal value to the other values (3)

Relations between ln and the exponential function (4)

Functional relation in complex (5)

Derivative (6)

General power (8)

SOLUTIONS TO PROBLEM SET 13.7, page 633

2. $\frac{1}{2} \ln 8 + \frac{1}{4}\pi i$

4. $\ln 5.001 \pm 0.02i$ (approximately)

6. $\ln 100 + \pi i = 4.605 + 3.142i$

8. $1 - \frac{1}{2}\pi i$

10. $\pm 2n\pi i$, $n = 0, 1, \cdots$

12. $1 \pm 2n\pi i$, $n = 0, 1, \cdots$

14. $\ln 5 + (\arctan \frac{3}{4} \pm 2n\pi)i$, $n = 0, 1, \cdots$

16. $\ln |e^{3i}| + i \arctan \left(\dfrac{\sin 3}{\cos 3} \right) \pm 2n\pi i = 0 + 3i \pm 2n\pi i$; see also (4b).

18. $-e^{2\pi}i$

20. $e^{e - \pi i} = -e^e = -15.154$

im13.qxd 9/21/05 12:35 PM Page 252

22. $i^{2i} = e^{2i\,\mathrm{Ln}\,i} = e^{2i\cdot i\pi/2} = e^{-\pi}$,

$$(2i)^i = e^{i\,\mathrm{Ln}\,2i} = e^{i(\ln 2+\pi i/2)} = e^{-\pi/2}[\cos(\ln 2) + i\sin(\ln 2)]$$

24. $e^{(1+i)\mathrm{Ln}(1-i)} = e^{(1+i)(\ln\sqrt{2}-\pi i/4)}$

$$= \exp(\ln\sqrt{2} - \pi i/4 + i\ln\sqrt{2} + \pi/4)$$
$$= \sqrt{2}e^{\pi/4}(\cos(-\tfrac{1}{4}\pi + \ln\sqrt{2}) + i\sin(-\tfrac{1}{4}\pi + \ln\sqrt{2}))$$
$$= 2.8079 - 1.3179i.$$

Note that this is the complex conjugate of the answer to Prob. 25.

26. $e^{(1-2i)\mathrm{Ln}(-1)} = e^{(1-2i)\pi i} = e^{\pi i+2\pi} = -e^{2\pi}$

28. We obtain

$$\exp(\tfrac{1}{3}\,\mathrm{Ln}\,(3-4i)) = \exp(\tfrac{1}{3}(\ln 5 - i\arctan\tfrac{4}{3}))$$
$$= \sqrt[3]{5}\,[\cos(\tfrac{1}{3}\arctan\tfrac{4}{3}) - i\sin(\tfrac{1}{3}\arctan\tfrac{4}{3})]$$
$$= 1.6289 - 0.5202i.$$

30. Team Project. (a) $w = \arccos z$, $z = \cos w = \frac{1}{2}(e^{iw} - e^{-iw})$. Multiply by $2e^{iw}$ to get a quadratic equation in e^{iw},

$$e^{2iw} - 2ze^{iw} + 1 = 0.$$

A solution is $e^{iw} = z + \sqrt{z^2-1}$, and by taking logarithms we get the given formula

$$\arccos z = w = -i\ln(z + \sqrt{z^2-1}).$$

(b) Similarly,

$$z = \sin w = \frac{1}{2i}(e^{iw} - e^{-iw}),$$

$$2ize^{iw} = e^{2iw} - 1,$$
$$e^{2iw} - 2ize^{iw} - 1 = 0,$$
$$e^{iw} = iz + \sqrt{-z^2+1}.$$

Now take logarithms, etc.

(c) $\cosh w = \frac{1}{2}(e^w + e^{-w}) = z$, $(e^w)^2 - 2ze^w + 1 = 0$, $e^w = z + \sqrt{z^2-1}$. Take logarithms.

(d) $z = \sinh w = \frac{1}{2}(e^w - e^{-w})$, $2ze^w = e^{2w} - 1$, $e^w = z + \sqrt{z^2+1}$. Take logarithms.

(e) $z = \tan w = \dfrac{\sin w}{\cos w} = -i\,\dfrac{e^{iw} - e^{-iw}}{e^{iw} + e^{-iw}} = -i\,\dfrac{e^{2iw} - 1}{e^{2iw} + 1}$,

$$e^{2iw} = \frac{i-z}{i+z}, \qquad w = \frac{1}{2i}\ln\frac{i-z}{i+z} = \frac{i}{2}\ln\frac{i+z}{i-z}$$

(f) This is similar to (e).

SOLUTIONS TO CHAP. 13 REVIEW QUESTIONS AND PROBLEMS, page 634

2. $5\sqrt{29}\,e^{-0.2630i}$, $5e^{0.9273i}$

16. $(2i)^6 = -64$

18. $3/58 + (7/58)i$

im13.qxd 9/21/05 12:35 PM Page 253

20. $\pm(2 - 3i)$

22. $\sqrt{10}\, e^{-i \arctan 3} = 3.1623\, e^{-1.2490i}$

24. $e^{-i \arctan (1/2)}$

26. $\sqrt{8}\, e^{\pi i/4}$

28. $\pm 4, \pm 4i$

30. $\pm(6 - 2i)$

32. $f(z) = -e^{-3z}$

34. $f(z) = \cos 2z$

36. No

38. $-e^{-x/2} \sin \frac{1}{2}y$. Problems 36–39 are in principle of the same kind as Probs. 31–35. We have included them here as a reminder that in using real or imaginary parts of an analytic function we are dealing with harmonic functions (to whose applications a whole chapter (Chap. 18) will be devoted, perhaps as the most important aspect of complex analysis from the viewpoint of the engineer and physicist).

40. $\sin 3 \cosh 4\pi + i \cos 3 \sinh 4\pi = 20233 - 141941i$. This is a reminder of the growth of the complex sine, as opposed to the sine in calculus whose absolute value never gets greater than 1 for all real x.

42. $-\cosh 2 = -3.7622$

44. We obtain

$$\frac{\sin 1 \cos 1 + i \sinh 1 \cosh 1}{\cos^2 1 + \sinh^2 1} = 0.2718 + 1.0839i.$$

im14.qxd 9/21/05 12:37 PM Page 254

CHAPTER 14 Complex Integration

Change

We now discuss the two main integration methods (indefinite integration and integration by the use of the representation of the path) directly after the definition of the integral, postponing the proof of the first of these methods until Cauchy's integral formula is available in Sec. 14.2. This order of the material seems desirable from a practical point of view.

Comment

The introduction to the chapter mentions two reasons for the importance of complex integration. Another practical reason is the extensive use of complex integral representations in the higher theory of special functions; see for instance, Ref. [GR10] listed in App. 1.

SECTION 14.1. Line Integral in the Complex Plane, page 637

Purpose. To discuss the definition, existence, and general properties of complex line integrals. Complex integration is rich in methods, some of them very elegant. In this section we discuss the first two methods, integration by the use of path and (under suitable assumptions given in Theorem 1!) by indefinite integration.

Main Content, Important Concepts

Definition of the complex line integral

Existence

Basic properties

Indefinite integration (Theorem 1)

Integration by the use of path (Theorem 2)

Integral of $1/z$ around the unit circle (basic!)

ML-inequality (13) (needed often in our work)

Comment on Content

Indefinite integration will be justified in Sec. 14.2, after we have obtained Cauchy's integral theorem. We discuss this method here for two reasons: (i) to get going a little faster and, more importantly, (ii) to answer the students' natural question suggested by calculus, that is, whether the method works and under what condition—that it does not work unconditionally can be seen from Example 7!

SOLUTIONS TO PROBLEM SET 14.1, page 645

2. Vertical straight segment from $5 + 6i$ to $5 - 6i$

4. Circle, center $1 + i$, radius 1, oriented clockwise, touching the axes

6. Semicircle, center $3 + 4i$, radius 5, passing through the origin

8. Portion of the parabola $y = 2(x - 1)^2$ from $-1 + 8i$ to $3 + 8i$, apex at $x = 1$

10. $z(t) = 1 + i + (3 - 3i)t \quad (0 \leqq t \leqq 1)$

12. $z(t) = a + ib + [c - a + i(d - b)]t \quad (0 \leqq t \leqq 1)$

im14.qxd 9/21/05 12:37 PM Page 255

14. $z(t) = a \cos t + ib \sin t \quad (0 \leqq t \leqq \pi)$

16. $z(t) = 2 - 3i + 4e^{it} \quad (0 \leqq t \leqq 2\pi)$ counterclockwise. For clockwise orientation the exponent is $-it$.

18. Ellipse, $z(t) = 1 + 3 \cos t + (-2 + 2 \sin t)i \quad (0 \leqq t \leqq 2\pi)$

20. $z(t) = t + it^2 \quad (0 \leqq t \leqq 1), \quad dz = (1 + 2it)\, dt, \quad \text{Re } z(t) = t$, so that

$$\int_0^1 t(1 + 2it)\, dt = \tfrac{1}{2} + \tfrac{2}{3}i.$$

This differs from Prob. 19. The integrand is not analytic!

22. $-\cos z \,|_0^{2i} = 1 - \cosh 2$ by the first method

24. By linearity we can integrate the two terms separately. The integral of z is 0 by Theorem 1. The integral of $1/z$ is $2\pi i$; see Example 5.

26. $z(t) = t + it^2 \quad (-1 \leqq t \leqq 1), \quad \dot{z}(t) = 1 + 2it, \quad \bar{z} = t - it^2, \quad$ so that

$$\int_{-1}^1 (t - it^2)(1 + 2it)\, dt = \int_{-1}^1 (2t^3 + it^2 + t)\, dt = \tfrac{1}{3}it^3 \Big|_{-1}^1 = \tfrac{2}{3}i.$$

28. $\text{Im } z^2 = 2xy$ is 0 on the axes. Thus the only contribution to the integral comes from the segment from 1 to i, represented by, say,

$$z(t) = 1 - t + it \qquad (0 \leqq t \leqq 1).$$

Hence $\dot{z}(t) = -1 + i$, and the integral is

$$\int_0^1 2(1 - t)t(-1 + i)\, dt = 2(-1 + i) \int_0^1 (t - t^2)\, dt = \tfrac{1}{3}(-1 + i).$$

30. $\frac{1}{3}z^3|_{-1-i}^{1+i} = -\frac{4}{3} + \frac{4}{3}i$, etc.

32. $|\text{Re } z| = |x| \leqq 1 = M$ on C, $L = \sqrt{2}$. The absolute value of the integral is $1/\sqrt{2}$ (see the answer to Prob. 19).

Applications will show that the point of the *ML*-inequality is to have an upper bound, regardless of how accurate it is. In a typical application the bound is used to show that a quantity remains bounded, in particular in some limit process, or sometimes may go to 0 in the limit. This point should be emphasized and explained to the student when applications arise in further work.

34. Team Project. (b) (i) $12.8i$, (ii) $\frac{1}{2}(e^{2+4i} - 1)$

(c) The integral of Re z equals $\frac{1}{2}\pi^2 - 2ai$. The integral of z equals $\frac{1}{2}\pi^2$. The integral of Re (z^2) equals $\pi^3/3 - \pi a^2/2 - 2a\pi i$. The integral of z^2 equals $\pi^3/3$.

(d) The integrals of the four functions in (c) have for the present paths the values $\frac{1}{2}a\pi i$, 0, $(4a^2 - 2)i/3$, and $-2i/3$, respectively.

Parts (c) and (d) may also help in motivating further discussions on path independence and the principle of deformation of path.

SECTION 14.2. Cauchy's Integral Theorem, page 646

Purpose. To discuss and prove the most important theorem in this chapter, Cauchy's integral theorem, which is basic by itself and has various basic consequences to be discussed in the remaining sections of the chapter.

im14.qxd 9/21/05 12:37 PM Page 256

Main Content, Important Concepts

Simply connected domain

Cauchy's integral theorem, Cauchy's proof

(Goursat's proof in App. 4)

Independence of path

Principle of deformation of path

Existence of indefinite integral

Extension of Cauchy's theorem to multiply connected domains

SOLUTIONS TO PROBLEM SET 14.2, page 653

2. 0, yes, since $3z = \pi i$, $z = \pi i/3$ lies outside the unit circle.

4. $1/\bar{z} = 1/e^{-it} = e^{it}$; hence $dz/\bar{z} = e^{it}ie^{it}\,dt$. *Answer:* 0, no

6. 0, yes, because $\cos(z/2) = 0$ for $z = \pm\pi$ etc., and these points lie outside the unit circle.

8. $1/(4z - 3) = \dfrac{1/4}{z - 3/4}$, so that the integral equals $\frac{1}{4} \cdot 2\pi i = \frac{1}{2}\pi i$ by the principle of deformation of path. The theorem does not apply.

10. 0, no; here $\bar{z}^2\,dz = e^{-2it}ie^{it}\,dt$.

12. (a) Yes. (b) No, since we would have to move the contour across $\pm 2i$, where $1/(z^2 + 4)$ is not analytic.

14. (a) $z = 0$ outside C, (b) $z = 0, \pm 1, \pm i$ outside C, (c) $0, \pm 3i$ outside C.

16. No, because of the principle of deformation of path.

18. Team Project. (b) (i) $\dfrac{2z + 3i}{z^2 + 1/4} = \dfrac{4}{z - i/2} - \dfrac{2}{z + i/2}$. From this, the principle of deformation of path, and (3) we obtain the *answer*

$$4 \cdot 2\pi i - 2 \cdot 2\pi i = 4\pi i.$$

(ii) Similarly,

$$\frac{z + 1}{z^2 + 2z} = \frac{1/2}{z} + \frac{1/2}{z + 2}.$$

Now $z = -2$ lies outside the unit circle. Hence the *answer* is $\frac{1}{2} \cdot 2\pi i = \pi i$.

(c) The integral of z, Im z, z^2, Re z^2, Im z^2 equals $1/2$, $a/6$, $1/3$, $1/3 - a^2/30 - ia/6$, $a/6 - ia^2/30$, respectively. Note that the integral of Re z^2 plus i times the integral of Im z^2 must equal $1/3$. Of course, the student should feel free to experiment with any functions whatsoever.

20. $\cosh z = 0$ at $\pm\pi i/2, \pm 3\pi i/2, \cdots$, which all lie outside C. *Answer:* 0.

22. The partial fraction reduction is

$$\frac{3}{z} + \frac{4}{z - 2}.$$

Answer: $2\pi i(3 + 4) = 14\pi i$.

24. 0

26. 0, because the branch cut extends from -2 to the left, outside C.

im14.qxd 9/21/05 12:37 PM Page 257

28. The partial fraction reduction is

$$\frac{1}{2i}\left(\frac{1}{z-i}-\frac{1}{z+i}\right).$$

Answer: (a) $2\pi i(-1/2i) = -\pi$, (b) π

30. 0, because $z = \pm\pi, \pm 3\pi, \cdots$ as well as ± 2 and $\pm 2i$ lie outside the contour C.

SECTION 14.3. Cauchy's Integral Formula, page 654

Purpose. To prove, discuss, and apply Cauchy's integral formula, the second major consequence of Cauchy's integral theorem (the first being the justification of indefinite integration).

Comment on Examples

The student has to find out how to write the integrand as a product $f(z)$ times $1/(z - z_0)$, and the examples (particularly Example 3) and problems are designed to give help in that technique.

SOLUTIONS TO PROBLEM SET 14.3, page 657

2. 0 by Cauchy's integral theorem; $\pm 2i$ lie outside C.

4. 0 by Cauchy's integral theorem

6. $f(z) = e^{3z}/3$. *Answer:* $\frac{1}{3} \cdot 2\pi i e^{i} = \frac{2}{3}\pi i(\cos 1 + i \sin 1) = -1.7624 + 1.1316i$

8. $z_0 = 1$. *Answer:* $2\pi i/2 = \pi i$

10. $z_0 = 2i$. *Answer:* $2\pi i e^{2i} = -2\pi \sin 2 + 2\pi i \cos 2 = -5.7133 - 2.6147i$

12. $2\pi i \tan i = -2\pi \tanh 1 = -4.7852$

14. $z_0 = i$ lies inside $|z - 2i| = 2$, and the corresponding integral equals

$$2\pi i(\text{Ln}\,(1 + i))/(2i) = \pi\,\text{Ln}\,(1 + i)$$
$$= \pi(\ln\sqrt{2} + \tfrac{1}{4}\pi i) = 1.089 + 2.467i.$$

The integral over the other circle is 0 because $z_0 = -i$ lies outside.

16. $z = 2i$ lies in the annulus bounded by the two given circles of C, but $z = 0$ does not. We thus obtain

$$2\pi i \left.\frac{\sin z}{z}\right|_{z=2i} = \pi i \sinh 2 = 11.394i.$$

18. For $z_1 = z_2$ use Example 6 in Sec. 14.1 with $m = -2$. For $z_1 \neq z_2$ use partial fractions

$$\frac{1}{(z-z_1)(z-z_2)} = \frac{1}{(z_1-z_2)(z-z_1)} - \frac{1}{(z_1-z_2)(z-z_2)}.$$

20. Team Project. (a) Eq. (2) is

$$\oint_C \frac{z^3-6}{z-\frac{1}{2}i}\,dz = \left[\left(\frac{i}{2}\right)^3 - 6\right]\oint_C \frac{dz}{z-\frac{1}{2}i} + \oint_C \frac{z^3-(\frac{1}{2}i)^3}{z-\frac{1}{2}i}\,dz$$
$$= \left(-\frac{i}{8} - 6\right)2\pi i + \oint_C \left(z^2 + \frac{1}{2}iz - \frac{1}{4}\right)dz = \frac{1}{4}\pi - 12\pi i$$

because the last integral is zero by Cauchy's integral theorem. The result agrees with that in Example 2, except for a factor 2.

im14.qxd 9/21/05 12:37 PM Page 258

(b) Using (12) in App. A3.1, we obtain (2) in the form

$$\oint_C \frac{\sin z}{z - \frac{1}{2}\pi}\, dz = (\sin \tfrac{1}{2}\pi) \oint_C \frac{dz}{z - \frac{1}{2}\pi} + \oint_C \frac{\sin z - \sin \frac{1}{2}\pi}{z - \frac{1}{2}\pi}\, dz$$

$$= 2\pi i + \oint_C \frac{2 \sin (\frac{1}{2}z - \frac{1}{4}\pi) \cos (\frac{1}{2}z + \frac{1}{4}\pi)}{z - \frac{1}{2}\pi}\, dz.$$

As ρ in Fig. 354 approaches 0, the integrand approaches 0.

SECTION 14.4. Derivatives of Analytic Functions, page 658

Purpose. To discuss and apply the most important consequence of Cauchy's integral formula, the theorem on the existence and form of the derivatives of an analytic function.

Main Content

Formulas for the derivatives of an analytic function (1)

Cauchy's inequality

Liouville's theorem

Morera's theorem (inverse of Cauchy's theorem)

Comments on Content

Technically the application of the formulas for derivatives in integration is practically the same as that in the last section.

The basic importance of (1) in giving the existence of all derivatives of an analytic function is emphasized in the text.

SOLUTIONS TO PROBLEM SET 14.4, page 661

2. $(2\pi i/3!)(-\cos(\pi i/2)) = -(\pi i/3)\cosh \frac{1}{2}\pi$

4. $(2\pi i/(2n)!)(-1)^n \cos 0 = (-1)^n \cdot 2\pi i/(2n)!$

6. $z_0 = -1$ lies inside C. Hence the integral equals

$$2\pi i \left(\frac{1}{z + 3} - \sin z \right) \Bigg|_{z=-1} = 2\pi i(\tfrac{1}{2} + \sin 1) = 8.429i.$$

8. $2\pi i e^a/(n - 1)!$ if $|a| < 2$ and 0 if $|a| > 2$.

10. 0 by Cauchy's integral theorem for a doubly connected domain; see (6) in Sec. 14.2.

12. $z = 0$ lies outside the "annulus" bounded by the two circles of C. The point $z = 2i$ lies inside the larger circle but outside the smaller. Hence the integral equals (differentiate once)

$$2\pi i \left(\frac{2e^{2z}}{z} - \frac{e^{2z}}{z^2} \right) \Bigg|_{z=2i} = 2\pi i \left(\frac{2e^{4i}}{2i} - \frac{e^{4i}}{-4} \right) = \pi e^{4i}(2 + \tfrac{1}{2}i).$$

14. Team Project. (a) If no such z existed, we would have $|f(z)| \leqq M$ for every $|z|$, which means that the entire function $f(z)$ would be bounded, hence a constant by Liouville's theorem.

im14.qxd 9/21/05 12:37 PM Page 259

(b) Let $f(z) = c_0 + c_1 z + \cdots + c_n z^n = z^n\left(c_n + \dfrac{c_{n-1}}{z} + \cdots + \dfrac{c_0}{z^n}\right)$, $c_n \neq 0$, $n > 0$. Set $|z| = r$. Then

$$|f(z)| > r^n \left(|c_n| - \frac{|c_{n-1}|}{r} - \cdots - \frac{|c_0|}{r^n}\right)$$

and $|f(z)| > \frac{1}{2} r^n |c_n|$ for sufficiently large r. From this the result follows.

(c) $|e^z| > M$ for real $z = x$ with $x > R = \ln M$. On the other hand, $|e^z| = 1$ for any pure imaginary $z = iy$ because $|e^{iy}| = 1$ for any real y (Sec. 13.5).

(d) If $f(z) \neq 0$ for all z, then $g = 1/f$ would be analytic for all z. Hence by (a) there would be values of z exterior to every circle $|z| = R$ at which, say, $|g(z)| > 1$ and thus $|f(z)| < 1$. This contradicts (b). Hence $f(z) \neq 0$ for all z cannot hold.

SOLUTIONS TO CHAP. 14 REVIEW QUESTIONS AND PROBLEMS, page 662

16. $(2 + i)^4 + (2 + i)^2 - ((-i)^4 + (-i)^2) = -4 + 28i$

18. 0

20. $2\pi i(e^{z^2})' \Big|_{z=1} = 4\pi i e$

22. $z_1(t) = t \quad (0 \leqq t \leqq 4), \quad z_2(t) = 4 + it \quad (0 \leqq t \leqq 3)$. *Answer:* $8 + 12i$

24. 0

26. $z(t) = re^{it}$. Hence

$$\int_0^{2\pi} (r \sin t) ire^{it}\, dt = ir^2 \int_0^{2\pi} (\sin t \cos t + i \sin^2 t)\, dt = -\pi r^2.$$

28. $2\pi i \pi/(\cos^2 \pi z) \Big|_{z=1} = 2\pi^2 i$

30. $\dfrac{2\pi i}{2!}(6z - \sin z) \Big|_{z=i} = \pi i(6i - i \sinh 1) = \pi(\sinh 1 - 6) = -15.158$

im15.qxd 9/21/05 12:56 PM Page 260

CHAPTER 15 Power Series, Taylor Series

Power series and, in particular, Taylor series, play a much more fundamental role in complex analysis than they do in calculus. The student may do well to review what has been presented about power series in calculus but should become aware that many new ideas appear in complex, mainly owing to the use of complex integration.

SECTION 15.1. Sequences, Series, Convergence Tests, page 664

Purpose. The beginnings on sequences and series in complex is similar to that in calculus (differences between real and complex appear only later). Hence this section can almost be regarded as a review from calculus plus a presentation of convergence tests for later use.

Main Content, Important Concepts

Sequences, series, convergence, divergence

Comparison test (Theorem 5)

Ratio test (Theorem 8)

Root test (Theorem 10)

SOLUTIONS TO PROBLEM SET 15.1, page 672

2. Bounded, divergent, 8 limit points (the values of $\sqrt[8]{1}$)

4. Unbounded, divergent

6. Bounded, convergent to 0 (the terms of the Maclaurin series of e^{3+4i})

8. Divergent. All terms have absolute value 1.

10. Convergent to 0

12. Let ℓ_1 and ℓ_2 be two limits, $d = |\ell_1 - \ell_2|$ and $\epsilon = d/3$. Then there is an $N(\epsilon)$ such that

$$|z_n - \ell_1| < \epsilon, \qquad |z_n - \ell_2| < \epsilon \qquad \text{for all } n > N.$$

This is impossible because the disks $|z - \ell_1| < \epsilon$ and $|z - \ell_2| < \epsilon$ are disjoint.

14. The sequences are bounded, $|z_n| < K$, $|z_n^*| < K$. Since they converge, for an $\epsilon > 0$ there is an N such that $|z_n - \ell| < \epsilon/(3K)$, $|z_n^* - \ell^*| < \epsilon/(3|\ell|)$ ($\ell \neq 0$; the case $\ell = 0$ is rather trivial), hence

$$\begin{aligned} |z_n z_n^* - \ell\ell^*| &= |(z_n - \ell)z_n^* + (z_n^* - \ell^*)\ell| \\ &\leqq |z_n - \ell|\,|z_n^*| + |z_n^* - \ell^*|\,|\ell| \\ &< \epsilon/3 + \epsilon/3 < \epsilon \quad (n > N). \end{aligned}$$

16. Convergent. Sum e^{10-15i}

18. Convergent because $\dfrac{1}{|n^2 - 2i|} < \dfrac{1}{n^2}$ and $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges.

20. Divergent because $1/\ln n > 1/n$ and the harmonic series diverges.

22. By the ratio test it converges because after simplification

$$\left|\frac{z_{n+1}}{z_n}\right| = \frac{(n+1)^3|1+i|}{(3n+3)(3n+2)(3n+1)} \to \frac{\sqrt{2}}{27}.$$

im15.qxd 9/21/05 12:56 PM Page 261

24. Convergent by the ratio test because $\left| \dfrac{(n+1)^2}{n^2} \dfrac{(i/3)^{n+1}}{(i/3)^n} \right| \to \dfrac{1}{3}$

30. Team Project. (a) By the generalized triangle inequality (6*), Sec. 13.2, we have

$$|z_{n+1} + \cdots + z_{n+p}| \leqq |z_{n+1}| + |z_{n+2}| + \cdots + |z_{n+p}|.$$

Since $|z_1| + |z_2| + \cdots$ converges by assumption, the sum on the right becomes less than any given $\epsilon > 0$ for every n greater than a sufficiently large N and $p = 1, 2, \cdots$, by Cauchy's convergence principle. Hence the same is true for the left side, which proves convergence of $z_1 + z_2 + \cdots$ by the same theorem.

(c) The form of the estimate of R_n suggests we use the fact that the ratio test is a comparison test based on the geometric series. This gives

$$R_n = z_{n+1} + z_{n+2} + \cdots = z_{n+1}\left(1 + \frac{z_{n+2}}{z_{n+1}} + \frac{z_{n+3}}{z_{n+1}} + \cdots\right),$$

$$\left|\frac{z_{n+2}}{z_{n+1}}\right| \leqq q, \quad \left|\frac{z_{n+3}}{z_{n+1}}\right| = \left|\frac{z_{n+3}}{z_{n+2}}\frac{z_{n+2}}{z_{n+1}}\right| \leqq q^2, \qquad \text{etc.},$$

$$|R_n| \leqq |z_{n+1}|\,(1 + q + q^2 + \cdots) = \frac{|z_{n+1}|}{1-q}.$$

(d) For this series we obtain the test ratio

$$\frac{1}{2}\left|\frac{n+1+i}{n+1}\cdot\frac{n}{n+i}\right| = \frac{n}{2(n+1)}\sqrt{\frac{(n+1)^2+1}{n^2+1}}$$

$$= \frac{1}{2}\sqrt{\frac{n^4+2n^3+2n^2}{n^4+2n^3+2n^2+2n+1}} < \frac{1}{2};$$

from this with $q = 1/2$ we have

$$|R_n| \leqq \frac{|z_{n+1}|}{1-q} = \frac{|n+1+i|}{2^n(n+1)} = \frac{\sqrt{(n+1)^2+1}}{2^n(n+1)} < 0.05.$$

Hence $n = 5$ (by computation), and

$$s = \frac{31}{32} + \frac{661}{960}\,i = 0.96875 + 0.688542i.$$

Exact to 6 digits is $1 + 0.693147i$.

SECTION 15.2. Power Series, page 673

Purpose. To discuss the convergence behavior of power series, which will be basic to our further work (and which is simpler than that of series having arbitrary complex functions as terms).

Comment. Most complex power series appearing in practical work and applications have real coefficients because most of the complex functions of practical interest are obtained from calculus by replacing the real variable x with the complex variable $z = x + iy$, retaining the real coefficients. Accordingly, in the problem set we consider primarily power series with real coefficients, also because complex coefficients would neither provide additional difficulties nor contribute new ideas.

im15.qxd 9/21/05 12:56 PM Page 262

Proof of the Assertions in Example 6

$R = 1/\widetilde{L}$ follows from $R = 1/\widetilde{l}$ by noting that in the case of convergence, $\widetilde{L} = \widetilde{l}$ (the only limit point). $\widetilde{l}$ exists by the Bolzano–Weierstrass theorem, assuming boundedness of $\{\sqrt[n]{|a_n|}\}$. Otherwise, $\sqrt[n]{|a_n|} > K$ for infinitely many n and any given K. Fix $z \neq z_0$ and take $K = 1/|z - z_0|$ to get

$$\sqrt[n]{|a_n(z - z_0)^n|} > K|z - z_0| = 1$$

and divergence for every $z \neq z_0$ by Theorem 9, Sec. 15.1.

Now, by the definition of a limit point, for a given $\epsilon > 0$ we have for infinitely many n

$$\widetilde{l} - \epsilon < \sqrt[n]{|a_n|} < \widetilde{l} + \epsilon;$$

hence for all $z \neq z_0$ and those n,

$$(*) \qquad (\widetilde{l} - \epsilon)|z - z_0| < \sqrt[n]{|a_n(z - z_0)^n|} < (\widetilde{l} + \epsilon)|z - z_0|.$$

The right inequality holds even for *all* $n > N$ (N sufficiently large), by the definition of a *greatest* limit point.

Let $\widetilde{l} = 0$. Since $\sqrt[n]{|a_n|} \geqq 0$, we then have convergence to 0. Fix any $z = z_1 \neq z_0$. Then for $\epsilon = 1/(2|z_1 - z_0|) > 0$ there is an N such that $\sqrt[n]{|a_n|} < \epsilon$ for all $n > N$; hence

$$|a_n(z_1 - z_0)^n| < \epsilon^n|z_1 - z_0|^n = \frac{1}{2^n},$$

and convergence for all z_1 follows by the comparison test.

Let $\widetilde{l} > 0$. We establish $1/\widetilde{l}$ as the radius of convergence of (1) by proving

$$\text{convergence of the series (1) if } |z - z_0| < 1/\widetilde{l},$$
$$\text{divergence of the series (1) if } |z - z_0| > 1/\widetilde{l}.$$

Let $|z - z_0| < 1/\widetilde{l}$. Then, say, $|z - z_0|\widetilde{l} = 1 - b < 1$. With this and $\epsilon = b/(2|z - z_0|) > 0$ in (*), for all $n > N$,

$$\sqrt[n]{|a_n(z - z_0)^n|} < \widetilde{l}\,|z - z_0| + \epsilon|z - z_0| = 1 - b + \tfrac{1}{2}b < 1.$$

Convergence now follows from Theorem 9, Sec. 15.1.

Let $|z - z_0| > 1/\widetilde{l}$. Then $|z - z_0|\widetilde{l} = 1 + c > 1$. With this and $\epsilon = c/(2|z - z_0|) > 0$ in (*), for infinitely many n,

$$\sqrt[n]{|a_n(z - z_0)^n|} > \widetilde{l}\,|z - z_0| - \epsilon|z - z_0| = 1 + c - \tfrac{1}{2}c > 1,$$

and divergence follows.

SOLUTIONS TO PROBLEM SET 15.2, page 677

4. Center $-2i$. In (6) we have

$$\frac{n^n(n + 1)!}{n!(n + 1)^{n+1}} = \frac{n^n}{(n + 1)^n} = \frac{1}{(1 + 1/n)^n} \to \frac{1}{e}$$

as is shown in calculus.

6. 0, ∞ because by (6)

$$\frac{2^{100n}}{n!} \cdot \frac{(n + 1)!}{2^{100(n+1)}} = \frac{n + 1}{2^{100}} \to \infty.$$

im15.qxd 9/21/05 12:56 PM Page 263

8. 0, ∞. The sum is the Bessel function $J_0(z)$.

10. 0, ∞. The sum is $\cosh 2z$.

12. 5, $\sqrt{2}/4$, where $\sqrt{2} = |1 + i|$.

14. 0, ∞. The sum is $\cos z$.

16. π, $|(5 - i)/(2 + 3i)| = \sqrt{2}$

18. $-\pi i$. In (6),

$$\frac{(4n)! \cdot 2^{n+1}\,(n+1)^4(n!)^4}{2^n(n!)^4(4n+4)(4n+3)(4n+2)(4n+1)(4n)!} \quad \to \quad \frac{2n^4}{(4n)^4} = \frac{1}{128}.$$

20. Team Project. (a) The faster the coefficients go to zero, the larger $|a_n/a_{n+1}|$ becomes.

(b) (i) Nothing. (ii) R is multiplied by $1/k$. (iii) The new series has radius of convergence $1/R$.

(c) In Example 6 we took the first term of one series, then the first term of the other, and so on alternately. We could have taken, for instance, the first three terms of one series, then the first five terms of the other, then again three terms and five terms, and so on; or we could have mixed three or more series term by term.

(d) No because $|30 + 10i| > |31 - 6i|$.

SECTION 15.3. Functions Given by Power Series, page 678

Purpose. To show what operations on power series are mathematically justified and to prove the basic fact that power series represent analytic functions.

Main Content

Termwise addition, subtraction, and multiplication of power series

Termwise differentiation and integration (Theorems 3, 4)

Analytic functions and derivatives (Theorem 5)

Comment on Content

That a power series is the Taylor series of its sum will be shown in the next section.

SOLUTIONS TO PROBLEM SET 15.3, page 682

2. 1/4, where $1/(n(n+1))$ can be produced by two integrations of the geometric series.

4. $|z/\pi|^2 < 1$ by integrating a geometric series. Thus $|z| < R = \pi$.

6. $\binom{n}{k} = \dfrac{n(n-1)\cdots(n-k+1)}{k!}$ consists of the fixed $k!$, which has no effect on R, and factors $n(n-1)\cdots(n-k+1)$, as obtained by differentiation. Since $\Sigma\,(z/4)^n$ has $R = 4$, the answer is 4.

8. ∞, because $2n(2n-1)$ results from differentiation, and for the coefficients without these factors we have in the Cauchy–Hadamard formula

$$\frac{1/n^n}{1/(n+1)^{n+1}} = \left(\frac{n+1}{n}\right)^n (n+1) \quad \to \quad \infty \qquad \text{as } n \to \infty$$

im15.qxd 9/21/05 12:56 PM Page 264

10. 1, by applying Theorem 3 to z^{n+m}

14. Set $f = \sqrt[n]{n}$ and apply l'Hôpital's rule to $\ln f$,

$$\lim_{n\to\infty} \ln f = \lim_{n\to\infty} \frac{\ln n}{n} = \lim_{n\to\infty} \frac{1/n}{1} = 0. \qquad \text{Hence} \qquad \lim_{n\to\infty} f = 1.$$

16. This is a useful formula for binomial coefficients. It follows from

$$(1+z)^p(1+z)^q = \sum_{n=0}^{p} \binom{p}{n} z^n \sum_{m=0}^{q} \binom{q}{m} z^m$$

$$= (1+z)^{p+q} = \sum_{r=0}^{p+q} \binom{p+q}{r} z^r$$

by equating the coefficients of z^r on both sides. To get $z^n z^m = z^r$ on the left, we must have $n + m = r$; thus $m = r - n$, and this gives the formula in the problem.

18. The odd-numbered coefficients are zero because $f(-z) = f(z)$ implies

$$a_{2m+1}(-z)^{2m+1} = -a_{2m+1}z^{2m+1} = a_{2m+1}z^{2m+1}.$$

20. Team Project. (a) Division of the recursion relation by a_n gives

$$\frac{a_{n+1}}{a_n} = 1 + \frac{a_{n-1}}{a_n}.$$

Take the limit on both sides, denoting it by L:

$$L = 1 + \frac{1}{L}.$$

Thus $L^2 - L - 1 = 0$, $L = (1 + \sqrt{5})/2 = 1.618$, an approximate value reached after just ten terms.

(b) The list is

1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233.

In the recursion, a_n is the number of pairs of rabbits present and a_{n-1} is the number of pairs of offsprings from the pairs of rabbits present at the end of the preceding month.

(c) Using the hint, we calculate

$$(1 - z - z^2)\sum_{n=0}^{\infty} a_n z^n = \sum_{n=0}^{\infty} (a_n - a_{n-1} - a_{n-2})z^n = 1$$

where $a_{-1} = a_{-2} = 0$, and Theorem 2 gives $a_0 = 1$, $a_1 - a_0 = 0$, $a_n - a_{n-1} - a_{n-2} = 0$ for $n = 2, 3, \cdots$. The converse follows from the uniqueness of a power series representation (see Theorem 2).

SECTION 15.4. Taylor and Maclaurin Series, page 683

Purpose. To derive and explain Taylor series, which include those for real functions known from calculus as special cases.

Main Content

Taylor series (1), integral formula (2) for the coefficients

Singularity, radius of convergence

im15.qxd 9/21/05 12:56 PM Page 265

Maclaurin series for e^z, $\cos z$, $\sin z$, $\cosh z$, $\sinh z$, $\operatorname{Ln}(1+z)$

Theorem 2 connecting Taylor series to the last section

Comment

The series just mentioned, with $z = x$, are familiar from calculus.

SOLUTIONS TO PROBLEM SET 15.4, page 690

2. $1 + z^3 + z^6 + z^9 + \cdots$, $R = 1$, geometric series

4. $\cos^2 z = \frac{1}{2} + \frac{1}{2}\cos 2z = 1 - z^2 + \frac{1}{3}z^4 - \frac{2}{45}z^6 + \frac{1}{315}z^8 - + \cdots$, $R = \infty$

6. $1 - (z-1) + (z-1)^2 - (z-1)^3 + - \cdots$, $R = 1$

8. $\operatorname{Ln}(1-i) - (\frac{1}{2} + \frac{1}{2}i)(z-i) - \frac{1}{4}i(z-i)^2 + (\frac{1}{12} - \frac{1}{12}i)(z-i)^3 + \cdots$, $R = \sqrt{2}$. This series is similar to that mentioned in the text preceding Theorem 2.

10. The series is

$$f = z + \frac{2}{1\cdot 3}z^3 + \frac{2^2}{1\cdot 3\cdot 5}z^5 + \frac{2^3}{1\cdot 3\cdot 5\cdot 7}z^7 + \cdots, \quad R = \infty.$$

It can be obtained in several ways. (a) Integrate the Maclaurin series of the integrand termwise and form the Cauchy product with the series of e^{z^2}. (b) f satisfies the differential equation $f' = 2zf + 1$. Use this, its derivatives $f'' = 2(f + zf')$, etc., $f(0) = 0$, $f'(0) = 1$, etc., and the coefficient formulas in (1). (c) Substitute $f = \sum_{n=0}^{\infty} a_n z^n$ and $f' = \sum_{n=0}^{\infty} n a_n z^{n-1}$ into the differential equation and compare coefficients; that is, apply the power series method (Sec. 5.1).

12. $(z-2i) + \dfrac{1}{3!}(z-2i)^3 + \dfrac{1}{5!}(z-2i)^5 + \cdots, \quad R = \infty$

14. $z - \dfrac{z^3}{3!3} + \dfrac{z^5}{5!5} - \dfrac{z^7}{7!7} + - \cdots; \quad R = \infty$

16. $z - \dfrac{z^5}{2!5} + \dfrac{z^9}{4!9} - \dfrac{z^{13}}{6!13} + - \cdots; \quad R = \infty$

18. First of all, since $\sin(w + 2\pi) = \sin w$ and $\sin(\pi - w) = \sin w$, we obtain all values of $\sin w$ by letting w vary in a suitable vertical strip of width π, for example, in the strip $-\pi/2 \leqq u \leqq \pi/2$. Now since

$$\sin\left(\frac{\pi}{2} - iy\right) = \sin\left(\frac{\pi}{2} + iy\right) = \cosh y$$

and

$$\sin\left(-\frac{\pi}{2} - iy\right) = \sin\left(-\frac{\pi}{2} + iy\right) = -\cosh y,$$

we have to exclude a part of the boundary of that strip, so we exclude the boundary in the lower half-plane. To solve our problem we have to show that the value of the series lies in that strip. This follows from $|z| < 1$ and

$$\left|\operatorname{Re}\left(z + \frac{1}{2}\,\frac{z^3}{3} + \cdots\right)\right| \leqq \left|z + \frac{1}{2}\,\frac{z^3}{3} + \cdots\right| \leqq |z| + \frac{1}{2}\,\frac{|z|^3}{3} + \cdots$$

$$= \arcsin|z| < \frac{\pi}{2}.$$

im15.qxd 9/21/05 12:56 PM Page 266

20. Team Project. (a) $(\text{Ln}\,(1+z))' = 1 - z + z^2 - z^3 + - \cdots = \dfrac{1}{1+z}$.

(c) For $y \neq 0$ the series

$$\frac{\sin iy}{iy} = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!}(iy)^{2n} = \sum_{n=0}^{\infty} \frac{1}{(2n+1)!}y^{2n}$$

has positive terms; hence its sum cannot be 0.

SECTION 15.5. Uniform Convergence. *Optional,* page 691

Purpose. To explain the concept of uniform convergence. To show that power series have the advantage that they converge uniformly (exact formulation in Theorem 1). To discuss properties of general uniformly convergent series.

Main Content

Uniform convergence of power series (Theorem 1)

Continuous sum (Theorem 2)

Termwise integration (Theorem 3) and differentiation (Theorem 4)

Weierstrass test for uniform convergence (Theorem 5)

The test in Theorem 5 is very simple, conceptually and technically in its application.

SOLUTIONS TO PROBLEM SET 15.5, page 697

2. This Maclaurin series of $\sinh z$ converges uniformly on every bounded set.

4. $|\sin^n |\pi z|| \leqq 1$, $1/(n(n+1)) < 1/n^2$, and $\Sigma\, 1/n^2$ converges. Use the Weierstrass M-test.

6. $|z^n| \leqq 1$, $1/(n^2 \cosh n|z|) \leqq 1/n^2$, and $\Sigma\, 1/n^2$ converges.

8. $|\cos n|z|| \leqq 1$ and $\Sigma\, 1/n^2$ converges.

10. This Taylor series of $\cosh z$ with center i converges uniformly on every bounded set.

12. $|z - \frac{1}{2}i| \leqq \frac{1}{2} - \delta$ $(\delta > 0)$

14. $|z| \leqq 1/\sqrt{3} - \delta$ $(\delta > 0)$

16. This Maclaurin series of $\cos z$ converges uniformly on every bounded set.

18. Team Project. (a) Convergence follows from the comparison test (Sec. 15.1). Let $R_n(z)$ and R_n^* be the remainders of (1) and (5), respectively. Since (5) converges, for given $\epsilon > 0$ we can find an $N(\epsilon)$ such that $R_n^* < \epsilon$ for all $n > N(\epsilon)$. Since $|f_m(z)| \leqq M_m$ for all z in the region G, we also have $|R_n(z)| \leqq R_n^*$ and therefore $|R_n(z)| < \epsilon$ for all $n > N(\epsilon)$ and all z in the region G. This proves that the convergence of (1) in G is uniform.

(b) Since $f_0' + f_1' + \cdots$ converges uniformly, we may integrate term by term, and the resulting series has the sum $F(z)$, the integral of the sum of that series. Therefore, the latter sum must be $F'(z)$.

(c) The converse is not true.

(d) Noting that this is a geometric series in powers of $q = (1+z^2)^{-1}$, we have $q = |1+z^2|^{-1} < 1$, $1 < |1+z^2|^2 = (1 + x^2 - y^2)^2 + 4x^2y^2$, the exterior of a lemniscate. The series converges also at $z = 0$.

im15.qxd 9/21/05 12:56 PM Page 267

(e) We obtain (add and subtract 1)

$$x^2 \sum_{m=1}^{\infty} \frac{1}{(1 + x^2)^m} = x^2\left(-1 + \sum_{m=0}^{\infty} \frac{1}{(1 + x^2)^m}\right)$$

$$= -x^2 + \frac{x^2}{1 - \dfrac{1}{1 + x^2}} = -x^2 + 1 + x^2 = 1.$$

20. We obtain

$$|B_n| = \frac{2}{L}\left|\int_0^L f(x) \sin \frac{n\pi x}{L}\, dx\right| < \frac{2}{L}\, ML$$

where M is such that $|f(x)| < M$ on the interval of integration. Thus

$$|B_n| < K\ (= 2M).$$

Now when $t \geqq t_0 > 0$,

$$|u_n| = \left|B_n \sin \frac{n\pi x}{L}\, e^{-\lambda_n{}^2 t}\right| < Ke^{-\lambda_n{}^2 t_0}$$

because $\left|\sin \dfrac{n\pi x}{L}\right| \leqq 1$ and the exponential function decreases in a monotone fashion as t increases. From this,

$$\left|\frac{\partial u_n}{\partial t}\right| = |-\lambda_n{}^2 u_n| = \lambda_n{}^2 |u_n| < \lambda_n{}^2 Ke^{-\lambda_n{}^2 t_0} \quad \text{when} \quad t \geqq t_0.$$

Consider

$$\sum_{n=1}^{\infty} \lambda_n{}^2 Ke^{-\lambda_n{}^2 t_0}.$$

Since $\lambda_n = \dfrac{cn\pi}{L}$, for the test ratio we have

$$\frac{\lambda_{n+1}^2 K \exp(-\lambda_{n+1}^2 t_0)}{\lambda_n{}^2 K \exp(-\lambda_n{}^2 t_0)} = \left(\frac{n + 1}{n}\right)^2 \exp\left[-(2n + 1)\left(\frac{c\pi}{L}\right)^2 t_0\right] \quad \to \quad 0$$

as $n \to \infty$, and the series converges. From this and the Weierstrass test it follows that $\sum \dfrac{\partial u_n}{\partial t}$ converges uniformly and, by Theorem 4, has the sum $\dfrac{\partial u}{\partial t}$, etc.

SOLUTIONS TO CHAP. 15 REVIEW QUESTIONS AND PROBLEMS, page 698

12. $\frac{1}{2}$, $\operatorname{Ln}(1 + 2z)$

14. ∞, $\cos \sqrt{z}$

$$1 + \frac{1}{2!}\,t + \frac{1}{3!}\,t^2 + \frac{1}{4!}\,t^3 + \cdots, \quad R = \infty.$$

Termwise integration from 0 to z gives

$$z + \tfrac{1}{4}z^2 + \tfrac{1}{18}z^3 + \tfrac{1}{96}z^4 + \tfrac{1}{600}z^5 + \cdots, \quad R = \infty.$$

30. $\dfrac{1}{2} - \dfrac{1}{2}\cos 2z = z^2 - \dfrac{2^3z^4}{4!} + \dfrac{2^5z^6}{6!} - + \cdots$, $R = \infty$

im16.qxd 9/21/05 1:05 PM Page 269

CHAPTER 16 Laurent Series. Residue Integration

This is another powerful and elegant integration method that has no analog in calculus. It uses Laurent series (roughly, series of positive and negative powers of z), more precisely, it uses just a single term of such a series (the term in $1/(z - z_0)$, whose coefficient is called the **residue** of the sum of the series that converges near z_0).

SECTION 16.1. Laurent Series, page 701

Purpose. To define Laurent series, to investigate their convergence in an annulus (a ring, in contrast to Taylor series, which converge in a disk), to discuss examples.

Major Content, Important Concepts

Laurent series

Convergence (Theorem 1)

Principal part of a Laurent series

Techniques of development (Examples 1–5)

SOLUTIONS TO PROBLEM SET 16.1, page 707

2. $z - \dfrac{1}{2z} + \dfrac{1}{24z^3} - + \cdots, \quad 0 < |z| < R = \infty$

4. $\dfrac{1}{z^2}\left(1 + \dfrac{(2z)^2}{2!} + \dfrac{(2z)^4}{4!} + \dfrac{(2z)^6}{6!} + \cdots\right) = \dfrac{1}{z^2} + 2 + \dfrac{2}{3}z^2 + \dfrac{4}{45}z^4 + \cdots,$

$0 < |z| < R = \infty$

6. We obtain

$$\frac{1}{z^2}e^z\frac{1}{1-z} = \frac{1}{z^2}\sum_{m=0}^{\infty}\frac{z^m}{m!}\sum_{n=0}^{\infty}z^n$$

$$= \frac{1}{z^2}\sum_{n=0}^{\infty}\left(\sum_{m=0}^{n}\frac{1}{m!}\right)z^n$$

$$= \frac{1}{z^2} + \frac{2}{z} + \frac{5}{2} + \frac{8}{3}z + \frac{65}{24}z^2 + \cdots, \quad 0 < |z| < R = 1.$$

8. Successive differentiation and use of $\cos\frac{1}{4}\pi = \sin\frac{1}{4}\pi = 1/\sqrt{2}$ gives

$$\frac{1}{\sqrt{2}}\left[\frac{1}{\left(z-\frac{\pi}{4}\right)^3} + \frac{1}{\left(z-\frac{\pi}{4}\right)^2} - \frac{1}{2!\left(z-\frac{\pi}{4}\right)} - \frac{1}{3!} + \frac{z-\frac{\pi}{4}}{4!} + \cdots\right],$$

$R = \infty.$

This can also be obtained from

$$\sin z = \sin\left[\left(z - \frac{\pi}{4}\right) + \frac{\pi}{4}\right] = \frac{1}{\sqrt{2}}\left[\sin\left(z - \frac{\pi}{4}\right) + \cos\left(z - \frac{\pi}{4}\right)\right]$$

and substitution of the usual series on the right.

im16.qxd 9/21/05 1:05 PM Page 270

10. $\displaystyle\sum_{n=0}^{\infty} \frac{(-1)^{n+1}}{(2n)!}(z-\pi)^{2n-4} = -\frac{1}{(z-\pi)^4} + \frac{1}{2!(z-\pi)^2} - \frac{1}{4!} + \frac{1}{6!}(z-\pi)^2 - + \cdots, \quad 0 < |z| < R = \infty$

12. $\displaystyle\frac{i}{(z+i)^2} - \frac{3}{z+i} - 3i + (z+i)$

14. $\displaystyle\sum_{n=0}^{\infty} \frac{1}{(2n+1)!z^{2n-1}} = z + \frac{1}{6z} + \frac{1}{120z^3} + \cdots, \quad 0 < |z| < R = \infty$

16. We obtain

$$\sum_{n=0}^{\infty} \frac{(-1)^{n+1}}{2^{n+1}}(z-1)^{n-1}, \quad 0 < |z-1| < 2,$$

$$\frac{1}{1-z^2} = \frac{1}{1-(z-1+1)^2} = \frac{-1}{(z-1)^2+2(z-1)}$$

$$= \frac{-1}{(z-1)^2\left(1+\dfrac{2}{z-1}\right)} = \sum_{n=0}^{\infty} \frac{(-1)^{n+1}2^n}{(z-1)^{n+2}}, \quad |z-1| > 2$$

18. $\displaystyle\sum_{n=0}^{\infty}(-1)^n(z-1)^n, \quad 0 < |z-1| < 1, \quad \sum_{n=0}^{\infty} \frac{(-1)^n}{(z-1)^{n+1}}, \quad |z-1| > 1$

20. $\displaystyle\sum_{n=0}^{\infty} \frac{a_n}{n!}(z-1)^{n-4}, \quad a_n = \sinh 1 \quad (n \text{ even}), \quad a_n = \cosh 1 \ (n \text{ odd}), \quad |z-1| > 0$

22. $\displaystyle\frac{1}{z^2} = \frac{1}{[i+(z-i)]^2} = \sum_{n=0}^{\infty} \binom{-2}{n} \frac{(z-i)^n}{i^{n+2}}, \quad |z-i| < 1,$

$$\frac{1}{z^2} = \frac{1}{(z-i)^2\left(1+\dfrac{i}{z-i}\right)^2} = \sum_{n=0}^{\infty} \binom{-2}{n} \frac{i^n}{(z-i)^{n+2}}, \quad |z-i| > 1$$

24. Team Project. (a) Let $\displaystyle\sum_{-\infty}^{\infty} a_n(z-z_0)^n$ and $\displaystyle\sum_{-\infty}^{\infty} c_n(z-z_0)^n$ be two Laurent series of the same function $f(z)$ in the same annulus. We multiply both series by $(z-z_0)^{-k-1}$ and integrate along a circle with center at z_0 in the interior of the annulus. Since the series converge uniformly, we may integrate term by term. This yields $2\pi i a_k = 2\pi i c_k$. Thus, $a_k = c_k$ for all $k = 0, \pm 1, \cdots$.

(b) No, because $\tan(1/z)$ is singular at $1/z = \pm\pi/2, \pm 3\pi/2, \cdots$, hence at $z = \pm 2/\pi$, $\pm 2/3\pi, \cdots$, which accumulate at 0.

(c) These series are obtained by termwise integration of the integrand. The second function is $\mathrm{Si}(z)/z^3$, where $\mathrm{Si}(z)$ is the sine integral [see (40) in App. A.31]. *Answer:*

$$\frac{1}{z} + \frac{1}{2!2} + \frac{z}{3!3} + \frac{z^2}{4!4} + \cdots,$$

$$\frac{1}{z^2} - \frac{1}{3!3} + \frac{z^2}{5!5} - + \cdots.$$

im16.qxd 9/21/05 1:05 PM Page 271

SECTION 16.2. Singularities and Zeros. Infinity, page 707

Purpose. *Singularities* just appeared in connection with the convergence of Taylor and Laurent series in the last sections, and since we now have the instrument for their classification and discussion (i.e., Laurent series), this seems the right time for doing so. We also consider *zeros,* whose discussion is somewhat related.

Main Content, Important Concepts

Principal part of a Laurent series convergent near a singularity

Pole, behavior (Theorem 1)

Isolated essential singularity, behavior (Theorem 2)

Zeros are isolated (Theorem 3)

Relation between poles and zeros (Theorem 4)

Point ∞, extended complex plane, behavior at ∞

Riemann sphere

SOLUTIONS TO PROBLEM SET 16.2, page 711

2. 0 (pole of second order), ∞ (simple pole)

4. 1 (essential singularity), ∞ (pole of third order)

6. $\pi/4 \pm n\pi$ (simple poles). These are the points where the sine and cosine curves intersect. They have a different tangent there, hence their difference $\cos z - \sin z$ cannot have a zero derivative at those points; accordingly, those zeros are simple and give simple poles of the given function. To make sure that no further zeros of $\cos z - \sin z$ exist, one must calculate

$$\cos z - \sin z = \left(\frac{1}{2} - \frac{1}{2i}\right)e^{iz} + \left(\frac{1}{2} + \frac{1}{2i}\right)e^{-iz} = 0,$$

and by simplification,

$$e^{2iz} = i, \qquad z = \frac{\pi}{4} \pm n\pi, \qquad n = 0, 1, \cdots,$$

so that we get no further solutions beyond those found by inspecting those two curves.

8. 0 (third-order pole). This problem emphasizes that the order of a pole is determined by the highest negative power, regardless of other terms (which may or may not be present).

10. 1, ∞ (essential singularities), $\pm 2n\pi i$ ($n = 0, 1, \cdots$, simple poles)

12. For $|z|$ small enough we have $|1 + z| > 1/\sqrt{2}$, $|1 - z| > 1/\sqrt{2}$; hence

$$|1 - z^2| = |1 + z|\,|1 - z| > 1/2$$

and

$$\left|\frac{1}{z^3} - \frac{1}{z}\right| = \frac{1}{|z|^3}\left|1 - z^2\right| > \frac{1}{2|z|^3} \quad \to \quad \infty \qquad \text{as} \qquad |z| \to 0.$$

This motivates the proof.

im16.qxd 9/21/05 1:05 PM Page 272

To prove the theorem, let $f(z)$ have a pole of mth order at some point $z = z_0$. Then

$$f(z) = \frac{b_m}{(z - z_0)^m} + \frac{b_{m-1}}{(z - z_0)^{m-1}} + \cdots$$

$$= \frac{b_m}{(z - z_0)^m}\left[1 + \frac{b_{m-1}}{b_m}(z - z_0) + \cdots\right], \qquad b_m \neq 0.$$

For given $M > 0$, no matter how large, we can find a $\delta > 0$ so small that

$$\frac{|b_m|}{\delta^m} > 2M \qquad \text{and} \qquad \left|\left[1 + \frac{b_{m-1}}{b_m}(z - z_0) + \cdots\right]\right| > \frac{1}{2}$$

for all $|z - z_0| < \delta$. Then

$$|f(z)| > \frac{|b_m|}{\delta^m}\ \frac{1}{2} > M.$$

Hence $|f(z)| \to \infty$ as $z \to z_0$.

14. $z^4 = 16$ has the solutions ± 2 and $\pm 2i$. Because of the other exponent 4 this gives zeros of fourth order.

16. $(\frac{1}{2} \pm n)\pi i$ (second order) because

$$\cosh z = \tfrac{1}{2}(e^z + e^{-z}) = 0; \qquad \text{hence} \qquad e^{2z} = -1$$

and this implies

$$2z = \operatorname{Ln}(-1) \pm 2n\pi i = (1 \pm 2n)\pi i$$

so that z has the values given at the beginning.

18. ± 1 (second order), $(\pm 1 \pm i)\sqrt{n\pi}$ (simple) because

$$e^{z^2} = 1, \qquad z^2 = \operatorname{Ln} 1 \pm 2n\pi i = \pm 2n\pi i;$$

hence

$$z = \sqrt{\pm 2n\pi i} = \pm\frac{1 \pm i}{\sqrt{2}}\sqrt{2n\pi}.$$

20. $\frac{1}{2}\pi \pm 2n\pi$ $(n = 0, 1, \cdots)$, sixth order, since

$$(\sin z - 1)' = \cos z = 0$$

at those points.

22. $e^z - e^{2z} = e^z(1 - e^z) = 0$, $e^z = 1$, $z = \operatorname{Ln} 1 \pm 2n\pi i = \pm 2n\pi i$. These zeros are simple because $(e^z - 1)' = e^z \neq 0$ for all z.

24. Team Project. (a) $f(z) = (z - z_0)^n g(z)$ gives

$$f'(z) = n(z - z_0)^{n-1}g(z) + (z - z_0)^n g'(z)$$

which implies the assertion because $g(z_0) \neq 0$.

(b) $f(z)$ as in (a) implies $1/f(z) = (z - z_0)^{-n}h(z)$, where $h(z) = 1/g(z)$ is analytic at z_0 because $g(z_0) \neq 0$.

(c) $f(z) - k = 0$ at those points. Apply Theorem 3.

(d) $f_1(z) - f_2(z)$ is analytic in D and zero at each z_n. Hence its zeros are not isolated because that sequence converges. Thus it must be constant, since otherwise it would contradict Theorem 3. And that constant must be zero because it is zero at those points. Thus $f_1(z)$ and $f_2(z)$ are identical in D.

im16.qxd 9/21/05 1:05 PM Page 273

SECTION 16.3. Residue Integration Method, page 712

Purpose. To explain and apply this most elegant integration method.

Main Content, Important Concepts

Formulas for the residues at poles (3)–(5)

Residue theorem (several singularities inside the contour)

Comment

The extension from the case of a single singularity to several singularities (residue theorem) is immediate.

SOLUTIONS TO PROBLEM SET 16.3, page 717

2. -8

4. The residue at $z = 0$ is 0 because $(\cos z)/z^6$ contains only even powers.

6. $z^2 - z = z(z - 1)$, simple poles at 0 and 1, and (4) gives

$$\operatorname*{Res}_{z=0} \frac{z^2 + 1}{z^2 - z} = \frac{z^2 + 1}{2z - 1}\bigg|_{z=0} = -1, \qquad \operatorname*{Res}_{z=1} \frac{z^2 + 1}{z^2 - z} = \frac{z^2 + 1}{2z - 1}\bigg|_{z=1} = 2.$$

8. $(-1)^{n+1}$ (at $z = (2n + 1)\pi/2$) because the simple zeros of $\cos z$ at the points $z = z_n = (2n + 1)\pi/2$ give simple poles of $\sec z$, and (4) yields

$$\frac{1}{(\cos z)'}\bigg|_{z_n} = \frac{-1}{\sin z}\bigg|_{z_n} = (-1)^{n+1}.$$

10. Simple poles at ± 1 and $\pm i$. In (4) we have $p(z)/q'(z) = 1/12z^3$. Hence the values of the residues are $\pm 1/12$ and $\pm i/12$, respectively.

12. Simple poles at ± 1 and $\pm i$, residues $\pm\frac{1}{4}$ and $\mp\frac{1}{4}i$, respectively.

14. Third-order pole at $z = 0$. No further singularities in the finite plane. Multiplying the Maclaurin series of $\sin \pi z$ by $1/z^4$ gives the Laurent series

$$\frac{1}{z^4}\left(\pi z - \frac{1}{3!}(\pi z)^3 + - \cdots\right) = \frac{\pi}{z^3} - \frac{1}{6z}\pi^3 + - \cdots.$$

Hence the residue is $-\pi^3/6$. *Answer:* $-\pi^4 i/3$.

16. $\sinh z = 0$ at $0, \pm\pi i, \pm 2\pi i, \cdots$. Hence $\sinh \frac{1}{2}\pi z = 0$ at 0 (inside C), $\pm 2i, \pm 4i, \cdots$ (all outside C). These are simple poles, and (4) gives the residue

$$\operatorname*{Res}_{z=0} \frac{1}{\sinh \frac{1}{2}\pi z} = \frac{1}{\frac{1}{2}\pi \cosh 0} = \frac{2}{\pi}.$$

Hence the *answer* is $2\pi i \cdot (2/\pi) = 4i$.

18. Simple poles at $z_0 = \pm\frac{1}{2}$ and $\pm\frac{3}{2}$ inside C and infinitely many others outside C. Formula (4) gives the residues $(\sin z_0)/(-\pi \sin z_0) = -1/\pi$. Hence the *answer* is $2\pi i \cdot 4 \cdot (-1/\pi) = -8i$.

20. Simple pole at 0, residue [by (4)]

$$\frac{\cosh z}{(\sinh z)'} = 1.$$

Answer: $2\pi i$.

im16.qxd 9/21/05 1:05 PM Page 274

22. Simple poles at 0 (inside C) and $3i$ (outside C), and (3) gives

$$\operatorname*{Res}_{z=0} \frac{\cosh z}{z^2 - 3iz} = \frac{\cosh z}{z - 3i}\bigg|_{z=0} = \frac{i}{3}.$$

Answer: $-2\pi/3$.

24. Simple poles at $z_0 = -i/2$, $i/2$ (inside C) and 2 (outside C), and (4) gives the residues

$$\operatorname*{Res}_{z=z_0} \frac{1 - 4z + 6z^2}{(z^2 + \frac{1}{4})(2 - z)} = \frac{1 - 4z + 6z^2}{[(z^2 + \frac{1}{4})(2 - z)]'}\bigg|_{z_0}$$

$$= \frac{1 - 4z_0 + 6{z_0}^2}{-3{z_0}^2 + 4z_0 - \frac{1}{4}} = -1, -1.$$

Answer: $2\pi i(-1 - 1) = -4\pi i$.

SECTION 16.4. Residue Integration of Real Integrals, page 718

Purpose 1. To show that certain classes of *real* integrals over finite or infinite intervals of integration can also be evaluated by residue integration.

Comment on Content

Since residue integration requires a closed path, one must have methods for producing such a path. We see that for the finite intervals in the text, this is done by (2), perhaps preceded by a translation and change of scale if another interval is given. (This is not shown in the text.) In the case of an infinite interval, we start from a finite one, close it by some curve in complex (here, a semicircle; Fig. 371), blow it up, and make assumptions on the integrand such that we can prove (once and for all) that the value of the integral over the complex curve added goes to zero.

Purpose 2. Extension of the second of the two methods just mentioned to integrals of practical interest in connection with Fourier integral representations (Sec. 11.7) and to discuss the case of singularities on the real axis.

Main Content

Integrals involving cos and sin (1), their transformation (2)

Improper integral (4), Cauchy principal value

Fourier integrals

Poles on the real axis (Theorem 1), Cauchy principal value

SOLUTIONS TO PROBLEM SET 16.4, page 725

2. This integral is of the form

$$\int_0^{\pi} \frac{d\theta}{a + b\cos\theta} = \frac{1}{2}\int_0^{2\pi} \frac{d\theta}{a + b\cos\theta}$$

$$= \frac{1}{2}\oint_C \frac{dz}{iz[a + \frac{1}{2}b(z + 1/z)]}$$

$$= \frac{1}{ib}\oint_C \frac{dz}{z^2 + 2az/b + 1} \qquad (a > b > 0).$$

im16.qxd 9/21/05 1:05 PM Page 275

The zeros of the denominator,

$$z_1 = -\frac{a}{b} + K, \qquad z_2 = -\frac{a}{b} - K, \qquad K^2 = \frac{a^2}{b^2} - 1$$

give poles at z_1 (inside the unit circle C because $a > b > 0$) and z_2 (outside C) with the residue

$$\operatorname*{Res}_{z=z_1} \frac{1}{z^2 + 2az/b + 1} = \frac{1}{z - z_2}\bigg|_{z_1} = \frac{1}{2K}$$

and the integral from 0 to π equals

$$2\pi i \cdot \frac{1}{2ibK} = \frac{\pi}{bK} = \frac{\pi}{\sqrt{a^2 - b^2}}$$

and $2\pi/bK$ if we integrate from 0 to 2π. In our case $a = 2$, $b = 1$ and the *answer* is $\pi/\sqrt{3}$.

4. This integral is of the form (similar to Prob. 2)

$$\begin{aligned}\int_0^{2\pi} \frac{d\theta}{a - b\sin\theta} &= \oint_C \frac{dz}{iz[a - (b/2i)(z - 1/z)]} \\ &= \frac{2}{-b} \oint_C \frac{dz}{z^2 - (2ai/b)z - 1} \\ &= \frac{-2}{b} \oint_C \frac{dz}{(z - z_1)(z - z_2)} \qquad (a > b > 0)\end{aligned}$$

where the zeros of the denominator (the poles of the integrand) are

$$z_1 = \frac{ai}{b} + iK, \qquad z_2 = \frac{ai}{b} - iK, \qquad K^2 = \frac{a^2}{b^2} - 1$$

and from (3), Sec. 16.3, we obtain the residue of the pole inside the unit circle

$$\operatorname*{Res}_{z=z_2} \frac{1}{(z - z_1)(z - z_2)} = \frac{1}{z_2 - z_1} = -\frac{1}{2iK}.$$

Hence the integral equals

$$2\pi i(-2/b)(-1/(2Ki)) = 2\pi/(bK) = 2\pi/\sqrt{a^2 - b^2}.$$

In our case, $a = 8$, $b = 2$ gives the *answer* $2\pi/\sqrt{60} = \pi/\sqrt{15}$.

All this also follows directly from Prob. 2 by using $-\sin\theta = \cos\theta^*$, where $\theta^* = \theta + \frac{1}{2}\pi$, and noting that the integrand is periodic with 2π.

6. The integral equals

$$\oint_C \frac{-\frac{1}{4}(z - 1/z)^2}{i[5z - 2(z^2 + 1)]}\, dz = \frac{-1/4}{-2i} \oint_C \frac{(z^2 - 1)^2}{z^2[z^2 - 5z/2 + 1]}\, dz.$$

From (5*), Sec. 16.3, we obtain for the integrand of the last integral (without the factor in front of it) at $z = 0$ (second-order pole) the residue

$$\left[\frac{(z^2 - 1)^2}{z^2 - 5z/2 + 1}\right]'_{z=0} = \frac{5}{2}$$

im16.qxd 9/21/05 1:05 PM Page 276

by straightforward differentiation. Also,

$$z^2 - 5z/2 + 1 = (z - 2)(z - \tfrac{1}{2})$$

and for the simple pole at $z = 1/2$ (inside the unit circle) we get the residue

$$\frac{(z^2 - 1)^2}{z^2(z - 2)}\bigg|_{z=1/2} = \frac{9/16}{(1/4)(-3/2)} = -\frac{3}{2}.$$

In front of the integral, $(-1/4)/(-2i) = -i/8$. Together,

$$2\pi i(-i/8)(5/2 - 3/2) = \pi/4.$$

8. The integral equals

$$\frac{1}{i}\oint_C \frac{1 + 2(z + z^{-1})}{z[17 - 4(z + z^{-1})]}\,dz = \frac{1}{-4i}\oint_C \frac{2z^2 + z + 2}{z(z - z_1)(z - z_2)}\,dz$$

where $z_1 = 1/4$ (inside the unit circle) and $z_2 = 4$ (outside) give simple poles. The residue for the last integrand (without the factor $1/(-4i)$) at $z = 0$ is $2/(z_1z_2) = 2$, and at $z = 1/4$ it is

$$\frac{2/16 + 1/4 + 2}{(1/4)(1/4 - 4)} = -\frac{38}{15}.$$

This gives the *answer*

$$\frac{2\pi i}{-4i}\left(2 - \frac{38}{15}\right) = \frac{4\pi}{15}.$$

10. *Answer* 0, because the integrand is an odd function. Or by calculating the residues $\mp i/4$ at the two simple poles at $(1 + i)/\sqrt{2}$ and $(-1 + i)/\sqrt{2}$, respectively, in the upper half-plane.

12. Second-order pole at $z_1 = 1 + 2i$ in the upper half-plane (and at $z_2 = 1 - 2i$ in the lower) with residue

$$\left[\frac{1}{(z - 1 + 2i)^2}\right]'_{z=z_1} = \frac{-2}{(z_1 - z_2)^3} = \frac{-2}{(4i)^3} = \frac{1}{32i}.$$

Answer: $2\pi i(1/(32i)) = \pi/16$.

14. Simple poles at $z_1 = (2 + 2i)/\sqrt{2}$ and $z_2 = (-2 + 2i)/\sqrt{2}$ in the upper half-plane (and at $(\pm 2 - 2i)/\sqrt{2}$ in the lower half-plane). From (4) in Sec. 16.3 we obtain the residues

$$1/(4z_1^3) = (-1 - i)/(32\sqrt{2}), \qquad 1/4z_2^3 = (1 - i)/(32\sqrt{2}).$$

Answer: $\pi/(8\sqrt{2})$.

16. Simple poles at i and $3i$ with residues $-i/16$ and $i/48$, respectively. *Answer:* $\pi/12$.

18. Denote the integrand by $f(x)$. The complex function $f(z)$ has simple poles at $z_1 = e^{\pi i/4}$ and $z_2 = e^{3\pi i/4}$ in the upper half-plane (and two further ones in the lower half-plane) with residues

$$\frac{1 + i}{2\sqrt{2}(-1 + i)} = -\frac{i}{\sqrt{8}} \qquad \text{and} \qquad \frac{1 - i}{2\sqrt{2}(1 + i)} = -\frac{i}{\sqrt{8}}$$

respectively, as obtained from (4) in Sec. 16.3. Hence the *answer* is $(-i/\sqrt{2})2\pi i = \pi\sqrt{2}$.

im16.qxd 9/21/05 1:05 PM Page 277

20. From $z^4 + 1 = 0$ we see that we have four simple poles, at $z_1 = (1 + i)/\sqrt{2}$ and $z_2 = (-1 + i)/\sqrt{2}$ in the upper half-plane (and at $(\pm 1 - i)/\sqrt{2}$ in the lower). From (4), Sec. 16.3, we find that the residues of $e^{iz}/(z^4 + 1)$, as presently needed, are

$$\frac{e^{iz_1}}{4z_1^3} = \frac{e^{-1/\sqrt{2}}(c + is)}{4(-2 + 2i)/2\sqrt{2}} = \frac{e^{-1/\sqrt{2}}}{8\sqrt{2}}(-2 - 2i)(c + is),$$

where $c + is = \cos(1/\sqrt{2}) + i \sin(1/\sqrt{2})$, and

$$\frac{e^{iz_2}}{4z_2^3} = \frac{e^{-1/\sqrt{2}}(c - is)}{4(2 + 2i)/2\sqrt{2}} = \frac{e^{-1/\sqrt{2}}}{8\sqrt{2}}(2 - 2i)(c - is).$$

We now take the sum of the imaginary parts of these two residues and multiply it by -2π, as indicated in the first formula in (10); this then gives the *answer*

$$\pi \frac{e^{-1/\sqrt{2}}}{\sqrt{2}} \left(\cos \frac{1}{\sqrt{2}} + \sin \frac{1}{\sqrt{2}}\right) = 1.544.$$

22. $z^4 + 5z^2 + 4 = (z^2 + 1)(z^2 + 4)$ shows that we have two simple poles at $z_1 = i$ and $z_2 = 2i$ in the upper half-plane (and two at $-i$ and $-2i$ in the lower). By (4), Sec. 16.3, the sum of the residues of $e^{4iz}/(z^4 + 5z^2 + 4)$ at z_1 and z_2 is

$$\frac{e^{-4}}{4i^3 + 10i} + \frac{e^{-8}}{4(2i)^3 + 20i} = -\frac{i}{6}e^{-4} + \frac{i}{12}e^{-8}.$$

From the first formula in (10) we thus obtain the *answer*

$$\pi(2e^{-4} - e^{-8})/6.$$

24. Simple poles at $z_0 = \pm 1$, i (and $-i$ outside, in the lower half-plane), with residue $z_0^2/(4z_0^3) = 1/(4z_0)$, as obtained from (4) in Sec. 16.3. Hence the *answer* is

$$2\pi i\left(-\frac{i}{4}\right) + \pi i(-\tfrac{1}{4} + \tfrac{1}{4}) = \tfrac{1}{2}\pi.$$

26. The integrand is p/q, where $p = 1$ and $q(x) = x^4 + 3x^2 - 4$; hence

$$q(z) = z^4 + 3z^2 - 4.$$

In (4) in Sec. 16.3 we need the derivative $q'(z) = 4z^3 + 6z$. Simple poles are at $2i$, -1, and 1 (and $-2i$, not needed), with residues $i/20$, $-1/10$, and $1/10$, respectively. Hence the value of the integral is

$$2\pi i \cdot \frac{i}{20} + \pi i\left(-\frac{1}{10} + \frac{1}{10}\right) = -\frac{\pi}{10}.$$

A graph of the integrand makes it plausible that the integral should have a negative value.

28. Team Project. (b) The integral of e^{-z^2} around C is zero. Writing it as the sum of four integrals over the four segments of C, we have

$$\int_{-a}^{a} e^{-x^2}\,dx + ie^{-a^2}\int_0^b e^{y^2-2ayi}\,dy + e^{b^2}\int_a^{-a} e^{-x^2-2ibx}\,dx + ie^{-a^2}\int_b^0 e^{y^2+2ayi}\,dy = 0.$$

im16.qxd 9/21/05 1:05 PM Page 278

Let $a \to \infty$. Then the terms having the factor e^{-a^2} approach zero. Taking the real part of the third integral, we thus obtain

$$-\int_{\infty}^{-\infty} e^{-x^2} \cos 2bx\, dx = 2\int_0^{\infty} e^{-x^2} \cos 2bx\, dx = e^{-b^2}\int_{-\infty}^{\infty} e^{-x^2}\, dx = e^{-b^2}\sqrt{\pi}.$$

Answer: $\frac{1}{2}e^{-b^2}\sqrt{\pi}$.

(c) Use the fact that the integrands are odd.

30. Let $q(z) = (z - a_1)(z - a_2) \cdots (z - a_k)$. Use (4) in Sec. 16.3 to form the sum of the residues $1/q'(a_1) + \cdots + 1/q'(a_k)$ and show that this sum is 0; here $k > 1$.

SOLUTIONS TO CHAP. 16 REVIEW QUESTIONS AND PROBLEMS, page 726

18. Third-order pole at $z = 0$ with residue best obtained from the series

$$\frac{\sin 2z}{z^4} = \sum_{n=0}^{\infty} \frac{(-1)^n 2^{2n+1}}{(2n+1)!}\, z^{2n-3}$$

namely, $1/z$ has the coefficient

$$\operatorname*{Res}_{z=0} z^{-4} \sin 2z = -\frac{2^3}{3!}.$$

Answer: $2\pi i(-8/6) = -8\pi i/3$.

20. Simple poles at $-i$ and $2i$, both inside C, with residues $2i/3$ and $i/3$, respectively, as obtained from (4), Sec. 16.3, or from the partial fraction representation

$$\frac{2i/3}{z+i} + \frac{i/3}{z-2i}$$

of the integrand. *Answer:* $2\pi i(2i/3 + i/3) = -2\pi$.

22. Simple poles at $-\pi/2$ inside C and others outside C, and (4), Sec. 16.3, gives the residue

$$\operatorname*{Res}_{z=-\pi/2} \frac{4z^3 + 7z}{\cos z} = -\frac{4(-\pi/2)^3 + 7(-\pi/2)}{\sin(-\pi/2)} = -\frac{1}{2}\pi^3 - \frac{7}{2}\pi.$$

Answer: $-i(\pi^3 + 7\pi) = -\pi^2(\pi^2 + 7)i = -166.5i$.

24. Simple poles at $z_0 = -\frac{1}{2}, \frac{1}{2}$ with residues (by (4) in Sec. 16.3)

$$\frac{{z_0}^2 \sin z_0}{8z_0} = \tfrac{1}{8}z_0 \sin z_0 = \tfrac{1}{16}\sin\tfrac{1}{2}.$$

Answer: $2\pi i \cdot 2 \cdot \frac{1}{16}\sin\frac{1}{2} = \frac{1}{4}\pi i \sin\frac{1}{2} = 0.3765i$.

26. Simple poles at 0 (inside C) and 2 (outside C), and (3), Sec. 16.3, gives the residue

$$\operatorname*{Res}_{z=0} \frac{z^2+1}{z^2-2z} = \left.\frac{z^2+1}{z-2}\right|_{z=0} = -\frac{1}{2}.$$

Answer: $2\pi i(-1/2) = -\pi i$.

28. $z^3 - 9z = z(z+3)(z-3) = 0$ at $z = -3, 0, 3$ gives simple poles, all three inside C: $|z| = 4$. From (4), Sec. 16.3, we get the residue

$$\operatorname*{Res}_{z=-3} \frac{15z+9}{z^3-9z} = \left.\frac{15z+9}{3z^2-9}\right|_{z=-3} = \frac{-36}{18} = -2$$

im16.qxd 9/21/05 1:05 PM Page 279

and similarly, at 0 the residue $9/(-9) = -1$ and at 3 the residue $54/18 = 3$. Since all three poles lie inside C, by the residue theorem we have to take the sum of all three residues, which is zero. *Answer:* 0.

30. $\pi/\sqrt{k^2 - 1}$, a special case of the class of integrals in the answer to Prob. 2 of Problem Set 16.4 with $a = k$ and $b = 1$.

32. The integral equals

$$\oint_C \frac{(z - 1/z)/(2i)}{iz\left[3 + \frac{1}{2}(z + 1/z)\right]}\,dz = -\oint_C \frac{z^2 - 1}{z[z^2 + 6z + 1]}\,dz.$$

At the simple pole at $z = 0$ the residue is -1. At the simple pole at $-3 + \sqrt{8}$ (inside the unit circle) the residue is

$$\frac{(-3 + \sqrt{8})^2 - 1}{3(-3 + \sqrt{8})^2 + 12(-3 + \sqrt{8}) + 1} = 1.$$

Answer: 0. Simpler: integrate from $-\pi$ to π and note that the integrand is odd.

34. Second-order poles at $z = i$ in the upper half-plane (and at $-i$ in the lower half-plane) with residue [by (5), Sec. 16.3]

$$\left[(z + i)^{-2}\right]'_{z=i} = -i/4.$$

Answer: $\frac{1}{2} \cdot 2\pi i(-i/4) = \pi/4$.

36. Set $x = t/\sqrt{2}$. Then $dx = dt/\sqrt{2}$ and

$$\frac{\pi}{2} = \int_0^\infty \frac{1 + 2x^2}{1 + 4x^4}\,dx = \frac{1}{\sqrt{2}} \int_0^\infty \frac{1 + t^2}{1 + t^4}\,dt = \frac{1}{2\sqrt{2}} \int_{-\infty}^\infty \frac{1 + t^2}{1 + t^4}\,dt.$$

Multiply by $2\sqrt{2}$ to get $\pi\sqrt{2}$ as the value of the integral on the right.

im17.qxd 9/21/05 1:08 PM Page 280

CHAPTER 17 Conformal Mapping

This is a new chapter. It collects and extends the material on conformal mapping contained in Chap. 12 of the previous edition.

SECTION 17.1. Geometry of Analytic Functions: Conformal Mapping, page 729

Purpose. To show conformality (preservation of angles in size and sense) of the mapping by an analytic function $w = f(z)$; exceptional are points with $f'(z) = 0$.

Main Content, Important Concepts

Concept of mapping. Surjective, injective, bijective

Conformal mapping (Theorem 1)

Magnification, Jacobian

Examples. Joukowski airfoil

Comment on the Proof of Theorem 1

The crucial point is to show that $w = f(z)$ rotates all straight lines (hence all tangents) passing through a point z_0 through the same angle $\alpha = \arg f'(z_0)$, but this follows from (3). This in a nutshell is the proof, once the stage has been set.

SOLUTIONS TO PROBLEM SET 17.1, page 733

2. By conformality

4. $u = x^2 - y^2$, $v = 2xy$, $y^2 = v^2/(4x^2)$, $x^2 = v^2/(4y^2)$; hence for $x = 1, 2, 3, 4$ we obtain

$$u = x^2 - v^2/(4x^2) = 1 - v^2/4, \quad 4 - v^2/16, \quad 9 - v^2/36, \quad 16 - v^2/64$$

and for $y = 1, 2, 3, 4$,

$$u = v^2/(4y^2) - y^2 = v^2/4 - 1, \quad v^2/16 - 4, \quad v^2/36 - 9, \quad v^2/64 - 16.$$

6. $w = 1/z$ is called **reflection in the unit circle.** The *answer* is

$$|w| = 3, 2, 1, 1/2, 1/3$$

and

$$\text{Arg } w = 0, \mp\pi/4, \mp\pi/2, \mp 3\pi/4, \mp\pi.$$

We see that the unit circle is mapped onto itself, but only 1 and -1 are mapped onto themselves. $e^{-i\theta}$ is mapped onto $e^{-i\theta}$, the complex conjugate, for example, i onto $-i$.

8. On the line $x = 1$ we have $z = 1 + iy$, $w = u + iv = 1/z = (1 - iy)/(1 + y^2)$, so that $v = -y/(1 + y^2)$ and, furthermore,

$$u = \frac{1}{1 + y^2}, \; u(1 - u) = \frac{1}{1 + y^2}\left(1 - \frac{1}{1 + y^2}\right) = \frac{y^2}{(1 + y^2)^2} = v^2.$$

Having obtained a relation between u and v, we have solved the problem. We now have $u^2 - u + v^2 = 0$, $(u - \frac{1}{2})^2 + v^2 = \frac{1}{4}$ and by taking roots $|w - \frac{1}{2}| = \frac{1}{2}$, a circle through 0 and 1 whose interior is the image of $x > 1$.

10. The lower half-plane

im17.qxd 9/21/05 1:08 PM Page 281

12. Annulus $1/e < |w| < e$ cut along the negative real axis

14. Whole w-plane except $w = 0$

16. CAS Experiment. Orthogonality is a consequence of conformality because in the w-plane, $u = const$ and $v = const$ are orthogonal. We obtain

(a) $u = x^4 - 6x^2y^2 + y^4, \quad v = 4x^3y - 4xy^3$

(b) $u = x/(x^2 + y^2), \quad v = -y/(x^2 + y^2)$

(c) $u = (x^2 - y^2)/(x^2 + y^2)^2, \quad v = -2xy/(x^2 + y^2)^2$

(d) $u = 2x/((1 - y)^2 + x^2), \quad v = (1 - x^2 - y^2)/((1 - y^2)^2 + x^2)$

18. $2z - 2z^{-3} = 0$, $z^4 = 1$, hence $\pm 1, \pm i$.

20. $(\cosh 2z)' = 2 \sinh 2z = 0$ at $z = 0, \pm \pi i/2, \pm \pi i, \cdots$

22. $(5z^4 - 80) \exp(z^5 - 80z) = 0$, $z^4 = 16$, $z = \pm 2, \pm 2i$

24. $M = |z| = 1$ on the unit circle, $J = |z|^2$

26. $M = 3|z|^2 = 1$ on the circle $|z| = 1/\sqrt{3}$, $J = 9|z|^4$

28. $w' = -1/z^2$, $M = |w'| = 1/|z|^2 = 1$ on the unit circle, $J = 1/|z|^4$

30. By the Taylor series, since the first few derivatives vanish at z_0,

$$f(z) = f(z_0) + (z - z_0)^k g(z), \qquad g(z_0) \neq 0, \text{ since } f^{(k)}(z_0) \neq 0.$$

Hence

$$\arg [f(z) - f(z_0)] = k \arg (z - z_0) + \arg g(z).$$

Now the angle α from the x-axis to the tangent of a smooth curve C at z_0 is

$$\alpha = \lim \arg (z - z_0) \qquad (z \to z_0 \text{ along } C).$$

Similarly for the angle β of the tangent to the image at $f(z_0)$:

$$\beta = \lim \arg [f(z) - f(z_0)] = k\alpha + \lim \arg g(z) = k\alpha + \arg g(z_0).$$

Note that $\gamma = \arg g(z_0)$ is defined since $g(z_0) \neq 0$. Hence the angle $\beta_2 - \beta_1$ between the tangents of the images of two curves at $f(z_0)$ is

$$\beta_2 - \beta_1 = k\alpha_2 + \gamma - (k\alpha_1 + \gamma) = k(\alpha_2 - \alpha_1),$$

as asserted.

SECTION 17.2. Linear Fractional Transformations, page 734

Purpose. Systematic discussion of linear fractional transformations (Möbius transformations), which owe their importance to a number of interesting properties shown in this section and the next one.

Main Content

Definition (1)

Special cases (3), Example 1

Images of circles and straight lines (Theorem 1)

One-to-one mapping of the extended complex plane

Inverse mapping (4)

Fixed points

im17.qxd 9/21/05 1:08 PM Page 282

SOLUTIONS TO PROBLEM SET 17.2, page 737

2. This follows by direct calculation and simplification.

4. $z = \dfrac{w - i}{3iz + 4}$

6. $z = \dfrac{-iw - i}{-w + 1}$

8. $z = 0, \pm 1/3, \pm i/3$

10. None. Translations have no fixed points.

12. $\pm i$

14. $z(z - 1) = 3z + 2$, $z^2 - 4z - 2 = 0$, $z = 2 \pm \sqrt{4 + 2}$

16. The equation with solutions 0 and 1 (the desired fixed points) is $z(z - 1) = 0$, thus $z^2 - z = 0$. Comparing this with the fixed-point equation (5),

$$cz^2 - (a - d)z - b = 0,$$

we see that we must have $c \neq 0$; so we can choose $c = 1$. Also, $a - d = 1$ and $b = 0$. This gives $a = 1 + d$ and the answer

$$w = \frac{(1 + d)z}{z + d},$$

where the student now may choose some d, except for $d = 0$, which would give the identity mapping; so it is quite interesting that d may be as close to zero as we please, but not zero.

18. By comparing $z = 0$ with the fixed-point equation (5), as in Prob. 16, we get $b = 0$, $a = d$. and

$$w = \frac{az}{cz + a}.$$

20. We get a fixed-point equation (5) without solutions if and only if we choose $c = 0$, $a - d = 0$, and $b \neq 0$. This gives a translation

$$w = (az + b)/a = z + b/a \qquad (a \neq 0),$$

as expected.

SECTION 17.3. Special Linear Fractional Transformations, page 737

Purpose. Continued discussion to show that linear fractional transformations map "standard domains" conformally onto each other.

Main Content

Determination by three points and their images

Mappings of standard domains (disks, half-planes)

Angular regions

SOLUTIONS TO PROBLEM SET 17.3, page 741

2. The inverse is

$$z = \frac{w + i}{iw + 1} = \frac{u + iv + i}{1 - v + iu} = \frac{(u + iv + i)(1 - v - iu)}{(1 - v)^2 + u^2}.$$

im17.qxd 9/21/05 1:08 PM Page 283

Multiplying out the numerator, a number of terms drop out, and the real part of the numerator is $2u$. This gives $\operatorname{Re} z = x$ in the form

$$x = \frac{2u}{(1-v)^2 + u^2}.$$

This yields the circles

$$(v-1)^2 + \left(u - \frac{1}{c}\right)^2 = \frac{1}{c^2}$$

as claimed.

4. The inverse is

$$z = \frac{4w - 1}{-2w + 1}.$$

The fixed points $z = -\frac{3}{4} \pm \frac{1}{4}\sqrt{17}$ are obtained as solutions of

$$2z^2 - (1-4)z - 1 = 0.$$

8. $w = 1/(z+1)$, almost without calculation

10. $w = iz$, a rotation, as a sketch of the points and their images shows.

12. Formula (2) gives

$$\frac{w+1}{w-\infty} \cdot \frac{-\infty}{1} = \frac{z}{z-i} \cdot \frac{-2i}{-i} = \frac{2z}{z-i}.$$

Replacing infinity on the left as indicated in the text, we get $w + 1$ on the left, so that the answer is

$$w = \frac{2z}{z-i} - 1 = \frac{z+i}{z-i}.$$

Caution! In setting up further problems by starting from the result, which is quite easy, one should check how complicated the solution, starting from (2), will be; this may often involve substantial work until one reaches the final form.

14. By (2),

$$\frac{w+1}{w-\infty} \cdot \frac{-\infty}{1} = \frac{z}{z+2i} \cdot \frac{4i}{2i};$$

hence, after getting rid of infinity,

$$w + 1 = \frac{2z}{z+2i}, \qquad w = \frac{2z}{z+2i} - 1 = \frac{z-2i}{z+2i}.$$

Second solution. 0 maps onto -1, hence $d = -b$. Next, $2i$ maps onto 0, hence $2ia + b = 0$. Finally, $-2i$ maps onto ∞, hence $-2ic + d = 0$. Choosing $a = 1$ gives $b = -2i$, $d = 2i$, $c = 1$ and confirms our previous result.

16. The requirement is that

$$w = u = \frac{ax + b}{cx + d}$$

must come out real for all real x. Hence the four coefficients must be real, except possibly for a common complex factor.

18. $w = -(z^2 + i)/(iz^2 + 1)$

20. Substitute one LFT into the other and simplify.

im17.qxd 9/21/05 1:08 PM Page 284

SECTION 17.4. Conformal Mapping by Other Functions, page 742

Purpose. So far we have discussed mapping properties of z^n, e^z, and linear fractional transformations. We now add to this a discussion of trigonometric and hyperbolic functions.

SOLUTIONS TO PROBLEM SET 17.4, page 745

2. Quarter-annulus $1/e \leqq |w| \leqq 1$ in the first quadrant $0 \leqq \arg w \leqq \pi/2$

4. $e^{-3} < |w| < e^3$, $\pi/4 < \arg w < 3\pi/4$

6. Right half of the interior of the unit circle $|w| < 1$, $-\pi/2 < \arg w < \pi/2$, without the segment on the v-axis

10. The region in the right half-plane bounded by the v-axis and the hyperbola $4u^2 - \frac{4}{3}v^2 = 1$ because

$$\sin z = u + iv = \sin x \cosh y + i \cos x \sinh y$$

reduces to

$$\sin iy = i \sinh y$$

when $x = 0$; thus $u = 0$ (the v-axis) is the left boundary of that region. For $x = \pi/6$ we obtain

$$\sin(\pi/6 + iy) = \sin(\pi/6)\cosh y + i\cos(\pi/6)\sinh y;$$

thus

$$u = \tfrac{1}{2}\cosh y, \qquad v = \tfrac{1}{2}\sqrt{3}\sinh y$$

and we obtain the right boundary curve of that region from

$$1 = \cosh^2 y - \sinh^2 y = 4u^2 - \tfrac{4}{3}v^2,$$

as asserted.

12. The region in the upper half-plane bounded by portions of the u-axis, the ellipse $u^2/\cosh^2 3 + v^2/\sinh^2 3 = 1$ and the hyperbola $u^2 - v^2 = \frac{1}{2}$.

Indeed, for $x = \pm\pi/4$ we get (see the formula for $\sin z$ in the solution to Prob. 10)

$$\sin(\pm\tfrac{1}{4}\pi + iy) = \sin(\pm\tfrac{1}{4}\pi)\cosh y + i\cos(\pm\tfrac{1}{4}\pi)\sinh y$$

$$= \pm(1/\sqrt{2})\cosh y + i(1/\sqrt{2})\sinh y$$

and from this

$$1 = \cosh^2 y - \sinh^2 y = 2u^2 - 2v^2, \qquad \text{thus} \qquad u^2 - v^2 = \tfrac{1}{2}.$$

For $y = 0$ we get $v = 0$ (the u-axis).

For $y = 3$ we get

$$u = \sin x \cosh 3, \qquad v = \cos x \sinh 3;$$

hence

$$1 = \sin^2 x + \cos^2 x = \frac{u^2}{\cosh^2 3} + \frac{v^2}{\sinh^2 3}.$$

14. If $x = c$, then (see the formula for $\sin z$ in the solution to Prob. 10)

$$u = \sin c \cosh y, \qquad v = \cos c \sinh y.$$

Hence if $c = 0$, then $u = 0$, so that the y-axis maps onto the v-axis.

If $c = \frac{1}{2}\pi$, then $v = 0$, $u \geqq 1$. If $c = -\frac{1}{2}\pi$, then $v = 0$, $u \leqq -1$.

If $c \neq 0, \pm\frac{1}{2}\pi, \pm\pi, \cdots$, then we obtain hyperbolas

$$\frac{u^2}{\sin^2 c} - \frac{v^2}{\cos^2 c} = 1.$$

im17.qxd 9/21/05 1:08 PM Page 285

16. $\cosh z = \cos(iz) = \sin(iz + \frac{1}{2}\pi)$

18. Interior of the ellipse $u^2/\cosh^2 2 + v^2/\sinh^2 2 = 1$ in the fourth quadrant (which looks almost like a quarter of a circular disk because the curves of the cosh and the sinh eventually come close together).

20. The lower boundary segment maps onto $\cos 1 \leqq u \leqq 1$ ($v = 0$). The left and right boundary segments map onto portions of the hyperbola

$$\frac{u^2}{\cos^2 1} - \frac{v^2}{\sin^2 1} = 1.$$

The upper boundary segment maps onto a portion of the ellipse

$$\frac{u^2}{\cosh^2 1} + \frac{v^2}{\sinh^2 1} = 1.$$

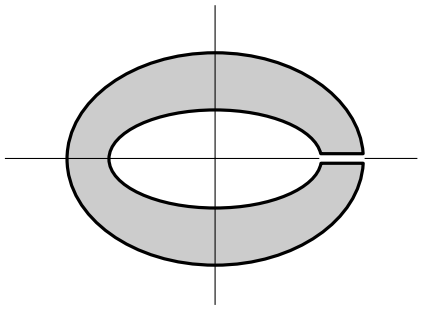
22. The upper boundary maps onto the ellipse

$$\frac{u^2}{\cosh^2 1} + \frac{v^2}{\sinh^2 1} = 1$$

and the lower boundary onto the ellipse

$$\frac{u^2}{\cosh^2 \frac{1}{2}} + \frac{v^2}{\sinh^2 \frac{1}{2}} = 1.$$

Since $0 < x < 2\pi$, we get the entire ellipses as boundaries of the image of the given domain, which therefore is an elliptical ring.



Now the vertical boundaries $x = 0$ and $x = 2\pi$ map onto the same segment

$$\sinh \tfrac{1}{2} \leqq u \leqq \sinh 1$$

of the u-axis because for $x = 0$ and $x = 2\pi$ we have

$$u = \cosh y, \qquad v = 0.$$

Answer: Elliptical annulus between those two ellipses and cut along that segment. See the figure.

Section 17.4. Problem 22

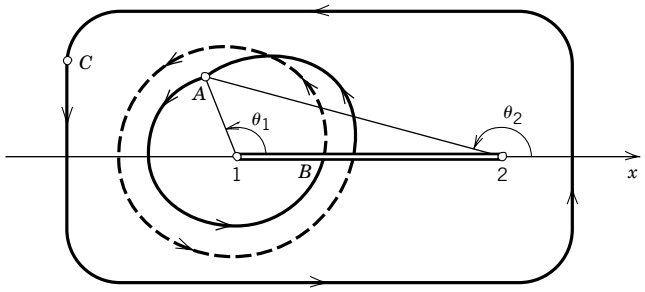
24. The images of the five points in the figure in the text can be obtained directly from the given function w.

im17.qxd 9/21/05 1:08 PM Page 286

SECTION 17.5. Riemann Surfaces. *Optional,* page 746

Purpose. To introduce the idea and some of the simplest examples of Riemann surfaces, on which multivalued relations become single-valued, that is, functions in the usual sense.
Short Courses. This section may be omitted.

SOLUTIONS TO PROBLEM SET 17.5, page 747

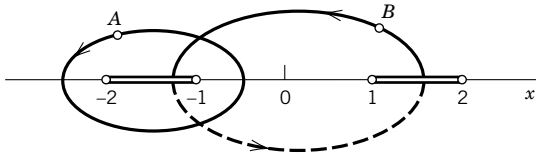


4. By the hint we have

$$w = \sqrt{r_1}e^{i\theta_1/2}\sqrt{r_2}e^{i\theta_2/2} = \sqrt{r_1 r_2}\, e^{i(\theta_1+\theta_2)/2}.$$

If we move from A in the first sheet (see the figure), we get into the second sheet at B (dashed curve) and get back to A after two loops around the branch point 1 (of first order).

Similarly for a loop around $z = 2$ (without encircling $z = 1$); this curve is not shown in the figure.



If we move from C and back to C as shown, we do not cross the cut, we stay in the same sheet, and we increase θ_1 and θ_2 by 2π each. Hence $(\theta_1 + \theta_2)/2$ is increased by 2π, and we have completed one loop in the w-plane. This makes it plausible that two sheets will be sufficient for the present w and that the cut along which the two sheets are joined crosswise is properly chosen.

Section 17.5. Problem 4

6. Branch points at ± 1 and ± 2, as shown in the figure, together with the cuts. If we pass a single cut, we get into the other sheet. If we cross two cuts, we are back in the sheet in which it started. The figure shows one path (A) that encircles two branch points and stays entirely in one sheet. The path from B and back to B also encloses two branch points, and since it crosses two cuts, part of it is in one sheet and part of it is in the other.

A discussion in terms of coordinates as in Prob. 4 would be similar to the previous one. Various other paths can be drawn and discussed in the figure.

Section 17.5. Problem 6

im17.qxd 9/21/05 1:08 PM Page 287

8. $4i/3$, infinitely many sheets

10. No branch points because e^z is never zero; thus the two sheets are nowhere connected with each other. Thus $\sqrt{e^z}$ represents two different functions, namely $e^{z/2}$ and $-e^{z/2}$.

SOLUTIONS TO CHAP. 17 REVIEW QUESTIONS AND PROBLEMS, page 747

12. $v = 2xy = -8$

14. $y = 0$ maps onto the nonnegative real axis $u = x^2$, $v = 0$. The other boundary $y = 2$ gives $u = x^2 - 4$, $v = 4x$. Elimination of x gives the parabola

$$u = v^2/16 - 4,$$

with apex at $u = -4$ and opening to the right.

Answer: The domain to the right of that parabola except for the nonnegative u-axis.

16. The w-plane except for the positive real axis, as follows from the fact that angles are doubled at the origin.

18. The image of the straight line $y = 1$ must lie inside the unit circle; hence it must be a circle. The latter must pass through the image $-i$ of i and through the image 0 of ∞. Hence the image must be the circle

$$|w + \tfrac{1}{2}i| = \tfrac{1}{2}.$$

By calculation this can be shown as follows. On the line $y = 1$ we have $z = x + i$, hence

$$\frac{1}{x+i} = \frac{x-i}{x^2+1}, \qquad \text{thus,} \qquad u = \frac{x}{x^2+1}, \qquad v = -\frac{1}{x^2+1}.$$

From this we obtain

$$\left(v + \frac{1}{2}\right)^2 = \left(\frac{1}{2} - \frac{1}{x^2+1}\right)^2 = \frac{(x^2-1)^2}{4(x^2+1)^2}.$$

It follows that

$$\left(v + \frac{1}{2}\right)^2 + u^2 = \frac{(x^2+1)^2}{4(x^2+1)^2} = \frac{1}{4},$$

in agreement with (1).

20. $|w| > 2$, $v > 0$ because the lower half-plane ($y < 0$) maps onto the upper half-plane ($v > 0$).

22. $u < 0$, $v < 0$, $|w| > 1$ because the interior of the unit circle maps onto the exterior, the left half-plane onto the left half-plane, and the upper half-plane onto the lower half-plane.

24. $f'(z) = 2 \sinh 2z = -2i \sin 2iz = 0$ if $2iz = \pm n\pi$, hence the *answer* is $z = \pm n\pi i/2$, $n = 0, 1, 2, \cdots$.

26. $z = \pm\sqrt{n}, \pm i\sqrt{n}$, $n = 0, 1, 2, \cdots$

28. $f'(z) = 1 - z^{-2} = 0$ at $z = \pm 1$. Applications of this function were considered in Sec. 17.1, where $z = \pm 1$ played a basic role in the construction of an airfoil.

30. $w = (z + 1)/z$

im17.qxd 9/21/05 1:08 PM Page 288

32. $w = 1 + iz$, a translation combined with a rotation

34. $w = iz/(z - i)$

36. $\pm i$

38. ± 1

40. $\pm 3, \pm 3i$

42. $w = 5/z$ maps $|z| = 1$ onto $|w| = 5$ and the interior onto the exterior. Hence $w + 1 = 5/z$ will give the *answer*

$$w = -1 + \frac{5}{z} = \frac{5 - z}{z}.$$

44. To map a semidisk onto a disk, we have to double angles; thus $w = z^2$ maps the given semidisk onto the unit disk $|w| \leqq 1$, and the exterior is obtained by taking the reciprocal.

Answer: $w = 1/z^2$.

im18.qxd 9/21/05 1:09 PM Page 289

CHAPTER 18 Complex Analysis and Potential Theory

This is perhaps the most important justification for teaching complex analysis to engineers, and it also provides for nice applications of conformal mapping.

SECTION 18.1. Electrostatic Fields, page 750

Purpose. To show how complex analysis can be used to discuss and solve two-dimensional electrostatic problems and to demonstrate the usefulness of **complex potential,** a major concept in this chapter.

Main Content, Important Concepts

Equipotential lines

Complex potential (2)

Combination of potentials by superposition

The main reason for using complex methods in two-dimensional potential problems is the possibility of using the complex potential, whose real and imaginary parts both have a physical meaning, as explained in the text. This fact should be emphasized in teaching from this chapter.

SOLUTIONS TO PROBLEM SET 18.1, page 753

2. $\Phi = 0.4x + 6.0$ kV, $F = 0.4z + 6.0$

4. Φ is expected to be linear because of the boundary (two parallel straight lines). From the boundary conditions and by inspection,

$$\Phi(x, y) = 100(y - x)/k.$$

This is the real part of the complex potential

$$F(z) = -100(1 + i)z/k.$$

The real potential can also be obtained systematically, starting from

$$\Phi(x, y) = ax + by + c.$$

By the first boundary condition, for $y = x$ this is zero:

(1) $$ax + bx + c = 0.$$

By the second boundary condition, for $y = x + k$ this equals 100:

(2) $$ax + b(x + k) + c = 100.$$

Subtract (1) from (2) to get

$$bk = 100, \qquad b = 100/k.$$

Substitute this into (1) to get

$$ax + \frac{100}{k}\,x + c = \left(a + \frac{100}{k}\right)x + c = 0.$$

im18.qxd 9/21/05 1:09 PM Page 290

Since this is an identity in x, the coefficients must vanish, $a = -100/k$ and $c = 0$. This gives the above result.

6. We have

$$\Phi(r) = a \ln r + b$$

and get from this and the two boundary conditions

$$\Phi(1) = b = 100$$

$$\Phi(10) = a \ln 10 + b = a \ln 10 + 100 = 1000.$$

Hence $a = 900/\ln 10$, so that the *answer* is

$$\Phi(r) = (900 \ln r)/\ln 10 + 100.$$

8. $\Phi(r) = 100 - (50/\ln 10) \ln r$, $F(z) = 100 - (50/\ln 10)\ \mathrm{Ln}\ z$

10. $w = \dfrac{iz + 1 + i}{z + 1 + i}$. $w = 0$ gives $z = z_0 = -1 + i$, $\mathrm{Arg}\ z_0 = 3\pi/4$. Hence at z_0 the potential is $(1/\pi)3\pi/4 = 3/4$.

By considering the three given points and their images we see that the potential on the unit circle in the w-plane is 0 for the quarter-circle in the first quadrant and 1 for the other portion of the circle. This corresponds to a conductor consisting of two portions of a cylinder separated by small slits of insulation at $w = 1$ and $w = i$, where the potential jumps.

12. CAS Experiment. (a) $x^2 - y^2 = c$, $xy = k$

(b) $xy = c$, $x^2 - y^2 = k$; the rotation caused by the multiplication by i leads to the interchange of the roles of the two families of curves.

(c) $x/(x^2 + y^2) = c$ gives $(x - 1/(2c))^2 + y^2 = 1/(4c^2)$. Also, $-y/(x^2 + y^2) = k$ gives the circles $x^2 + (y + 1/(2k))^2 = 1/(4k^2)$. All circles of both families pass through the origin.

(d) Another interchange of the families, compared to (c), $(y - 1/(2c))^2 + x^2 = 1/(4c^2)$, $(x - 1/(2k))^2 + y^2 = 1/(4k^2)$.

14. $\Phi = 110(x^3 - 3xy^2) = \mathrm{Re}\ (110z^3)$

SECTION 18.2. Use of Conformal Mapping, page 754

Purpose. To show how conformal mapping helps in solving potential problems by mapping given domains onto simpler ones or onto domains for which the solution of the problem (subject to the transformed boundary conditions) is known.

The theoretical basis of this application of conformal mapping is given by Theorem 1, characterizing the behavior of harmonic functions under conformal mapping.

Problem 10 gives a hint on possibilities of generalizing potential problems for which the solution is known or can be easily obtained. The idea extends to more sophisticated situations.

SOLUTIONS TO PROBLEM SET 18.2, page 757

2. Figure 383 in Sec. 17.1 shows D (a semi-infinite horizontal strip) and D^* (the upper half of the unit circular disk); and $\Phi = e^x \cos y\ e^x \sin y = \frac{1}{2}e^{2x} \sin 2y = 0$ on $y = 0$ and $y = \pi$, and $\frac{1}{2} \sin 2y$ on the vertical boundary $x = 0$ of D.

im18.qxd 9/21/05 1:09 PM Page 291

6. $\Phi = 2 \sin x \cos x \cosh y \sinh y = \frac{1}{2} \sin 2x \sinh 2y = 0$ if $x = 0$ or $x = \frac{1}{2}\pi$ or $y = 0$, and $\frac{1}{2} \sin 2x \sinh 2$ if $y = 1$.

8. Team Project. We map $0 \mapsto r_0$, $2c \mapsto -r_0$, obtaining from (2) with $b = z_0$ the conditions

$$r_0 = -\frac{-z_0}{-1} = z_0, \qquad -r_0 = \frac{2c - z_0}{2z_0 c - 1} = \frac{2c - r_0}{2r_0 c - 1},$$

hence

$$r_0 = \frac{1}{2c}\,(1 - \sqrt{1 - 4c^2}).$$

r_0 is real for positive $c \leqq \frac{1}{2}$. Note that with increasing c the image (an annulus) becomes slimmer and slimmer.

10. $z = (2Z - i)/(-iZ - 2)$ by (3) in Sec. 17.3

12. $\pm i$ are fixed points, and straight lines are mapped onto circles (or straight lines). From this the assertion follows. (Alternatively, it also follows very simply by setting $x = 0$ and calculating $|w|$.)

14. Apply $w = z^2$.

SECTION 18.3. Heat Problems, page 757

Purpose. To show that previous examples and new ones can be interpreted as potential problems in time-independent heat flow.

Comment on Interpretation Change

Boundary conditions of importance in one interpretation may be of no interest in another; this is about the only handicap in a change of interpretation. Hence one should emphasize that, in other words, whereas the unifying underlying theory remains the same, problems of interest will change from field to field of application. This can be seen most distinctly by comparing the problem sets in this chapter.

SOLUTIONS TO PROBLEM SET 18.3, page 760

2. By inspection,

$$T(x, y) = 5 + 7.5(y - x).$$

This is the real part of the complex potential

$$F(z) = 5 - 7.5(1 + i)z.$$

A systematic derivation is as follows. The boundary and boundary values suggest that $T(x, y)$ is linear in x and y,

$$T(x, y) = ax + by + c.$$

From the boundary conditions,

(1) $\qquad T(x, x - 2) = ax + b(x - 2) + c = -10$

(2) $\qquad T(x, x + 2) = ax + b(x + 2) + c = \quad 20.$

By addition,

$$2ax + 2bx + 2c = 10.$$

im18.qxd 9/21/05 1:09 PM Page 292

Since this is an identity in x, we must have $a = -b$ and $c = 5$. From this and (1),

$$-bx + bx - 2b + 5 = -10.$$

Hence $b = 7.5$. This agrees with our result obtained by inspection.

4. $T(x, y) = 20 + (90/\pi)$ Arg z. This is quite similar to Example 3.

6. The lines of heat flow are perpendicular to the isotherms, and heat flows from higher to lower temperatures. Accordingly, heat flows from the portion of higher temperature of the unit circle $|Z| = 1$ to that kept at a lower temperature, along the circular arcs that intersect the isotherms at right angles.

Of course, as temperatures on the boundary we must choose values that are physically possible, for example, 20°C and 300°C.

8. Team Project. (a) Arg z or Arg w is a basic building block when we have jumps in the boundary values. To obtain Arg z or Arg w as the real part of an analytic function (a logarithm), we have to multiply the logarithm by $-i$. Otherwise we just incorporate the real constants that appear in $T(x, y)$. *Answer:*

$$F^*(w) = T_1 - i\,\frac{T_2 - T_1}{\pi}\,\text{Ln}\,(w - a),$$

$$T^*(u, v) = \text{Re}\,F^*(w) = T_1 + \frac{T_2 - T_1}{\pi}\,\text{Arg}\,(w - a).$$

(b) $w - a = z^2$. Hence Arg $(w - a) =$ Arg $z^2 = 2$ Arg z. Thus (a) gives

$$T_1 + \frac{2}{\pi}(T_2 - T_1)\,\text{Arg}\,z$$

and we see that $T = T_1$ on the x-axis and $T = T_2$ on the y-axis are the boundary data.

Geometrically, the a in $w = a + z^2$ is a translation, and z^2 opens the quadrant up onto the upper half-plane, so that the result of (a) becomes applicable and gives the potential in the quadrant.

(c) $T^* = \dfrac{T_0}{\pi}\,\text{Arg}\,(w - 1) - \dfrac{T_0}{\pi}\,\text{Arg}\,(w + 1)$. This is the real part of

$$F^*(w) = -i\,\frac{T_0}{\pi}\,[\text{Ln}\,(w - 1) - \text{Ln}\,(w + 1)].$$

On the u-axis both arguments are 0 for $u > 1$, one equals π if $-1 < u < 1$, and both equal π, giving $\pi - \pi = 0$ if $u < -1$.

(d) The temperature is

$$T(x, y) = \frac{T_0}{\pi}\,\text{Arg}\,\frac{\cosh z - 1}{\cosh z + 1}\,.$$

The boundary in Fig. 409 is mapped onto the u-axis; $\cosh x$, $0 \leqq x < \infty$, gives $u \geqq 1$; $\cosh (x + \pi i) = -\cosh x$, $0 \leqq x < \infty$, gives $u < -1$; the vertical segment $(x = 0)$ is mapped onto $-1 < u < 1$.

10. $(200/\pi)$ Arg z. This is similar to Example 3.

12. $T(x, y)$ satisfying the boundary conditions is obtained by adding 1 to the answer to Team Project 8(d) and choosing $T_0 = -1$; thus

im18.qxd 9/21/05 1:09 PM Page 293

$$T(x, y) = 100 - \frac{100}{\pi} \operatorname{Arg} \frac{\cosh z - 1}{\cosh z + 1}$$
$$= 100 - \frac{100}{\pi} \operatorname{Arg} \frac{(e^{z/2} - e^{-z/2})^2}{(e^{z/2} + e^{-z/2})^2}$$
$$= 100 - \frac{200}{\pi} \operatorname{Arg} \left(\tanh \frac{z}{2}\right)$$
$$= 100 - \frac{200}{\pi} \arctan \frac{\operatorname{Im} \tanh (z/2)}{\operatorname{Re} \tanh (z/2)} .$$

In calculating these real and imaginary parts we use the abbreviations

$$\mathrm{C}x = \cosh (x/2), \qquad \mathrm{S}x = \sinh (x/2)$$

and

$$\mathrm{c}y = \cos (y/2), \qquad \mathrm{s}y = \sin (y/2).$$

Then

$$\tanh \frac{z}{2} = \frac{\mathrm{S}x\ \mathrm{c}y + i\ \mathrm{C}x\ \mathrm{s}y}{\mathrm{C}x\ \mathrm{c}y + i\ \mathrm{S}x\ \mathrm{s}y} .$$

We now multiply both numerator and denominator by the conjugate of the denominator. The numerator of the resulting expression is

$$N = (\mathrm{S}x\ \mathrm{c}y + i\ \mathrm{C}x\ \mathrm{s}y)(\mathrm{C}x\ \mathrm{c}y - i\ \mathrm{S}x\ \mathrm{s}y).$$

Its real part is

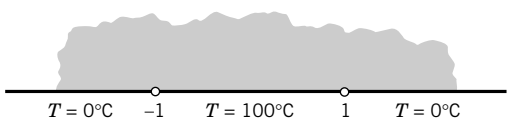
$$\operatorname{Re} N = \mathrm{S}x\ \mathrm{c}y\ \mathrm{C}x\ \mathrm{c}y + \mathrm{C}x\ \mathrm{S}x\ \mathrm{s}y^2 = \mathrm{C}x\ \mathrm{S}x = \tfrac{1}{2} \sinh x.$$

Its imaginary part is

$$\operatorname{Im} N = -\mathrm{S}x^2\ \mathrm{c}y\ \mathrm{s}y + \mathrm{C}x^2\ \mathrm{s}y\ \mathrm{c}y = \mathrm{c}y\ \mathrm{s}y = \tfrac{1}{2} \sin y.$$

Hence the *answer* in its simplest form is

$$T(x, y) = 100 - \frac{200}{\pi} \arctan \frac{\sin y}{\sinh x} .$$



14. The *answer* is

$$\frac{100}{\pi} \left[\operatorname{Arg} (z^2 - 1) - \operatorname{Arg} (z^2 + 1)\right]$$

because $w = z^2$ maps the first quadrant onto the upper half-plane with $1 \mapsto 1$ and $i \mapsto -1$. The figure shows the transformed boundary conditions. The temperature is

$$\frac{100}{\pi} [\operatorname{Arg} (w - 1) - \operatorname{Arg} (w + 1)] = \frac{100}{\pi} \left[\operatorname{Arg} (z^2 - 1) - \operatorname{Arg} (z^2 + 1)\right],$$

in agreement with Team Project 8(c) with $T_0 = 100$.

Section 18.3. Problem 14

im18.qxd 9/21/05 1:09 PM Page 294

SECTION 18.4. Fluid Flow, page 761

Purpose. To give an introduction to complex analysis in potential problems of fluid flow. These two-dimensional flows are given by their velocity vector field, and our presentation in the text begins with an explanation of handling this field by complex methods.

It is interesting that we use complex potentials as before, but whereas in electrostatics the real part (the real potential) is of central interest, here it is the imaginary part of the complex potential which gives the *streamlines* of the flow.

Important Concepts

Stream function Ψ, streamlines $\Psi = const$

Velocity potential Φ, equipotential lines $\Phi = const$

Complex potential $F = \Phi + i\Psi$

Velocity $V = \overline{F'(z)}$

Circulation (6), vorticity, rotation (9)

Irrotational, incompressible

Flow around a cylinder (Example 2, Team Project 16)

SOLUTIONS TO PROBLEM SET 18.4, page 766

2. $w = f(z) = iz^2/K$, $F^*(w) = -iKw$, $F(z) = F^*(w) = -iKiz^2/K = z^2$

4. Rotation of the whole flow pattern about the origin through the angle α

8. $F(z) = iz^3 = i(x^3 + 3ix^2y - 3xy^2 - iy^3) = -3x^2y + y^3 + i(x^3 - 3xy^2)$ gives the streamlines

$$x(x^2 - 3y^2) = const.$$

This includes the three straight-line asymptotes $x = 0$ and $y = \pm x/\sqrt{3}$ (which make 60° angles with one another, dividing the plane into six angular regions of angle 60° each), and we could interpret the flow as a flow in such a region. This is similar to the case $F(z) = z^2$, where we had four angular regions of 90° opening each (the four quadrants of the plane) and the streamlines were hyperbolas. In the present case the streamlines look similar but they are "squeezed" a little so that each stays within its region, whose two boundary lines it has for asymptotes.

The velocity vector is

$$V = -6xy + 3i(y^2 - x^2)$$

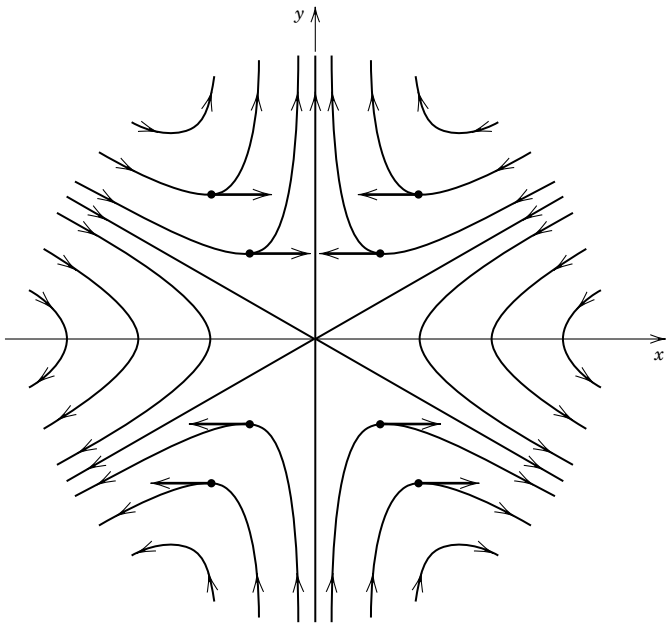
so that $V_2 = 0$ on $y = x$ and $y = -x$. See the figure.

10. $F(z) = iz^2 = i(x^2 - y^2) - 2xy$ gives the streamlines

$$x^2 - y^2 = const$$

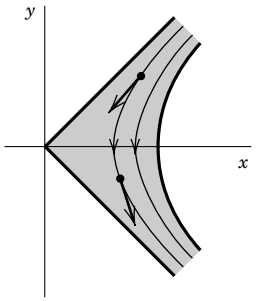
The equipotential lines are

$$xy = const.$$



The velocity vector is

$$V = \overline{F}' = -2i\bar{z} = -2y - 2ix.$$



See the figure.

12. $F(z) = z^2 + 1/z^2$, $\Psi = (r^2 - 1/r^2)\sin 2\theta = 0$ if $r = 1$ (the cylinder wall) or $\theta = 0$, $\pm\pi/2$, π. The unit circle and the axes are streamlines. For large $|z|$ the flow is "parallel" to the x-axis and also to the y-axis. For smaller $|z|$ it is a flow in the first quadrant around a quarter of $|z| = 1$. Similarly in the other quadrants.

im18.qxd 9/21/05 1:09 PM Page 295

Section 18.4. Problem 8

Section 18.4. Problem 10

14. $w = \text{arccosh}\, z$ implies

$$z = x + iy = \cosh w = \cos iw = \sin (iw + \tfrac{1}{2}\pi).$$

Along with an interchange of the roles of the z- and w-planes, this reduces the present problem to the consideration of the sine function in Sec. 17.4 (compare with Fig. 388). We now have the hyperbolas

$$\frac{x^2}{\sin^2 c} - \frac{y^2}{\cos^2 c} = 1$$

where c is different from the zeros of sine and cosine, and as limiting cases the y-axis and the two portions of the aperture.

16. Team Project. (b) We have

$$F(z) = -\frac{iK}{2\pi} \ln z = -\frac{iK}{2\pi} \ln |z| + \frac{K}{2\pi} \arg z.$$

im18.qxd 9/21/05 1:09 PM Page 296

Hence the streamlines are circles

$$\frac{K}{2\pi} \ln |z| = const, \qquad \text{thus} \qquad |z| = const.$$

The formula also shows the increase of the potential

$$\Phi(x, y) = \frac{K}{2\pi} \arg z$$

under an increase of $\arg z$ by 2π, as asserted in (b).

(d) $F_1(z) = \dfrac{1}{2\pi} \ln (z + a)$ (source). $F_2(z) = -\dfrac{1}{2\pi} \ln (z - a)$ (sink). The minus sign has the consequence that the flow is directed radially inward toward the sink because the velocity vector V is

$$V = \overline{F}'(z) = -\frac{1}{2\pi} \cdot \frac{1}{\bar{z} - a} = -\frac{1}{2\pi} \cdot \frac{1}{x - iy - a}$$

$$= -\frac{1}{2\pi} \cdot \frac{x - a + iy}{(x - a)^2 + y^2} .$$

For instance, at $z = a + i$ (above the sink),

$$V = -\frac{i}{2\pi} ,$$

which is directed vertically downward, that is, in the direction of the sink at a.

(e) The addition gives

$$F(z) = z + \frac{1}{z} - \frac{iK}{2\pi} \ln z$$

$$= x + \frac{x}{x^2 + y^2} + \frac{K}{2\pi} \arg z$$

$$+ i\left(y - \frac{y}{x^2 + y^2} - \frac{K}{2\pi} \ln \sqrt{x^2 + y^2}\right) .$$

Hence the streamlines are

$$\Psi(x, y) = \operatorname{Im} F(z) = y - \frac{y}{x^2 + y^2} - \frac{K}{2\pi} \ln \sqrt{x^2 + y^2} = const.$$

In both flows that we have added, $|z| = 1$ is a streamline; hence the same is true for the flow obtained by the addition.

Depending on the magnitude of K, we may distinguish among three types of flow having either two or one or no stagnation points on the cylinder wall. The speed is

$$|V| = |\overline{F'(z)}| = |F'(z)| = \left|\left(1 - \frac{1}{z^2}\right) - \frac{iK}{2\pi z}\right| .$$

We first note that $|V| \to 1$ as $|z| \to \infty$; actually, $V \to 1$, that is, for points at a great distance from the cylinder the flow is nearly parallel and uniform. The stagnation points are the solutions of the equation $V = 0$, that is,

(A) $$z^2 - \frac{iK}{2\pi} z - 1 = 0.$$

im18.qxd 9/21/05 1:09 PM Page 297

We obtain

$$z = \frac{iK}{4\pi} \pm \sqrt{\frac{-K^2}{16\pi^2} + 1}.$$

If $K = 0$ (no circulation), then $z = \pm 1$, as in Example 2. As K increases from 0 to 4π, the stagnation points move from $z = \pm 1$ up on the unit circle until they unite at $z = i$. The value $K = 4\pi$ corresponds to a double root of the equation (A). If $K > 4\pi$, the roots of (A) become imaginary, so that one of the stagnation points lies on the imaginary axis in the field of flow while the other one lies inside the cylinder, thus losing its physical meaning.

SECTION 18.5. Poisson's Integral Formula for Potentials, page 768

Purpose. To represent the potential in a standard region (a disk $|z| \leqq R$) as an integral (5) over the boundary values; to derive from (5) a series (7) that gives the potential and for $|z| = R$ is the Fourier series of the boundary values. So here we see another important application of Fourier series, much less obvious than that of vibrational problems, where one can "see" the cosine and sine terms of the series.

Comment on Footnote 2

Poisson's discovery (1812) that Laplace's equation holds only outside the masses (or charges) resulted in the Poisson equation (Sec. 12.1). The publication on the Poisson distribution (Sec. 24.7) appeared in 1837.

SOLUTIONS TO PROBLEM SET 18.5, page 771

4. $r^2 \sin 2\theta$

6. $\cos^2 5\theta = \frac{1}{2} + \frac{1}{2}\cos 10\theta$ gives the *answer* $\frac{1}{2} + \frac{1}{2}r^{10}\cos 10\theta$.

8. $\pi - 2\left(r\sin\theta + \dfrac{r^2}{2}\sin 2\theta + \dfrac{r^3}{3}\sin 3\theta + \cdots\right)$.

Note that $\Phi(1, \theta)$ is neither even nor odd, but $\Phi(1, \theta) - \pi$ is odd, so that we get a sine series plus the constant term π.

10. $\cos^4\theta = \frac{3}{8} + \frac{1}{2}\cos 2\theta + \frac{1}{8}\cos 4\theta$ gives the *answer*

$$\tfrac{3}{8} + \tfrac{1}{2}r^2\cos 2\theta + \tfrac{1}{8}r^4\cos 4\theta.$$

12. $\dfrac{1}{2} + \dfrac{2}{\pi}\left(r\cos\theta - \dfrac{1}{3}r^3\cos 3\theta + \dfrac{1}{5}r^5\cos 5\theta - + \cdots\right)$

14. Team Project. (a) $r = 0$ in (5) gives $\Phi(0) = \dfrac{1}{2\pi}\displaystyle\int_0^{2\pi}\Phi(R, \alpha)\,d\alpha$. Note that the interval of integration has length 2π, not $2\pi R$.

(b) $\nabla^2 u = 0$, $u = g(r)h(\theta)$, $g''h + \dfrac{1}{r}g'h + \dfrac{1}{r^2}gh'' = 0$; hence by separating variables

$$r^2\frac{g''}{g} + r\frac{g'}{g} = n^2, \qquad \frac{h''}{h} = -n^2, \qquad h = a_n\cos n\theta + b_n\sin n\theta.$$

Also,

$$r^2g'' + rg' - n^2g = 0.$$

A solution is r^n/R^n.

im18.qxd 9/21/05 1:09 PM Page 298

(c) By the Cauchy–Riemann equations,

$$\Psi_r = -\frac{1}{r}\,\Phi_\theta = -\sum_{n=1}^{\infty} \frac{r^{n-1}}{R^n}(-a_n \sin n\theta + b_n \cos n\theta)n,$$

$$\Psi = \Psi(0) + \sum_{n=1}^{\infty} \left(\frac{r}{R}\right)^n (-b_n \cos n\theta + a_n \sin n\theta).$$

(d) From the series for Φ and Ψ we obtain by addition

$$F(z) = a_0 + i\Psi(0) + \sum_{n=1}^{\infty} \left(\frac{r}{R}\right)^n [(a_n - ib_n)\cos n\theta + i(a_n - ib_n)\sin n\theta]$$

$$= a_0 + i\Psi(0) + \sum_{n=1}^{\infty} \left(\frac{r}{R}\right)^n (a_n - ib_n)e^{in\theta},$$

$$a_n - ib_n = \frac{1}{\pi}\int_0^{2\pi} \Phi(R, \alpha)e^{-in\alpha}\,d\alpha.$$

Using $z = re^{i\theta}$, we have the power series

$$F(z) = a_0 + i\Psi(0) + \sum_{n=1}^{\infty} \frac{a_n - ib_n}{R^n}\, z^n.$$

SECTION 18.6. General Properties of Harmonic Functions, page 771

Purpose. We derive general properties of analytic functions and from them corresponding properties of harmonic functions.

Main Content, Important Properties

Mean value of analytic functions over circles (Theorem 1)

Mean value of harmonic functions over circles, over disks (Theorem 2)

Maximum modulus theorem for analytic functions (Theorem 3)

Maximum principle for harmonic functions (Theorem 4)

Uniqueness theorem for the Dirichlet problem (Theorem 5)

Comment on Notation

Recall that we introduced F to reserve f for conformal mappings (beginning in Sec. 18.2), and we continue to use F also in this last section of Chap. 18.

SOLUTIONS TO PROBLEM SET 18.6, page 774

2. Use (2). We obtain

$$F(2) = 27 = \frac{1}{2\pi}\int_0^{2\pi} (3 + e^{i\alpha})^3\,d\alpha = \frac{1}{2\pi}(2\pi \cdot 27 + 0).$$

4. Use (2). $F(0) = 0$

6. By (3) with $r_0 = 1$,

im18.qxd 9/21/05 1:09 PM Page 299

$$\frac{1}{\pi}\int_0^1\int_0^{2\pi}\left[(3+\cos\alpha)^2-(8+\sin\alpha)^2\right]r\,dr\,d\alpha$$

$$=\frac{1}{2\pi}\int_0^{2\pi}\left[(3+\cos\alpha)^2-(8+\sin\alpha)^2\right]d\alpha$$

$$=\frac{1}{2\pi}\left[\left(9+0+\frac{1}{2}\right)-\left(64+0+\frac{1}{2}\right)\right]\cdot 2\pi=-55.$$

8. Set $r = 0$.

10. Team Project. (a) (i) Polar coordinates show that $|F(z)| = |z|^2$ assumes its maximum 52 and its minimum 20 at the boundary points $6 + 4i$ and $4 + 2i$, respectively, and at no interior point.

(ii) Use the fact that $|e^{3z}| = e^{3x}$ is monotone.

(iii) At $z = \pm i$ we obtain the maximum

$$|F(z)| = [\sin^2 x + \sinh^2 y]^{1/2} = \sinh 1 = 1.1752$$

and at $z = 0$ the minimum 0.

(b) $|\cos z|^2 = \cos^2 x + \sinh^2 y$ (Sec. 13.6) shows that, for instance, in the unit disk the maximum $\sqrt{1 + \sinh^2 1} = 1.5431$ is taken at $z = \pm i$.

(c) $F(z)$ is not analytic.

(d) The extension is simple. Since the interior R of C is simply connected, Theorem 3 applies. The maximum of $|F(z)|$ is assumed on C, by Theorem 3, and if $F(z)$ had no zeros inside C, then, by Theorem 3, it would follow that $|F(z)|$ would also have its minimum on C, so that $F(z)$ would be constant, contrary to our assumption. This proves the assertion.

The fact that $|F(z)| = const$ implies $F(z) = const$ for any analytic function $F(z)$ was shown in Example 3, Sec. 13.4.

12. Since $|z| \leqq 1$, the triangle inequality yields $|az + b| \leqq |a| + |b|$. The maximum lies on $|z| = 1$. Write $a = |a|e^{i\alpha}$, $z = e^{i\theta}$, $b = |b|e^{i\beta}$. Choose $\theta = \beta - \alpha$. Then

$$|az+b| = \left||a|e^{i\alpha+i(\beta-\alpha)} + |b|e^{i\beta}\right| = (|a| + |b|)|e^{i\beta}| = |a| + |b|.$$

Answer: $|a| + |b|$, taken at $z = e^{i(\beta-\alpha)}$.

14. $e^x \leqq e^b$ with equality only at b. Also, $\cos y \leqq 1$ with equality only at 0 and 2π, and $(b, 0)$ and $(b, 2\pi)$ lie on the boundary.

16. $\Phi = \exp(x^2 - y^2)\cos 2xy$, R: $|z| \leqq 1$, $x \geqq 0$, $y \geqq 0$. Yes, $(u_1, v_1) = (1, 0)$ is the image of $(x_1, y_1) = (1, 0)$; this is typical. (u_1, v_1) is found by noting that on the boundary (semicircle), $\Phi^* = e^u \cos(\sqrt{1 - u^2})$ increases monotone with u. Similarly for R.

SOLUTIONS TO CHAP. 18 REVIEW QUESTIONS AND PROBLEMS, page 775

12. $\Phi = (20/\ln 10)\ln r$

14. $\Phi = (220 \ln r)/\ln 4$; $\Phi = 0$ if $r = 1$, the unit circle, which is closer to the inner circle than to the outer, reflecting the convexity of the curve of the logarithm.

16. $\Phi = 10 - (12/\pi)\operatorname{Arg} z$

im18.qxd 9/21/05 1:09 PM Page 300

18. $\Phi = \dfrac{x + y}{x^2 + y^2} = \dfrac{1}{2c}$, $(x - c)^2 + (y - c)^2 = 2c^2$, circles through the origin with center on $y = x$.

20. $\Phi = 600[1 + (2/\pi) \operatorname{Arg} z]$, so that the answer is 900 V and 600 V.

22. $T(x, y) = 50\left[1 - \dfrac{1}{\pi} \operatorname{Arg} (z - 2)\right]$

24. 43.22°C, which is obtained as follows. We have

$$T(r) = a \ln r + b$$

and at the outer cylinder,

(1) $$T(10) = a \ln 10 + b = 20$$

and from the condition to be achieved

(2) $$T(5) = a \ln 5 + b = 30.$$

(1) subtracted from (2) gives

$$a(\ln 5 - \ln 10) = 10, \qquad a = 10/\ln \tfrac{1}{2} = -14.43.$$

From this and (1)

$$b = 20 - a \ln 10 = 53.22.$$

Hence on the inner cylinder we should have

$$T(2) = a \ln 2 + b = 43.22.$$

26. $z/4 + 4/z$

28. $25 - \dfrac{100}{\pi}\left(r \cos \theta - \dfrac{1}{3} r^3 \cos 3\theta + \dfrac{1}{5} r^5 \cos 5\theta - + \cdots\right)$

30. $\frac{1}{3}\pi^2 - 4(r \cos \theta - \frac{1}{4} r^2 \cos 2\theta + \frac{1}{9} r^3 \cos 3\theta - \frac{1}{16} r^4 \cos 4\theta + - \cdots)$

im19.qxd 9/21/05 1:10 PM Page 301

PART E. Numeric Analysis

The subdivision into three chapters has been retained. All three chapters have been updated in the light of computer requirements and developments. A list of suppliers of software (with addresses etc.) can be found at the beginning of Part E of the book and another list at the beginning of Part G.

CHAPTER 19 Numerics in General

Major Changes

Updating of this chapter consists of the inclusion of ideas, such as error estimation by halving, changes in Sec. 19.4 on splines, the presentation of adaptive integration and Romberg integration, and further error estimation techniques in integration.

SECTION 19.1. Introduction, page 780

Purpose. To familiarize the student with some facts of numerical work in general, regardless of the kind of problem or the choice of method.

Main Content, Important Concepts

Floating-point representation of numbers, overflow, underflow,

Roundoff

Concept of algorithm

Stability

Errors in numerics, their propagation, error estimates

Loss of significant digits

Short Courses. Mention the roundoff rule and the definitions of error and relative error.

SOLUTIONS TO PROBLEM SET 19.1, page 786

2. $-0.286403 \cdot 10^{-1}$, $0.112584 \cdot 10^{2}$, $-0.316816 \cdot 10^{5}$

6. 19.9499, 0.0501; 19.9499, 0.0501256

8. -99.980, -0.020; -99.980, -0.020004

10. Small terms first. $(0.0004 + 0.0004) + 1.000 = 1.001$, but

$$(1.000 + 0.0004) + 0.0004 = 1 \text{ (4S)}$$

14. The proof is practically the same as that in the text. With the same notation we get

$$\begin{aligned} |\epsilon| &= |x + y - (\tilde{x} + \tilde{y})| \\ &= |(x - \tilde{x}) + (y - \tilde{y})| \\ &= |\epsilon_1 + \epsilon_2| \leqq |\epsilon_1| + |\epsilon_2| \leqq \beta_1 + \beta_2. \end{aligned}$$

16. Since $x_2 = 2/x_1$ and 2 is exact, $|\epsilon_r(x_2)| = |\epsilon_r(x_1)|$ by Theorem 1b. Since x_1 is rounded to 4S, we have $|\epsilon(x_1)| \leqq 0.005$, hence

$$|\epsilon_r(x_1)| \leqq 0.005/39.95.$$

im19.qxd 9/21/05 1:10 PM Page 302

This implies

$$|\epsilon(x_2)| = |\epsilon_r(x_2)x_2| = |\epsilon_r(x_1)x_2|$$
$$\leqq (0.005/39.95) \cdot 0.0506$$
$$< 0.00001.$$

18. $61.2 - 7.5 \cdot 15.5 + 11.2 \cdot 3.94 + 2.80 = 61.2 - 116 + 44.1 + 2.80 = -7.90$

$$((x - 7.5)x + 11.2)x + 2.80 = (-3.56 \cdot 3.94 + 11.2)3.94 + 2.80$$
$$= (-14.0 + 11.2)3.94 + 2.80$$
$$= -11.0 + 2.80 = -8.20$$

Exact: -8.336016

SECTION 19.2. Solution of Equations by Iteration, page 787

Purpose. Discussion of the most important methods for solving equations $f(x) = 0$, a very important task in practice.

Main Content, Important Concepts

Solution of $f(x) = 0$ by iteration (3) $x_{n+1} = g(x_n)$

Condition sufficient for convergence (Theorem 1)

Newton (–Raphson) method (5)

Speed of convergence, order

Secant, bisection, false position methods

Comments on Content

Fixed-point iteration gives the opportunity to discuss the idea of a **fixed point,** which is also of basic significance in modern theoretical work (existence and uniqueness of solutions of differential, integral, and other functional equations).

The less important *method of bisection* and *method of false position* are included in the problem set.

SOLUTIONS TO PROBLEM SET 19.2, page 796

2. $x_0 = 1, x_1 = 0, x_2 = 1, x_3 = 0, \cdots$
$x_0 = 0.5, x_1 = 0.875, x_2 = 0.330, \cdots$
$x_0 = 2, x_1 = -7, x_2 = 344, x_3 = -40\,707\,583, \cdots$

4. $g = \sqrt[4]{x - 0.2}$, 1, 0.9457, 0.9293, 0.9241, 0.9225, 0.9220, 0.9218, 0.9217, 0.9217

12. 1.537902, 1.557099, 1.557146, 1.557146

14. 2, 2.452, 2.473; temperature 39.02°C

im19.qxd 9/21/05 1:10 PM Page 303

16. (a) 0.906180 (6S exact, 4 steps, $x_0 = 1$). (b) $\frac{1}{3}\sqrt{5 + \frac{2}{7}\sqrt{70}} = 0.906179846$

18. $f(x) = x^k - c, \quad x_{n+1} = x_n - (x_n - c/x_n^{k-1})/k$

$$= \left(1 - \frac{1}{k}\right)x_n + \frac{c}{kx_n^{k-1}}.$$

In each case, x_4 is the first value that gives the desired accuracy, 1.414 214, 1.259 921, 1.189 207, 1.148 698.

20. Team Project. (a)

ALGORITHM REGULA FALSI (f, a_0, b_0, ϵ, N). Method of False Position

This algorithm computes an interval $[a_n, b_n]$ containing a solution of $f(x) = 0$ (f continuous) or a solution c_n.

INPUT: Continuous function f, initial interval $[a_0, b_0]$, tolerance ϵ, maximum number of iterations N.

OUTPUT: Interval $[a_n, b_n]$ containing a solution, or a solution c_n, or message of failure.

For $n = 0, 1, \cdots, N - 1$ do:

Compute $c_n = \dfrac{a_n f(b_n) - b_n f(a_n)}{f(b_n) - f(a_n)}$.

If $f(c_n) = 0$ then OUTPUT c_n. Stop. [*Successful completion*]
Else continue.
If $f(a_n)f(c_n) < 0$ then set $a_{n+1} = a_n$ and $b_{n+1} = c_n$.
Else set $a_{n+1} = c_n$ and $b_{n+1} = b_n$.
If $b_{n+1} - a_{n+1} \leqq \epsilon$ then OUTPUT $[a_{n+1}, b_{n+1}]$. Stop.
[*Successful completion*]
Else continue.

End

OUTPUT $[a_N, b_N]$ and message "Failure". Stop.

[*Unsuccessful completion; N iterations did not give an interval of length not exceeding the tolerance.*]

End REGULA FALSI

24. 0.5, 1, 0.725482, 0.738399, 0.739087, 0.739085, 0.739085

SECTION 19.3. Interpolation, page 797

Purpose. To discuss methods for interpolating (or extrapolating) given data $(x_0, f_0), \cdots, (x_n, f_n)$, all x_j different, arbitrarily or equally spaced, by polynomials of degree not exceeding n.

Main Content, Important Concepts

Lagrange interpolation (4) (arbitrary spacing)

Error estimate (5)

Newton's divided difference formula (10) (arbitrary spacing)

Newton's difference formulas (14), (18) (equal spacing)

im19.qxd 9/21/05 1:10 PM Page 304

Short Courses. Lagrange's formula briefly, Newton's forward difference formula (14).

Comment on Content

For given data, the interpolation polynomial $p_n(x)$ is unique, regardless of the method by which it is derived. Hence the error estimate (5) is generally valid (provided f is $n + 1$ times continuously differentiable).

SOLUTIONS TO PROBLEM SET 19.3, page 808

2. This parallels Example 3. From (5) we get

$$\epsilon_1(9.4) = (x - 9)(x - 9.5)\left.\frac{f''(t)}{2}\right|_{x=9.4} = \frac{0.02}{t^2},$$

where $9 \leqq t \leqq 9.5$. Now the right side is a monotone function of t, hence its extrema occur at 9.0 and 9.5. We thus obtain

$$0.00022 \leqq a - \tilde{a} \leqq 0.00025.$$

This gives the *answer*

$$2.2407 \leqq a \leqq 2.2408.$$

2.2407 is exact to 4D.

4. From (5) we obtain

$$\epsilon_2(9.2) = (x - 9)(x - 9.5)(x - 11)\left.\frac{(\ln t)'''}{6}\right|_{x=9.2} = \frac{0.036}{t^3}.$$

The right side is monotone in t, hence its extreme values occur at the ends of the interval $9 \leqq t \leqq 11$. This gives

$$0.000027 \leqq \epsilon_2(9.4) = a - \tilde{a} \leqq 0.000049$$

and by adding $\tilde{a} = 2.2192$ (and rounding)

$$2.2192 \leqq a \leqq 2.2193.$$

6. From (5) we obtain

$$\epsilon_2(0.75) = (x - 0.25)(x - 0.5)(x - 1)\left.\frac{f'''(t)}{6}\right|_{x=0.75} = -0.005\,208 f'''(t)$$

where, by differentiation,

$$f'''(t) = \frac{-4}{\sqrt{\pi}}(1 - 2t^2)e^{-t^2}.$$

Another differentiation shows that f''' is monotone on the interval $0.25 \leqq t \leqq 1$ because

$$f^{iv} = -\frac{8t}{\sqrt{\pi}}(-3 + 2t^2)e^{-t^2} \neq 0$$

on that interval. Hence the extrema of f''' occur at the ends of the interval, so that we obtain

$$-0.00432 \leqq a - \tilde{a} \leqq 0.00967$$

and by adding $\tilde{a} = 0.70929$

$$0.70497 \leqq a \leqq 0.71896.$$

Exact: 0.71116 (5D).

im19.qxd 9/21/05 1:10 PM Page 305

8. 0.8032 ($\epsilon = -0.0244$), 0.4872 ($\epsilon = -0.0148$); the quadratic interpolation polynomial is

$$p_2(x) = 0.3096x^2 - 0.9418x + 1$$

and gives the values 0.7839 ($\epsilon = -0.0051$) and 0.4678 ($\epsilon = 0.0046$).

10. From

$$L_0(x) = x^2 - 20.5x + 104.5$$

$$L_1(x) = \frac{1}{0.75}(-x^2 + 20x - 99)$$

$$L_2(x) = \frac{1}{3}(x^2 - 18.5x + 85.5)$$

(see Example 2) and the 5S-values of the logarithm in the text we obtain

$$p_2(x) = -0.005\,233x^2 + 0.205\,017x + 0.775\,950.$$

This gives the values and errors

2.2407, error 0
2.3028, error −0.0002
2.3516, error −0.0002
2.4415, error 0.0008
2.4826, error 0.0024.

It illustrates that in extrapolation one may usually get less accurate values than one does in interpolation. $p_2(x)$ would change if we took more accurate values of the logarithm.

12. $4x^2 - 6x + 5$

14. $p_2(x) = 1.0000 - 0.0112r + 0.0008r(r-1)/2 = x^2 - 2.580x + 2.580$, $r = (x-1)/0.02$; 0.9943, 0.9835, 0.9735

16. The divided difference table is

x_j	$f(x_j)$	$f[x_j, x_{j+1}]$	$f[x_j, x_{j+1}, x_{j+2}]$	$f[x_j, \cdots, x_{j+3}]$
6.0	0.1506			
		0.1495		
7.0	0.3001		−0.1447	
		−0.0676		0.0088
7.5	0.2663		−0.1299	
		−0.1585		
7.7	0.2346			

From it and (10) we obtain

$$\begin{aligned} p_3(6.5) &= 0.1506 + (6.5 - 6.0) \cdot 0.1495 \\ &\quad + (6.5 - 6.0)(6.5 - 7.0) \cdot (-0.1447) \\ &\quad + (6.5 - 6.0)(6.5 - 7.0)(6.5 - 7.5) \cdot 0.0088 \\ &= 0.2637. \end{aligned}$$

im19.qxd 9/21/05 1:10 PM Page 306

18. The difference table is

x_j	$J_1(x_j)$	Δ	Δ^2	Δ^3	Δ^4	Δ^5
0.0	0.00000					
		9950				
0.2	0.09950		−297			
		9653		−289		
0.4	0.19603		−586		22	
		9067		−267		5
0.6	0.28670		−853		27	
		8214		−240		
0.8	0.36884		−1093			
		7121				
1.0	0.44005					

From this and (14) we get by straightforward calculation

$$p_5(x) = 0.00130x^5 + 0.00312x^4 - 0.06526x^3 + 0.00100x^2 + 0.49988x.$$

This gives as the values of $J_1(x)$, $x = 0.1, 0.3, 0.5, 0.7, 0.9$,

$$0.04993, \quad 0.14832, \quad 0.24227, \quad 0.32899, \quad 0.40595,$$

the errors being 1, 0, 0, 1, 0 unit of the last given digit.

22. Team Project. (a) For $p_1(x)$ we need

$$L_0 = \frac{x - x_1}{x_0 - x_1} = 19 - 2x, \qquad L_1 = \frac{x - x_0}{x_1 - x_0} = -18 + 2x$$

$$p_1(x) = 2.19722(19 - 2x) + 2.25129(-18 + 2x)$$
$$= 1.22396 + 0.10814x,$$
$$p_1(9.2) = 2.21885.$$

Exact, 2.21920, error 0.00035.

For p_2 we need

$$L_0 = 104.5 - \tfrac{41}{2}x + x^2$$
$$L_1 = -132 + \tfrac{80}{3}x - \tfrac{4}{3}x^2$$
$$L_2 = 28.5 - \tfrac{37}{6}x + \tfrac{1}{3}x^2$$

This gives (with 10S-values for the logarithm)

$$p_2(x) = 0.779466 + 0.204323x - 0.0051994x^2,$$

hence $p_2(9.2) = 2.21916$, error 0.00004. The error estimate is

$$p_2(9.2) - p_1(9.2) = 0.00031.$$

(b) Extrapolation gives a much larger error. The difference table is

0.2	0.9980		
		−0.0294	
0.4	0.9686		−0.0949
		−0.1243	
0.6	0.8443		−0.1842
		−0.3085	
0.8	0.5358		−0.2273
		−0.5358	
1.0	0.0000		

im19.qxd 9/21/05 1:10 PM Page 307

The differences not shown are not needed. Taking $x = 0.6, 0.8, 1.0$ gives the best result. Newton's formula (14) with $r = 0.1/0.2 = 0.5$ gives

$$0.8443 + 0.5 \cdot (-0.3085) + \frac{0.5 \cdot (-0.5)}{2} \cdot (-0.2273) = 0.7185, \quad \epsilon = -0.0004.$$

Similarly, by taking $x = 0.4, 0.6, 0.8$ we obtain

$$0.9686 + 1.5 \cdot (-0.1243) + \frac{1.5 \cdot 0.5}{2} \cdot (-0.1842) = 0.7131, \quad \epsilon = 0.0050.$$

Taking $x = 0.2, 0.4, 0.6$, we extrapolate and get a much poorer result:

$$0.9980 + 2.5 \cdot (-0.0294) + \frac{2.5 \cdot 1.5}{2} \cdot (-0.0949) = 0.7466, \quad \epsilon = -0.0285.$$

(e) 0.386 4185, exact to 7S.

SECTION 19.4. Splines, page 810

Purpose. Interpolation of data $(x_0, f_0), \cdots, (x_n, f_n)$ by a (cubic) spline, that is, a twice continuously differentiable function

$$g(x)$$

which in each of the intervals between adjacent nodes is given by a polynomial of third degree at most,

on $[x_0, x_1]$ by $q_0(x)$, on $[x_1, x_2]$ by $q_1(x)$, $\cdots$, on $[x_{n-1}, x_n]$ by $q_{n-1}(x)$.

Short Courses. This section may be omitted.

Comments on Content

Higher order polynomials tend to oscillate between nodes—the polynomial $P_{10}(x)$ in Fig. 431 is typical—and splines were introduced to avoid that phenomenon. This motivates their application.

It is stated in the text that splines also help lay the foundation of **CAD (computer-aided design).**

If we impose the additional condition (3) with given k_0 and k_n (tangent direction of the spline at the beginning and at the end of the total interval considered), then for given data the cubic spline is unique.

SOLUTIONS TO PROBLEM SET 19.4, page 815

2. Writing $f(x_j) = f_j$, $f(x_{j+1}) = f_{j+1}$, $x - x_j = F$, $x - x_{j+1} = G$, we get (6) in the form

$$\begin{aligned} q_j(x) = {} & f_j c_j^2 G^2 (1 + 2c_j F) \\ & + f_{j+1} c_j^2 F^2 (1 - 2c_j G) \\ & + k_j c_j^2 F G^2 \\ & + k_{j+1} c_j^2 F^2 G. \end{aligned}$$

If $x = x_j$, then $F = 0$, so that because $c_j = 1/(x_{j+1} - x_j)$,

$$q_j(x_j) = f_j c_j^2 (x_j - x_{j+1})^2 = f_j.$$

im19.qxd 9/21/05 1:10 PM Page 308

Similarly, if $x = x_{j+1}$, then $G = 0$ and

$$q_j(x_{j+1}) = f_{j+1}c_j^2(x_{j+1} - x_j)^2 = f_{j+1}.$$

This verifies (4).

By differenting (6) we obtain

$$\begin{aligned} q_j'(x) = {} & f_j c_j^2\big[2G(1 + 2c_jF) + 2c_jG^2\big] \\ & + f_{j+1}c_j^2\big[2F(1 - 2c_jG) - 2c_jF^2\big] \\ & + k_j c_j^2[G^2 + 2FG] \\ & + k_{j+1}c_j^2[2FG + F^2]. \end{aligned}$$

If $x = x_j$, then $F = 0$, and in the first line the expression in the brackets $[\cdots]$ reduces to

$$2G(1 + c_jG) = 2(x_j - x_{j+1})\left(1 + \frac{x_j - x_{j+1}}{x_{j+1} - x_j}\right) = 0.$$

In the second and fourth lines we obtain zero. There remains

$$q_j'(x_j) = k_j c_j^2(x_{j+1} - x_j)^2 = k_j.$$

Similarly, if $x = x_{j+1}$, then $G = 0$ and

$$\begin{aligned} q_j'(x_{j+1}) &= f_{j+1}c_j^2\big[2(x_{j+1} - x_j) - 2c_j(x_{j+1} - x_j)^2\big] \\ &\quad + k_{j+1}c_j^2(x_{j+1} - x_j)^2 \\ &= 0 + k_{j+1} \cdot 1 = k_{j+1}. \end{aligned}$$

This verifies (5).

4. This derivation is simple and straightforward.

8. $p_2(x) = x^2$. $[f(x) - p_2(x)]' = 4x^3 - 2x = 0$ gives the points of maximum deviation $x = \pm 1/\sqrt{2}$ and by inserting this, the maximum deviation itself,

$$|f(1/\sqrt{2}) - p_2(1/\sqrt{2})| = |\tfrac{1}{4} - \tfrac{1}{2}| = \tfrac{1}{4}.$$

For the spline $g(x)$ we get, taking $x \geqq 0$,

$$[f(x) - g(x)]' = 4x^3 + 2x - 6x^2 = 0.$$

A solution is $x = 1/2$. The corresponding maximum deviation is

$$f(\tfrac{1}{2}) - g(\tfrac{1}{2}) = \tfrac{1}{16} - (-\tfrac{1}{4} + 2 \cdot \tfrac{1}{8}) = \tfrac{1}{16},$$

which is merely 25% of the previous value.

10. We obtain

$$\begin{aligned} q_0 &= -\tfrac{3}{4}(x + 2)^2 + \tfrac{3}{4}(x + 2)^3 \\ &= 3 + 6x + \tfrac{15}{4}x^2 + \tfrac{3}{4}x^3 \\ q_1 &= \tfrac{3}{4}(x + 1) + \tfrac{3}{2}(x + 1)^2 - \tfrac{5}{4}(x + 1)^3 \\ &= 1 - \tfrac{9}{4}x^2 - \tfrac{5}{4}x^3 \\ q_2 &= 1 - \tfrac{9}{4}x^2 + \tfrac{5}{4}x^3 \\ q_3 &= -\tfrac{3}{4}(x - 1) + \tfrac{3}{2}(x - 1)^2 - \tfrac{3}{4}(x - 1)^3 \\ &= 3 - 6x + \tfrac{15}{4}x^2 - \tfrac{3}{4}x^3. \end{aligned}$$

im19.qxd 9/21/05 1:10 PM Page 309

12. $n = 3$, $h = 2$, so that (14) is

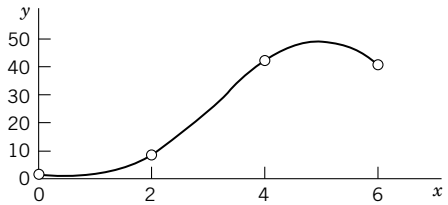
$$k_0 + 4k_1 + k_2 = \tfrac{3}{2}(f_2 - f_0) = 60$$

$$k_1 + 4k_2 + k_3 = \tfrac{3}{2}(f_3 - f_1) = 48.$$

Since $k_0 = 0$ and $k_3 = -12$, the solution is $k_1 = 12$, $k_2 = 12$.

In (13) with $j = 0$ we have $a_{00} = f_0 = 1$, $a_{01} = k_0 = 0$,

$$a_{02} = \tfrac{3}{4}(9 - 1) - \tfrac{1}{2}(12 + 0) = 0$$



$$a_{03} = \tfrac{2}{8}(1 - 9) + \tfrac{1}{4}(12 + 0) = 1.$$

From this and, similarly, from (13) with $j = 1$ and $j = 2$ we get the spline $g(x)$ consisting of the three polynomials (see the figure)

$$q_0(x) = 1 + x^3 \qquad (0 \leqq x \leqq 2)$$

$$q_1(x) = 9 + 12(x - 2) + 6(x - 2)^2 - 2(x - 2)^3 = 25 - 36x + 18x^2 - 2x^3 \qquad (2 \leqq x \leqq 4)$$

$$q_2(x) = 41 + 12(x - 4) - 6(x - 4)^2 = -103 + 60x - 6x^2 \qquad (4 \leqq x \leqq 6).$$

Section 19.4. Spline in Problem 12

14. $q_0(x) = x^3$,
$q_1(x) = 1 + 3(x - 1) + 3(x - 1)^2 - (x - 1)^3$,
$q_2(x) = 6 + 6(x - 2) - 2(x - 2)^3$

16. $3x/\pi - 4x^3/\pi^3$

18. The purpose of the experiment is to see that the advantage of the spline over the polynomial increases drastically with m. The greatest deviation of p_m occurs at the ends. Formulas for the p_m as a CAS will give them are

$$p_4(x) = 1 - \tfrac{5}{4}x^2 + \tfrac{1}{4}x^4$$

$$p_6(x) = 1 - \tfrac{49}{36}x^2 + \tfrac{7}{18}x^4 - \tfrac{1}{36}x^6$$

$$p_8(x) = 1 - \tfrac{205}{144}x^2 + \tfrac{91}{192}x^4 - \tfrac{5}{96}x^6 + \tfrac{1}{576}x^8$$

and so on.

20. Team Project.

(b) $x(t) = \frac{1}{2}t + \frac{5}{2}t^2 - 2t^3$, $y(t) = \frac{1}{2}t + (\frac{1}{4}\sqrt{3} - 1)t^2 + (\frac{1}{2} - \frac{1}{4}\sqrt{3})t^3$

(c) $x(t) = t + 2t^2 - 2t^3$, $y(t) = t + (\frac{1}{2}\sqrt{3} - 2)t^2 + (1 - \frac{1}{2}\sqrt{3})t^3$

Note that the tangents in (b) and (c) are not parallel.

SECTION 19.5. Numeric Integration and Differentiation, page 817

Purpose. Evaluation of integrals of empirical functions, functions not integrable by elementary methods, etc.

im19.qxd 9/21/05 1:10 PM Page 310

Main Content, Important Concepts

Simpson's rule (7) (most important), error (8), (10)

Trapezoidal rule (2), error (4), (5)

Gaussian integration

Degree of precision of an integration formula

Adaptive integration with Simpson's rule (Example 6)

Numerical differentiation

Short Courses. Discuss and apply Simpson's rule.

Comments on Content

The range of numerical integration includes empirical functions, as measured or recorded in experiments, functions that cannot be integrated by the usual methods, or functions that can be integrated by those methods but lead to expressions whose computational evaluation would be more complicated than direct numerical integration of the integral itself.

Simpson's rule approximates the integrand by quadratic parabolas. Approximations by higher order polynomials are possible, but lead to formulas that are generally less practical.

Numerical differentiation can sometimes be avoided by changing the mathematical model of the problem.

SOLUTIONS TO PROBLEM SET 19.5, page 828

2. Let A_j and B_j be lower and upper bounds for f in the jth subinterval. Then $A \leqq J \leqq B$, where $A = h\Sigma A_j$ and $B = h\Sigma B_j$. In Example 1 the maximum and minimum of the integrand in a subinterval occur at the ends. Hence we obtain A and B by choosing the left and right endpoints, respectively, of each subinterval instead of the midpoints as in (1). *Answer:* $0.714 \leqq J \leqq 0.778$, rounded to 3S.

4. The first term, 1/20, results from $(1 + \frac{1}{2}) \cdot 0.1/3$. We obtain

$$\frac{1}{20} + \frac{2}{15}\sum_{j=1}^{5}\frac{1}{0.9 + 0.2j} + \frac{1}{15}\sum_{j=1}^{4}\frac{1}{1 + 0.2j} = 0.6931502.$$

The 7S-exact value is 0.6931472.

6. 1.5576070 (8S-exact value 1.5574077)

8. 0.9080057 (8S-exact 0.9084218)

10. $J_{h/2} + \epsilon_{h/2} = 1.5574211 - 0.0000124 = 1.5574087$ (8S-exact 1.5574077)

12. $J_{h/2} + \epsilon_{h/2} = 0.9083952 + 0.0000260 = 0.9084212$

14. From (5) and the values in Prob. 13 we obtain

$$0.94583 + \tfrac{1}{3}(0.94583 - 0.94508) = 0.94608$$

which is exact to 5S.

16. From (10) and Prob. 15 we obtain

$$0.94608693 + \tfrac{1}{15}(0.94608693 - 0.94614588) = 0.94608300$$

which is exact to 6S, the error being 7 units of the 8th decimal.

18. We obtain

$$\tfrac{1}{24}\left(4\sum_{j=1}^{5}\sin(\tfrac{1}{4}j - \tfrac{1}{8})^2 + 2\sum_{k=1}^{4}\sin\tfrac{1}{16}k^2 + \sin\tfrac{25}{16}\right) = 0.545941.$$

The exact 6S-value is 0.545962.

im19.qxd 9/21/05 1:10 PM Page 311

20. $h|\frac{1}{2}\epsilon_0 + \epsilon_1 + \cdots + \epsilon_{n-1} + \frac{1}{2}\epsilon_n| \leqq [(b-a)/n]nu = (b-a)u$. This is similar to the corresponding proof for Simpson's rule given in the text.

22. Since the cosine is even, we can take terms together,

$$\int_0^{\pi/2} \cos x\, dx = \tfrac{1}{2}\int_{-\pi/2}^{\pi/2} \cos x\, dx = \frac{\pi}{4}\int_{-1}^{1} \cos \tfrac{1}{2}\pi t\, dt$$

$$\approx \frac{\pi}{4}\,[2A_1 \cos \tfrac{1}{2}\pi t_1 + 2A_2 \cos \tfrac{1}{2}\pi t_2 + A_3 \cdot 1] = 1.00000\,00552.$$

24. $x = (t+1)/1.6$ gives $x = 0$ when $t = -1$ and $x = 1.25$ when $t = 1$. Also $dx = dt/1.6$. The computation gives 0.5459627. The 7S-exact value is 0.5459623. This is the value of the Fresnel integral $S(x)$ at $x = 1.25$.

26. Team Project. The factor $2^4 = 16$ comes in because we have replaced h by $\frac{1}{4}h$, giving for h^2 now $(\frac{1}{4}h)^2 = \frac{1}{16}h^2$. In the next step (with $h/8$) the error ϵ_{43} has the factor $1/(2^6 - 1) = \frac{1}{63}$, etc.

For $f(x) = e^{-x}$ the table of J and ϵ values is

$$\begin{array}{lllll}
J_{11} = 1.135335 & & & & \\
 & \epsilon_{21} = -0.066596 & & & \\
J_{21} = 0.935547 & & J_{22} = 0.868951 & & \\
 & \epsilon_{31} = -0.017648 & & \epsilon_{32} = -0.000266 & \\
J_{31} = 0.882604 & & J_{32} = 0.864956 & & J_{33} = 0.864690
\end{array}$$

Note that J_{33} is exact to 4D.

For $f(x) = \frac{1}{4}\pi x^4 \cos \frac{1}{4}\pi x$ the table is

$$\begin{array}{lllll}
J_{11} = 0 & & & & \\
 & \epsilon_{21} = 0.185120 & & & \\
J_{21} = 0.555360 & & J_{22} = 0.74048 & & \\
 & \epsilon_{31} = 0.168597 & & \epsilon_{32} = 0.03262 & \\
J_{31} = 1.06115 & & J_{32} = 1.22975 & & J_{33} = 1.26236 \\
 & \epsilon_{41} = 0.049142 & & \epsilon_{42} = 0.001864 & \epsilon_{43} = -0.00004 \\
J_{41} = 1.20857 & & J_{42} = 1.25771 & & J_{43} = 1.25958 \qquad J_{44} = 1.25953
\end{array}$$

Note that J_{44} is exact to 5D.

28. 0.240, which is not exact. It can be shown that the error term of the present formula is $h^3 f^{(4)}(\xi)/12$, whereas that of (15) is $h^4 f^{(5)}(\xi)/30$, where $x_2 - h < \xi < x_2 + h$. In our case this gives the exact value $0.240 + 0.016 = 0.256$ and $0.256 + 0 = 0.256$, respectively.

30. Differentiating (14) in Sec. 19.3 with respect to r and using $dr = dx/h$ we get

$$\frac{df(x)}{dr} = hf'(x) \approx \Delta f_0 + \frac{2r-1}{2!}\,\Delta^2 f_0 + \frac{3r^2 - 6r + 2}{3!}\,\Delta^3 f_0 + \cdots.$$

Now $x = x_0$ gives $r = (x - x_0)/h = 0$ and the desired formula follows.

SOLUTIONS TO CHAP. 19 REVIEW QUESTIONS AND PROBLEMS, page 830

16. $-0.35287 \cdot 10^0$, $0.12748 \cdot 10^4$, $-0.61400 \cdot 10^{-2}$, $0.24948 \cdot 10^2$, $0.33333 \cdot 10^0$, $0.12143 \cdot 10^2$

18. 8.2586, 8.258, 9.9, impossible

20. 199.98, 0.02; 199.98, 0.020002

22. $-7.9475 \leqq d \leqq -7.9365$

im19.qxd 9/21/05 1:10 PM Page 312

24. $\epsilon_r(\tilde{a}^2) = \dfrac{a^2 - \tilde{a}^2}{a^2} = \dfrac{a + \tilde{a}}{a} \cdot \dfrac{a - \tilde{a}}{a} \approx \dfrac{2a}{a} \cdot \dfrac{a - \tilde{a}}{a} = 2\epsilon_r(\tilde{a})$

26. Because $|g'(x)|$ is small (0.038) near the solution 0.739085.

28. 0.739. As mentioned before, this method is good for starting but should not be used once one is close to the solution.

30. $2 - 3x + 2x^3$ if $-1 \leqq x \leqq 1$, $1 + 3(x - 1) + 6(x - 1)^2 - (x - 1)^3$ if $1 \leqq x \leqq 3$, $23 + 15(x - 3) - (x - 3)^3$ if $3 \leqq x \leqq 5$

32. $J_{0.5} = 0.90266$, $J_{0.25} = 0.90450$, $\epsilon_{0.25} = 0.00012$

im20.qxd 9/21/05 1:21 PM Page 313

CHAPTER 20 Numeric Linear Algebra

SECTION 20.1. Linear Systems: Gauss Elimination, page 833

Purpose. To explain the Gauss elimination, which is a solution method for linear systems of equations by systematic elimination (reduction to triangular form).

Main Content, Important Concepts

Gauss elimination, back substitution

Pivot equation, pivot, choice of pivot

Operations count, order [e.g., $O(n^3)$]

Comments on Content

This section is independent of Chap. 7 on matrices (in particular, independent of Sec. 7.3, where the Gauss elimination is also considered).

Gauss's method and its variants (Sec. 20.2) are the most important solution methods for those systems (with matrices that do not have too many zeros).

The Gauss–Jordan method (Sec. 20.2) is less practical because it requires more operations than the Gauss elimination.

Cramer's rule (Sec. 7.7) would be totally impractical in numeric work, even for systems of modest size.

SOLUTIONS TO PROBLEM SET 20.1, page 839

2. $x_1 = 0.65x_2$, x_2 arbitrary. Both equations represent the same straight line.

4. $x_1 = 0$, $x_2 = -3$

6. $x_1 = (30.6 + 15.48x_2)/25.38$, x_2 arbitrary

8. No solution; the matrix obtained at the end is

$$\begin{bmatrix} 5 & 3 & 1 & 2 \\ 0 & -4 & 8 & -3 \\ 0 & 0 & 0 & 5 \end{bmatrix}.$$

10. $x_1 = 0.5$, $x_2 = -0.5$, $x_3 = 3.5$

12. $x_1 = 0.142857$, $x_2 = 0.692308$, $x_3 = -0.173913$

14. $x_1 = 1.05$, $x_2 = 0$, $x_3 = -0.45$, $x_4 = 0.5$

16. Team Project. (a) (i) $a \neq 1$ to make $D = a - 1 \neq 0$; (ii) $a = 1$, $b = 3$; (iii) $a = 1$, $b \neq 3$.

(b) $x_1 = \frac{1}{2}(3x_3 - 1)$, $x_2 = \frac{1}{2}(-5x_3 + 7)$, x_3 arbitrary is the solution of the first system. The second system has no solution.

(c) $\det \mathbf{A} = 0$ can change to $\det \mathbf{A} \neq 0$ because of roundoff.

(d) $(1 - 1/\epsilon)x_2 = 2 - 1/\epsilon$ eventually becomes $x_2/\epsilon \approx 1/\epsilon$, $x_2 = 1$, $x_1 = (1 - x_2)/\epsilon \approx 0$. The exact solution is $x_1 = 1/(1 - \epsilon)$, $x_2 = (1 - 2\epsilon)/(1 - \epsilon)$. We obtain it if we take $x_1 + x_2 = 2$ as the pivot equation.

(e) The exact solution is $x_1 = 1$, $x_2 = -4$. The 3-digit calculation gives $x_2 = -4.5$, $x_1 = 1.27$ without pivoting and $x_2 = -6$, $x_1 = 2.08$ with pivoting. This shows that

im20.qxd 9/21/05 1:21 PM Page 314

3S is simply not enough. The 4-digit calculations give $x_2 = -4.095$, $x_1 = 1.051$ without pivoting and the exact result $x_2 = -4$, $x_1 = 1$ with pivoting.

SECTION 20.2. Linear Systems: LU-Factorization, Matrix Inversion, page 840

Purpose. To discuss Doolittle's, Crout's, and Cholesky's methods, three methods for solving linear systems that are based on the idea of writing the coefficient matrix as a product of two triangular matrices ("LU-factorization"). Furthermore, we discuss matrix inversion by the Gauss–Jordan elimination.

Main Content, Important Concepts

Doolittle's and Crout's methods for arbitrary square matrices

Cholesky's method for positive definite symmetric matrices

Numerical matrix inversion

Short Courses. Doolittle's method and the Gauss–Jordan elimination.

Comment on Content

L suggests "lower triangular" and U "upper triangular." For Doolittle's method, these are the same as the matrix of the multipliers and of the triangular system in the Gauss elimination.

The point is that in the present methods, one solves one equation at a time, no systems.

SOLUTIONS TO PROBLEM SET 20.2, page 844

2. $\begin{bmatrix} 1 & 0 \\ 1.5 & 1 \end{bmatrix} \begin{bmatrix} 2 & 9 \\ 0 & -18.5 \end{bmatrix}$, $x_1 = -2$, $x_2 = 5$

4. $\begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ \frac{1}{2} & \frac{1}{2} & 1 \end{bmatrix} \begin{bmatrix} 2 & 1 & 2 \\ 0 & 3 & 3 \\ 0 & 0 & -\frac{9}{2} \end{bmatrix}$, $x_1 = 4$, $x_2 = 8$, $x_3 = -8$

6. $\begin{bmatrix} 1 & 0 & 0 \\ -1/3 & 1 & 0 \\ -2/3 & 4/5 & 1 \end{bmatrix} \begin{bmatrix} -3/2 & -7/2 & -52/5 \\ 0 & -25/6 & -1/6 \\ 0 & 0 & -21/5 \end{bmatrix}$, $x_1 = -0.2$, $x_2 = 2.4$, $x_3 = -2.8$

8. Team Project. (a) The formulas for the entries of $\mathbf{L} = [l_{jk}]$ and $\mathbf{U} = [u_{jk}]$ are

$$l_{j1} = a_{j1} \qquad j = 1, \cdots, n$$

$$u_{1k} = \frac{a_{1k}}{l_{11}} \qquad k = 2, \cdots, n$$

$$l_{jk} = a_{jk} - \sum_{s=1}^{k-1} l_{js}u_{sk} \qquad j = k, \cdots, n; \quad k \geqq 2$$

$$u_{jk} = \frac{1}{l_{jj}} \left(a_{jk} - \sum_{s=1}^{j-1} l_{js}u_{sk} \right) \qquad k = j + 1, \cdots, n; \quad j \geqq 2.$$

im20.qxd 9/21/05 1:21 PM Page 315

(b) The factorizations and solutions are

$$\begin{bmatrix} 3 & 0 \\ 15 & 1 \end{bmatrix} \begin{bmatrix} 1 & 2/3 \\ 0 & 1 \end{bmatrix}, \mathbf{y} = \begin{bmatrix} 76/15 \\ 13/10 \end{bmatrix}, \mathbf{x} = \begin{bmatrix} 4.2 \\ 1.3 \end{bmatrix}$$

and for Prob. 7

$$\begin{bmatrix} 3 & 0 & 0 \\ 18 & -6 & 0 \\ 9 & -54 & -3 \end{bmatrix} \begin{bmatrix} 1 & 3 & 2 \\ 0 & 1 & -\frac{1}{2} \\ 0 & 0 & 1 \end{bmatrix}, \mathbf{y} = \begin{bmatrix} 23/30 \\ 1/30 \\ 1/5 \end{bmatrix}, \mathbf{x} = \begin{bmatrix} -1/30 \\ 2/15 \\ 1/5 \end{bmatrix}.$$

(c) The three factorizations are

$$\begin{bmatrix} 1 & 0 & 0 \\ -4 & 1 & 0 \\ 2 & 4/3 & 1 \end{bmatrix} \begin{bmatrix} 1 & -4 & 2 \\ 0 & 9 & 12 \\ 0 & 0 & 4 \end{bmatrix} \text{ (Doolittle)}$$

$$\begin{bmatrix} 1 & 0 & 0 \\ -4 & 9 & 0 \\ 2 & 12 & 4 \end{bmatrix} \begin{bmatrix} 1 & -4 & 2 \\ 0 & 1 & 4/3 \\ 0 & 0 & 1 \end{bmatrix} \text{ (Crout)}$$

$$\begin{bmatrix} 1 & 0 & 0 \\ -4 & 3 & 0 \\ 2 & 4 & 2 \end{bmatrix} \begin{bmatrix} 1 & -4 & 2 \\ 0 & 3 & 4 \\ 0 & 0 & 2 \end{bmatrix} \text{ (Cholesky).}$$

(d) For fixing the notation, for $n = 4$ we have

$$\mathbf{A} = \mathbf{LU} = \begin{bmatrix} a_1 & c_1 & 0 & 0 \\ b_2 & a_2 & c_2 & 0 \\ 0 & b_3 & a_3 & c_3 \\ 0 & 0 & b_4 & a_4 \end{bmatrix} = \begin{bmatrix} \alpha_1 & 0 & 0 & 0 \\ b_2 & \alpha_2 & 0 & 0 \\ 0 & b_3 & \alpha_3 & 0 \\ 0 & 0 & b_4 & \alpha_4 \end{bmatrix} \begin{bmatrix} 1 & \gamma_1 & 0 & 0 \\ 0 & 1 & \gamma_2 & 0 \\ 0 & 0 & 1 & \gamma_3 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

where

$$\alpha_1 = a_1, \qquad \alpha_j = a_j - b_j\gamma_{j-l}, \qquad j = 2, \cdots, n$$
$$\gamma_1 = c_1/\alpha_1, \qquad \gamma_j = c_j/\alpha_j, \qquad j = 2, \cdots, n-1$$

(e) If **A** is symmetric

10.
$$\begin{bmatrix} 0.2 & 0 & 0 \\ 0 & 0.8 & 0 \\ 0.6 & 0.4 & 0.2 \end{bmatrix} \begin{bmatrix} 0.2 & 0 & 0.6 \\ 0 & 0.8 & 0.4 \\ 0 & 0 & 0.2 \end{bmatrix} \begin{matrix} x_1 = 5 \\ x_2 = -2.5 \\ x_3 = 10 \end{matrix}$$

12.
$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ -1 & 2 & 0 & 0 \\ 3 & -1 & 3 & 0 \\ 2 & 0 & -1 & 4 \end{bmatrix} \begin{bmatrix} 1 & -1 & 3 & 2 \\ 0 & 2 & -1 & 0 \\ 0 & 0 & 3 & -1 \\ 0 & 0 & 0 & 4 \end{bmatrix} \begin{matrix} x_1 = 4 \\ x_2 = -6 \\ x_3 = 8 \\ x_4 = -2 \end{matrix}$$

im20.qxd 9/21/05 1:21 PM Page 316

16. The inverse is

$$\tfrac{1}{9}\begin{bmatrix} 2 & -2 & 1 \\ 1 & 2 & 2 \\ 2 & 1 & -2 \end{bmatrix} = \tfrac{1}{9}\mathbf{A}^{\mathsf{T}}.$$

Hence $\frac{1}{3}\mathbf{A}$ is orthogonal.

18. The inverse is

$$\begin{bmatrix} \frac{57}{35} & -\frac{26}{35} & \frac{6}{35} \\ \frac{1}{105} & -\frac{26}{105} & -\frac{8}{105} \\ -\frac{5}{21} & \frac{4}{21} & -\frac{2}{21} \end{bmatrix}.$$

20. $\det \mathbf{A} = 0$ as given, but rounding makes $\det \mathbf{A} \neq 0$ and may completely change the situation with respect to existence of solutions of linear systems, a point to be watched for when using a CAS. In the present case we get (a) -0.00000035, (b) -0.00001998, (c) -0.00028189, (d) 0.002012, (e) 0.00020000.

SECTION 20.3. Linear Systems: Solution by Iteration, page 845

Purpose. To familiarize the student with the idea of solving linear systems by iteration, to explain in what situations that is practical, and to discuss the most important method (Gauss–Seidel iteration) and its convergence.

Main Content, Important Concepts

Distinction between direct and indirect methods

Gauss–Seidel iteration, its convergence, its range of applicability

Matrix norms

Jacobi iteration

Short Courses. Gauss–Seidel iteration only.

Comments on Content

The Jacobi iteration appeals by its simplicity but is of limited practical value.

A word on the frequently occurring sparse matrices may be good. For instance, we have about 99.5% zeros in solving the Laplace equation in two dimensions by using a 1000×1000 grid and the usual five-point pattern (Sec. 21.4).

SOLUTIONS TO PROBLEM SET 20.3, page 850

2. The eigenvalues of $\mathbf{I} - \mathbf{A}$ are 0.5, 0.5, -1. Here $\mathbf{A}$ is $\frac{1}{2}$ times the coefficient matrix of the given system; thus,

$$\mathbf{I} - \mathbf{A} = \begin{bmatrix} 0 & -\frac{1}{2} & -\frac{1}{2} \\ -\frac{1}{2} & 0 & -\frac{1}{2} \\ -\frac{1}{2} & -\frac{1}{2} & 0 \end{bmatrix}.$$

im20.qxd 9/21/05 1:21 PM Page 317

4. Row 1 becomes Row 3, Row 2 becomes Row 1, and Row 3 becomes Row 2. The exact solution is $x_1 = 0.5$, $x_2 = -2.5$, $x_3 = 4.0$. The choice of $\mathbf{x_0}$ is of much less influence than one would expect. We obtain for $\mathbf{x_0} = [0 \quad 0 \quad 0]^T$

1, [0, −1.75000, 3.89286]
2, [0.350000, −2.45715, 3.99388]
3, [0.491430, −2.49755, 3.99966]
4, [0.499510, −2.49987, 3.99998]
5, [0.499974, −2.50000, 4.00000]
6, [0.500000, −2.50000, 4.00000]

for $\mathbf{x_0} = [1 \quad 1 \quad 1]^T$

1, [−0.200000, −1.88333, 3.91190]
2, [0.376666, −2.46477, 3.99497]
3, [0.492954, −2.49798, 3.99971]
4, [0.499596, −2.49988, 3.99998]
5, [0.499976, −2.50000, 4.00000]
6, [0.500000, −2.50000, 4.00000]

for $\mathbf{x_0} = [10 \quad 10 \quad 10]^T$

1, [−2, −3.08333, 4.08333]
2, [0.616666, −2.53333, 4.00476]
3, [0.506666, −2.50190, 4.00027]
4, [0.500380, −2.50010, 4.00001]
5, [0.500020, −2.50000, 4.00000]
6, [0.500000, −2.50000, 4.00000]

and for $\mathbf{x_0} = [100 \quad 100 \quad 100]^T$

1, [−20, −15.0833, 5.79761]
2, [3.01666, −3.21905, 4.10271]
3, [0.643810, −2.54108, 4.00587]
4, [0.508216, −2.50235, 4.00034]
5, [0.500470, −2.50013, 4.00001]
6, [0.500026, −2.50000, 4.00000]

The spectral radius of $\mathbf{C}$ (and its only nonzero eigenvalue) is $2/35 = 0.057$.

6. The exact solution $\mathbf{x} = [3 \quad -9 \quad 6]^T$ is reached at Step 8 rather quickly owing to the fact that the spectral radius of $\mathbf{C}$ is 0.125, hence rather small; here

$$\mathbf{C} = \begin{bmatrix} 0 & 1/4 & 0 \\ 0 & 1/16 & 1/4 \\ 0 & 1/64 & 1/16 \end{bmatrix}.$$

im20.qxd 9/21/05 1:21 PM Page 318

8. Interchange the first equation and the last equation. Then the exact solution $-2.5, 2, 4.5$ is reached at Step 11, the spectral radius of

$$\mathbf{C}=\begin{bmatrix} 0 & -\frac{1}{4} & -\frac{1}{8} \\ 0 & \frac{1}{24} & -\frac{5}{16} \\ 0 & \frac{1}{5} & \frac{1}{10} \end{bmatrix}$$

being $1/\sqrt{15} = 0.258199$. (The eigenvalues are complex conjugates, and the third eigenvalue is 0, as always for the present **C**.)

10. In (a) we obtain

$$\begin{aligned} \mathbf{C} &= -(\mathbf{I}+\mathbf{L})^{-1}\mathbf{U} \\ &= -\begin{bmatrix} 1 & 0 & 0 \\ -0.1 & 1 & 0 \\ -0.09 & -0.1 & 1 \end{bmatrix}\begin{bmatrix} 0 & 0.1 & 0.1 \\ 0 & 0 & 0.1 \\ 0 & 0 & 0 \end{bmatrix} \\ &= \begin{bmatrix} 0 & -0.100 & -0.100 \\ 0 & 0.010 & -0.090 \\ 0 & 0.009 & 0.019 \end{bmatrix} \end{aligned}$$

and $\|\mathbf{C}\| = 0.2 < 1$ by (11), which implies convergence by (8).

In (b) we have

$$\begin{bmatrix} 1 & 1 & 10 \\ 10 & 1 & 1 \\ 1 & 10 & 1 \end{bmatrix} = (\mathbf{I}+\mathbf{L})+\mathbf{U}$$

$$= \begin{bmatrix} 1 & 0 & 0 \\ 10 & 1 & 0 \\ 1 & 10 & 1 \end{bmatrix} + \begin{bmatrix} 0 & 1 & 10 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}.$$

From this we compute

$$\mathbf{C} = -(\mathbf{I}+\mathbf{L})^{-1}\mathbf{U} = -\begin{bmatrix} 1 & 0 & 0 \\ -10 & 1 & 0 \\ 99 & -10 & 1 \end{bmatrix}\begin{bmatrix} 0 & 1 & 10 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$$

$$= -\begin{bmatrix} 0 & 1 & 10 \\ 0 & -10 & -99 \\ 0 & 99 & 980 \end{bmatrix}$$

$$= \begin{bmatrix} 0 & -1 & -10 \\ 0 & 10 & 99 \\ 0 & -99 & -980 \end{bmatrix}.$$

im20.qxd 9/21/05 1:21 PM Page 319

Developing the characteristic determinant of c by its first column, we obtain

$$-\lambda \begin{vmatrix} -\lambda + 10 & 99 \\ -99 & -\lambda - 980 \end{vmatrix} = -\lambda(\lambda^2 + 970\lambda + 1)$$

which shows that one of the eigenvalues is greater than 1 in absolute value, so that we have divergence. In fact, $\lambda = -0$, 0.001 and -970, approximately.

12. $\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 5.5 \\ -10.75 \\ 8.5 \end{bmatrix}, \begin{bmatrix} 2.5625 \\ -7.75 \\ 5.5625 \end{bmatrix}, \begin{bmatrix} 3.3125 \\ -9.21875 \\ 6.3125 \end{bmatrix}, \begin{bmatrix} 2.94531 \\ -8.84375 \\ 5.94531 \end{bmatrix}, \begin{bmatrix} 3.03906 \\ -9.02734 \\ 6.03906 \end{bmatrix}.$

Step 5 of the Gauss–Seidel iteration gives the better result

$$[2.99969 \quad -9.00015 \quad 5.99996]^T. \qquad \text{Exact: } [3 \quad -9 \quad 6]^T.$$

14. $\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \begin{bmatrix} -1.8125 \\ 2.58333 \\ 1.7 \end{bmatrix}, \begin{bmatrix} -2.29583 \\ 2.81875 \\ 3.95 \end{bmatrix}, \begin{bmatrix} -2.63594 \\ 2.14931 \\ 4.33667 \end{bmatrix}, \begin{bmatrix} -2.51691 \\ 2.07710 \\ 4.60875 \end{bmatrix}, \begin{bmatrix} -2.53287 \\ 1.96657 \\ 4.51353 \end{bmatrix}$

Step 5 of the Gauss–Seidel iteration gives the more accurate result

$$[-2.49475 \quad 1.99981 \quad 4.49580]^T. \qquad \text{Exact: } [-2.5 \quad 2 \quad 4.5]^T.$$

16. $\sqrt{193} = 13.89$, 12, 12

18. $\sqrt{151} = 12.29$, 13 (column sum norm), 11 (row sum norm)

20. $\sqrt{537} = 23.17$, 28 (column sum norm), 31 (row sum norm)

SECTION 20.4. Linear Systems: Ill-Conditioning, Norms, page 851

Purpose. To discuss ill-conditioning quantitatively in terms of norms, leading to the condition number and its role in judging the effect of inaccuracies on solutions.

Main Content, Important Concepts

Ill-conditioning, well-conditioning

Symptoms of ill-conditioning

Residual

Vector norms

Matrix norms

Condition number

Bounds for effect of inaccuracies of coefficients on solutions

Comment on Content

Reference [E9] in App. 1 gives some help when $\mathbf{A}^{-1}$, needed in $\kappa(\mathbf{A})$, is unknown (as is the case in practice).

SOLUTIONS TO PROBLEM SET 20.4, page 858

2. 9.6, $\sqrt{65.6} = 8.099$, 8, $[0.05 \quad -0.15 \quad 0 \quad 1]^T$

4. 1, 1, 1, the given vector is a unit vector.

im20.qxd 9/21/05 1:21 PM Page 320

6. 210, $\sqrt{17774} = 133.3$, 119, $[16/119 \quad 21/119 \quad 54/119 \quad -1]^T$

8. 6, $\sqrt{18}$, 3, $[1 \quad 0 \quad 0 \quad -1 \quad 0]^T$

10. $\mathbf{A}^{-1} = \begin{bmatrix} -0.2 & 0.4 \\ 0.1 & 0.3 \end{bmatrix}$, $\|\mathbf{A}\|_1 = 6$, $\|\mathbf{A}^{-1}\|_1 = 0.7$, $\kappa = 4.2$. The matrix is well-conditioned.

12. $\mathbf{A}^{-1} = \begin{bmatrix} 1/\sqrt{3} & 1 \\ 0 & -1/\sqrt{3} \end{bmatrix}$, $\kappa = (3 + \sqrt{3})(1 + 1/\sqrt{3}) = 4 + 2\sqrt{3}$

Well-conditioned.

14. **A** is the 4×4 Hilbert matrix times 21. Its inverse is

$$\mathbf{A}^{-1} = \tfrac{1}{21} \begin{bmatrix} 16 & -120 & 240 & -140 \\ -120 & 1200 & -2700 & 1680 \\ 240 & -2700 & 6480 & -4200 \\ -140 & 1680 & -4200 & 2800 \end{bmatrix}.$$

This gives the condition number (in both norms, since $\mathbf{A}$ and $\mathbf{A}^{-1}$ are symmetric)

$$\kappa = 43.75 \cdot \frac{13620}{21} = 28375.000$$

showing that **A** is very ill-conditioned.

16. $\|\mathbf{Ax}\|_\infty = 4.4 < 1.2 \cdot 5 = 6$

20. $[1 \quad 1]^T$, $[1.7 \quad 1.5]^T$, $\kappa = 289$

22. By (12), $1 = \|\mathbf{I}\| = \|\mathbf{A}\mathbf{A}^{-1}\| \leqq \|\mathbf{A}\| \ \|\mathbf{A}^{-1}\| = \kappa(\mathbf{A})$. For the Frobenius norm, $\sqrt{n} = \|\mathbf{I}\| \leqq \kappa(\mathbf{A})$.

24. **Team Project.** (a) Formula (18a) is obtained from

$$\max |x_j| \leqq \Sigma |x_k| = \|\mathbf{x}\|_1 \leqq n \max |x_j| = n\|\mathbf{x}\|_\infty.$$

Equation (18b) follows from (18a) by division by n.

(b) To get the first inequality in (19a), consider the square of both sides and then take square roots on both sides. The second inequality in (19a) follows by means of the Cauchy–Schwarz inequality and a little trick worth remembering,

$$\sum |x_j| = \sum 1 \cdot |x_j| \leqq \sqrt{\sum 1^2} \sqrt{\sum |x_j|^2} = \sqrt{n}\, \|\mathbf{x}\|_2.$$

To get (19b), divide (19a) by $\sqrt{n}$.

(c) Let $\mathbf{x} \neq \mathbf{0}$. Set $\mathbf{x} = \|\mathbf{x}\|\mathbf{y}$. Then $\|\mathbf{y}\| = \|\mathbf{x}\|/\|\mathbf{x}\| = 1$. Also,

$$\mathbf{Ax} = \mathbf{A}(\|\mathbf{x}\|\mathbf{y}) = \|\mathbf{x}\|\, \mathbf{Ay}$$

since $\|\mathbf{x}\|$ is a number. Hence $\|\mathbf{Ax}\|/\|\mathbf{x}\| = \|\mathbf{Ay}\|$, and in (9), instead of taking the maximum over *all* $\mathbf{x} \neq \mathbf{0}$, since $\|\mathbf{y}\| = 1$ we only take the maximum over all $\mathbf{y}$ of norm 1. Write $\mathbf{x}$ for $\mathbf{y}$ to get (10) from this.

(d) These "axioms of a norm" follow from (3), which are the axioms of a vector norm.

im20.qxd 9/21/05 1:21 PM Page 321

SECTION 20.5. Least Squares Method, page 859

Purpose. To explain Gauss's least squares method of "best fit" of straight lines to given data $(x_0, y_0), \cdots, (x_n, y_n)$ and its extension to best fit of quadratic polynomials, etc.

Main Content, Important Concepts

Least squares method

Normal equations (4) for straight lines

Normal equations (8) for quadratic polynomials

Short Courses. Discuss the linear case only.
Comment. Normal equations are often ***ill-conditioned,*** so that results may be sensitive to round-off. For another (theoretically much more complicated) method, see Ref. [E5], p. 201.

SOLUTIONS TO PROBLEM SET 20.5, page 862

2. The line shifts upward; its slope *decreases* slightly. If you added, say, (5, 20), the slope would *increase* slightly.

4. $U = -5.20 + 53.4i$. Estimate: $R = 53.\ 4\ \Omega$. Note that the line does not pass through the origin, as it should. This is typical.

6. $F = -0.00206 + 0.50098s$; hence $k = 0.50098$

8. $y = 0.15 - 0.55x + 2.25x^2$

10. $y = 1.790 - 0.433x + 0.105x^2$

12.
$$b_0 n + b_1\Sigma x_j + b_2\Sigma x_j^2 + b_3\Sigma x_j^3 = \Sigma y_j$$
$$b_0\Sigma x_j + b_1\Sigma x_j^2 + b_2\Sigma x_j^3 + b_3\Sigma x_j^4 = \Sigma x_j y_j$$
$$b_0\Sigma x_j^2 + b_1\Sigma x_j^3 + b_2\Sigma x_j^4 + b_3\Sigma x_j^5 = \Sigma x_j^2 y_j$$
$$b_0\Sigma x_j^3 + b_1\Sigma x_j^4 + b_2\Sigma x_j^5 + b_3\Sigma x_j^6 = \Sigma x_j^3 y_j$$

16. Team Project. (a) We substitute $F_m(x)$ into the integral and perform the square. This gives

$$\|f - F_m\|^2 = \int_a^b f^2\,dx - 2\sum_{j=0}^{m} a_j \int_a^b f y_j\,dx + \sum_{j=0}^{m}\sum_{k=0}^{m} a_j a_k \int_a^b y_j y_k\,dx.$$

This is a quadratic function in the coefficients. We take the partial derivative with respect to any one of them, call it a_l, and equate this derivative to zero. This gives

$$0 - 2\int_a^b f y_l\,dx + 2\sum_{j=0}^{m} a_j \int_a^b y_j y_l\,dx = 0.$$

Dividing by 2 and taking the first integral to the right gives the system of normal equations, with $l = 0, \cdots, m$.

(b) In the case of a polynomial we have

$$\int_a^b y_j y_l\,dx = \int_a^b x^{j+l}\,dx$$

which can be readily integrated. In particular, if $a = 0$ and $b = 1$, integration from 0 to 1 gives $1/(j + l + 1)$, and we obtain the **Hilbert matrix** as the coefficient matrix.

im20.qxd 9/21/05 1:21 PM Page 322

(c) In the case of an orthogonal system we see from (4), Sec. 5.8, with $r(x) = 1$ (as for the Legendre polynomials, or with any weight function $r(x)$ corresponding to the given system) and l instead of m that $a_l = b_l/\|y_l\|^2$.

SECTION 20.6. Matrix Eigenvalue Problems: Introduction, page 863

Purpose. This section is a collection of concepts and a handful of theorems on matrix eigenvalues and eigenvectors that are frequently needed in numerics; some of them will be discussed in the remaining sections of the chapter and others can be found in more advanced or more specialized books listed in Part E of App. 1.

The section frees both the instructor and the student from the task of locating these matters in Chaps. 7 and 8, which contain much more material and should be consulted only if problems on one or another matter are wanted (depending on the background of the student) or if a proof might be of interest.

SECTION 20.7. Inclusion of Matrix Eigenvalues, page 866

Purpose. To discuss theorems that give approximate values and error bounds of eigenvalues of general (square) matrices (Theorems 1, 2, 4, Example 2) and of special matrices (Theorem 6).

Main Content, Important Concepts

Gerschgorin's theorem (Theorem 1)

Sharpened Gerschgorin's theorem (Theorem 2)

Gerschgorin's theorem improved by similarity (Example 2)

Strict diagonal dominance (Theorem 3)

Schur's inequality (Theorem 4), normal matrices

Perron's theorem (Theorem 5)

Collatz's theorem (Theorem 6)

Short Courses. Discuss Theorems 1 and 6.

Comments on Content

It is important to emphasize that one must always make sure whether or not a thoerem applies to a given matrix. Some theorems apply to any real or complex square matrices whatsoever, whereas others are restricted to certain classes of matrices.

The exciting Gerschgorin's theorem was one of the early theorems on numerics for eigenvalues; it appeared in the *Bull. Acad. Sciences de l'URSS* (Classe mathém, 7-e série, Leningrad, 1931, p. 749), and shortly thereafter in the German *Zeitschrift für angewandte Mathematik und Mechanik.*

SOLUTIONS TO PROBLEM SET 20.7, page 871

2. 5, 8, 9, radii $2 \cdot 10^{-2}$. Estimates of this kind can be useful when a matrix has been diagonalized numerically and some very small nonzero entries are left.

4. $1 + i$, $-3 + 2i$, $4 - i$, radii 0.8, 0.4, 0.3

6. 10, 6, 3, radii 0.3, 0.1, 0.2

im20.qxd 9/21/05 1:21 PM Page 323

8. $\mathbf{T}$ with $t_{11} = t_{22} = 1$, $t = 34$ gives

$$\mathbf{T}^{-1}\mathbf{A}\mathbf{T} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \frac{1}{34} \end{bmatrix} \begin{bmatrix} 10 & 0.1 & -0.2 \\ 0.1 & 6 & 0 \\ -0.2 & 0 & 3 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 34 \end{bmatrix}$$

$$= \begin{bmatrix} 10 & 0.1 & -6.8 \\ 0.1 & 6 & 0 \\ -\frac{0.2}{34} & 0 & 3 \end{bmatrix}.$$

Note that the disk with center 3 is still disjoint from that with center 10.

10. This is a *"continuity proof."* Let $S = D_1 \cup D_2 \cup \cdots \cup D_p$ without restriction, where D_j is the Gerschgorin disk with center a_{jj}. We write $\mathbf{A} = \mathbf{B} + \mathbf{C}$, where $\mathbf{B} = \text{diag}\,(a_{jj})$ is the diagonal matrix with the main diagonal of $\mathbf{A}$ as its diagonal. We now consider

$$\mathbf{A}_t = \mathbf{B} + t\mathbf{C} \qquad \text{for } 0 \leqq t \leqq 1.$$

Then $\mathbf{A_0} = \mathbf{B}$ and $\mathbf{A_1} = \mathbf{A}$. Now by algebra, the roots of the characteristic polynomial $f_t(\lambda)$ of $\mathbf{A}_t$ (that is, the eigenvalues of $\mathbf{A}_t$) depend continuously on the coefficients of $f_t(\lambda)$, which in turn depend continuously on t. For $t = 0$ the eigenvalues are $a_{11}, \cdots, a_{nn}$. If we let t increase continuously from 0 to 1, the eigenvalues move continuously and, by Theorem 1, for each t lie in the Gerschgorin disks with centers a_{jj} and radii

$$tr_j \qquad \text{where} \qquad r_j = \sum_{k \neq j} |a_{jk}|.$$

Since at the end, S is disjoint from the other disks, the assertion follows.

12. Proofs follow readily from the definitions of these classes of matrices. This *normality* is of interest, since normal matrices have important properties; in particular, they have an orthonormal set of n eigenvectors, where n is the size of the matrix. See [B3], vol. I, pp. 268–274.

14. An example is

$$\mathbf{A} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

The eigenvalues are -1 and 1, so that the entire spectrum lies on the circle. A similar-looking 3×3 matrix or 4×4 matrix, etc., can be constructed with some or all of its eigenvalues on the circle.

16. $\sqrt{145.1} = 12.0457$

18. $\mathbf{y} = [12 \quad 13 \quad 15]^\mathsf{T}$, $[13 \quad 22 \quad 18]^\mathsf{T}$, $[25 \quad 35 \quad 33]^\mathsf{T}$. This gives the inclusion intervals for the eigenvalue of maximum absolute value

$$12 \leqq \lambda \leqq 15, \qquad 11 \leqq \lambda \leqq 18, \qquad 35/3 \leqq \lambda \leqq 33/2.$$

The eigenvalue is (4S) 13.69. The other eigenvalues are 9.489 and 6.820.

20. CAS Experiment. (a) The midpoint is an approximation for which the endpoints give error bounds.

(b) Nonmonotone behavior may occur if by chance you pick an initial vector close to an eigenvector corresponding to an eigenvalue that is not the greatest in absolute value.

im20.qxd 9/21/05 1:21 PM Page 324

SECTION 20.8. Power Method for Eigenvalues, page 872

Purpose. Explanation of the power method for determining approximations and error bounds for eigenvalues of real symmetric matrices.

Main Content, Important Concepts

Iteration process of the power method

Rayleigh quotient (the approximate value)

Improvement of convergence by a spectral shift

Scaling (for eigenvectors)

Short Courses. Omit spectral shift.

Comments on Content

The method is simple but converges slowly, in general.

Symmetry of the matrix is essential to the validity of the error bound (2). The method as such can be applied to more general matrices.

SOLUTIONS TO PROBLEM SET 20.8, page 875

2. $q = 0.8, 0.8, 0.8$; $|\epsilon| \leqq 0.6, 0.6, 0.6$. Eigenvalues -1, 1.

4. $q = 6.333, 6.871, 6.976$; $|\epsilon| \leqq 2.5, 1.3, 0.49$. Spectrum $\{-7, -3, 7\}$.

6. We obtain the following values:

Step	1	2	3	$\cdots$	10	20	50	100
$q =$	8.5	8.9938	8.9750	$\cdots$	8.5117	6.3511	-8.8546	-9.9558
$\|\epsilon\| \leqq$	2.9580	2.0876	2.2048	$\cdots$	3.6473	6.8543	4.4640	0.1085

This illustrates how the iteration begins near an eigenvector not corresponding to an eigenvalue of maximum absolute value but eventually moves away to an eigenvector of the latter. Note also that the bounds become smaller only near the end of the iteration given here. Eigenvalues (4S) -9.956, -1.558, 2.283, 9.232.

8. The eigenvalues are $\lambda = \pm 1$. Corresponding eigenvectors are

$$\mathbf{z}_1 = \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \qquad \mathbf{z}_2 = \begin{bmatrix} 1 \\ -2 \end{bmatrix}$$

and we have chosen $\mathbf{x}_0$ as

$$\mathbf{x}_0 = \begin{bmatrix} 3 \\ -1 \end{bmatrix} = \mathbf{z}_1 + \mathbf{z}_2,$$

so that

$$\mathbf{x}_1 = \mathbf{z}_1 - \mathbf{z}_2 = [1 \quad 3]^\mathsf{T}$$
$$\mathbf{x}_2 = \mathbf{z}_1 + \mathbf{z}_2 = [3 \quad -1]^\mathsf{T}$$

etc. From this,

$$\mathbf{x}_0{}^\mathsf{T}\mathbf{x}_1 = 0$$

and for the error bound we get

$$\delta = \sqrt{\frac{\mathbf{x}_1{}^\mathsf{T}\mathbf{x}_1}{\mathbf{x}_0{}^\mathsf{T}\mathbf{x}_0} - q^2} = \sqrt{\frac{10}{10} - 0} = 1,$$

im20.qxd 9/21/05 1:21 PM Page 325

and similarly in all the further steps. This shows that our error bound is the best possible in general.

10. Let $\mathbf{z}_1, \cdots, \mathbf{z}_n$ be orthonormal eigenvectors corresponding to the eigenvalues $\lambda_1, \cdots, \lambda_n$, respectively. Then for any initial vector $\mathbf{x}_0$ we have (summations from 1 to n)

$$\mathbf{x}_0 = \Sigma\, c_j \mathbf{z}_j$$
$$\mathbf{x}_1 = \Sigma\, c_j \lambda_j \mathbf{z}_j$$
$$\mathbf{x}_s = \Sigma\, c_j \lambda_j^s \mathbf{z}_j$$
$$\mathbf{x}_{s+1} = \Sigma\, c_j \lambda_j^{s+1} \mathbf{z}_j$$

and, using the last step, for the Rayleigh quotient

$$q = \frac{\mathbf{x}_{s+1}^{\mathsf{T}} \mathbf{x}_s}{\mathbf{x}_s^{\mathsf{T}} \mathbf{x}_s} = \frac{\Sigma\, c_j^2 \lambda_j^{2s+1}}{\Sigma\, c_j^2 \lambda_j^{2s}} \approx \lambda_m$$

where λ_m is of maximum absolute value, and the quality of the approximation increases with increasing number of steps s. Here we have to assume that $c_m \neq 0$, that is, that not just by chance we picked an $\mathbf{x}_0$ orthogonal to the eigenvector $\mathbf{z}_m$ of λ_m. The chance that this happens is practically zero, but should it occur, then rounding will bring in a component in the direction of $\mathbf{z}_m$ and one should eventually expect good approximations, although perhaps only after a great number of steps.

12. CAS Experiment. (a) We obtain

16, 41.2, 34.64, 32.888, 32.317, 32.116, 32.043, 32.0158, 32.0059, 32.0022,

etc. The spectrum is $\{32, 12, 8\}$. Eigenvectors are $[3 \quad 6 \quad -7]^{\mathsf{T}}$, $[1 \quad 0 \quad -1]^{\mathsf{T}}$, $[3 \quad -2 \quad 1]^{\mathsf{T}}$.

(b) For instance, for $\mathbf{A} - 10\mathbf{I}$ we get

$$q = 6, \quad 22.5, \quad 22.166, \quad 22.007, \quad 22.00137,$$

etc. Whereas for $\mathbf{A}$ the ratio of eigenvalues is 32/12, for $\mathbf{A} - 10\mathbf{I}$ we have the spectrum $\{22, 2, -2\}$, hence the ratio 22/2. This explains the improvement of convergence.

(d) $\mathbf{A}$ in (a) provides an example,

q	16	41.2	34.64	32.888	32.317
δ	59	5.5	1.45	0.557	0.225

etc. Also $\mathbf{A} - 10\mathbf{I}$ does,

q	6	22.5	22.166	22.007	22.00137
δ	59	3.0	0.072	0.023	0.00055

Further examples can easily be found. For instance, the matrix

$$\begin{bmatrix} -2 & 12 \\ 1 & -1 \end{bmatrix}$$

has the spectrum $\{-5, 2\}$, but we obtain, with $\mathbf{x}_0 = [1 \quad 1]^{\mathsf{T}}$,

q	5	-7	-4.3208	-5.2969
δ	5	2	0.37736	0.2006

etc.

im20.qxd 9/21/05 1:21 PM Page 326

SECTION 20.9. Tridiagonalization and QR-Factorization, page 875

Purpose. Explanation of an optimal method for determining the whole spectrum of a real symmetric matrix by first reducing the matrix to a tridiagonal matrix with the same spectrum and then applying the QR-method, an iteration in which each step consists of a factorization (5) and a multiplication.

Comment on Content

The $n - 2$ Householder steps ($n \times n$ the size of the matrix) correspond to similarity transformations; hence the spectrum is preserved. The same holds for QR. But we can perform any number of QR steps, depending on the desired accuracy.

SOLUTIONS TO PROBLEM SET 20.9, page 882

2. Householder gives

$$\begin{bmatrix} 0 & -\sqrt{2} & 0 \\ -\sqrt{2} & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix}.$$

Hence -1 is an eigenvalue. The other eigenvalues, -1 and 2, are now obtained by solving the remaining quadratic characteristic equation.

4. By Householder's method we obtain

$$\begin{bmatrix} 8 & -8.48528 & 0 & 0 \\ -8.48528 & 10 & -2.82843 & 0 \\ 0 & -2.82843 & 0 & 0 \\ 0 & 0 & 0 & 2 \end{bmatrix}$$

We see that 2 is an eigenvalue. The others are 0, 8, 18, unknown in practice, and approximations can be obtained by the QR-method applied to the left upper 3×3 principal submatrix.

6. The matrices **B** in the first three steps are

$$\begin{bmatrix} 1.29252 & -0.294200 & 0 \\ -0.294200 & 0.840232 & 0.125969 \\ 0 & 0.125969 & 0.207245 \end{bmatrix}$$

$$\begin{bmatrix} 1.397577 & -0.169658 & 0 \\ -0.169658 & 0.760770 & 0.030349 \\ 0 & 0.030349 & 0.181653 \end{bmatrix}$$

$$\begin{bmatrix} 1.42892 & -0.0886236 & 0 \\ -0.0886236 & 0.730977 & 0.00743888 \\ 0 & 0.00743888 & 0.180102 \end{bmatrix}$$

im20.qxd 9/21/05 1:21 PM Page 327

The eigenvalues are 1.44, 0.72, 0.18 (exactly). The present calculations were done with 10S and then rounded in the result to 6S, and similarly for the other odd- and even-numbered problems because rounding errors tended to accumulate.

8. QR gives the matrices **B** as follows.

$$\begin{bmatrix} 16.2005 & -0.0265747 & 0 \\ -0.0265747 & -4.30089 & 0.190694 \\ 0 & 0.190694 & 4.10043 \end{bmatrix}$$

$$\begin{bmatrix} 16.2005 & -0.00706202 & 0 \\ -0.00706202 & -4.30131 & 0.181822 \\ 0 & 0.181822 & 4.10083 \end{bmatrix}$$

$$\begin{bmatrix} 16.2005 & -0.00187668 & 0 \\ -0.00187668 & -4.30167 & 0.173362 \\ 0 & 0.173362 & 4.10118 \end{bmatrix}$$

6S-values of the eigenvalues are 16.2005, −4.30525, and 4.10476. Hence the diagonal entries are more accurate than one would expect by looking at the size of the off-diagonal entries.

SOLUTIONS TO CHAP. 20 REVIEW QUESTIONS AND PROBLEMS, page 883

16. $[3.9 \quad 4.3 \quad 1.8]^T$

18. $[3 \quad 3x_3 + 2 \quad x_3]^T$, x_3 arbitrary, or $[3 \quad t \quad \frac{1}{3}(t-2)]$, t arbitrary

20. All nonzero entries of the triangular matrices are 1.

22. The inverse matrix is

$$\begin{bmatrix} 0 & -4 & 2 \\ 1 & 1 & -1 \\ -2 & 4 & 0 \end{bmatrix}.$$

24. The inverse matrix is (5S)

$$\begin{bmatrix} 0.21239 & -0.035398 & -0.026549 \\ -0.035398 & 0.17257 & 0.0044248 \\ -0.026549 & 0.0044248 & 0.12832 \end{bmatrix}.$$

26. Exact solution 1.6, 0.9, 3.2. The iteration gives the vectors

$$\begin{bmatrix} 1.625 \\ 0.35 \\ 3.20625 \end{bmatrix}, \quad \begin{bmatrix} 1.4625 \\ 0.90156 \\ 3.16562 \end{bmatrix}, \quad \begin{bmatrix} 1.60039 \\ 0.89141 \\ 3.20010 \end{bmatrix}.$$

28. 22, $\sqrt{194}$, 11

30. 1, 1, 1

im20.qxd 9/21/05 1:21 PM Page 328

32. 2.5, $\sqrt{2.45}$, 1.4

34. This is the row "sum" norm, equal to 20.

36. $4.5 \cdot 6 = 27$, which is rather large

38. $9 \cdot 0.274336 = 2.46902$

40. $\Sigma x_j = 15$, $\Sigma x_j^2 = 55$, $\Sigma x_j^3 = 225$, $\Sigma x_j^4 = 979$, $\Sigma y_j = 30$, $\Sigma x_j y_j = 86$, $\Sigma x_j^2 y_j = 320$; hence the normal equations are

$$\begin{aligned} 5b_0 + \ 15b_1 + \ 55b_2 &= \ 30 \\ 15b_0 + \ 55b_1 + 225b_2 &= \ 86 \\ 55b_0 + 225b_1 + 979b_2 &= 320. \end{aligned}$$

Solving by Gauss, we get $b_0 = 14.2$, $b_1 = -6.4$, $b_2 = 1$. Hence the *answer* is

$$y = 14.2 - 6.4x + x^2.$$

42. By Gerschgorin's theorem, the disks have

center 1.5,	radius 3
center 3.5	radius 3.5
center 9.0	radius 2.5.

The eigenvalues are (4D)

$$0.2635, \quad 4.0768, \quad 9.6597.$$

44. $q_1 = 23/3$, $|\epsilon_1| \leqq 0.95$; $q_2 = 7.88$, $|\epsilon_2| \leqq 0.82$, $q_3 = 8.04$, $|\epsilon_3| \leqq 0.70$, $q_4 = 8.15$, $|\epsilon_4| \leqq 0.58$ (2D)

The eigenvalues of the matrix are (5S)

$$8.3429, \quad 6.4707, \quad 4.1864.$$

im21.qxd 9/21/05 1:41 PM Page 329

CHAPTER 21 Numerics for ODEs and PDEs

Major Changes

These include automatic variable step size selection in modern codes, the discussion of the Runge–Kutta–Fehlberg method, backward Euler's method and its application to stiff ODEs, and the extension of Euler and Runge–Kutta methods to systems and higher order equations.

SECTION 21.1. Methods for First-Order ODEs, page 886

Purpose. To explain three numerical methods for solving initial value problems $y' = f(x, y)$, $y(x_0) = y_0$ by stepwise computing approximations to the solution at $x_1 = x_0 + h$, $x_2 = x_0 + 2h$, etc.

Main Content, Important Concepts

Euler's method (3)

Automatic variable step size selection

Improved Euler method (8), Table 21.2

Classical Runge–Kutta method (Table 21.4)

Error and step size control

Runge–Kutta–Fehlberg method

Backward Euler's method

Stiff ODEs

Comments on Content

Euler's method is good for explaining the principle but is too crude to be of practical value.

The improved Euler method is a simple case of a predictor–corrector method.

The classical Runge–Kutta method is of order h^4 and is of great practical importance.

Principles for a good choice of h are important in any method.

f in the equation must be such that the problem has a unique solution (see Sec. 1.7).

SOLUTIONS TO PROBLEM SET 21.1, page 897

2. $y = e^x$. Computed values are

x_n	y_n	$y(x_n)$	Error	Error in Prob. 1
0.01	1.010000	1.010050	0.000050	
0.02	1.020100	1.020201	0.000101	
0.03	1.030301	1.030455	0.000154	
0.04	1.040604	1.040811	0.000207	
0.05	1.051010	1.051271	0.000261	
0.06	1.061520	1.061837	0.000317	
0.07	1.072135	1.072508	0.000373	
0.08	1.082857	1.083287	0.000430	
0.09	1.093685	1.094174	0.000489	
0.10	1.104622	1.105171	0.000549	0.005171

im21.qxd 9/21/05 1:41 PM Page 330

We see that the error of the last value has decreased by a factor 10, owing to the smaller step.

In most cases the method will be too inaccurate.

4. This is a special Riccati equation. Set $y + x = u$, then $u' = u^2 + 1$ and

$$u'/(u^2 + 1) = 1.$$

By integration, $\arctan u = x + c$ and

$$u = \tan(x + c) = y + x$$

so that

$$y = \tan(x + c) - x$$

and $c = 0$ from the initial condition. Hence $y = \tan x - x$. The calculation is

x_n	y_n	$y(x_n)$	Error
0.1	0.000000	0.000335	0.000335
0.2	0.001000	0.002710	0.001710
0.3	0.005040	0.009336	0.004296
0.4	0.014345	0.022793	0.008448
0.5	0.031513	0.046302	0.014789
0.6	0.059764	0.084137	0.024373
0.7	0.103292	0.142288	0.038996
0.8	0.167820	0.289639	0.061818
0.9	0.261488	0.360158	0.098670
1.0	0.396393	0.557408	0.161014

Although the ODE is similar to that in Prob. 3, the error is greater by about a factor 10. This is understandable because $\tan x$ becomes infinite as $x \to \frac{1}{2}\pi$.

6. The solution is $y = 1/(1 + 4e^{-x})$. The 10S-computation, rounded to 6D, gives

x_n	y_n	$y(x_n)$	Error $y(x_n) - y_n$
0.1	0.216467	0.216481	0.000014
0.2	0.233895	0.233922	0.000027
0.3	0.252274	0.252317	0.000043
0.4	0.271587	0.271645	0.000058
0.5	0.291802	0.291875	0.000073
0.6	0.312876	0.312965	0.000089
0.7	0.334754	0.334858	0.000104
0.8	0.357366	0.357485	0.000119
0.9	0.380633	0.380767	0.000134
1.0	0.404462	0.404609	0.000147

8. The solution is $y = 3\cos x - 2\cos^2 x$. The 10S-computation rounded to 6D gives

x_n	y_n	$y(x_n)$	Error $y(x_n) - y_n$
0.1	1.00492	1.00494	0.00002
0.2	1.01900	1.01914	0.00014
0.3	1.04033	1.04068	0.00035
0.4	1.06583	1.06647	0.00064
0.5	1.09140	1.09245	0.00105

(continued)

im21.qxd 9/21/05 1:41 PM Page 331

x_n	y_n	$y(x_n)$	Error $y(x_n) - y_n$
0.6	1.11209	1.11365	0.00156
0.7	1.12237	1.12456	0.00219
0.8	1.11636	1.11932	0.00296
0.9	1.08817	1.09203	0.00386
1.0	1.03212	1.03706	0.00494

10. The solution is $y = 2 \tanh \frac{1}{2}x$. The 10S-computation rounded to 6D gives

x_n	y_n	$y(x_n)$	Error $y(x_n) - y_n$
0.1	0.099875	0.099917	0.000042
0.2	0.199252	0.199336	0.000084
0.3	0.297644	0.297770	0.000126
0.4	0.394582	0.394750	0.000168
0.5	0.489626	0.489838	0.000212
0.6	0.582372	0.582626	0.000254
0.7	0.672455	0.672752	0.000297
0.8	0.759561	0.759898	0.000337
0.9	0.843421	0.843798	0.000377
1.0	0.923819	0.924234	0.000415

The error is growing relatively slowly, because the solution itself remains less than 2.

12. The solution is $y = 1/(1 + 4e^{-x})$. The computation is

x_n	y_n	Error $y(x_n) - y_n$
0.1	0.2164806848	$0.043 \cdot 10^{-7}$
0.2	0.2339223328	$0.085 \cdot 10^{-7}$
0.3	0.2523167036	$0.128 \cdot 10^{-7}$
0.4	0.2716446148	$0.170 \cdot 10^{-7}$
0.5	0.2918751118	$0.209 \cdot 10^{-7}$
0.6	0.3129648704	$0.249 \cdot 10^{-7}$
0.7	0.3348578890	$0.284 \cdot 10^{-7}$
0.8	0.3574855192	$0.318 \cdot 10^{-7}$
0.9	0.3807668746	$0.346 \cdot 10^{-7}$
1.0	0.4046096381	$0.370 \cdot 10^{-7}$

To apply (10), we need the calculation of five steps with $h = 0.2$. We obtain (the third column would not be needed)

x_n	y_n	Error $y(x_n) - y_n$
0.2	0.2339222103	$1.310 \cdot 10^{-7}$
0.4	0.2716443697	$2.621 \cdot 10^{-7}$
0.6	0.3129645099	$3.854 \cdot 10^{-7}$
0.8	0.3574850569	$4.941 \cdot 10^{-7}$
1.0	0.4046090919	$5.832 \cdot 10^{-7}$

Hence the required error estimate is

$$(0.4046096381 - 0.4046090919)/15 = 0.364 \cdot 10^{-7}.$$

The actual error is $0.370 \cdot 10^{-7}$; the estimate is closer than one can expect in general.

im21.qxd 9/21/05 1:41 PM Page 332

14. The solution is $y = \sqrt{4x - x^2}$; thus $(x - 2)^2 + y^2 = 4$ (see Example 6 in Sec. 1.3 with $c = 4$). The computation with RK gives

x_n	y_n	Error $y(x_n) - y_n$
2.0	2.000000000	0
2.2	1.989975031	$-0.157 \cdot 10^{-6}$
2.4	1.959592041	$-0.247 \cdot 10^{-6}$
2.6	1.907878667	$-0.264 \cdot 10^{-6}$
2.8	1.833030447	$-0.169 \cdot 10^{-6}$
3.0	1.732050655	$+0.153 \cdot 10^{-6}$
3.2	1.599998963	$0.1037 \cdot 10^{-5}$
3.4	1.428281966	$0.3720 \cdot 10^{-5}$
3.6	1.199985280	0.000014720
3.8	0.8716743295	+0.0001054592
4.0	0.0977998883	−0.0977998883

A graph shows that these values lie on the corresponding quarter-circle within the accuracy of graphing and that they are irregularly spaced as the x-values suggest.

16. The solution is $y = 3 \cos x - 2 \cos^2 x$. The computation gives

x_n	y_n	Error $y(x_n) - y_n$	Error in Prob. 15
0.2	1.019137566	$0.1173 \cdot 10^{-5}$	$0.74 \cdot 10^{-7}$
0.4	1.066471079	$0.5194 \cdot 10^{-5}$	$0.328 \cdot 10^{-6}$
0.6	1.113634713	$0.14378 \cdot 10^{-4}$	$0.904 \cdot 10^{-6}$
0.8	1.119282901	$0.36749 \cdot 10^{-4}$	$0.2277 \cdot 10^{-5}$
1.0	1.036951866	$0.101888 \cdot 10^{-3}$	$0.6142 \cdot 10^{-5}$

Note that the ratio of the errors is about the same for all x_n, about 2^4.

18. From $y' = x + y$ and the given formula we get, with $h = 0.2$,

$$
\begin{aligned}
k_1 &= 0.2(x_n + y_n) \\
k_2 &= 0.2[x_n + 0.1 + y_n + 0.1(x_n + y_n)] \\
&= 0.2[1.1(x_n + y_n) + 0.1] \\
k_3^* &= 0.2[x_n + 0.2 + y_n - 0.2(x_n + y_n) + 0.4[1.1(x_n + y_n) + 0.1]] \\
&= 0.2[1.24(x_n + y_n) + 0.24]
\end{aligned}
$$

and from this

$$y_{n+1} = y_n + \tfrac{1}{6}[1.328(x_n + y_n) + 0.128].$$

The computed values are

x_n	y_n	Error
0.0	0.000 000	0.000 000
0.2	0.021 333	0.000 067
0.4	0.091 655	0.000 165
0.6	0.221 808	0.000 312
0.8	0.425 035	0.000 505
1.0	0.717 509	0.000 771

im21.qxd 9/21/05 1:41 PM Page 333

20. CAS Experiment. (b) The computation is

x_n	y_n	Error Estimate (10) · 10^9	Error · 10^9
0.1	1.2003346725	3.0	−0.4
0.2	1.4027100374	3.7	−1.9
0.3	1.6093362546	5.9	−5.0
0.4	1.8227932298	9.4	−11.0
0.5	2.0463025124	13.1	−22.5

0.8	2.8296387346	−38.8	−177.6
0.9	3.1601585865	−191.1	−369.0
1.0	3.5574085377	−699.9	−813.0

SECTION 21.2. Multistep Methods, page 898

Purpose. To explain the idea of a multistep method in terms of the practically important Adams–Moulton method, a predictor–corrector method that in each computation uses four preceding values.

Main Content, Important Concepts

Adams–Bashforth method (5)

Adams–Moulton method (7)

Self-starting and not self-starting

Numerical stability, fair comparison

Short Courses. This section may be omitted.

SOLUTIONS TO PROBLEM SET 21.2, page 901

2. The computation with the use of the given starting values is as follows. The exact solution is $y = e^x$.

n	x_n	Starting y_n	Predicted y_n^*	Corrected y_n	Exact
0	0.0	1.000 000			
1	0.1	1.105 171			
2	0.2	1.221 403			
3	0.3	1.349 859			
4	0.4		1.491 821	1.491 825	1.491 825
5	0.5		1.648 717	1.648 722	1.648 721
6	0.6		1.822 114	1.822 120	1.822 119
7	0.7		2.013 748	2.013 754	2.013 753
8	0.8		2.225 536	2.225 543	2.225 541
9	0.9		2.459 598	2.459 605	2.459 603
10	1.0		2.718 277	2.718 285	2.718 282

im21.qxd 9/21/05 1:41 PM Page 334

4. The solution is $y = e^{x^2}$. The computation gives

x_n	y_n	Error $\cdot 10^6$
0.4	1.173518	−7
0.5	1.284044	−19
0.6	1.433364	−35
0.7	1.632374	−59
0.8	1.896572	−92
0.9	2.248046	−139
1.0	2.718486	−205

6. The comparison shows that in the present case, RK is better. The comparison is fair since we have four evaluations per step for RK, but only two for AM. The errors are:

x	0.4	0.6	0.8	1.0
AM	$-0.7 \cdot 10^{-5}$	$-3.5 \cdot 10^{-5}$	$-9.2 \cdot 10^{-5}$	$-20.5 \cdot 10^{-5}$
RK	$0.1 \cdot 10^{-5}$	$0.8 \cdot 10^{-5}$	$4.0 \cdot 10^{-5}$	$17.5 \cdot 10^{-5}$

8. The solution is $y^2 - x^2 = 8$. Computation gives:

x_n	y_n	Error $\cdot 10^6$
1.2	3.07246	−0.02
1.4	3.15595	−0.04
1.6	3.24962	−0.06
1.8	3.35261	−0.8
2.0	3.46410	−1.3
2.2	3.58330	−1.6
2.4	3.70945	−1.7
2.6	3.84188	−1.7
2.8	3.97995	−1.6
3.0	4.12311	−1.5

10. The solution is $y = \frac{1}{2} \tanh 2x$. Computation gives:

x_n	y_n	Exact	Error $\cdot 10^6$
0.1	0.98686	0.098688	1
0.2	0.189971	0.189974	3
0.3	0.268519	0.268525	6
0.4	0.332007	0.332018	11
0.5	0.380726	0.380797	71
0.6	0.416701	0.416828	127
0.7	0.442532	0.442676	144
0.8	0.460706	0.460834	128
0.9	0.473306	0.473403	97
1.0	0.481949	0.482014	65

im21.qxd 9/21/05 1:41 PM Page 335

14. $y = e^{x^2}$. Some of the values and errors are:

x_n	y_n ($h = 0.05$)	Error $\cdot 10^6$	y_n ($h = 0.1$)	Error $\cdot 10^6$
0.1	1.010050		1.01005	
0.2	1.040817	−6	1.040811	
0.3	1.094188	−14	1.094224	−50
0.4	1.173535	−24	1.173623	−112
0.5	1.284064	−38	1.284219	−194
0.6	1.433388	−58	1.433636	−307
0.7	1.632404	−87	1.632782	−466
0.8	1.896612	−131	1.897175	−694
0.9	2.248105	−197	2.248931	−1023
1.0	2.718579	−297	2.719785	−1503

The errors differ by a factor 4 to 5, approximately.

SECTION 21.3. Methods for Systems and Higher Order ODEs, page 902

Purpose. Extension of the methods in Sec. 21.1 to first-order systems and to higher order ODEs.

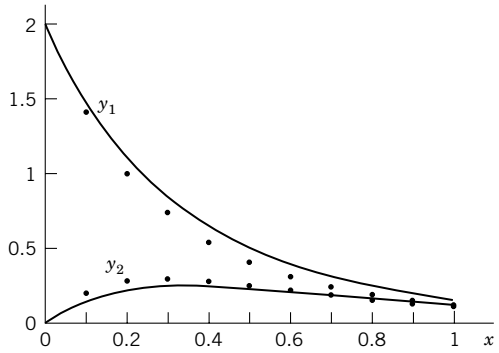
Content

Euler's method for systems (5)

Classical Runge–Kutta method extended to systems (6)

Runge–Kutta–Nyström method (7)

Short Courses. Discuss merely Runge–Kutta (6), which shows that this "vectorial extension" of the method is conceptually quite simple.



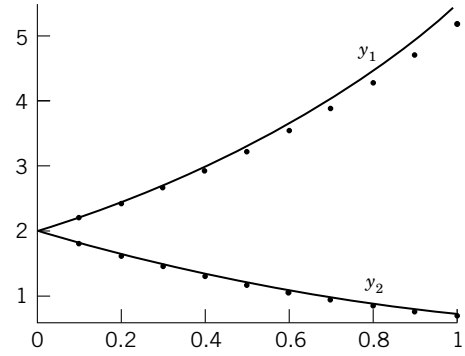
SOLUTIONS TO PROBLEM SET 21.3, page 908

2. The solution is $y_1 = e^{-2x} + e^{-4x}$, $y_2 = e^{-2x} - e^{-4x}$. The computation is

x_n	$y_{1,n}$	Error	$y_{2,n}$	Error
0.1	1.4	0.0890	0.2	−0.0516
0.2	1.00	0.1196	0.28	−0.0590
0.3	0.728	0.1220	0.296	−0.0484
0.4	0.5392	0.1120	0.2800	−0.0326
0.5	0.4054	0.0978	0.2499	−0.0174

The figure shows (for $x = 0, \cdots, 1$) that these values give a qualitatively correct impression, although they are rather inaccurate. Note that the error of y_1 is not monotone.

im21.qxd 9/21/05 1:41 PM Page 336

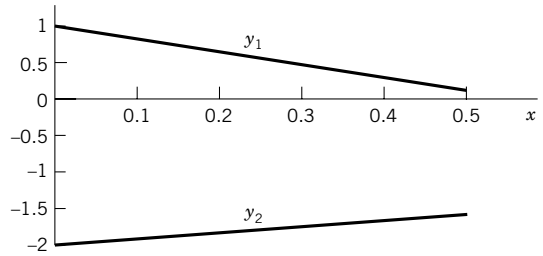


Section 21.3. Solution curves and computed values in Problem 2

4. Solution $y_1 = 2e^x$, $y_2 = 2e^{-x}$ (see also Example 3 in Sec. 4.3). The computation is

x_n	$y_{1,n}$	Error	$y_{2,n}$	Error
0.1	2.2	0.0104	1.8	0.0097
0.2	2.42	0.0228	1.62	0.0175
0.3	2.662	0.0378	1.458	0.0236
0.4	2.9282	0.0554	1.3122	0.0284
0.5	3.2210	0.0764	1.1810	0.0321
0.6	3.5431	0.1011	1.0629	0.0347
0.7	3.8974	0.1302	0.95659	0.03659
0.8	4.2872	0.1638	0.86093	0.03773
0.9	4.7159	0.2033	0.77484	0.03830
1.0	5.1875	0.2491	0.69736	0.03840

The figure illustrates that the error of y_1 is monotone increasing and is positive (the points lie below that curve), and similarly for y_2.

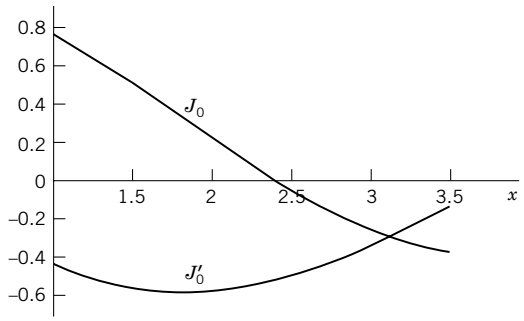


Section 21.3. Solution curves and computed values (the dots) in Problem 4

6. The system is $y_1' = y_2$, $y_2' = y_1 + x$, $y_1(0) = 1$, $y_2(0) = -2$. The exact solution is $y = y_1 = e^{-x} - x$; hence $y' = y_2 = -e^{-x} - 1$. The computation is

im21.qxd 9/21/05 1:41 PM Page 337

x_n	$y_{1,n}$	Error	$y_{2,n}$	Error
0.1	0.8	0.0048	−1.9	−0.0048
0.2	0.61	0.0087	−1.81	−0.0087
0.3	0.429	0.0118	−1.729	−0.0118
0.4	0.2561	0.0142	−1.6561	−0.0142
0.5	0.0905	0.0160	−1.5905	−0.0160



Section 21.3. Solution curves in Problem 6. Computed values lie practically on the curves.

10. The error has decreased by about a factor 10^5. The computation is:

x_n	$y_{1,n}$	Error · 10^6	$y_{2,n}$	Error · 10^6
0.1	0.804837500	−0.082	−1.90483750	0.08
0.2	0.618730902	−0.15	−1.81873090	0.15
0.3	0.440818422	−0.20	−1.74081842	0.20
0.4	0.270320289	−0.24	−1.67032029	0.24
0.5	0.106530935	−0.27	−1.60653093	0.27

12. Division by x gives $y'' + y'/x + y = 0$. The system is $y_1' = y_2$, $y_2' = y'' = -y_2/x - y_1$. Because of the factor $1/x$ we have to choose $x_0 \neq 0$. The computation gives, with the initial values taken from Ref. [GR1] in App. 1:

x_n	$J_0(x_n)$	$J_0'(x_n)$	10^6 · Error of $J_0(x_n)$
1	0.765198	−0.440051	0
1.5	0.511903	−0.558002	−76
2	0.224008	−0.576897	−117
2.5	−0.048289	−0.497386	−95
3	−0.260055	−0.339446	+3
3.5	−0.380298	−0.137795	170

Section 21.3. Solution curves in Problem 12. Computed values lie practically on the curves.

im21.qxd 9/21/05 1:41 PM Page 338

14. The error is reduced very substantially, by about a factor 1000. The computation is:

x_n	$y_{1,n}$	Error $\cdot 10^4$	$y_{2,n}$	Error $\cdot 10^4$
0.1	1.489133	−0.82	0.148333	0.78
0.2	1.119760	−1.11	0.220888	1.03
0.3	0.850119	−1.13	0.247515	1.03
0.4	0.651327	−1.02	0.247342	0.90
0.5	0.503301	−0.87	0.232469	0.75

16.

x_n	y_n	k_1	k_2	k_3	k_4	$10^6 \cdot$ Error of y_n
1.0	0.765 198	−0.081 287	−0.056 989	−0.061 848	−0.034 604	0
1.5	0.511 819	−0.034 970	−0.007 296	−0.011 250	+0.015 740	+9
2.0	+0.223 946	+0.016 098	+0.041 840	+0.038 979	0.061 098	−55
2.5	−0.048 241	0.061 767	0.080 770	0.079 042	0.092 562	−143
3.0	−0.259 845	0.093 218	0.102 154	0.101 466	0.104 389	−207
3.5	−0.379 914					−214

In the present case the errors of the two methods are of the same order of magnitude. An exact comparison is not possible, since the errors change sign in a different fashion in each method.

18. This gives the second solution ($y = x \ln x + 1$) in Example 3 of Sec. 5.4, which has a logarithmic term. (The first solution is $y = x$.) For RKN we write the ODE as

$$y'' = (x^2 - x)^{-1}(xy' - y).$$

We choose $x_0 = 1/2$, between the critical points 0 and 1, and restrict the computation to four steps, to avoid reaching $x = 1$. The computation is:

x_n	y_n	y_n'	$10^5 \cdot$ Error of y_n
0.5	0.653426	0.306853	0
0.6	0.693512	0.489173	−0.8
0.7	0.750337	0.643313	−0.9
0.8	0.821492	0.776823	−0.7
0.9	0.905188	0.894503	−1.3

20. CAS Experiment. (b) A general answer seems difficult to give, since the form of the coefficients, their variability, and other general properties are essential.

(c) Elimination of the first derivative tends to complicate the ODE, so that one may lose more than gain in using the simpler algorithm.

SECTION 21.4. Methods for Elliptic PDEs, page 909

Purpose. To explain numerical methods for the Dirichlet problem involving the Laplace equation, the typical representative of elliptic PDEs.

Main Content, Important Concepts

Elliptic, parabolic, hyperbolic equations

Dirichlet, Neumann, mixed problems

Difference analogs (7), (8) of Poisson's and Laplace's equations

im21.qxd 9/21/05 1:41 PM Page 339

Coefficient scheme (9)

Liebmann's method of solution (identical with Gauss–Seidel, Sec. 20.3)

Peaceman–Rachford's ADI method (15)

Short Courses. Omit the ADI method.

Comments on Content

Neumann's problem and the mixed problem follow in the next section, including the modification in the case of irregular boundaries.

The distinction between the three kinds of PDEs (elliptic, parabolic, hyperbolic) is not merely a formal matter because the solutions of the three types behave differently in principle, and the boundary and initial conditions are different; this necessitates different numerical methods, as we shall see.

SOLUTIONS TO PROBLEM SET 21.4, page 916

2. Gauss gives the values of the exact solution $u(x, y) = x^3 - 3xy^2$. Gauss–Seidel needs about 10 steps for producing 5S-values:

n	u_{11}	u_{21}	u_{12}	u_{22}
1	50.25	44.062	31.062	5.031
2	19.031	12.516	−0.4845	−10.742
3	3.2579	4.6290	−8.3710	−14.686
4	−0.6855	2.6571	−10.343	−15.672
5	−1.6715	2.1641	−10.836	−15.918
6	−1.9180	2.0410	−10.959	−15.980
7	−1.9795	2.0101	−10.990	−15.995
8	−1.9950	2.0025	−10.998	−15.999
9	−1.9989	2.0005	−11.000	−16.000
10	−1.9999	2.0000	−11.000	−16.000

It is interesting that it takes only 4 or 5 steps to turn the values away from the starting values to values that are already relatively close to the respective limits.

4. The values of the exact solution of the Laplace equation are

$$u(1, 1) = -4, \qquad u(2, 1) = u(1, 2) = -7, \qquad u(2, 2) = -64.$$

Gauss gives -2, -5, -5, -62. Corresponding errors are -2, -2, -2, -2. Gauss–Seidel needs about 10 steps for producing 5S-values:

n	u_{11}	u_{21}	u_{12}	u_{22}
1	50.50	48.625	48.625	−35.188
2	24.812	8.4060	8.4060	−55.297
3	4.7030	−1.648	−1.648	−60.324
4	−0.32400	−4.162	−4.162	−61.581
5	−1.5810	−4.790	−4.790	−61.895
6	−1.8950	−4.948	−4.948	−61.974
7	−1.9740	−4.987	−4.987	−61.994
8	−1.9935	−4.997	−4.997	−61.998
9	−1.9985	−4.999	−4.999	−62.000
10	−1.9995	−5.000	−5.000	−62.000

im21.qxd 9/21/05 1:41 PM Page 340

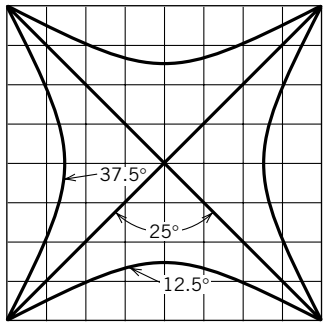
6. 165, 165, 165, 165 by Gauss. The Gauss–Seidel computation gives

n	u_{11}	u_{21}	u_{12}	u_{22}
1	132.50	140.62	140.62	152.81
2	152.81	158.90	158.90	161.95
3	161.95	163.48	163.48	164.24
4	164.24	164.62	164.62	164.81
5	164.81	164.90	164.90	164.95
6	164.95	164.98	164.98	164.99
7	164.99	165.00	165.00	165.00
8	165.00	165.00	165.00	165.00

8. 6 steps. Some results are

[93.75 90.625 65.625 64.0625] (Step 2)

[87.8906 87.6953 62.6953 62.5976] (Step 4)



[87.5244 87.5122 62.5122 62.5061] (Step 6)

[87.5001 87.5000 62.5000 62.5000] (Step 10)

10. $u_{11} = 92.86$, $u_{21} = 90.18$, $u_{12} = 81.25$, $u_{22} = 75.00$, $u_{13} = 57.14$, $u_{23} = 47.32$, $u_{31} = u_{11}$, etc., by symmetry.

12. All the isotherms must begin and end at a corner. The diagonals are isotherms $u = 25$, because of the data obtained and for reasons of symmetry. Hence we obtain a qualitative picture as the figure shows.

In Prob. 7 the situation is similar.

Section 21.4. Problem 12

14. This shows the importance of good starting values; it then does not take long until the approximations come close to the solution. A rule of thumb is to take a rough estimate of the average of the boundary values at the points that enter the linear system. By starting from **0** we obtain

[0.09472 0.10148 0.31798 0.32136] (Step 3)

[0.10740 0.10782 0.32432 0.32454] (Step 5).

16. ***Step 1.*** First come ***rows*** $j = 1$, $j = 2$; for these, (14a) is

im21.qxd 9/21/05 1:41 PM Page 341

$$
\begin{aligned}
j = 1, \quad i = 1. \qquad & u_{01} - 4u_{11} + u_{21} = -u_{10} - u_{12} \\
i = 2. \qquad & u_{11} - 4u_{21} + u_{31} = -u_{20} - u_{22} \\
j = 2, \quad i = 1. \qquad & u_{02} - 4u_{12} + u_{22} = -u_{11} - u_{13} \\
i = 2. \qquad & u_{12} - 4u_{22} + u_{32} = -u_{21} - u_{23}.
\end{aligned}
$$

Six of the boundary values are zero, and the two on the upper edge are

$$u_{13} = u_{23} = \sqrt{3}/2 = 0.866\,025.$$

Also, on the right we substitute the starting values 0. With this, our four equations become

$$
\begin{aligned}
-4u_{11} + u_{21} &= 0 \\
u_{11} - 4u_{21} &= 0 \\
-4u_{12} + u_{22} &= -0.866\,025 \\
u_{12} - 4u_{22} &= -0.866\,025.
\end{aligned}
$$

From the first two equations,

$$u_{11} = 0, \qquad u_{21} = 0$$

and from the other two equations,

$$u_{12} = 0.288\,675, \qquad u_{22} = 0.288\,675.$$

Step 1. Now come ***columns;*** for these, (14b) is

$$
\begin{aligned}
i = 1, \quad j = 1. \qquad & u_{10} - 4u_{11} + u_{12} = -u_{01} - u_{21} \\
j = 2. \qquad & u_{11} - 4u_{12} + u_{13} = -u_{02} - u_{22} \\
i = 2, \quad j = 1. \qquad & u_{20} - 4u_{21} + u_{22} = -u_{11} - u_{31} \\
j = 2. \qquad & u_{21} - 4u_{22} + u_{23} = -u_{12} - u_{32}.
\end{aligned}
$$

With the boundary values and the previous solution ***on the right***, this becomes

$$
\begin{aligned}
-4u_{11} + u_{12} &= 0 \\
u_{11} - 4u_{12} &= -0.866\,025 - 0.288\,675 \\
-4u_{21} + u_{22} &= 0 \\
u_{21} - 4u_{22} &= -0.866\,025 - 0.288\,675.
\end{aligned}
$$

The solution is

$$
\begin{aligned}
u_{11} &= 0.076\,98 \\
u_{21} &= 0.076\,98 \\
u_{12} &= 0.307\,92 \\
u_{22} &= 0.307\,92.
\end{aligned}
$$

Step 2. Rows. We can use the previous equations, changing only the right sides:

$$
\begin{aligned}
-4u_{11} + u_{21} &= -0.307\,92 \\
u_{11} - 4u_{21} &= -0.307\,92 \\
-4u_{12} + u_{22} &= -0.866\,025 - 0.076\,98 \\
u_{12} - 4u_{22} &= -0.866\,025 - 0.076\,98
\end{aligned}
$$

im21.qxd 9/21/05 1:41 PM Page 342

Solution:

$$u_{11} = u_{21} = 0.102\,640, \qquad u_{12} = u_{22} = 0.314\,335.$$

Step 2. Columns. The equations with the new right sides are

$$\begin{aligned} -4u_{11} + u_{12} &= -0.102\,640 \\ u_{11} - 4u_{12} &= -0.866\,025 - 0.314\,335 \\ -4u_{21} + u_{22} &= -0.102\,640 \\ u_{21} - 4u_{22} &= -0.866\,025 - 0.314\,335. \end{aligned}$$

Final result (solution of these equations):

$$\begin{aligned} u_{11} &= 0.106\,061 \\ u_{21} &= 0.106\,061 \\ u_{12} &= 0.321\,605 \\ u_{22} &= 0.321\,605. \end{aligned}$$

Exact 3D values:

$$u_{11} = u_{21} = 0.108, \qquad u_{12} = u_{22} = 0.325.$$

18. CAS Project. (b) The solution of the linear system (rounded to integers), with the values arranged as the points in the *xy*-plane, is

160	170	157	110
138	145	125	75
138	145	125	75
160	170	157	110

Twenty steps gave accuracies of 3S–5S, with slight variations between the components of the output vector.

SECTION 21.5. Neumann and Mixed Problems. Irregular Boundary, page 917

Purpose. Continuing our discussion of elliptic PDEs, we explain the ideas needed for handling Neumann and mixed problems and the modifications required when the domain is no longer a rectangle.

Main Content, Important Concepts

Mixed problem for a Poisson equation (Example 1)

Modified stencil (6) (notation in Fig. 459)

Comments on Content

Neumann's problem can be handled as explained in Example 1 on the mixed problem.

In all the cases of an elliptic PDE we need only *one* boundary condition at each point (given u or given u_n).

SOLUTIONS TO PROBLEM SET 21.5, page 921

6. $0 = u_{01,x} = \dfrac{1}{2h}(u_{11} - u_{-1,1})$ gives $u_{-1,1} = u_{11}$. Similarly, $u_{41} = u_{21} + 3$ from the condition on the right edge, so that the equations are

im21.qxd 9/21/05 1:41 PM Page 343

$$
\begin{aligned}
-4u_{01} + 2u_{11} &= 1 \\
u_{01} - 4u_{11} + u_{21} &= -0.25 + 0.75 = 0.5 \\
u_{11} - 4u_{21} + u_{31} &= -1 \\
2u_{21} - 4u_{31} &= -2.25 - 1.25 - 3 = -6.5.
\end{aligned}
$$

$u_{01} = -0.25$, $u_{11} = 0$, $u_{21} = 0.75$, $u_{31} = 2$; this agrees with the values of the exact solution $u(x, y) = x^2 - y^2$ of the problem.

8. The exact solution of the Poisson equation is $u = x^2y^2$. The approximate solution results from $\mathbf{Au} = \mathbf{b}$, where

$$
\mathbf{A} = \begin{bmatrix} -4 & 1 & 0 & 1 & 0 & 0 \\ 1 & -4 & 1 & 0 & 1 & 0 \\ 0 & 2 & -4 & 0 & 0 & 1 \\ 1 & 0 & 0 & -4 & 1 & 0 \\ 0 & 1 & 0 & 1 & -4 & 1 \\ 0 & 0 & 1 & 0 & 2 & -4 \end{bmatrix}, \qquad \mathbf{b} = \begin{bmatrix} 4 \\ 10 \\ 8 \\ 1 \\ -20 \\ -103 \end{bmatrix}
$$

where the six equations correspond to P_{11}, P_{21}, P_{31}, P_{12}, P_{22}, P_{32}, in our usual order. The components of $\mathbf{b}$ are of the form $a - c$ with a resulting from $2(x^2 + y^2)$ and c from the boundary values; thus, $4 - 0 = 4$, $10 - 0 = 10$, $20 - 12 = 8$, $10 - 9 = 1$, $16 - 36 = -20$, $26 - 81 - 48 = -103$. The solution of this system agrees with the values obtained at the P_{jk} from the exact solution, $u_{11} = 1$, $u_{21} = u_{12} = 4$, $u_{22} = 16$, and $u_{31} = 9$, $u_{32} = 36$ on the boundary. $u_{41} = u_{21} + 12$ and $u_{42} = u_{22} + 48$ produced entries 2 in $\mathbf{A}$ and -12 and -48 in $\mathbf{b}$.

10. Exact solution $u = 9y \sin \frac{1}{3}\pi x$. Linear system $\mathbf{Au} = \mathbf{b}$, where

$$
\mathbf{A} = \begin{bmatrix} -4 & 1 & 1 & 0 & 0 & 0 \\ 1 & -4 & 0 & 1 & 0 & 0 \\ 1 & 0 & -4 & 1 & 1 & 0 \\ 0 & 1 & 1 & -4 & 0 & 1 \\ 0 & 0 & 2 & 0 & -4 & 1 \\ 0 & 0 & 0 & 2 & 1 & -4 \end{bmatrix}, \qquad \mathbf{b} = \begin{bmatrix} a \\ a \\ 2a \\ 2a \\ 3a + c \\ 3a + c \end{bmatrix}
$$

$a = -8.54733$, $c = -\sqrt{243} = -15.5885$. The solution of this system is (exact values of u in parentheses)

$$
\begin{aligned}
u_{11} = u_{21} &= 8.46365 \quad (\text{exact } \tfrac{9}{2}\sqrt{3} = 7.79423) \\
u_{12} = u_{22} &= 16.8436 \quad (\text{exact } 9\sqrt{3} = 15.5885) \\
u_{13} = u_{23} &= 24.9726 \quad (\text{exact } \tfrac{27}{2}\sqrt{3} = 23.3827).
\end{aligned}
$$

12. Let v denote the unknown boundary potential. Then v occurs in $\mathbf{Au} = \mathbf{b}$, where

$$
\mathbf{A} = \begin{bmatrix} -4 & 1 & 1 & 0 \\ 1 & -4 & 0 & 1 \\ 1 & 0 & -4 & 1 \\ 0 & \frac{2}{3} & \frac{2}{3} & -4 \end{bmatrix}, \qquad \mathbf{b} = \begin{bmatrix} 0 \\ -v \\ -v \\ -\frac{8}{3}v \end{bmatrix}.
$$

im21.qxd 9/21/05 1:41 PM Page 344

The solution of this linear system is $\mathbf{u} = \frac{v}{19}[5 \quad 10 \quad 10 \quad 16]^T$. From this and $5v/19 = 100$ (the potential at P_{11}) we have $v = 380$ V as the constant boundary potential on the indicated portion of the boundary.

14. Two equations are as usual:

$$\begin{aligned} -4u_{11} + u_{21} + u_{12} - 2 &= 2 \\ u_{11} - 4u_{21} - 0.5 &= 2 \end{aligned}$$

where the right side is due to the fact that we are dealing with the Poisson equation. The third equation results from (6) with $a = p = q = 1$ and $b = 1/2$. We get

$$2\left[\frac{u_{22}}{2} + \frac{u_{1,5/2}}{3/4} + \frac{u_{02}}{2} + \frac{u_{11}}{3/2} - \frac{3/2}{1/2}u_{12}\right] = 2.$$

The first two terms are zero and $u_{02} = -2$; these are given boundary values. There remains

$$\tfrac{2}{3}u_{11} - 3u_{12} = 1 + 1 = 2.$$

Our three equations for the three unknowns have the solution

$$u_{11} = -1.5, \qquad u_{21} = -1, \qquad u_{12} = -1.$$

SECTION 21.6. Methods for Parabolic PDEs, page 922

Purpose. To show the numerical solution of the heat equation, the prototype of a parabolic equation, on the region given by $0 \leqq x \leqq 1$, $t \geqq 0$, subject to one initial condition (initial temperature) and one boundary condition on each of the two vertical boundaries.

Content

Direct method based on (5), convergence condition (6)

Crank–Nicolson method based on (8)

Special case (9) of (8)

Comment on Content

Condition (6) restricts the size of time steps too much, a disadvantage that the Crank–Nicolson method avoids.

SOLUTIONS TO PROBLEM SET 21.6, page 927

4. 0, 0.6625, 1.25, 1.7125, 2, 2.1, 2, 1.7125, 1.25, 0.6625, 0

6. Note that $h = 0.2$ and $k = 0.01$ gives $r = 0.25$. The computation gives

t	$x = 0.2$	$x = 0.4$	$x = 0.6$	$x = 0.8$
0.00	0.2	0.4	0.4	0.2
0.01	0.2	0.35	0.35	0.2
0.02	0.1875	0.3125	0.3125	0.185
0.03	0.171875	0.281250	0.281250	0.171875
0.04	0.156250	0.253906	0.253906	0.156250
0.05	0.141602	0.229492	0.229492	0.141602

0.08	0.104905	0.169755	0.169755	0.104905

im21.qxd 9/21/05 1:41 PM Page 345

8. We have $k = 0.01$. The boundary condition on the left is that the normal derivative is zero. Now if we were at an inner point, we would have, by (5),

$$u_{0,j+1} = \tfrac{1}{4}u_{-1,j} + \tfrac{1}{2}u_{0j} + \tfrac{1}{4}u_{1j}.$$

Here, by the central difference formula for the normal derivative (partial derivative with respect to x) we get

$$0 = \frac{\partial u_{0j}}{\partial x} = \frac{1}{2h}(u_{1j} - u_{-1,j})$$

so that the previous formula gives what we need,

$$u_{0,j+1} = \tfrac{1}{2}(u_{0j} + u_{1j}).$$

The underlying idea is quite similar to that in Sec. 21.5. The computation gives

t	$x = 0$	$x = 0.2$	$x = 0.4$	$x = 0.6$	$x = 0.8$	$x = 1$
0	0	0	0	0	0	0

14. We need the matrix

$$\mathbf{A} = \begin{bmatrix} 4 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 4 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 4 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 4 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 4 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 4 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 4 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 4 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 4 \end{bmatrix}.$$

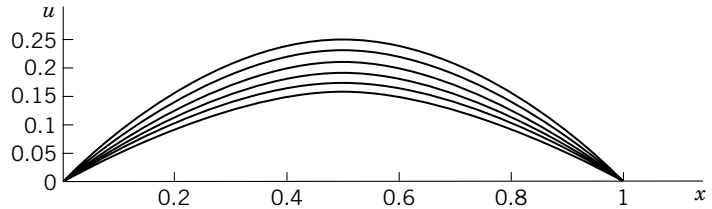
3S-values computed by Crank–Nicolson for $x = 0.1$ (and 0.9), 0.2 (and 0.8), 0.3 (and 0.7), 0.4 (and 0.6), 0.5 and $t = 0.01, 0.02, \cdots, 0.05$ are

0.0754	0.141	0.190	0.220	0.230
0.0669	0.126	0.172	0.201	0.210
0.0600	0.114	0.156	0.183	0.192
0.0541	0.103	0.141	0.166	0.174
0.0490	0.093	0.128	0.150	0.158

5S-values for $t = 0.04$ are

0.054120 0.10277 0.14117 0.16568 0.17409.

The corresponding values in Prob. 13 are



0.10182 0.16727.

Exact 5S-values computed by (9) and (10) in Sec. 12.5 (two nonzero terms suffice) are

0.053947 0.10245 0.14074 0.16519 0.17359.

We see that the present values are better than those in Prob. 13.

im21.qxd 9/21/05 1:41 PM Page 347

Section 21.6. $u(x, t)$ for constant $t = 0.01, \cdots, 0.05$ as polygons with the Crank–Nicolson values as vertices in Problem 14

SECTION 21.7. Method for Hyperbolic PDEs, page 928

Purpose. Explanation of the numerical solution of the wave equation, the prototype of a hyperbolic PDE, on a region of the same type as in the last section, subject to initial and boundary conditions that guarantee the uniqueness of the solution.

Comments on Content

We now have two initial conditions (given initial displacement and given initial velocity), in contrast to the heat equation in the last section, where we had only one initial condition.

The computation by (6) is simple. Formula (8) gives the values of the first time-step in terms of the initial data.

SOLUTIONS TO PROBLEM SET 21.7, page 930

2. Note that the curve of $f(x)$ is no longer symmetric with respect to $x = 0.5$. The solution was required for $0 \leqq t \leqq 1$. We present it here for a full cycle $0 \leqq t \leqq 2$:

t	$x = 0.2$	$x = 0.4$	$x = 0.6$	$x = 0.8$
0	0.032	0.096	0.144	0.128
0.2	0.048	0.088	0.112	0.072
0.4	0.056	0.064	0.016	−0.016
0.6	0.016	−0.016	−0.064	−0.056
0.8	−0.072	−0.112	−0.088	−0.048
1.0	−0.128	−0.144	−0.096	−0.032
1.2	−0.072	−0.112	−0.088	−0.048
1.4	0.016	−0.016	−0.064	−0.056
1.6	0.056	0.064	0.016	−0.016
1.8	0.048	0.088	0.112	0.072
2.0	0.032	0.096	0.144	0.128

4. By (13), Sec. 12.4, with $c = 1$ the left side of (6) is

(A) $$u_{i,j+1} = u(ih, (j+1)h) = \tfrac{1}{2}[f(ih + (j+1)h) + f(ih - (j+1)h)]$$

and the right side is the sum of the six terms

$$u_{i-1,j} = \tfrac{1}{2}[f((i-1)h + jh) + f((i-1)h - jh)],$$
$$u_{i+1,j} = \tfrac{1}{2}[f(i+1)h + jh) + f((i+1)h - jh)],$$
$$-u_{i,j-1} = -\tfrac{1}{2}[f(ih + (j-1)h) + f(ih - (j-1)h].$$

Four of these six terms cancel in pairs, and the remaining expression equals the right side of (A).

im21.qxd 9/21/05 1:41 PM Page 348

6. From (12), Sec. 12.4, with $c = 1$ we get the exact solution

$$u(x, t) = \frac{1}{2} \int_{x-ct}^{x+ct} \sin \pi s \, ds = \frac{1}{2\pi} [\cos \pi(x - ct) - \cos \pi(x + ct)].$$

From (8) we have $kg_i = 0.1g_i = 0.1 \sin 0.1\pi i$. Because of the symmetry with respect to $x = 0.5$ we need to list only the following values (with the exact values in parentheses):

t	$x = 0.1$	$x = 0.2$	$x = 0.3$	$x = 0.4$	$x = 0.5$
0.0	0	0	0	0	0
0.1	0.030902	0.058779	0.080902	0.095106	0.100000
	(0.030396)	(0.057816)	(0.079577)	(0.093549)	(0.098363)
0.2	0.058779	0.111804	0.153885	0.180902	0.190212
	(0.057816)	(0.109973)	(0.151365)	(0.177941)	(0.187098)
0.3	0.080902	0.153884	0.211803	0.248990	0.261803
	(0.079577)	(0.151365)	(0.208337)	(0.244914)	(0.257518)
0.4	0.095106	0.180902	0.248990	0.292705	0.307768
	(0.093549)	(0.177941)	(0.244914)	(0.287914)	(0.302731)

8. Since $u(x, 0) = f(x)$, the derivation is immediate. Formula (8) results if the integral equals $2kg_i$.

10. Exact solution: $u(x, t) = (x + t)^2$. The values obtained in the computation are those of the exact solution. $u_{11}, u_{21}, u_{31}, u_{41}$ are obtained from (8) and the initial conditions $u_{i0} = (0.2i)^2$, $g_i = 0.2i$. In connection with the left boundary condition we can use the central difference formula

$$\frac{1}{2h} (u_{1,j} - u_{-1,j}) \approx u_x(0, jk) = 2jk$$

to obtain $u_{-1,j}$ and then (8) to compute u_{01} and (6) to compute $u_{0,j+1}$.

1.0	2.3346	0.3837

This illustrates again that the method is too inaccurate for most practical purposes.

im21.qxd 9/21/05 1:41 PM Page 349

18. $y = \tan x - x + 4$; $y = 4$, 4.002707, 4.022789, 4.084133, 4.229637, 4.557352, 5.370923, 8.341089. For $x \leqq 1.0$ the error is of the order 10^{-5}, but then $\epsilon(1.2) = 10^{-3}$, $\epsilon(1.4) = 0.06$ since we are getting close to $\pi/2$.

20. (a) 0.1, 0.2034, 0.3109, 0,4217, 0.5348, 0.6494, 0.7649, 0.8806, error 0.0044, 0.0122, $\cdots$, 0.0527. (b) 0.2055, 0.4276, 0.6587, 0.8924, error 0.0101, 0.0221, 0.0322, 0.0409. (c) 0.4352, 0.9074, error 0.0145, 0.0258

22. $y = \tan x - x$. The computation is:

x_n	y_n	Error $\cdot 10^5$
0.2	0.00270741	0.26
0.4	0.0227890	0.40
0.6	0.0841334	0.34
0.8	0.229637	0.24
1.0	0.557352	5.6

24. $y_1 = 0.021400$ (starting value), $y_2 = 0.092322$, $y_3 = 0.223342$, $y_4 = 0.427788$, $y_5 = 0.721945$. This shows that the method is rather inaccurate, the error of y_5 being 0.003663. Exact: $y = e^x - x - 1$.

26. $y = \sin x$. The computation is:

x_n	y_n	Error $\cdot 10^5$
0.2	0.198667	0.2
0.4	0.389413	0.5
0.6	0.564635	0.7
0.8	0.717347	0.9
1.0	0.841461	1.0

28. The solution is $y_1 = 3e^{-2x} - e^{-8x}$, $y_2 = 3e^{-2x} + e^{-8x}$. The computation gives:

x_n	$y_{1,n}$	Error	$y_{2,n}$	Error
0.1	2.00447	0.00239	2.90793	−0.00241
0.2	1.80691	0.00215	2.21504	−0.00218
0.3	1.55427	0.00145	1.73863	−0.00147
0.4	1.30636	0.00087	1.38965	−0.00090
0.5	1.08484	0.00048	1.12247	−0.00051

30. $u(P_{11}) = u(P_{22}) = u(P_{33}) = 35$, $u(P_{21}) = u(P_{32}) = 20$, $u(P_{31}) = 10$, $u(P_{12}) = u(P_{23}) = 50$, $u(P_{13}) = 60$

32. $u(P_{21}) = 500$, $u(P_{22}) = 200$, $u = 100$ at all other gridpoints

36. From the 3D-values given below we see that at each point $x > 0$ the temperature oscillates with a phase lag and a maximum amplitude that decreases with decreasing x.

im21.qxd 9/21/05 1:41 PM Page 350

CHAPTER 22 Unconstrained Optimization. Linear Programming

SECTION 22.1. Basic Concepts. Unconstrained Optimization, page 936

Purpose. To explain the concepts needed throughout this chapter. To discuss Cauchy's method of steepest descent or gradient method, a popular method of unconstrained optimization.

Main Content, Important Concepts

Objective function

Control variables

Constraints, unconstrained optimization

Cauchy's method

SOLUTIONS TO PROBLEM SET 22.1, page 939

2. The line of approach is tangent to a particular curve C: $f(\mathbf{x}) = const$, the point of contact P giving the minimum, whereas the next gradient of C at P is perpendicular to C.

4. $f(\mathbf{x}) = (x_1 - 0.5)^2 + 2(x_2 - 1.5)^2 - 4.75$. The computation gives:

Step	x_1	x_2	$f(\mathbf{x})$
1	0.25342	1.5206	−4.6884
2	0.49351	1.4805	−4.7492
3	0.49680	1.5003	−4.7500

6. $f(\mathbf{x}) = (x_1 + 4)^2 + 0.1(x_2 + 5)^2 + 4$. The computation gives:

Step	x_1	x_2	$f(\mathbf{x})$
1	−4.0240	−1.4016	5.2958
2	−3.7933	−4.8622	4.0449
3	−4.0008	−4.8760	4.0015
4	−3.9929	−4.9952	4.0000
5	−4.0000	−4.9957	4.0000
6	−3.9997	−5.0000	4.0000
7	−4.0000	−5.0000	4.0000

8. The calculation gives for Steps 1−5:

x_1	x_2	$f(\mathbf{x})$
−1.33333	2.66667	−5.3334
−3.55556	−1.77778	9.4815
2.37037	−4.74074	−16.8560
6.32099	3.16049	29.9662
−4.21399	8.42798	−53.2731

im22.qxd 9/21/05 1:53 PM Page 352

This is the beginning of a broken line of segments spiraling away from the origin. At the corner points, f is alternatingly positive and negative and increases monotone in absolute value.

10. $f(\mathbf{x}) = x_1^2 - x_2$ gives

$$\mathbf{z}(t) = \mathbf{x} - t[2x_1, -1] = [(1 - 2t)x_1, x_2 + t],$$

hence

$$g(t) = (1 - 2t)^2 x_1^2 - x_2 - t,$$
$$g'(t) = -4(1 - 2t)x_1^2 - 1 = 0.$$

From this,

$$1 - 2t = -\frac{1}{4x_1^2}, \qquad t = \frac{1}{2} + \frac{1}{8x_1^2}.$$

For this t,

$$\mathbf{z}(t) = \left[-\frac{1}{4x_1}, x_2 + \frac{1}{2} + \frac{1}{8x_1^2}\right].$$

From this, with $x_1 = 1$, $x_2 = 1$, we get successively

$$\mathbf{z}_{(1)} = \left[-\tfrac{1}{4}, \quad 1 + \tfrac{1}{2} + \tfrac{1}{8}\right]^\mathsf{T}$$
$$\mathbf{z}_{(2)} = \left[1, \quad 1 + 2 \cdot \tfrac{1}{2} + \tfrac{1}{8} + 2\right]^\mathsf{T}$$
$$\mathbf{z}_{(3)} = \left[-\tfrac{1}{4}, \quad 1 + 3 \cdot \tfrac{1}{2} + 2 \cdot \tfrac{1}{8} + 2\right]^\mathsf{T} \qquad \text{etc.}$$

The student should sketch this, to see that it is reasonable. The process continues indefinitely, as had to be expected.

12. CAS Experiment. (c) For $f(\mathbf{x}) = x_1^2 + x_2^4$ the values converge relatively rapidly to $[0 \quad 0]^\mathsf{T}$, and similarly for $f(\mathbf{x}) = x_1^4 + x_2^4$.

SECTION 22.2. Linear Programming, page 939

Purpose. To discuss the basic ideas of linear programming in terms of very simple examples involving two variables, so that the situation can be handled graphically and the solution can be found geometrically. To prepare conceptually for the case of three or more variables $x_1, \cdots, x_n$.

Main Content, Important Concepts

Linear programming problem

Its normal form. Slack variables

Feasible solution, basic feasible solution

Optimal solution

Comments on Content

Whereas the function to be maximized (or minimized) by Cauchy's method was arbitrary (differentiable), but we had no constraints, we now simply have a linear objective function, but constraints, so that calculus no longer helps.

No systematic method of solution is discussed in this section; these follow in the next sections.

im22.qxd 9/21/05 1:53 PM Page 353

SOLUTIONS TO PROBLEM SET 22.2, page 943

2. No. For instance, $f = 5x_1 + 2x_2$ gives maximum profit $f = 12$ for every point on the segment AB because AB has the same slope as $f = const$ does.

4. Nonnegativity is an immediate consequence of the definition of a slack variable. We need as many slack variables as we have inequalities that we want to convert into equations, with each one giving one of the constraints.

8. Ordinarily a vertex of a region is the intersection of only *two* straight lines given by inequalities taken with the equality sign. Here, (5, 4) is the intersection of *three* such lines. This may merit special attention in some cases, as we discuss in Sec. 22.4.

10. The first inequality could be dropped from the problem because it does not restrict the region determined by the other inequalities. Note that that region is unbounded (stretches to infinity). This would cause a problem in maximizing an objective function with positive coefficients.

12. $f_{\max} = -18$ at every point of the segment with endpoints (2/9, 28/9) and (4, 5)

14. $f_{\min} = f(3/7, 24/7) = 78/7 = 11.14$

16. $f = x_1 + x_2$, $2x_1 + 3x_2 \leqq 1200$, $4x_1 + 2x_2 \leqq 1600$, $x_1 = 300$, $x_2 = 200$, $f_{\max} = f(300, 200) = 500$

18. x_1 = Number of days of operation of Kiln I, x_2 = Number of days of operation of Kiln II. Objective function $f = 400x_1 + 600x_2$. Constraints:

$$\begin{aligned} 3000x_1 + 2000x_2 &\geqq 18000 \quad \text{(Gray bricks)} \\ 2000x_1 + 5000x_2 &\geqq 34000 \quad \text{(Red bricks)} \\ 300x_1 + 1500x_2 &\geqq 9000 \quad \text{(Glazed bricks).} \end{aligned}$$

$f_{\min} = f(2, 6) = 4400$, as can be seen from a sketch of the region in the x_1x_2-plane resulting from the constraints in the first quadrant. Operate Kiln I two days and Kiln II six days in filling that order. Note that the region determined by the constraints in the first quadrant of the x_1x_2-plane is unbounded, which causes no difficulty because we minimize (not maximize) the objective function.

20. x_1 units of A and x_2 units of B cost $f = 1.8x_1 + 2.1x_2$. Constraints are

$$\begin{aligned} 15x_1 + 30x_2 &\geqq 150 \quad \text{(Protein)} \\ 600x_1 + 500x_2 &\geqq 3900 \quad \text{(Calories).} \end{aligned}$$

From a sketch of the region we see that $f_{\min} = f(4, 3) = 13.50$. Hence the minimum-cost diet consists of 4 units A and 3 units B.

SECTION 22.3. Simplex Method, page 944

Purpose. To discuss the standard method of linear programming for systematically finding an optimal solution by a finite sequence of transformations of matrices.

Main Content, Important Concepts

Normal form of the problem

Initial simplex table (initial augmented matrix)

Pivoting, further simplex tables (augmented matrices)

im22.qxd 9/21/05 1:53 PM Page 354

Comment on Concepts and Method

The given form of the problem involves inequalities. By introducing slack variables we convert the problem to the normal form. This is a linear system of equations. The initial simplex table is its augmented matrix. It is transformed by first selecting the column of a pivot and then the row of that pivot. The rules for this are entirely different from those for pivoting in connection with solving a linear system of equations. The selection of a pivot is followed by a process of elimination by row operations similar to that in the Gauss–Jordan method (Sec. 7.8). This is the first step, leading to another simplex table (another augmented matrix). The next step is done by the same rules, and so on. The process comes to an end when the first row of the simplex table obtained contains no more negative entries. From this final simplex table one can read the optimal solution of the problem because the first row corresponds to the objective function $f(x)$ to be maximized (or minimized).

SOLUTIONS TO PROBLEM SET 22.3, page 946

2. From the given data we have the augmented matrix (the initial simplex table)

$$\mathbf{T_0} = \begin{bmatrix} 1 & -1 & -1 & 0 & 0 & 0 \\ 0 & 2 & 3 & 1 & 0 & 1200 \\ 0 & 4 & 2 & 0 & 1 & 1600 \end{bmatrix}.$$

The pivot is 4 since $1600/4 < 1200/2$. The indicated calculations give

$$\mathbf{T_1} = \begin{bmatrix} 1 & 0 & -\frac{1}{2} & 0 & \frac{1}{4} & 400 \\ 0 & 0 & 2 & 1 & -\frac{1}{2} & 400 \\ 0 & 4 & 2 & 0 & 1 & 1600 \end{bmatrix} \begin{matrix} \text{Row 1} + \frac{1}{4}\,\text{Row 3} \\ \text{Row 2} - \frac{2}{4}\,\text{Row 3} \\ \text{Row 3.} \end{matrix}$$

The pivot is 2 in Row 2. The indicated calculations give

$$\mathbf{T_2} = \begin{bmatrix} 1 & 0 & 0 & \frac{1}{4} & \frac{1}{8} & 500 \\ 0 & 0 & 2 & 1 & -\frac{1}{2} & 400 \\ 0 & 4 & 0 & -1 & \frac{3}{2} & 1200 \end{bmatrix} \begin{matrix} \text{Row 1} + \frac{1}{4}\,\text{Row 2} \\ \text{Row 2} \\ \text{Row 3} - \frac{2}{2}\,\text{Row 2.} \end{matrix}$$

This shows that the solution is

$$f\left(\frac{1200}{4}, \frac{400}{2}\right) = 500.$$

4. From the given data we obtain the augmented matrix

$$\mathbf{T_0} = \begin{bmatrix} 1 & -2 & -3 & -1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 1 & 0 & 0 & 4.8 \\ 0 & 10 & 0 & 1 & 0 & 1 & 0 & 9.9 \\ 0 & 0 & 1 & -1 & 0 & 0 & 1 & 0.2 \end{bmatrix}.$$

im22.qxd 9/21/05 1:53 PM Page 355

The pivot is 10. The indicated calculations give

$$\mathbf{T}_1 = \begin{bmatrix} 1 & 0 & -3 & -\frac{4}{5} & 0 & \frac{1}{5} & 0 & 1.98 \\ 0 & 0 & 1 & \frac{9}{10} & 1 & -\frac{1}{10} & 0 & 3.81 \\ 0 & 10 & 0 & 1 & 0 & 1 & 0 & 9.9 \\ 0 & 0 & 1 & -1 & 0 & 0 & 1 & 0.2 \end{bmatrix} \begin{matrix} \text{Row 1} + \frac{2}{10}\,\text{Row 3} \\ \text{Row 2} - \frac{1}{10}\,\text{Row 3} \\ \text{Row 3} \\ \text{Row 4} \end{matrix}$$

The next pivot is 1 in Row 4 and Column 3. The indicated calculations give

$$\mathbf{T}_2 = \begin{bmatrix} 1 & 0 & 0 & -\frac{19}{5} & 0 & \frac{1}{5} & 3 & 2.58 \\ 0 & 0 & 0 & \frac{19}{10} & 1 & -\frac{1}{10} & -1 & 3.61 \\ 0 & 10 & 0 & 1 & 0 & 1 & 0 & 9.9 \\ 0 & 0 & 1 & -1 & 0 & 0 & 1 & 0.2 \end{bmatrix} \begin{matrix} \text{Row 1} + 3\,\text{Row 4} \\ \text{Row 2} - \text{Row 4} \\ \text{Row 3} \\ \text{Row 4} \end{matrix}$$

The last pivot needed is 19/10 in Row 2 and Column 4. We obtain

$$\mathbf{T}_3 = \begin{bmatrix} 1 & 0 & 0 & 0 & 2 & 0 & 1 & 9.8 \\ 0 & 0 & 0 & \frac{19}{10} & 1 & -\frac{1}{10} & -1 & 3.61 \\ 0 & 10 & 0 & 0 & -\frac{10}{19} & \frac{20}{19} & \frac{10}{19} & 8 \\ 0 & 0 & 1 & 0 & \frac{10}{19} & -\frac{1}{19} & \frac{9}{19} & 2.1 \end{bmatrix} \begin{matrix} \text{Row 1} + 2\,\text{Row 2} \\ \text{Row 2} \\ \text{Row 3} - \frac{10}{19}\,\text{Row 2} \\ \text{Row 4} + \frac{10}{19}\,\text{Row 2} \end{matrix}$$

Hence a solution of our problem is

$$f\left(\frac{8}{10}, \frac{2.1}{1}, \frac{3.61}{19/10}\right) = f(0.8, 2.1, 1.9) = 9.8.$$

Actually, all solutions are

$$(x_1, \quad 2.5 - 0.5x_1, \quad 2.3 - 0.5x_1)$$

where x_1 is arbitrary, satisfying $0 \leqq x_1 \leqq 0.8$, thus giving a straight segment with endpoints (0, 2.5, 2.3) and (0.8, 2.1, 1.9), where $x_1 = 0.8$ results from solving the system of three equations of the constraints taken with equality signs. The reason for the nonuniqueness is that the plane $f(x_1, x_2, x_3) = 9.8$ contains an edge of the region to which x_1, x_2, x_3 are restricted, whereas in general it will have just a single point (a vertex) in common with that region.

6. The matrices and pivot selections are

$$\mathbf{T}_0 = \begin{bmatrix} 1 & -4 & 10 & 20 & 0 & 0 & 0 & 0 \\ 0 & 3 & 4 & 5 & 1 & 0 & 0 & 60 \\ 0 & 2 & 1 & 0 & 0 & 1 & 0 & 20 \\ 0 & 2 & 0 & 3 & 0 & 0 & 1 & 30 \end{bmatrix}$$

$60/4 = 15 < 20/1 = 20$, pivot 4

im22.qxd 9/21/05 1:53 PM Page 356

$$\mathbf{T}_1 = \begin{bmatrix} 1 & -\frac{23}{2} & 0 & \frac{15}{2} & -\frac{5}{2} & 0 & 0 & -150 \\ 0 & 3 & 4 & 5 & 1 & 0 & 0 & 60 \\ 0 & \frac{5}{4} & 0 & -\frac{5}{4} & -\frac{1}{4} & 1 & 0 & 5 \\ 0 & 2 & 0 & 3 & 0 & 0 & 1 & 30 \end{bmatrix} \begin{matrix} \text{Row 1} - \frac{10}{4}\,\text{Row 2} \\ \text{Row 2} \\ \text{Row 3} - \frac{1}{4}\,\text{Row 2} \\ \text{Row 4} \end{matrix}$$

$60/5 > 30/3$, pivot 3

$$\mathbf{T}_2 = \begin{bmatrix} 1 & -\frac{33}{2} & 0 & 0 & -\frac{5}{2} & 0 & -\frac{5}{2} & -225 \\ 0 & -\frac{1}{3} & 4 & 0 & 1 & 0 & -\frac{5}{3} & 10 \\ 0 & \frac{25}{12} & 0 & 0 & -\frac{1}{4} & 1 & \frac{5}{12} & \frac{35}{2} \\ 0 & 2 & 0 & 3 & 0 & 0 & 1 & 30 \end{bmatrix} \begin{matrix} \text{Row 1} - \frac{15}{6}\,\text{Row 4} \\ \text{Row 2} - \frac{5}{3}\,\text{Row 4} \\ \text{Row 3} + \frac{5}{12}\,\text{Row 4} \\ \text{Row 4} \end{matrix}$$

$f_{\min} = -225$ at $x_1 = 0$, $x_2 = 10/4 = 2.5$, $x_3 = 30/3 = 10$.

8. We minimize! The augmented matrix is

$$\mathbf{T}_0 = \begin{bmatrix} 1 & 1.8 & 2.1 & 0 & 0 & 0 \\ 0 & 15 & 30 & 1 & 0 & 150 \\ 0 & 600 & 500 & 0 & 1 & 3900 \end{bmatrix}.$$

The pivot is 600. The calculation gives

$$\mathbf{T}_1 = \begin{bmatrix} 1 & 0 & \frac{6}{10} & 0 & -\frac{3}{1000} & -\frac{117}{10} \\ 0 & 0 & \frac{35}{2} & 1 & -\frac{1}{40} & \frac{105}{2} \\ 0 & 600 & 500 & 0 & 1 & 3900 \end{bmatrix} \begin{matrix} \text{Row 1} - \frac{1.8}{600}\,\text{Row 3} \\ \text{Row 2} - \frac{15}{600}\,\text{Row 3} \\ \text{Row 3} \end{matrix}$$

The next pivot is 35/2. The calculation gives

$$\mathbf{T}_2 = \begin{bmatrix} 1 & 0 & 0 & -\frac{6}{175} & -\frac{3}{1400} & -\frac{27}{2} \\ 0 & 0 & \frac{35}{2} & 1 & -\frac{1}{40} & \frac{105}{2} \\ 0 & 600 & 0 & -\frac{200}{7} & \frac{12}{7} & 2400 \end{bmatrix} \begin{matrix} \text{Row 1} - \frac{1.2}{35}\,\text{Row 2} \\ \text{Row 2} \\ \text{Row 3} - \frac{1000}{35}\,\text{Row 2} \end{matrix}$$

Hence $-f$ has the maximum value -13.5, so that f has the minimum value 13.5, at the point

$$(x_1, x_2) = \left(\frac{2400}{600}, \frac{105/2}{35/2}\right) = (4, 3).$$

SECTION 22.4. Simplex Method: Difficulties, page 947

Purpose. To explain ways of overcoming difficulties that may arise in applying the simplex method.

Main Content, Important Concepts

Degenerate feasible solution

Artificial variable (for overcoming difficulties in starting)

Short Courses. Omit this section because these difficulties occur only quite infrequently in practice.

im22.qxd 9/21/05 1:53 PM Page 357

SOLUTIONS TO PROBLEM SET 22.4, page 952

2. In the second step in Prob. 1 we had a choice of the pivot, and in the present problem, owing to our rule of choice, we took the other pivot. The result remained the same. Of course, the problem can be solved by inspection. The calculation is as follows.

$$\mathbf{T}_0 = \begin{bmatrix} 1 & -6 & -12 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 4 \\ 0 & 6 & 12 & 0 & 0 & 1 & 72 \\ 0 & 0 & 1 & 0 & 1 & 0 & 4 \end{bmatrix}$$

$$\mathbf{T}_1 = \begin{bmatrix} 1 & 0 & -12 & 6 & 0 & 0 & 24 \\ 0 & 1 & 0 & 1 & 0 & 0 & 4 \\ 0 & 0 & 12 & -6 & 0 & 1 & 48 \\ 0 & 0 & 1 & 0 & 1 & 0 & 4 \end{bmatrix} \quad \begin{matrix} \text{R1} + 6\,\text{R2} \\ \text{R2} \\ \text{R3} - 6\,\text{R2} \\ \text{R4} \end{matrix}$$

$$\mathbf{T}_2 = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 1 & 72 \\ 0 & 1 & 0 & 1 & 0 & 0 & 4 \\ 0 & 0 & 12 & -6 & 0 & 1 & 48 \\ 0 & 0 & 0 & \frac{1}{2} & 1 & -\frac{1}{12} & 0 \end{bmatrix} \quad \begin{matrix} \text{R1} + \text{R3} \\ \text{R2} \\ \text{R3} \\ \text{R4} - \frac{1}{12}\,\text{R3} \end{matrix}$$

This gives $x_1 = 4$, $x_2 = 48/12 = 4$, $x_3 = 0$, $x_4 = 0$, $x_5 = 0$, $f(4, 4) = 72$.

4. The calculation is as follows.

$$\mathbf{T}_0 = \begin{bmatrix} 1 & -300 & -500 & 0 & 0 & 0 & 0 \\ 0 & 2 & 8 & 1 & 0 & 0 & 60 \\ 0 & 2 & 1 & 0 & 1 & 0 & 30 \\ 0 & 4 & 4 & 0 & 0 & 1 & 60 \end{bmatrix}$$

$$\mathbf{T}_1 = \begin{bmatrix} 1 & 0 & -350 & 0 & 150 & 0 & 4500 \\ 0 & 0 & 7 & 1 & -1 & 0 & 30 \\ 0 & 2 & 1 & 0 & 1 & 0 & 30 \\ 0 & 0 & 2 & 0 & -2 & 1 & 0 \end{bmatrix} \quad \begin{matrix} \text{R1} + 150\,\text{R3} \\ \text{R2} - \text{R3} \\ \text{R3} \\ \text{R4} - 2\,\text{R3} \end{matrix}$$

$$\mathbf{T}_2 = \begin{bmatrix} 1 & 0 & 0 & 0 & -200 & 175 & 4500 \\ 0 & 0 & 0 & 1 & 6 & -\frac{7}{2} & 30 \\ 0 & 2 & 0 & 0 & 2 & -\frac{1}{2} & 30 \\ 0 & 0 & 2 & 0 & -2 & 1 & 0 \end{bmatrix} \quad \begin{matrix} \text{R1} + 175\,\text{R4} \\ \text{R2} - \frac{7}{2}\,\text{R4} \\ \text{R3} - \frac{1}{2}\,\text{R4} \\ \text{R4} \end{matrix}$$

im22.qxd 9/21/05 1:53 PM Page 358

$z = 4500$ is the same as in the step before. But we shall now be able to reach the maximum $f(10, 5) = 5500$ in the final step.

$$\mathbf{T}_3 = \begin{bmatrix} 1 & 0 & 0 & \frac{100}{3} & 0 & \frac{175}{3} & 5500 \\ 0 & 0 & 0 & 1 & 6 & -\frac{7}{2} & 30 \\ 0 & 2 & 0 & -\frac{1}{3} & 0 & \frac{2}{3} & 20 \\ 0 & 0 & 2 & \frac{1}{3} & 0 & -\frac{1}{6} & 10 \end{bmatrix} \quad \begin{matrix} \text{R1} + \frac{100}{3}\,\text{R2} \\ \text{R2} \\ \text{R3} - \frac{1}{3}\,\text{R2} \\ \text{R4} + \frac{1}{3}\,\text{R2} \end{matrix}$$

We see that $x_1 = 20/2 = 10$, $x_2 = 10/2 = 5$, $x_3 = 0$, $x_4 = 30/6 = 5$, $x_5 = 0$, $z = 5500$.

Problem 5 shows that the extra step (which gave no increase of $z = f(x)$) could have been avoided if we had chosen 4 (instead of 2) as the first pivot.

6. The maximum $f(0, 2.4, 0) = 2.4$ is obtained as follows.

$$\mathbf{T}_0 = \begin{bmatrix} 1 & -1 & -1 & -1 & 0 & 0 & 0 \\ 0 & 4 & 5 & 8 & 1 & 0 & 12 \\ 0 & 8 & 5 & 4 & 0 & 1 & 12 \end{bmatrix}$$

$$\mathbf{T}_1 = \begin{bmatrix} 1 & 0 & -\frac{3}{8} & -\frac{1}{2} & 0 & \frac{1}{8} & \frac{3}{2} \\ 0 & 0 & \frac{5}{2} & 6 & 1 & -\frac{1}{2} & 6 \\ 0 & 8 & 5 & 4 & 0 & 1 & 12 \end{bmatrix} \quad \begin{matrix} \text{R1} + \frac{1}{8}\,\text{R3} \\ \text{R2} - \frac{1}{2}\,\text{R3} \\ \text{R3} \end{matrix}$$

$$\mathbf{T}_2 = \begin{bmatrix} 1 & 0 & 0 & \frac{2}{5} & \frac{3}{20} & \frac{1}{20} & \frac{12}{5} \\ 0 & 0 & \frac{5}{2} & 6 & 1 & -\frac{1}{2} & 6 \\ 0 & 8 & 0 & -8 & -2 & 2 & 0 \end{bmatrix} \quad \begin{matrix} \text{R1} + \frac{3}{20}\,\text{R2} \\ \text{R2} \\ \text{R3} - 2\,\text{R2} \end{matrix}$$

From $\mathbf{T}_2$ we see that $x_1 = 0/8 = 0$, $x_2 = 6/\frac{5}{2} = 12/5$, $x_3 = 0$, $x_4 = 0$, $x_5 = 0$, $z = 12/5$.

8. Maximize $\tilde{f} = -2x_1 + x_2$. The result is $-\tilde{f}_{\min} = \tilde{f}_{\max} = \tilde{f}(2, 3) = -1$, hence $f_{\min} = 1$. The calculation is as follows. An artificial variable x_6 is defined by

$$x_3 = -5 + x_1 + x_2 + x_6.$$

A corresponding objective function is

$$\tilde{\tilde{f}} = \tilde{f} - Mx_6 = (-2 + M)x_1 + (1 + M)x_2 - Mx_3 - 5M.$$

The corresponding matrix is

$$\mathbf{T}_0 = \begin{bmatrix} 1 & 2 - M & -1 - M & M & 0 & 0 & -5M \\ 0 & 1 & 1 & -1 & 0 & 0 & 5 \\ 0 & -1 & 1 & 0 & 1 & 0 & 1 \\ 0 & 5 & 4 & 0 & 0 & 1 & 40 \end{bmatrix}.$$

im22.qxd 9/21/05 1:53 PM Page 359

From this we obtain

$$\mathbf{T}_1 = \begin{bmatrix} 1 & 0 & -3 & 2 & 0 & 0 & -10 \\ 0 & 1 & 1 & -1 & 0 & 0 & 5 \\ 0 & 0 & 2 & -1 & 1 & 0 & 6 \\ 0 & 0 & -1 & 5 & 0 & 1 & 15 \end{bmatrix} \begin{matrix} \text{R1} + (M-2)\text{R2} \\ \text{R2} \\ \text{R3} + \text{R2} \\ \text{R4} - 5\,\text{R2} \end{matrix}$$

and

$$\mathbf{T}_2 = \begin{bmatrix} 1 & 0 & 0 & \frac{1}{2} & \frac{3}{2} & 0 & -1 \\ 0 & 1 & 0 & -\frac{1}{2} & -\frac{1}{2} & 0 & 2 \\ 0 & 0 & 2 & -1 & 1 & 0 & 6 \\ 0 & 0 & 0 & \frac{9}{2} & \frac{1}{2} & 1 & 18 \end{bmatrix} \begin{matrix} \text{R1} + \frac{3}{2}\,\text{R3} \\ \text{R2} - \frac{1}{2}\,\text{R3} \\ \text{R3} \\ \text{R4} + \frac{1}{2}\,\text{R3} \end{matrix}$$

We see that $x_1 = 2/1 = 2$, $x_2 = 6/2 = 3$, $x_3 = 0$, $x_4 = 0$, $x_5 = 18$, $\tilde{\tilde{f}} = -1$.

10. An artificial variable x_6 is defined by

$$x_4 = x_1 + 2x_2 - 6 + x_6$$

and a corresponding objective function by

$$\begin{aligned} \hat{f} &= 2x_1 + x_2 - Mx_6 = 2x_1 + x_2 - M(x_4 - x_1 - 2x_2 + 6) \\ &= (2 + M)x_1 + (1 + 2M)x_2 - Mx_4 - 6M. \end{aligned}$$

This gives the matrix

$$\mathbf{T}_0 = \begin{bmatrix} 1 & -2-M & -1-2M & 0 & M & 0 & -6M \\ 0 & 2 & 1 & 1 & 0 & 0 & 2 \\ 0 & 1 & 2 & 0 & -1 & 0 & 6 \\ 0 & 1 & 1 & 0 & 0 & 1 & 4 \end{bmatrix}$$

and from it

$$\mathbf{T}_1 = \begin{bmatrix} 1 & 0 & -\frac{3}{2}M & 1+\frac{1}{2}M & M & 0 & 2-5M \\ 0 & 2 & 1 & 1 & 0 & 0 & 2 \\ 0 & 0 & \frac{3}{2} & -\frac{1}{2} & -1 & 0 & 5 \\ 0 & 0 & \frac{1}{2} & -\frac{1}{2} & 0 & 1 & 3 \end{bmatrix} \begin{matrix} \text{R1} + (1+\frac{1}{2}M)\,\text{R2} \\ \text{R2} \\ \text{R3} - \frac{1}{2}\,\text{R2} \\ \text{R4} - \frac{1}{2}\,\text{R2} \end{matrix}$$

and from this

$$\mathbf{T}_2 = \begin{bmatrix} 1 & 3M & 0 & 1+2M & M & 0 & 2-2M \\ 0 & 2 & 1 & 1 & 0 & 0 & 2 \\ 0 & -3 & 0 & -2 & -1 & 0 & 2 \\ 0 & -1 & 0 & -1 & 0 & 1 & 2 \end{bmatrix} \begin{matrix} \text{R1} + \frac{3}{2}M\,\text{R2} \\ \text{R2} \\ \text{R3} - \frac{3}{2}\,\text{R2} \\ \text{R4} - \frac{1}{2}\,\text{R2} \end{matrix}$$

which still contains M.

im22.qxd 9/21/05 1:53 PM Page 360

SOLUTIONS TO CHAP. 22 REVIEW QUESTIONS AND PROBLEMS, page 952

4. Replace $-\nabla f$ by $+\nabla f$.

8. $[6 \quad 3]^T$, $[0.9153 \quad -0.8136]^T$, $[0.2219 \quad 0.1109]^T$, $[0.0338 \quad -0.0301]^T$. Slimmer ellipses give slower convergence, as can be seen from Fig. 472 in Sec. 22.1.

10. $f(\mathbf{x}) = x_1^2 + 1.5x_2^2$ implies

$$\mathbf{z}(t) = [(1 - 2t)x_1 \quad (1 - 3t)x_2]^T,$$

$$g(t) = f(\mathbf{z}(t)) = (1 - 2t)^2 x_1^2 + 1.5(1 - 3t)^2 x_2^2$$

and by differentiation,

$$g'(t) = -4(1 - 2t)x_1^2 - 9(1 - 3t)x_2^2 = 0.$$

The solution is

$$t_1 = \frac{4x_1^2 + 9x_2^2}{8x_1^2 + 27x_2^2}$$

so that

$$1 - 2t_1 = \frac{9x_2^2}{8x_1^2 + 27x_2^2}, \qquad 1 - 3t_1 = \frac{-4x_1^2}{8x_1^2 + 27x_2^2}.$$

For $x_1 = 1.5$, $x_2 = 1$ this gives

$$\mathbf{x}_1 = \mathbf{z}(t_1) = 0.2[1.5 \quad -1]^T,$$

and, furthermore, $\mathbf{x}_2 = 0.04[1.5 \quad +1]^T$, etc.

12. Nine steps give the solution $[-1 \quad 2]$ to 6S. Steps 1–5 give

x_1	x_2
−1.01462	3.77669
−0.888521	2.07432
−1.00054	2.06602
−0.995857	2.00276
−1.00002	2.00245

14. The values obtained are

x_1	x_2
−1.04366	0.231924
−0.758212	1.51642
−1.01056	1.57250
−0.941538	1.88308
−1.00255	1.89664

Gradients (times a scalar) are obtained by calculating differences of subsequent values. Orthogonality follows from the fact that we change direction when we are tangent to a level curve and then proceed perpendicular to it.

im22.qxd 9/21/05 1:53 PM Page 361

22. The augmented matrix of the given data is

$$\mathbf{T_0} = \begin{bmatrix} 1 & -1 & -1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 2 & 1 & 0 & 0 & 10 \\ 0 & 2 & 1 & 0 & 1 & 0 & 10 \\ 0 & 0 & 1 & 0 & 0 & 1 & 4 \end{bmatrix}.$$

The pivot is 2 in Row 3 and Column 2. The calculation gives

$$\mathbf{T_1} = \begin{bmatrix} 1 & 0 & -\frac{1}{2} & 0 & \frac{1}{2} & 0 & 5 \\ 0 & 0 & \frac{3}{2} & 1 & -\frac{1}{2} & 0 & 5 \\ 0 & 2 & 1 & 0 & 1 & 0 & 10 \\ 0 & 0 & 1 & 0 & 0 & 1 & 4 \end{bmatrix} \begin{matrix} \text{Row 1} + \frac{1}{2}\,\text{Row 3} \\ \text{Row 2} - \frac{1}{2}\,\text{Row 3} \\ \text{Row 3} \\ \text{Row 4.} \end{matrix}$$

The next pivot is 3/2 in Row 2. The calculation gives

$$\mathbf{T_2} = \begin{bmatrix} 1 & 0 & 0 & \frac{1}{3} & \frac{1}{3} & 0 & \frac{20}{3} \\ 0 & 0 & \frac{3}{2} & 1 & -\frac{1}{2} & 0 & 5 \\ 0 & 2 & 0 & -\frac{2}{3} & \frac{4}{3} & 0 & \frac{20}{3} \\ 0 & 0 & 0 & -\frac{2}{3} & \frac{1}{3} & 1 & \frac{2}{3} \end{bmatrix} \begin{matrix} \text{Row 1} + \frac{1}{3}\,\text{Row 2} \\ \text{Row 2} \\ \text{Row 3} - \frac{2}{3}\,\text{Row 2} \\ \text{Row 4} - \frac{2}{3}\,\text{Row 2.} \end{matrix}$$

We see from the last matrix that for the maximum we have

$$f\left(\frac{20/3}{2}, \frac{5}{3/2}\right) = f\left(\frac{10}{3}, \frac{10}{3}\right) = \frac{20}{3}.$$

24. The matrix of the given data is

$$\mathbf{T_0} = \begin{bmatrix} 1 & -60 & -30 & 0 & 0 & 0 \\ 0 & 40 & 40 & 1 & 0 & 1800 \\ 0 & 200 & 20 & 0 & 1 & 6300 \end{bmatrix}$$

The pivot is 200. The calculation gives

$$\mathbf{T_1} = \begin{bmatrix} 1 & 0 & -24 & 0 & \frac{3}{10} & 1890 \\ 0 & 0 & 36 & 1 & -\frac{1}{5} & 540 \\ 0 & 200 & 20 & 0 & 1 & 6300 \end{bmatrix} \begin{matrix} \text{Row 1} + \frac{60}{200}\,\text{Row 3} \\ \text{Row 2} - \frac{1}{5}\,\text{Row 3} \\ \text{Row 3} \end{matrix}$$

The next pivot is 36. The calculation gives

$$\mathbf{T_2} = \begin{bmatrix} 1 & 0 & 0 & \frac{2}{3} & \frac{1}{6} & 2250 \\ 0 & 0 & 36 & 1 & -\frac{1}{5} & 540 \\ 0 & 200 & 0 & -\frac{5}{9} & \frac{10}{9} & 6000 \end{bmatrix} \begin{matrix} \text{Row 1} + \frac{24}{36}\,\text{Row 2} \\ \text{Row 2} \\ \text{Row 3} - \frac{20}{36}\,\text{Row 2} \end{matrix}$$

Hence the solution is

$$f\left(\frac{6000}{200}, \frac{540}{36}\right) = f(30, 15) = 2250.$$

im23.qxd 9/21/05 2:01 PM Page 362

CHAPTER 23 Graphs. Combinatorial Optimization

SECTION 23.1. Graphs and Digraphs, page 954

Purpose. To explain the concepts of a graph and a digraph (directed graph) and related concepts, as well as their computer representations.

Main Content, Important Concepts

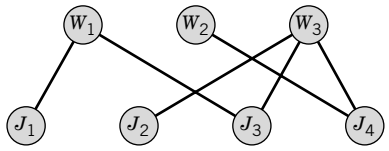
Graph, vertices, edges

Incidence of a vertex v with an edge, degree of v

Digraph

Adjacency matrix

Incidence matrix



Vertex incidence list, edge incidence list

Comment on Content

Graphs and digraphs have become more and more important, due to an increase of supply and demand—a supply of more and more powerful methods of handling graphs and digraphs, and a demand for those methods in more and more problems and fields of application. Our chapter, devoted to the modern central area of combinatorial optimization, will give us a chance to get a feel for the usefulness of graphs and digraphs in general.

SOLUTIONS TO PROBLEM SET 23.1, page 958

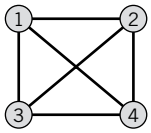
2.

6. The adjacency matrix is

$$\begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 0 \end{bmatrix}.$$

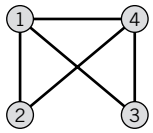
Adding the edge between 3 and 4, we would have a complete graph. The only zeros of the matrix outside the main diagonal correspond to that edge.

8.



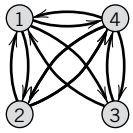
$$\begin{bmatrix} 0 & 1 & 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \end{bmatrix}$$

im23.qxd 9/21/05 2:01 PM Page 363



10.
$$\begin{bmatrix} 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 1 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 \end{bmatrix}$$

12.
$$\begin{bmatrix} 0 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \end{bmatrix}$$



14.

16.

18.

20. If and only if G is complete.

In this case the adjacency matrix of G has $n^2 - n = n(n-1)$ ones, and since every edge contributes two ones, the number of edges is $n(n-1)/2$. This gives another proof of Prob. 19.

22. The matrix is

		Edge						
		e_1	e_2	e_3	e_4	e_5	e_6	e_7
Vertex	1	1	0	1	0	0	0	0
	2	1	1	0	1	0	0	0
	3	0	1	0	0	1	0	0
	4	0	0	1	1	1	1	1
	5	0	0	0	0	0	1	0
	6	0	0	0	0	0	0	1

im23.qxd 9/21/05 2:01 PM Page 364

24. The matrix is

Vertex	e_1	e_2	e_3	e_4
1	−1	−1	1	−1
2	1	0	0	0
3	0	1	−1	0
4	0	0	0	1

SECTION 23.2. Shortest Path Problems. Complexity, page 959

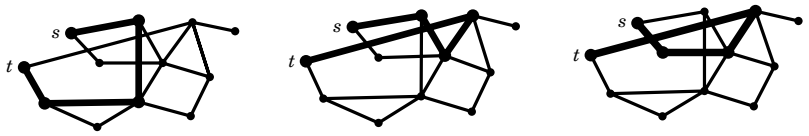
Purpose. To explain a method (by Moore) of determining a shortest path from a given vertex s to a given vertex t in a graph, all of whose edges have length 1.

Main Content, Important Concepts

Moore's algorithm (Table 23.1)

BFS (Breadth First Search), DFS (Depth First Search)

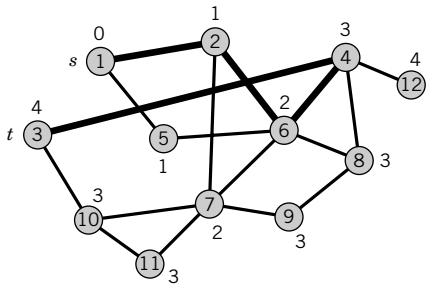
Complexity of an algorithm



Efficient, polynomially bounded

Comment on Content

The basic idea of Moore's algorithm is quite simple. A few related ideas and problems are illustrated in the problem set.



SOLUTIONS TO PROBLEM SET 23.2, page 962

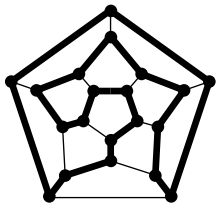
2. There are three shortest paths, of length 4 each:

(*a*) (*b*) (*c*)

Which one we obtain in backtracking depends on the numbering (not labeling!) of the vertices and on the backtracking rule. For the rule in Example 1 and the numbering shown in the following figure we get (B).

If we change the rule and let the computer look for largest (instead of smallest) numbers, we get (A).

im23.qxd 9/21/05 2:01 PM Page 365



4. The length of a shortest path is 5. No uniqueness.

6. The length of the unique shortest path is 4.

8. $n - 1$. If it had more, a vertex would appear more than once and the corresponding cycle could be omitted. One edge.

10. This is true for $l = 0$ since then $v = s$. Let it be true for an $l - 1$. Then $\lambda(v_{l-1}) = l - 1$ for the predecessor v_{l-1} of v on a shortest path $s \to v$. We claim that when v_{l-1} gets labeled, v is still unlabeled (so that we shall have $\lambda(v) = l$ as wanted). Indeed, if v were labeled, it would have a label less than l, hence distance less than l by Prob. 9, contradicting that v has distance l.

12.

14. Delete the edge (2, 4).

16. $1 - 2 - 3 - 4 - 5 - 3 - 1$, $1 - 3 - 4 - 5 - 3 - 2 - 1$, and these two trails traversed in the opposite sense

18. Let T: $s \to s$ be a shortest postman trail and v any vertex. Since T includes each edge, T visits v. Let T_1: $s \to v$ be the portion of T from s to the *first* visit of v and T_2: $v \to s$ the other portion of T. Then the trail $v \to v$ consisting of T_2 followed by T_1 has the same length as T and solves the postman problem.

SECTION 23.3. Bellman's Principle. Dijkstra's Algorithm, page 963

Purpose. This section extends the previous one to graphs whose edges have any (positive) length and explains a popular corresponding algorithm (by Dijkstra).

Main Content, Important Concepts

Bellman's optimality principle, Bellman's equations

Dijkstra's algorithm (Table 23.2)

Comment on Content

Throughout this chapter, one should emphasize that algorithms are needed because most practical problems are so large that solution by inspection would fail, even if one were satisfied with approximately optimal solutions.

SOLUTIONS TO PROBLEM SET 23.3, page 966

2. Dijkstra's algorithm gives

1. $L_1 = 0$, $\tilde{L}_2 = 4$, $\tilde{L}_3 = 12$, $\tilde{L}_4 = 16$, $\tilde{L}_5 = \infty$

2. $L_2 = 4$, $k = 2$

3. $\tilde{L}_3 = \min\{12, 4 + l_{23}\} = 10$
$\tilde{L}_4 = \min\{16, 4 + l_{24}\} = 16$
$\tilde{L}_5 = \min\{\infty, 4 + \infty\} = \infty$

2. $L_3 = 10$, $k = 3$

3. $\tilde{L}_4 = \min\{16, 10 + l_{34}\} = 16$
$\tilde{L}_5 = \min\{\infty, 10 + \infty\} = \infty$

im23.qxd 9/21/05 2:01 PM Page 366

2. $L_4 = 16$, $k = 4$

3. $\widetilde{L}_5 = \min\{\infty, 16 + l_{45}\} = 56$

2. $L_5 = 56$, $k = 5$,

so that the *answer* is

$$(1, 2), (1, 4), (2, 3), (4, 5); \quad L_2 = 4, L_3 = 10, L_4 = 16, L_5 = 56.$$

4. Dijkstra's algorithm gives

1. $L_1 = 0$, $\widetilde{L}_2 = 8$, $\widetilde{L}_3 = 10$, $\widetilde{L}_4 = \infty$, $\widetilde{L}_5 = 5$, $\widetilde{L}_6 = \infty$

2. $L_5 = 5$

3. $\widetilde{L}_2 = \min\{8, 5 + l_{52}\} = 7$
$\widetilde{L}_3 = \min\{10, 5 + l_{53}\} = 10$
$\widetilde{L}_4 = \min\{\infty, 5 + l_{54}\} = 10$
$\widetilde{L}_6 = \min\{\infty, 5 + l_{56}\} = 7$

2. $L_2 = 7$

3. $\widetilde{L}_3 = \min\{10, 7 + l_{23}\} = 9$
$\widetilde{L}_4 = \min\{10, 7 + l_{24}\} = 10$
$\widetilde{L}_6 = \min\{7, 7 + l_{26}\} = 7$

2. $L_6 = 7$

3. $\widetilde{L}_3 = \min\{9, 7 + l_{63}\} = \min\{9, 7 + \infty\} = 9$
$\widetilde{L}_4 = \min\{10, 7 + l_{64}\} = 8$

2. $L_4 = 8$

3. $\widetilde{L}_3 = \min\{9, 8 + l_{43}\} = \min\{9, 8 + \infty\} = 9$

2. $L_3 = 9$.

The *answer* is (1, 5), (2, 3), (2, 5), (4, 6), (5, 6); $L_2 = 7$, $L_3 = 9$, $L_4 = 8$, $L_5 = 5$, $L_6 = 7$.

6. Dijkstra's algorithm gives

1. $L_1 = 0$, $\widetilde{L}_2 = 15$, $\widetilde{L}_3 = 2$, $\widetilde{L}_4 = 10$, $\widetilde{L}_5 = 6$

2. $L_3 = 2$

3. $\widetilde{L}_2 = \min\{15, 2 + l_{32}\} = 15$
$\widetilde{L}_4 = \min\{10, 2 + l_{34}\} = 10$
$\widetilde{L}_5 = \min\{6, 2 + l_{35}\} = 5$

2. $L_5 = 5$

3. $\widetilde{L}_2 = \min\{15, 5 + l_{52}\} = \min\{15, 5 + \infty\} = 15$
$\widetilde{L}_4 = \min\{10, 5 + l_{54}\} = 9$

2. $L_4 = 9$

3. $\widetilde{L}_2 = \min\{15, 9 + l_{42}\} = 14$

2. $L_2 = 14$.

The *answer* is (1, 3), (2, 4), (3, 5), (4, 5); $L_2 = 14$, $L_3 = 2$, $L_4 = 9$, $L_5 = 5$.

8. Let j be the vertex that gave k its present label L_k, namely, $L_j + l_{jk}$. After this label was assigned, j did not change its label, since it was then removed from $\mathcal{TL}$. Next, find the vertex which gave j its permanent label, etc. This backward search traces a path from 1 to k, whose length is exactly L_k.

im23.qxd 9/21/05 2:01 PM Page 367

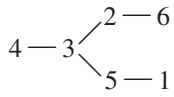
SECTION 23.4. Shortest Spanning Trees: Greedy Algorithm, page 966

Purpose. After the discussion of shortest paths between two given vertices, this section is devoted to the construction of a tree in a given graph that is spanning (contains all vertices of the graph) and is of minimum length.

Main Content, Important Concepts

Tree

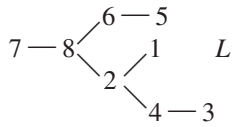
Cycle



Kruskal's greedy algorithm (Table 23.3)

Comment on Content

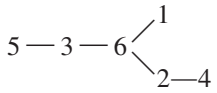
Figure 490 illustrates that Kruskal's algorithm does not necessarily give a tree during each intermediate step, in contrast to another algorithm to be discussed in the next section.



SOLUTIONS TO PROBLEM SET 23.4, page 969

2.

$L = 30$



4.

$L = 40$

Note that trees, just as general graphs, can be sketched in different ways.

6. We obtain the edges in the order (1, 6), (2, 6), (3, 5), (3, 6), (2, 4) and can sketch the tree, for instance, in the form

Its length is L = 17.

8. Order the edges in descending order of length and choose them in this order, rejecting when a cycle would arise.

10. Order the edges in descending order of length and delete them in this order, retaining an edge only if it would lead to the omission of a vertex or to a disconnected graph.

12. New York – Washington – Chicago – Dallas – Denver – Los Angeles

14. Let P_1: $u \to v$ and P_2: $u \to v$ be different. Let $e = (w, x)$ be in P_1 but not in P_2. Then P_1 without e together with P_2 is a connected graph. Hence it contains a path P_3: $w \to x$. Hence P_3 together with e is a cycle in T, a contradiction.

16. Extend an edge e into a path by adding edges to its ends if such edges exist. A new edge attached at the end of the path introduces a new vertex, or closes a cycle, which contradicts our assumption. This extension terminates on both sides of e, yielding two vertices of degree 1.

18. True for $n = 2$. Assume truth for all trees with less than n vertices. Let T be a tree with $n \geqq 2$ vertices, and (u, v) an edge of T. Then T without (u, v) contains no path $u \to v$, by Prob. 14. Hence this graph is disconnected. Let G_1, G_2 be its connected components, having n_1 and n_2 vertices, hence $n_1 - 1$ and $n_2 - 1$ edges, respectively, by the induction hypothesis, so that G has $n_1 - 1 + n_2 - 1 + 1 = n - 1$ edges.

im23.qxd 9/21/05 2:01 PM Page 368

20. If G is a tree, it has no cycles, and has $n - 1$ edges by Prob. 18. Conversely, let G have no cycles and $n - 1$ edges. Then G has 2 vertices of degree 1 by Prob. 16. Now prove connectedness by induction. True when $n = 2$. Assume true for $n = k - 1$. Let G with k vertices have no cycles and $k - 1$ edges. Omit a vertex v and its incident edge e, apply the induction hypothesis and add e and v back on.

SECTION 23.5. Shortest Spanning Trees: Prim's Algorithm, page 970

Purpose. To explain another algorithm (by Prim) for constructing a shortest spanning tree in a given graph whose edges have arbitrary (positive) lengths.

Comments on Content

In contrast to Kruskal's greedy algorithm (Sec. 23.4), Prim's algorithm gives a tree at each intermediate step.

The problem set illustrates a few concepts that can be included into the present cycle of ideas.

SOLUTIONS TO PROBLEM SET 23.5, page 972

2. The algorithm proceeds as follows:

Vertex	Initial Label	Relabeling			
		(I)	(II)	(III)	(IV)
2	$l_{12} = 20$	$l_{12} = 20$	$l_{32} = 4$	$l_{32} = 4$	
3	∞	$l_{53} = 6$			
4	∞	$l_{54} = 12$	$l_{34} = 2$		
5	$l_{15} = 8$				
6	$l_{16} = 30$	$l_{16} = 30$	$l_{16} = 30$	$l_{16} = 30$	$l_{26} = 10$

Hence we got successively

$$(1, 5), (3, 5), (3, 4), (2, 3), (2, 6), \quad \text{and} \quad L = 30.$$

In Prob. 1 of Sec. 23.4 we got the same edges, but in the order

$$(3, 4), (2, 3), (3, 5), (1, 5), (2, 6).$$

4. The algorithm gives

Vertex	Initial Label	Relabeling					
		(I)	(II)	(III)	(IV)	(V)	(VI)
2	$l_{12} = 3$						
3	∞	$l_{23} = 4$					
4	∞	∞	$l_{34} = 3$	$l_{64} = 1$			
5	∞	∞	$l_{35} = 5$	$l_{35} = 5$	$l_{35} = 5$		
6	∞	$l_{26} = 10$	$l_{36} = 2$				
7	∞	$l_{27} = 7$	$l_{37} = 6$	$l_{37} = 6$	$l_{37} = 6$	$l_{37} = 6$	
8	$l_{18} = 8$	$l_{28} = 7$	$l_{28} = 7$	$l_{28} = 7$	$l_{28} = 7$	$l_{28} = 7$	$l_{28} = 7$

im23.qxd 9/21/05 2:01 PM Page 369

We see that we got

(1, 2), (2, 3), (3, 6), (4, 6), (3, 5), (3, 7) (2, 8).

The length is $L = 28$.

6. The algorithm gives

Vertex	Initial Label	Relabeling		
		(I)	(II)	(III)
2	$l_{12} = 6$	$l_{32} = 3$		
3	$l_{13} = 1$			
4	∞	$l_{34} = 10$	$l_{34} = 10$	$l_{54} = 2$
5	$l_{15} = 15$	$l_{15} = 15$	$l_{25} = 9$	

We see that we got

(1, 3), (2, 3), (2, 5), (4, 5).

The tree has the length $L = 15$.

8. In Step 2 we first select a smallest l_{1j} for the $n - 1$ vertices outside U; these are $n - 2$ comparisons. Step 3 then requires $n - 2$ updatings (pairwise comparisons). In the next round we have $n - 3$ comparisons in Step 2 and $n - 3$ updatings in Step 3, and so on, until we finally end up with 1 comparison and 1 updating. The sum of all these numbers is $(n - 2)(n - 1) = O(n^2)$.

10. An algorithm for minimum spanning trees must examine each entry of the distance matrix at least once, because an entry not looked upon might have been one that should have been included in a shortest spanning tree. Hence, examining the relevant given information is already $O(n^2)$ work.

12. Team Project. (a) $\epsilon(1) = 16$, $\epsilon(2) = 22$, $\epsilon(3) = 12$.

(b) $d(G) = 24$, $r(G) = 12 = \epsilon(3)$, center $\{3\}$.

(c) 20, 14, center $\{3, 4\}$

(e) Let T^* be obtained from T by deleting all endpoints (= vertices of degree 1) together with the edges to which they belong. Since for fixed u, max $d(u, v)$ occurs only when v is an endpoint, $\epsilon(u)$ is one less in T^* than it is in T. Hence the vertices of minimum eccentricity in T are the same as those in T^*. Thus T has the same center as T^*. Delete the endpoints of T^* to get a tree T^{**} whose center is the same as that of T, etc. The process terminates when only one vertex or two adjacent vertices are left.

(f) Choose a vertex u and find a farthest v_1. From v_1 find a farthest v_2. Find w such that $d(w, v_1)$ is as close as possible to being equal to $\frac{1}{2}d(v_1, v_2)$.

SECTION 23.6. Flows in Networks, page 973

Purpose. After shortest paths and spanning trees we discuss in this section a third class of practically important problems, the optimization of flows in networks.

Main Content, Important Concepts

Network, source, target (sink)

Edge condition, vertex condition

Path in a digraph, forward edge, backward edge

Flow augmenting path

im23.qxd 9/21/05 2:01 PM Page 370

Cut set, Theorems 1 and 2

Augmenting path theorem for flows (Theorem 3)

Max-flow min-cut theorem

Comment on Content

An algorithm for determining flow augmenting paths follows in the next section.

SOLUTIONS TO PROBLEM SET 23.6, page 978

2. Flow augmenting paths are

$$P_1\text{: } 1-2-4-6,\ \Delta f = 1$$
$$P_2\text{: } 1-3-5-6,\ \Delta f = 1$$
$$P_3\text{: } 1-2-3-5-6,\ \Delta f = 1$$
$$P_4\text{: } 1-2-3-4-5-6,\ \Delta f = 1, \text{ etc.}$$

4. Flow augmenting paths are

$$P_1\text{: } 1-2-4-5,\ \Delta f = 2$$
$$P_2\text{: } 1-2-5,\ \Delta f = 2$$
$$P_3\text{: } 1-2-3-5,\ \Delta f = 3$$
$$P_4\text{: } 1-3-5,\ \Delta f = 5, \text{ etc.}$$

6. The maximum flow is $f = 4$. It can be realized by

$$f_{12} = 2,\ f_{13} = 2,\ f_{24} = 1,\ f_{23} = 1,\ f_{35} = 1,\ f_{34} = 2,\ f_{45} = 0,\ f_{46} = 3,\ f_{56} = 1.$$

f is unique, but the way in which it is achieved is not, in general. In the present case we can change f_{45} from 0 to 1, f_{46} from 3 to 2, f_{56} from 1 to 2.

8. The maximum flow is $f = 17$. It can be achieved by

$$f_{12} = 8,\ f_{13} = 9,\ f_{23} = 0,\ f_{24} = 4,\ f_{25} = 4,\ f_{35} = 10,\ f_{43} = 1,\ f_{45} = 3.$$

10. {3, 6}, 14

12. The cut set in Prob. 10

14. {3, 5, 6, 7}, 14

16. {6, 7}, 14

18. One is interested in flows *from s to t,* not in the opposite direction.

SECTION 23.7. Maximum Flow: Ford–Fulkerson Algorithm, page 979

Purpose. To discuss an algorithm (by Ford and Fulkerson) for systematically increasing a flow in a network (e.g., the zero flow) by constructing flow augmenting paths until the maximum flow is reached.

Main Content, Important Concepts

Forward edge, backward edge

Ford–Fulkerson algorithm (Table 23.8)

Scanning of a labeled vertex

im23.qxd 9/21/05 2:01 PM Page 371

Comment on Content

Note that this is the first section in which we are dealing with digraphs.

SOLUTIONS TO PROBLEM SET 23.7, page 982

2. Not more work than in Example 1. Steps 1–7 are similar to those in the example and give the flow augmenting path

$$P_1: \qquad 1 - 2 - 3 - 6,$$

which augments the flow from 0 to 11.

In determining a second flow augmenting path we scan 1, labeling 2 and 4 and getting $\Delta_2 = 9$, $\Delta_4 = 10$. In scanning 2, that is, trying to label 3 and 5, we cannot label 3 because $c_{ij} = c_{23} = f_{ij} = f_{23} = 11$, and we cannot label 5 because $f_{52} = 0$. In scanning 4 (i.e., labeling 5) we get $\Delta_5 = 7$. In scanning 5 we cannot label 3 because $f_{35} = 0$, and we further get $\Delta_6 = 3$. Hence a flow augmenting path is

$$P_2: \qquad 1 - 4 - 5 - 6$$

and $\Delta_t = 3$. Together we get the maximum flow $11 + 3 = 14$ because no further flow augmenting paths can be found. The result agrees with that in Example 1.

4. Scanning the vertices in the order of their numbers, we get a flow augmenting path

$$P_1: \qquad 1 - 2 - 4 - 6$$

with $\Delta_t = 1$ and then

$$P_2: \qquad 1 - 3 - 4 - 6$$

with $\Delta_t = 1$, but no further flow augmenting path. Since the initial flow was 2, this gives the total flow $f = 4$.

6. The given flow equals 9. We first get the flow augmenting path

$$P_1: \qquad 1 - 2 - 5 \qquad \text{with} \qquad \Delta_t = 2,$$

then the flow augmenting path

$$P_2: \qquad 1 - 3 - 5 \qquad \text{with} \qquad \Delta_t = 5,$$

and finally the flow augmenting path

$$P_3: \qquad 1 - 2 - 3 - 5 \qquad \text{with} \qquad \Delta_t = 1.$$

The maximum flow is $9 + 2 + 5 + 1 = 17$.

8. At each vertex, the inflow and the outflow are increased by the same amount.

12. Start from the zero flow. If it is not maximum, there is an augmenting path by which we can augment the flow by an amount that is an integer, since the capacities are integers, etc.

14. The forward edges of the set are used to capacity; otherwise one would have been able to label their other ends. Similarly for the backward edges of the set, which carry no flow.

16. $f = 7$

18. Let G have k edge-disjoint paths $s \to t$, and let $\tilde{f}$ be a maximum flow in G. Define on those paths a flow f by $f(e) = 1$ on each of their edges. Then $f = k \leqq \tilde{f}$ since $\tilde{f}$ is maximum. Now let G^* be obtained from G by deleting edges that carry no portion of $\tilde{f}$. Then, since each edge has capacity 1, there exist $\tilde{f}$ edge-disjoint paths in G^*, hence also in G, and $\tilde{f} \leqq k$. Together, $\tilde{f} = k$.

im23.qxd 9/21/05 2:01 PM Page 372

20. Since (S, T) is a cut set, there is no directed path $s \to t$ in G with the edges of (S, T) deleted. Since all edges have capacity 1, we thus obtain

$$\text{cap}\,(S, T) \geqq q.$$

Now let E_0 be a set of q edges whose deletion destroys all directed paths $s \to t$, and let G_0 denote G without these q edges. Let V_0 be the set of all those vertices v in G_0 for which there is a directed path $s \to v$. Let V_1 be the set of the other vertices in G. Then (V_0, V_1) is a cut set since $s \in V_0$ and $t \in V_1$. This cut set contains none of the edges of G_0, by the definition of V_0. Hence all the edges of (V_0, V_1) are in E_0, which has q edges. Now (S, T) is a *minimum* cut set, and all the edges have capacity 1. Thus,

$$\text{cap}\,(S, T) \leqq \text{cap}\,(V_0, V_1) \leqq q.$$

Together, $\text{cap}\,(S, T) = q$.

SECTION 23.8. Bipartite Graphs. Assignment Problems, page 982

Purpose. As the last class of problems, in this section we explain assignment problems (of workers to jobs, goods to storage spaces, etc.), so that the vertex set V of the graph consists of two subsets S and T and vertices in S are assigned (related by edges) to vertices in T.

Main Content, Important Concepts

Bipartite graph $G = (V, E) = (S, T; E)$

Matching, maximum cardinality matching

Exposed vertex

Alternating path, augmenting path

Matching algorithm (Table 23.9)

Comment on Content

A few additional problems on graphs, related to the present circle of ideas as well as of a more general nature, are contained in the problem set.

SOLUTIONS TO PROBLEM SET 23.8, page 986

2. Yes, $S = \{1, 4\}$, $T = \{2, 3\}$

4. Yes, $S = \{1, 3, 5\}$, $T = \{2, 4, 6\}$

6. Yes, $S = \{1, 3, 4\}$, $T = \{2, 5\}$

8. $7 - 8 \mathbf{-} 3 - 4 \mathbf{-} 5 - 6 \mathbf{-} 1 - 2$

Part G. PROBABILITY, STATISTICS

CHAPTER 24 Data Analysis. Probability Theory

SECTION 24.1. Data Representation. Average. Spread, page 993

Purpose. To discuss standard graphical representations of data in statistics. To introduce concepts that characterize the average size of the data values and their spread (their variability).

Main Content, Important Concepts

Stem-and-leaf plot

Histogram

Boxplot

Absolute frequency, relative frequency

Cumulative relative frequency

Outliers

Mean

Variance, standard deviation

Median, quartiles, interquartile range

Comment on Content

The graphical representations of data to be discussed in this section have become standard in connection with statistical methods. Average size and variability give the two most important general characterizations of data. Relative frequency will motivate probability as its theoretical counterpart. This is a main reason for presenting this material here before the beginning of our discussion of probability in this chapter. Randomness is not mentioned in this section because the introduction of samples (random samples) as a concept can wait until Chap. 25 when we shall need them in connection with statistical methods. The connection with this section will then be immediate and will provide no difficulty or duplication.

SOLUTIONS TO PROBLEM SET 24.1, page 996

2. $q_L = 2$, $q_M = 5$, $q_U = 6$

4. $q_L = 10.0$, $q_M = 11.6$, $q_U = 12.4$

6. $q_L = -0.52$, $q_M = -0.19$, $q_U = 0.24$

8. $q_L = 85$, $q_M = 87$, $q_U = 89$

10. $q_L = q_M = 14$, $q_U = 14.5$

12. $\bar{x} = 4.3$, $s = 2.541$, IQR $= 4$

14. $\bar{x} = -0.064$, $s = 0.542$, IQR $= 0.76$

16. $\bar{x} = 12.6$ but $q_M = 7$. The data are not sufficiently symmetric. $s = 9.07$, IQR $= 17$

18. $x_{\min} \leqq x_j \leqq x_{\max}$. Now sum over j from 1 to n. Then divide by n to get $x_{\min} \leqq \bar{x} = x_{\max}$.

20. Points to consider are the amounts of calculation, the size of the data (in using quartiles we lose information—the larger the number of data points, the more more information we lose), and the symmetry and asymmetry of the data. In the case of symmetry we

im24.qxd 9/21/05 5:14 PM Page 375

have better agreement between quartiles on the one hand and mean and variance on the other, as in the case of data with considerable deviation from symmetry.

SECTION 24.2. Experiments, Outcomes, Events, page 997

Purpose. To introduce basic concepts needed throughout Chaps. 24 and 25.

Main Content, Important Concepts

Experiment

Sample space S, outcomes, events

Union, intersection, complements of events

Mutually exclusive events

Representation of sets by Venn diagrams

Comment on Content

To make the chapter self-contained, we explain the modest amount of set-theoretical concepts needed in the next sections, although most students will be familiar with these matters.

SOLUTIONS TO PROBLEM SET 24.2, page 999

Section 24.4 will help us to get the answer without listing cases.

im24.qxd 9/21/05 5:14 PM Page 376

10. We obtain

$$A = \{(1, 1), (2, 2), (3, 3), (4, 4), (5, 5) (6, 6)\}$$
$$B = \{(4, 6), (5, 5), (6, 4), (5, 6), (6, 5), (6, 6)\}$$
$$C = \{(1, 6), (2, 5), (3, 4), (4, 3), (5, 2), (6, 1)\}.$$

12. $(5, 5, 5) \in A \cap B$, hence the answer is no. Note that

$$A \cap B = \{(3, 6, 6), (4, 5, 6), (4, 6, 5), (5, 4, 6), (5, 5, 5), (5, 6, 4), (6, 3, 6), (6, 4, 5), (6, 5, 4), (6, 6, 3)\}.$$

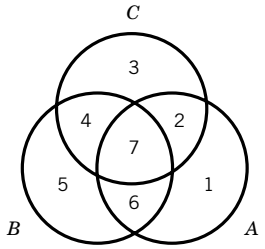
14. The subsets are

$$\varnothing, \{a\}, \{b\}, \{c\}, \{a, b\}, \{a, c\}, \{b, c\}, S.$$

16. For instance, for the first formula we can proceed as follows (see the figure). On the right,

$$A \cup B\text{: All except 3}$$
$$A \cup C\text{: All except 5}$$

and the intersection of these two is



Right side: All except 3 and 5.

On the left,

$$A = 1 \cup 2 \cup 6 \cup 7$$
$$B \cap C = 4 \cup 7$$

and the union of these two gives the same as on the right.

Similarly for the other formula.

Section 24.2. Problem 16

18. Obviously, $A \subseteq B$ implies $A \cap B = A$. Conversely, if $A \cap B = A$, then every element of A must also be in B, by the definition of intersection; hence $A \subseteq B$.

20. $A \cup B = B$ implies $A \subseteq B$ by the definition of union. Conversely, $A \subseteq B$ implies that $A \cup B = B$ because always $B \subseteq A \cup B$, and if $A \subseteq B$, we must have equality in the previous relation.

SECTION 24.3. Probability, page 1000

Purpose. To introduce

1. Laplace's elementary probability concept based on *equally likely* outcomes,
2. The general probability concept defined axiomatically.

im24.qxd 9/21/05 5:14 PM Page 377

Main Content, Important Concepts

Definition 1 of probability

Definition 2 of probability

Motivation of the axioms of probability by relative frequency

Complementation rule, addition rules

Conditional probability

Multiplication rule, independent events

Sampling with and without replacement

Comments on Content

Whereas Laplace's definition of probability takes care of some applications and some statistical methods (for instance, nonparametric methods in Sec. 25.8), the major part of applications and theory will be based on the axiomatic definition of probability, which should thus receive the main emphasis in this section.

Sampling with and without replacement will be discussed in detail in Sec. 24.7.

SOLUTIONS TO PROBLEM SET 24.3, page 1005

2. (a) (i) $0.1 \cdot 0.9^2 \cdot 3 + 0.1^2 \cdot 0.9 \cdot 3 + 0.1^3 = 27.1\%$, as can be seen by noting that

$$E = \{DNN, \quad NDN, \quad NND, \quad DDN, \quad DND, \quad NDD, \quad DDD\}.$$

(ii) The complement of the answer in Prob.1 is $1 - 0.729 = 27.1\%$.

(b) (i) $\dfrac{10}{100} \cdot \dfrac{90}{99} \cdot \dfrac{89}{98} \cdot 3 + \dfrac{10}{100} \cdot \dfrac{9}{99} \cdot \dfrac{90}{98} \cdot 3 + \dfrac{10}{100} \cdot \dfrac{9}{99} \cdot \dfrac{8}{98} = 27.35\%$

(ii) $1 - 0.7265 = 27.35\%$

4. If the sample is small compared to the size of the population from which we sample (this condition is rather obvious) and if the population contains *many* items in each class we are interested in (e.g., many defective as well as many nondefective items, etc.).

6. Increase from $\dfrac{24}{25} = 0.96$ to $\dfrac{20}{25} \cdot \dfrac{19}{24} + \dfrac{20}{25} \cdot \dfrac{5}{24} + \dfrac{5}{25} \cdot \dfrac{20}{24} = 0.96667$, as can be seen from

$$E = \{RR, \quad RL, \quad LR\}.$$

8. We list the outcomes that favor the event whose probability we want to determine, and after each outcome the corresponding probability (F = female, M = male):

FF	1/4
MFF	1/8
FMF	1/8
MMFF	1/16
MFMF	1/16
FMMF	1/16

This gives the answer 11/16.

Note that the result does not depend on the number n ($\geqq 6$) of cards, but only on the ratio F/M.

im24.qxd 9/21/05 5:14 PM Page 378

10. 15/36. This is obtained by noting that

Sum 5 has 4 outcomes (1, 4), (2, 3), (3, 2), (4, 1),

Sum 6 has 5 outcomes, and Sum 7 has 6 outcomes.

12. The event *"odd product"* consists of 9 outcomes

(1, 1), (1, 3), (1, 5)
(3, 1), (3, 3), (3, 5)
(5, 1), (5, 3), (5, 5).

Three of them consist of equal numbers, so that the complement of the event in Prob. 11 consists of $9 - 3 = 6$ outcomes, and $1 - 6/36 = 30/36$, in agreement with Prob. 11.

14. $P^3 = 0.95$ gives $P = 0.983$ as the probability that a single switch does not fail during a given time interval, and the answer is the complement of this, namely, 1.7%.

16. By the complementation rule,

$$P = 1 - 0.95^4 = 18.5\%.$$

18. We have

$$A = B \cup (A \cap B^c)$$

where B and $A \cap B^c$ are disjoint because B and B^c are disjoint. Hence by Axiom 3,

$$P(A) = P(B) + P(A \cap B^c) \geqq P(B)$$

because $P(A \cap B^c)$ is a probability, hence nonnegative.

20. We have

$$P(A) = 2/4 = 1/2, \qquad P(B) = 1/2, \qquad P(C) = 1/2$$

and

$$P(A \cap B) = 1/4, \qquad P(B \cap C) = 1/4, \qquad P(C \cap A) = 1/4,$$

but $P(A \cap B \cap C) = 0$ because there is no chip numbered 111; hence

$$P(A \cap B \cap C) \neq P(A)P(B)P(C) = 1/8.$$

SECTION 24.4. Permutations and Combinations, page 1006

Purpose. To discuss permutations and combinations as tools necessary for systematic counting in experiments with a large number of outcomes.

Main Content

Theorems 1–3 contain the main properties of permutations and combinations we must know.

Formulas (5)–(14) contain the main properties of factorials and binomial coefficients we need in practice.

Comment on Content

The student should become aware of the surprisingly large size of the numbers involved in (1)–(4), even for relatively modest numbers n of given elements, a fact that would make attempts to list cases a very impractical matter.

im24.qxd 9/21/05 5:14 PM Page 379

SOLUTIONS TO PROBLEM SET 24.4, page 1010

2. The 5!/3! = 120/6 = 20 permutations are

·	*ae*	*ai*	*ao*	*au*
ea	·	*ei*	*eo*	*eu*
ia	*ie*	·	*io*	*iu*
oa	*oe*	*oi*	·	*ou*
ua	*ue*	*ui*	*uo*	·

The $\binom{5}{2} = 10$ combination without repetition are obtained from the previous list by regarding the two pairs consisting of the same two letters (in opposite orders) as equal. The $\binom{5+2-1}{2} = \binom{6}{2} = 15$ combinations with repetitions consist of the 10 combinations just mentioned plus the 5 combinations

aa *ee* *ii* *oo* *uu*.

4. $\binom{80}{4} = 1581580$

6. $\binom{10}{3}\binom{5}{2}\binom{6}{2} = 18000$

8. There are $\binom{100}{12}$ samples of 12 from 100; hence the probability of picking a particular one is $1 \Big/ \binom{100}{12}$. Now the number of samples containing the two male mice is $\binom{98}{10}$ because these are obtained by picking the two male mice and then 10 female mice from 98, which can be done in $\binom{98}{10}$ ways. Hence the answer is

$$\binom{98}{10} \Big/ \binom{100}{12} = \frac{1}{75} = 1.3\%.$$

10. By a factor 7293 because

$$\frac{4!6!8!}{18!} \Big/ \frac{2!3!4!}{9!} = \frac{1}{17 \cdot 13 \cdot 11 \cdot 3} = \frac{1}{7293}.$$

12. In 5!/5 = 4! = 24 ways, where the denominator $n = 5$ gives the number of cyclic permutations that give the same order on a round table.

14. The complementary event (no two people have a common birthday) has probability

$$\frac{1}{365^{20}}\ 365 \cdot 364 \cdots 346 = 0.5886$$

(which can also be nicely computed by the Stirling formula). This gives the answer 41%, which is surprisingly large.

16. 9 possible choices for the first unknown digit (0 to 9, not 5) and then 8 for the second. *Answer:* 72.

im24.qxd 9/21/05 5:14 PM Page 380

18. Team Project. (a) There are n choices for the first thing and we terminate with the kth thing, for which we have $n - k + 1$ choices.

(b) The theorem holds when $k = 1$. Assuming that it holds for any fixed positive k, we show that the number of combinations of $(k + 1)$th order is $\binom{n + k}{k + 1}$. From the assumption it follows that there are $\binom{n + k - 1}{k}$ combinations of $(k + 1)$th order of n elements whose first element is 1 (this is the number of combinations of kth order of n elements *with* repetitions). Then there are $\binom{n + k - 2}{k}$ combinations of $(k + 1)$th order whose first element is 2 (this is the number of combinations of kth order of the $n - 1$ elements $2, 3, \cdots, n$, the combinations no longer containing 1 because the combinations containing 1 have just been taken care of). Then there are $\binom{n + k - 3}{k}$ combinations of $(k + 1)$th order of the $n - 2$ elements $3, 4, \cdots, n$ whose first element is 3, etc., and, by (13),

$$\binom{n + k - 1}{k} + \binom{n + k - 2}{k} + \cdots + \binom{k}{k} = \sum_{s=0}^{n-1} \binom{k + s}{k} = \binom{n + k}{k + 1}.$$

(d) $a^k b^{n-k}$ is obtained by picking k of the n factors

$$(a + b)(a + b) \cdots (a + b) \qquad (n \text{ factors})$$

and choosing a from each of k factors (and b from the remaining $n - k$ factors); by Theorem 3, this can be done in $\binom{n}{k}$ ways.

(e) Apply the binomial theorem to

$$(1 + b)^p (1 + b)^q = (1 + b)^{p+q}.$$

b^r has the coefficient $\binom{p + q}{r}$ on the right and $\sum_{k=0}^{r} \binom{p}{k} \binom{q}{r - k}$ on the left.

SECTION 24.5. Random Variables. Probability Distributions, page 1010

Purpose. To introduce the concepts of discrete and continuous random variables and their distributions (to be followed up by the most important special distributions in Secs. 24.7 and 24.8).

Main Content, Important Concepts

Random variable X, distribution function $F(x)$

Discrete random variable, its probability function

Continuous random variable, its density

Comments on Content

The definitions in this section are general, but the student should not be scared because the number of distributions one needs in practice is small, as we shall see.

Discrete random variables occur in experiments in which we ***count,*** continuous random variables in experiments in which we ***measure.***

im24.qxd 9/21/05 5:14 PM Page 381

For both kinds of random variables X the definition of the distribution function $F(x)$ is the same, namely, $F(x) = P(X \leqq x)$, so that it permits a uniform treatment of all X. For discrete X the function $F(x)$ is piecewise constant; for continuous X it is continuous. For obtaining an impression of the distribution of X the probability function or density is more useful than $F(x)$.

SOLUTIONS TO PROBLEM SET 24.5, page 1015

2. Using (10), we have

$$k\int_0^5 x^2\,dx = \frac{5^3k}{3} = 1, \qquad k = \frac{3}{125}.$$

Hence $F(x) = 0$ $(x \leqq 0)$, $F(x) = x^3/125$ $(0 < x \leqq 5)$, $F(x) = 1$ $(x > 5)$.

4. $P(0 \leqq x \leqq 4) = \frac{1}{2}$; $k = 1/8$, so that

$$\int_{-c}^{c} k\,dx = \int_{-c}^{c} \frac{1}{8}\,dx = \frac{c}{4} = 0.95; \qquad \text{hence} \qquad c = 3.8.$$

6. $f(x) = F'(x)$ gives $f(x) = 0$ if $x < 0$, $f(x) = 3e^{-3x}$ if $x > 0$. This illustrates that a density may have discontinuities, whereas the distribution function of a continuous distribution must be continuous.

These first few problems should help the student to recognize the conceptual distinction between probability and density as well as the fact that in many cases the distribution function is given by different formulas over different intervals and that the same holds for the density.

Furthermore, $F(x) = 0.9$ gives $0.1 = e^{-3x}$; hence $x = \frac{1}{3}\ln 10 = 0.7675$.

8. k is obtained from

$$k\sum_{x=0}^{\infty} 2^{-x} = 2k = 1; \qquad \text{hence } k = \tfrac{1}{2}.$$

Furthermore,

$$P(X \geqq 4) = 1 - P(X \leqq 3)$$

where

$$P(X \leqq 3) = \tfrac{1}{2}(1 + \tfrac{1}{2} + \tfrac{1}{4} + \tfrac{1}{8}) = \tfrac{1}{2}(2 - \tfrac{1}{8}) = 1 - \tfrac{1}{16}$$

so that the *answer* is 1/16.

10. From the given distribution function and (9) we obtain

$$\frac{3}{4}\int_{-c}^{c} (1 - x^2)\,dx = \frac{3}{4}\left(2c - \frac{2}{3}c^3\right) = 0.95.$$

This gives the *answer* $c = 0.8114$.

12. Integrating the density, we obtain the distribution function

$$F(x) = 0 \text{ if } x < -1,\ F(x) = \tfrac{1}{2}(x + 1)^2 \text{ if } -1 \leqq x < 0,$$
$$F(x) = 1 - \tfrac{1}{2}(x - 1)^2 \text{ if } 0 \leqq x < 1,\ F(x) = 1 \text{ if } x \geqq 1.$$

About 50 of the cans will contain 50 gallons or more because $Y = 50$ corresponds to $X = 0$ and $F(0) = 0.5$. Similarly, $Y = 49.5$ corresponds to $X = -0.5$ and $F(-0.5) = 0.125$; this is the probability that a can will contain less than 49.5 gallons. Finally, $F(-1) = 0$ is the answer to the last question.

im24.qxd 9/21/05 5:14 PM Page 382

14. By differentiation,

$$f(x) = 0.4x \quad \text{if } 2 < x < 3, \qquad f(x) = 0 \quad \text{otherwise.}$$

Furthermore,

$$P(2.5 < X \leqq 5) = F(5) - F(2.5) = 1 - 0.45 = 0.55,$$

that is, 55%.

16. To have the area under the density curve equal to 1, we must have $k = 5$. If A denotes *"Defective"* and $B = A^c$, we have

$$P(B) = 5 \int_{119.92}^{120.08} dx = 0.8, \qquad P(A) = 0.2,$$

so that about 100 of the 500 axles will be defective.

18. The point of the last two problems is to tell the student to be careful with respect to $<$ and $\leqq$ as well as with $>$ and $\geqq$, where the distinction does not matter in the continuous case but does matter for a discrete distribution. The answers are

$$13\tfrac{1}{3}\%,\ 53\tfrac{1}{3}\%,\ 33\tfrac{1}{3}\%,\ 0,\ 66\tfrac{2}{3}\%,\ 86\tfrac{2}{3}\%,\ 33\tfrac{1}{3}\%,\ 86\tfrac{2}{3}\%.$$

SECTION 24.6. Mean and Variance of a Distribution, page 1016

Purpose. To introduce the two most important parameters of a distribution, the *mean* μ of X (also called *expectation* of X), which measures the central location of the values of X, and the *variance* σ^2 of X, which measures the spread of those values.

Main Content, Important Concepts

Mean μ given by (1)

Variance σ^2 given by (2), standard deviation σ

Standardized random variable (6)

Short Courses. Mention definitions of mean and variance and go on to the special distributions in the next two sections.

Comments on Content

Important practical applications follow in Secs. 24.7, 24.8, and later.

The transformation theorem (Theorem 2) will be basic in Sec. 24.8 and will have various applications in Chap. 25.

Moments (8) and (9) will play no great role in our further work, but would be more important in a more theoretical approach on a higher level. We shall use them in Sec. 25.2.

SOLUTIONS TO PROBLEM SET 24.6, page 1019

2. From the defining formulas we compute

$$\mu = 0 + 0.384 + 2 \cdot 0.096 + 3 \cdot 0.008 = 0.6$$

and

$$\sigma^2 = 0.6^2 \cdot 0.512 + 0.4^2 \cdot 0.384 + 1.4^2 \cdot 0.096 + 2.4^2 \cdot 0.008 = 0.48.$$

This is a special case of the binomial distribution ($n = 3$, $p = 0.2$) to be considered in the next section; the point of this and similar problems is that the student gets a

im24.qxd 9/21/05 5:14 PM Page 383

feel for the concepts of mean and variance, before applying standard formulas for those quantities in the case of special distributions.

4. Theorem 2 gives

$$\mu^* = -\tfrac{8}{3} + 5 = \tfrac{7}{3} \qquad \text{and} \qquad \sigma^{*2} = \tfrac{16}{18} = \tfrac{8}{9}.$$

6. We obtain

$$\mu = \int_0^\infty 2xe^{-2x}\,dx = \tfrac{1}{2}, \qquad \sigma^2 = \int_0^\infty 2(x - \tfrac{1}{2})^2 e^{-2x}\,dx = \tfrac{1}{4}.$$

8. Writing $k = 0.001$ (and in fact for any positive k) we obtain by integrating by parts

$$\mu = k\int_0^\infty xe^{-kx}\,dx = \frac{1}{k}\,.$$

Hence in our case the answer is 1000 hours.

10. About 35

12. We are asking for the sale x such that $F(x) = 0.95$. Integration of $f(x)$ gives

$$F(x) = 3x^2 - 2x^3 \qquad \text{if} \quad 0 \leqq x < 1.$$

From this we get the solution 0.865, meaning that with a probability of 95% the sale will not exceed 8650 gallons (because we measure here in ten thousands of gallons). Thus

$$P(X \leqq 0.865) = 0.95$$

and the complementary event that the sale will exceed 8650 gallons thus has a 5% chance,

$$P(X > 0.865) = 0.05$$

and then the tank will be empty if it has a capacity of 8650 gallons.

14. 1.45%, because for nondefective bolts we obtain

$$\begin{aligned} k\int_{1-0.09}^{1+0.09} f(x)\,dx &= 750\int_{0.91}^{1.09} (x - 0.9)(1.1 - x)\,dx \\ &= 750 \cdot 2\int_0^{0.09} (0.1 + z)(0.1 - z)\,dz \\ &= 0.9855. \end{aligned}$$

16. Team Project. (a) $E(X - \mu) = E(X) - \mu E(1) = \mu - \mu = 0$. Furthermore,

$$\begin{aligned} \sigma^2 = E([X - \mu]^2) &= E(X^2 - 2\mu X + \mu^2) \\ &= E(X^2) - 2\mu E(X) + \mu^2 E(1) \end{aligned}$$

where $E(X) = \mu$ and $E(1) = 1$, so that the result follows. The formula obtained has various practical and theoretical applications.

(b) $g(X) = X$ and the definition of expectation gives the defining formula for the mean. Similarly for (11). For $E(1)$ we get the sum of all possible values or the integral of the density taken over the x-axis, and in both cases the value is 1 because of (6) and (10) in Sec. 24.5.

im24.qxd 9/21/05 5:14 PM Page 384

(c) $E(X^k) = (b^{k+1} - a^{k+1})/[(b - a)(k + 1)]$ by straightforward integration.

(d) Set $x - \mu = t$, write τ instead of t, set $\tau = -t$, and use $f(\mu - t) = f(\mu + t)$. Then

$$E([X - \mu]^3) = \int_{-\infty}^{\infty} t^3 f(\mu + t)\, dt = \int_{-\infty}^{0} \tau^3 (f(\mu + \tau)\, dt + \int_{0}^{\infty} t^3 f(\mu + t)\, dt$$

$$= \int_{\infty}^{0} (-t)^3 f(\mu - t)(-dt) + \int_{0}^{\infty} t^3 f(\mu + t)\, dt = 0.$$

(e) $\mu = 2$, $\sigma^2 = 2$, $\gamma = 4/2^{3/2} = \sqrt{2}$

(g) $f(1) = \frac{1}{2}$, $f(-4) = \frac{1}{3}$, $f(5) = \frac{1}{6}$. But for distributions of interest in applications, the skewness will serve its purpose.

SECTION 24.7. Binomial, Poisson, and Hypergeometric Distributions, page 1020

Purpose. To introduce the three most important *discrete* distributions and to illustrate them by typical applications.

Main Content, Important Concepts

Binomial distribution (2)–(4)

Poisson distribution (5), (6)

Hypergeometric distribution (8)–(10)

Short Courses. Discuss the binomial and hypergeometric distributions in terms of Examples 1 and 4.

Comments on Content

The "symmetric case" $p = q = 1/2$ of the binomial distribution with probability function (2*) is of particular practical interest. Formulas (3) and (4) will be needed from time to time. The approximation of the binomial distribution by the normal distribution will be discussed in the next section.

SOLUTIONS TO PROBLEM SET 24.7, page 1025

2. The complementary event of not hitting the target has the probability 0.9^{10}, so that the *answer* is $P = 1 - 0.9^{10} = 65\%$.

4. The mean is $\mu = np = 50 \cdot 0.03$, so that we get

$$f(x) = \binom{50}{x} 0.03^x 0.97^{50-x} \approx 1.5^x e^{-1.5}/x!.$$

The numerical values are 0.223, 0.335, 0.251, 0.126, 0.047, 0.014. Note that their sum is 0.996, leaving 0.4% for all the other remaining possibilities together (except for a roundoff error).

6. Let X be the number of calls per minute. By assumption the average number of calls per minute is $300/60 = 5$. Hence X has a Poisson distribution with mean $\mu = 5$. By assumption, the board is overtaxed if $X > 10$. From Table A6, App. 5, we see that the complementary event $X \leqq 10$ has probability

$$P(X \leqq 10) = 0.9863.$$

Hence the answer is 1.4%.

im24.qxd 9/21/05 5:14 PM Page 385

8. Let X be the number of defective screws in a sample of size n. The process will be halted if $X \geqq 1$. The manufacturer wants n to be such that $P(X \geqq 1) \approx 0.95$ when $p = 0.1$, thus $P(X = 0) = q^n = 0.9^n \approx 0.05$, and $n \ln 0.9 \approx \ln 0.05$, $n = 28.4$. *Answer:* $n = 28$ or 29.

It is perhaps worthwhile to point to the fact that the situation is typical; in the case of a discrete distribution, one will in general not be able to fulfill percentage requirements exactly.

10. $0.99^{10} = 90.4\%$

12. (a) $\mu = 6$ defects per 300 m, $f(x) = 6^x e^{-6}/x!$,
(b) $f(0) = e^{-6} = 0.00248 \approx 0.25\%$

14. For this problem, the hypergeometric distribution has the probability function

$$f(x) = \binom{5}{x}\binom{15}{3-x}\Big/\binom{20}{3}.$$

The numeric values are

x	0	1	2	3
$P(X = x)$	$\frac{455}{1140}$	$\frac{525}{1140}$	$\frac{150}{1140}$	$\frac{10}{1140}$

These values sum up to 1, as they should.

16. Team Project. (a) In each differentiation we get a factor x_j by the chain rule, so that

$$G^{(k)}(t) = \sum_j x_j{}^k e^{tx_j} f(x_j).$$

If we now set $t = 0$, the exponential function becomes 1 and we are left with the definition of $E(X^k)$. Similarly for a continuous random variable.

(d) By differentiation,

$$G'(t) = n(pe^t + q)^{n-1}pe^t,$$
$$G''(t) = n(n-1)(pe^t + q)^{n-2}(pe^t)^2 + n(pe^t + q)^{n-1}pe^t.$$

This gives, since $p + q = 1$,

$$E(X^2) = G''(0) = n(n-1)p^2 + np.$$

From this we finally obtain the desired result,

$$\sigma^2 = E(X^2) - \mu^2 = n(n-1)p^2 + np - n^2p^2 = npq.$$

(e) $G(t)$ gives $G(0) = 1$ and furthermore,

$$G'(t) = e^{-\mu}\exp\left[\mu e^t\right]\mu e^t = \mu e^t G(t)$$
$$G''(t) = \mu e^t[G(t) + G'(t)]$$
$$E(X^2) = G''(0) = \mu + \mu^2$$
$$\sigma^2 = E(X^2) - \mu^2 = \mu.$$

(f) By definition,

$$\mu = \sum xf(x) = \frac{1}{\binom{N}{n}}\sum x\binom{M}{x}\binom{N-M}{n-x}$$

im24.qxd 9/21/05 5:14 PM Page 386

(summation over x from 0 to n). Now

$$x\binom{M}{x} = \frac{xM(M-1)\cdots(M-x+1)}{x!} = \frac{M(M-1)\cdots(M-x+1)}{(x-1)!} = M\binom{M-1}{x-1}.$$

Thus

$$\mu = \frac{M}{\binom{N}{n}} \sum \binom{M-1}{x-1}\binom{N-M}{n-x}.$$

Now (14), Sec. 24.4, is

$$\sum \binom{p}{k}\binom{q}{r-k} = \binom{p+q}{r}$$

(summation over k from 0 to r). With $p = M-1$, $k = x-1$, $q = N-M$, $r-k = n-x$ we have $p+q = N-1$, $r = k+n-x = n-1$ and the formula gives

$$\mu = \frac{M}{\binom{N}{n}}\binom{N-1}{n-1} = n\frac{M}{N}.$$

SECTION 24.8. Normal Distribution, page 1026

Purpose. To discuss Gauss's normal distribution, the practically and theoretically most important distribution. Use of the normal tables in App. 5.

Main Content, Important Concepts

Normal distribution, its density (1) and distribution function (2)

Distribution function $\Phi(z)$, Tables A7, A8 in App. 5

De Moivre–Laplace limit theorem

Short Course. Emphasis on the use of Tables A7 and A8 in terms of some of the given examples an problems.

Comments on Content

Although the normal tables become superfluous when a CAS (Maple, Mathematica, etc.) is used, their discussion may be advisable for a better understanding of the distribution and its numerical values.

Applications of the *De Moivre–Laplace limit theorem* follow in Chap. 25.

Bernoulli's law of large numbers is included in the problem set.

SOLUTIONS TO PROBLEM SET 24.8, page 1031

2. $\Phi\left(\frac{126-120}{4}\right) = \Phi(1.5) = 0.9332, 1-\Phi\left(\frac{116-120}{4}\right) = 1-\Phi(-1) = 0.8413.$

im24.qxd 9/21/05 5:14 PM Page 387

Similarly,

$$\Phi\left(\frac{130-120}{4}\right)-\Phi\left(\frac{125-120}{4}\right)=\Phi(2.5)-\Phi(1.25)$$
$$=0.9938-0.8944=0.0994.$$

4. We obtain $c=\mu=4.2$ and, furthermore,

$$\Phi\left(\frac{c-4.2}{0.2}\right)=0.9, \qquad \frac{c-4.2}{0.2}=1.282, \qquad c=4.4563$$

and

$$\Phi\left(\frac{c}{0.2}\right)=0.995, \qquad \frac{c}{0.2}=2.576 \qquad c=0.515.$$

6. Smaller. This should help the student in qualitative thinking and an understanding of standard deviation and variance.

8. We get the maximum load c from the condition

$$P(X\leqq c)=\Phi\left(\frac{c-1250}{55}\right)=5\%.$$

By Table A8 in App. 5,

$$\frac{c-1250}{55}=-1.645, \qquad c=1160 \text{ kg}.$$

10. About 680 (Fig. 520a)

12. The complementary event has the probability

$$P(X\leqq 15000)=\Phi\left(\frac{15000-12000}{2000}\right)=\Phi(1.5)=0.9332.$$

Hence the *answer* is 6.7%.

14. Team Project. (c) Let e denote the exponential function in (1). Then

$$(\sigma\sqrt{2\pi}f)''=\left(-\frac{x-\mu}{\sigma^2}e\right)'=\left(-\frac{1}{\sigma^2}+\left(\frac{x-\mu}{\sigma^2}\right)^2\right)e=0, \quad (x-\mu)^2=\sigma^2,$$

hence $x=\mu\pm\sigma$.

(d) Proceeding as suggested, we obtain

$$\Phi^2(\infty)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}e^{-u^2/2}\,du\;\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}e^{-v^2/2}\,dv$$
$$=\frac{1}{2\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}e^{-u^2/2}e^{-v^2/2}\,du\,dv=\frac{1}{2\pi}\int_0^{2\pi}\int_0^{\infty}e^{-r^2/2}r\,dr\,d\theta.$$

The integral over θ equals 2π, which cancels the factor in front, and the integral over r equals 1, which proves the desired result.

im24.qxd 9/21/05 5:14 PM Page 388

(e) Writing β instead of σ in (1) and using $(x - \mu)/\beta = u$ and $dx = \beta\, du$, we obtain

$$\sigma^2 = \frac{1}{\sqrt{2\pi}\,\beta} \int_{-\infty}^{\infty} (x - \mu)^2 \exp\left[-\frac{1}{2} \left(\frac{x - \mu}{\beta} \right)^2 \right] dx$$

$$= \frac{1}{\sqrt{2\pi}\,\beta} \int_{-\infty}^{\infty} \beta^2 u^2 e^{-u^2/2} \beta\, du = \frac{\beta^2}{\sqrt{2\pi}} \int_{-\infty}^{\infty} u^2 e^{-u^2/2}\, du$$

$$= \frac{\beta^2}{\sqrt{2\pi}} \int_{-\infty}^{\infty} (-u)(-ue^{-u^2/2})\, du$$

$$= \beta^2 \left[\frac{1}{\sqrt{2\pi}} (-u) e^{-u^2/2} \Big|_{-\infty}^{\infty} + \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-u^2/2}\, du \right] = \beta^2 (0 + 1) = \beta^2.$$

(f) We have

$$P\left(\left| \frac{X}{n} - p \right| < \epsilon \right) = P([p - \epsilon]n < X < [p + \epsilon]n)$$

and apply (11) with $a = (p - \epsilon)n$, $b = (p + \epsilon)n$. Then, since np cancels,

$$\beta = (\epsilon n + 0.5)/\sqrt{npq}, \qquad \alpha = -\beta,$$

and $\alpha \to -\infty$, $\beta \to \infty$ as $n \to \infty$. Hence the above probability approaches $\Phi(\infty) - \Phi(-\infty) = 1 - 0 = 1$.

(g) Set $x^* = c_1 x + c_2$. Then $(x - \mu)/\sigma = (x^* - \mu^*)/\sigma^*$ and

$$\begin{aligned} F(x^*) &= P(X^* \leqq x^*) \\ &= P(X \leqq x) \\ &= \Phi((x - \mu)/\sigma) \\ &= \Phi((x^* - \mu^*)/\sigma^*). \end{aligned}$$

SECTION 24.9. Distributions of Several Random Variables, page 1032

Purpose. To discuss distributions of two-dimensional random variables, with an extension to n-dimensional random variables near the end of the section.

Main Content, Important Concepts

Discrete two-dimensional random variables and distributions

Continuous two-dimensional random variables and distributions

Marginal distributions

Independent random variables

Addition of means and variances

Short Courses. Omit this section. (Use the addition theorems for means and variances in Chap. 25 without proof.)

Comments on Content

The addition theorems (Theorems 1 and 3) resulting from the present material will be needed in Chap. 25; this is the main reason for the inclusion of this section.

Note well that the addition theorem for variances holds for *independent* random variables only. In contrast, the addition of means is true without that condition.

im24.qxd 9/21/05 5:14 PM Page 389

SOLUTIONS TO PROBLEM SET 24.9, page 1040

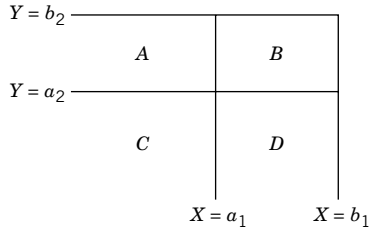
2. The answers are 0 and 1/8. Since the density is constant in that triangle, these results can be read off from a sketch of the triangle and the regions determined by the inequalities $x > 2$, $y > 2$ and $x \leqq 1$, $y \leqq 1$, respectively, without any integrations.

4. We have to integrate $f(x, y) = 1/8$ over y from 0 to $4 - x$, where this upper integration limit follows from $x + y = 4$. This gives the density of the desired marginal distribution in the form

$$f_1(x) = \int_0^{4-x} \frac{1}{8}\, dy = \frac{1}{2} - \frac{1}{8}\, x \quad \text{if } 0 \leqq x \leqq 4 \quad \text{and} \quad 0 \text{ otherwise.}$$

6. By Theorem 1 the mean is $10\,000 \cdot 10 = 100$ kg. By Theorem 3, assuming independence (which is reasonable), we find the variance $10\,000 \cdot (0.05)^2 = 25$, hence the standard deviation 5 grams. Note that the mean is multiplied by $n = 10\,000$, whereas the standard deviation is multiplied only by $\sqrt{n} = 100$.

8. By Theorem 1 the mean is 77 lb. By Theorem 3, assuming independence, we get the variance $0.01 + 0.64$, hence the standard deviation $\sqrt{0.65} = 0.806$ lb.



10. The distributions in Prob. 17 and Example 1

12. (a) From the given distributions we obtain

$$f_1(x) = 50 \text{ if } 0.99 < x < 1.01 \text{ and } 0 \text{ otherwise,}$$
$$f_2(y) = 50 \text{ if } 1.00 < y < 1.02 \text{ and } 0 \text{ otherwise.}$$

(b) A pin fits that hole if $X < 1$, and $P(X < 1) = 50\%$.

14. (X, Y) takes a value in A, B, C, or D (see the figure) with probability $F(b_1, b_2)$, a value in A or C with probability $F(a_1, b_2)$, a value in C or D with probability $F(b_1, a_2)$, a value in C with probability $F(a_1, a_2)$, hence a value in B with probability given by the right side of (2).

16. $x^2 + y^2 = 1$ implies $y = \pm\sqrt{1 - x^2}$, $x = \pm\sqrt{1 - y^2}$; this gives the limits of integration in the integrals for the marginal densities. k times the area π must equal 1, hence $k = 1/\pi$. The marginal distributions have the densities

$$f_1(x) = \int f(x, y)\, dy = \frac{1}{\pi} \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} dy = \frac{2}{\pi}\sqrt{1 - x^2} \quad \text{if } -1 \leqq x \leqq 1$$

and

$$f_2(y) = \int f(x, y)\, dx = \frac{1}{\pi} \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} dx = \frac{2}{\pi}\sqrt{1 - y^2} \quad \text{if } -1 \leqq y \leqq 1$$

im24.qxd 9/21/05 5:14 PM Page 390

and 0 otherwise. Furthermore,

$$P = \frac{1}{\pi}\ \pi \cdot \frac{1}{4} = 25\%$$

(without integration).

18. No. Whereas for the mean it is *not* essential that the trials are not independent and one still obtains from $\mu = M/N$ (single trial) the result $\mu = nM/N$ (n trials) via Theorem 1, one cannot use Theorem 3 here; indeed, the variance $\sigma^2 = M(N - M)/N^2$ (single trial) does not lead to (10), Sec. 24.7.

20. In the continuous case, (18) is obtained from (17) by differentiation, and (17) is obtained from (18) by integration. In the discrete case the proof results from the following theorem. *Two random variables X and Y are independent if and only if the events of the form $a_1 < X \leqq b_1$ and $a_2 < Y \leqq b_2$ are independent*. This theorem can be proved as follows. From (2), Sec. 24.5, we have

$$P(a_1 < X \leqq b_1)P(a_2 < Y \leqq b_2) = [F_1(b_1) - F_1(a_1)][F_2(b_2) - F_2(a_2)].$$

In the case of independence of the variables X and Y we conclude from (17) that the expression on the right equals

$$F(b_1, b_2) - F(a_1, b_2) - F(b_1, a_2) + F(a_1, a_2).$$

Hence, by (2),

$$P(a_1 < X \leqq b_1)P(a_2 < Y \leqq b_2) = P(a_1 < X \leqq b_1, a_2 < Y \leqq b_2).$$

This means independence of $a_1 < X \leqq b_1$ and $a_2 < Y \leqq b_2$; see (14), Sec. 24.3. Conversely, suppose that the events are independent for any a_1, b_1, a_2, b_2. Then

$$P(a_1 < X \leqq b_1)P(a_2 < Y \leqq b_2) = P(a_1 < X \leqq b_1, a_2 < Y \leqq b_2).$$

Let $a_1 \to -\infty$, $a_2 \to -\infty$ and set $b_1 = x$, $b_2 = y$. This yields (17), that is, X and Y are independent.

SOLUTIONS TO CHAP. 24 REVIEW QUESTIONS AND PROBLEMS, page 1041

22. $Q_L = 210$, $Q_M = 212$, $Q_U = 215$

24. $\bar{x} = 211.9$, $s = 4.0125$, $s^2 = 16.1$

26. *HHH*, *HHT*, *HTH*, *THH*, *HTT*, *THT*, *TTH*, *TTT*

28. $F(x) = 0$ if $x < 0$, $F(x) = 0.80816$ if $0 \leqq x < 1$,
$F(x) = 0.99184$ if $1 \leqq x < 2$, $F(x) = 1$ if $x \geqq 2$

30. Obviously, $A \subseteq B$ implies $A \cap B = A$. Conversely, if $A \cap B = A$, then every element of A must also be in B, by the definition of intersection; hence $A \subseteq B$.

32. $\binom{6}{2} = \binom{6}{4} = 15$

34. 42/90, 42/90, 6/90, 0, 48/90

36. We first need

$$\mu = 2\int_0^1 x(1 - x)\,dx = 2\left(\frac{1}{2} - \frac{1}{3}\right) = \frac{1}{3}\,.$$

im24.qxd 9/21/05 5:14 PM Page 391

In the further integrations we can use the defining integrals of $E[X - \mu)^2]$ and $E[(X - \mu)^3]$ or, more simply,

$$\sigma^2 = E(X^2) - \mu^2 = 2\int_0^1 x^2(1 - x)\,dx - \frac{1}{9} = 2\left(\frac{1}{3} - \frac{1}{4}\right) - \frac{1}{9} = \frac{1}{18}$$

and similarly,

$$\begin{aligned} E[(X - \mu)^3] &= E(X^3) - 3\mu E(X^2) + 3\mu^2 E(X) - \mu^3 \\ &= E(X^3) - 3\mu E(X^2) + 2\mu^3 \\ &= 2\int_0^1 x^3(1 - x)\,dx - 3 \cdot \frac{1}{3} \cdot \frac{1}{6} + \frac{2}{27} \\ &= 2\left(\frac{1}{4} - \frac{1}{5}\right) - \frac{1}{6} + \frac{2}{27} = \frac{1}{135}\,. \end{aligned}$$

This gives

$$\gamma = \frac{18\sqrt{18}}{5 \cdot 27} = \frac{2\sqrt{2}}{5}\,.$$

38. $f(x) = 0.2$ if $0 < x < 5$, $f(x) = 0$ elsewhere

40. The 100 bags are normal with mean $100 \cdot 50 = 5000$ kg and, assuming independence (which is reasonable), variance $100 \cdot 1$; hence standard deviation 10 kg. Thus 5030 is just one of the two three-sigma limits, so that the answer is about 0.13%.

im25.qxd 9/21/05 2:06 PM Page 392

CHAPTER 25 Mathematical Statistics

Changes

Regression and a short introduction to correlation have been combined in the same section (Sec. 25.9).

SECTION 25.1. Introduction. Random Sampling, page 1044

Purpose. To explain the role of (random) samples from populations.

Main Content, Important Concepts

Population

Sample

Random numbers, random number generator

Sample mean: $\bar{x}$; see (1)

Sample variance s^2; see (2)

Comments on Content

Sample mean and sample variance are the two most important parameters of a sample. $\bar{x}$ measures the central location of the sample values and s^2 their spread (their variability). Small s^2 may indicate high quality of production, high accuracy of measurement, etc.

Note well that $\bar{x}$ and s^2 will generally vary from sample to sample taken from the same population, whose mean μ and variance σ^2 are unique, of course. This is an important conceptual distinction that should be mentioned explicitly to the students.

SECTION 25.2. Point Estimation of Parameters, page 1046

Purpose. As a first statistical task we discuss methods for obtaining approximate values of unknown population parameters from samples; this is called *estimation of parameters.*

Main Content, Important Concepts

Point estimate, interval estimate

Method of moments

Maximum likelihood method

SOLUTIONS TO PROBLEM SET 25.2, page 1048

2. Put $\mu = 0$ in Example 1 and proceed with the second equation in (8), as in the example, to get the estimate

$$\tilde{\sigma}^2 = \frac{1}{n}\sum_{i=1}^{n} x_i^2.$$

4. The likelihood function is (we can drop the binomial factors)

$$\begin{aligned}\ell &= p^{k_1}(1-p)^{n-k_1} \cdots p^{k_m}(1-p)^{n-k_m} \\ &= p^{k_1+\cdots+k_m}(1-p)^{nm-(k_1+\cdots+k_m)}.\end{aligned}$$

im25.qxd 9/21/05 2:06 PM Page 393

The logarithm is

$$\ln \ell = (k_1 + \cdots + k_m) \ln p + [nm - (k_1 + \cdots + k_m)] \ln (1 - p).$$

Equating the derivative with respect to p to zero, we get, with a factor -1 from the chain rule,

$$(k_1 + \cdots + k_m) \frac{1}{p} = [nm - (k_1 + \cdots + k_m)] \frac{1}{1 - p}.$$

Multiplication by $p(1 - p)$ gives

$$(k_1 + \cdot \cdot + k_m)(1 - p) = [nm - (k_1 + \cdots + k_m)]p.$$

By simplification,

$$k_1 + \cdot \cdot \cdot k_m = nmp.$$

The result is

$$\hat{p} = \frac{1}{nm} \sum_{i=1}^{m} k_i.$$

6. We obtain

$$\begin{aligned} \ell &= f(x_1)f(x_2) \cdot \cdot \cdot f(x_n) \\ &= p(1 - p)^{x_1 - 1} p(1 - p)^{x_2 - 1} \cdot \cdot \cdot p(1 - p)^{x_n - 1} \\ &= p^n (1 - p)^{x_1 + \cdots + x_n - n}. \end{aligned}$$

The logarithm is

$$\ln \ell = n \ln p + \left(\sum_{m=1}^{n} x_m - n \right) \ln (1 - p).$$

Differentiation with respect to p gives, with a factor -1 from the chain rule,

$$\frac{\partial \ln \ell}{\partial p} = \frac{n}{p} - \sum_{m=1}^{n} \frac{x_m - n}{1 - p}.$$

Equating this derivative to zero gives

$$n(1 - \hat{p}) = \hat{p} \left(\sum_{m=1}^{n} x_m - n \right).$$

Thus $\hat{p} = 1/\bar{x}$.

8. $\hat{p} = 2/(7 + 6) = 2/13$, by Prob. 6.

10. $\ell = 1(b - a)^n$ is maximum if $b - a$ is as small as possible, that is, a equal to the smallest sample value and b equal to the largest.

12. $\mu = 1/\theta$, $\hat{\mu} = \bar{x}$

14. $\hat{\theta} = 1/\bar{x} = 2$, $F(x) = 1 - e^{-2x}$ if $x \geqq 0$ and 0 otherwise. A graph shows that the step function $\tilde{F}(x)$ (the sample distribution function) approximates $F(x)$ reasonably well. (For goodness of fit, see Sec. 25.7.)

SECTION 25.3. Confidence Intervals, page 1049

Purpose. To obtain interval estimates ("confidence intervals") for unknown population parameters for the normal distribution and other distributions.

im25.qxd 9/21/05 2:06 PM Page 394

Main Content, Important Concepts

Confidence interval for μ if σ^2 is known

Confidence interval for μ if σ^2 is unknown

t-distribution, its occurrence (Theorem 2)

Confidence interval for σ^2

Chi-square distribution, its occurrence (Theorem 3)

Distribution of a sum of independent normal random variables

Central limit theorem

Comments on Content

The present methods are designed for the normal distribution, but the central limit theorem permits their extension to other distributions, provided we can use sufficiently large samples.

The theorems giving the theory underlying the present methods also serve as the theoretical basis of tests in the next section. Hence these theorems are of basic importance.

We see that, although our task is the development of methods for the normal distribution, other distributions (t and chi-square) appear in the mathematical foundation of those methods.

SOLUTIONS TO PROBLEM SET 25.3, page 1057

2. In Prob. 1 we have $\bar{x} = 40.667$, $k = 3.201$. Instead of $c = 1.96$ we now have $c = 2.576$ in Table 25.1. Hence k (and thus the length of the interval) is multiplied by 2.576/1.960, so that the new k is 4.207, giving the longer interval

$$\text{CONF}_{0.99}\{36.460 \leqq \mu \leqq 44.874\}.$$

4. $k = 1.645 \cdot 0.5/\sqrt{100} = 0.08225$, $\text{CONF}_{0.9}\{212.218 \leqq \mu \leqq 212.382\}$.

The large sample size and small population variance have given a short interval, although the probability that it does not contain μ is 10%, due to the choice of γ. But for larger γ (<1) the interval is still rather short.

6. This is a fast way of limited accuracy. More importantly, it should help the student get a better understanding of the whole idea of confidence intervals.

From the figure we obtain $L/\sigma = 2k/\sigma = k = 0.27$, approximately. Thus the confidence interval is roughly $\text{CONF}_{0.95}\{119.73 \leqq \mu \leqq 120.27\}$. Calculation gives the more exact value $k = 0.277$.

8. $n - 1 = 3$ degrees of freedom; $F(c) = 0.995$ gives $c = 5.84$. From the sample we compute

$$\bar{x} = 426.25, \qquad s^2 = 39.58.$$

Hence $k = 18.37$ in Table 25.2, Step 4. This gives the confidence interval

$$\text{CONF}_{0.99}\{407 \leqq \mu \leqq 445\}.$$

10. $n - 1 = 5$; $F(c) = 0.995$ gives $c = 4.03$. From the sample we compute

$$\bar{x} = 9533, \qquad s^2 = 49667.$$

Hence $k = 367$ in Table 25.2, Step 4. This gives the confidence interval

$$\text{CONF}_{0.99}\{9166 \leqq \mu \leqq 9900\}.$$

im25.qxd 9/21/05 2:06 PM Page 395

12. $n - 1 = 4$; $F(c) = 0.995$ gives $c = 4.60$. From the sample we compute

$$\bar{x} = 661.2, \qquad s^2 = 22.70.$$

Hence $k = 9.8$ in Table 25.2, Step 4. This gives the confidence interval

$$\text{CONF}_{0.99}\{651.3 \leqq \mu \leqq 671.1\}.$$

14. $n = 24\,000$, $\bar{x} = 12\,012$, $\hat{p} = \bar{x}/n = 0.5005$. Now the random variable

$$X = \textit{Number of heads in } 24\,000 \textit{ trials}$$

is approximately normal with mean $24\,000p$ and variance $24\,000p(1 - p)$. Estimators are

$$24\,000\hat{p} = 12\,012 \qquad \text{and} \qquad 24\,000\hat{p}(1 - \hat{p}) = 5999.99.$$

For the standardized normal random variable we get from Table A8 in App. 5 (or from a CAS) and $\Phi(c) = 0.995$ the value

$$c = 2.576 = \frac{c^* - 12\,012}{\sqrt{6000}}$$

and

$$c^* - 12\,012 = 2.576\sqrt{6000} = 199.5$$

so that

$$\text{CONF}_{0.99}\{11\,812 \leqq \mu \leqq 12\,212\}$$

and by division by n,

$$\text{CONF}_{0.99}\{0.492 \leqq p \leqq 0.509\}.$$

16. $n - 1 = 19$, $c_1 = 8.91$, $c_2 = 32.85$, $19 \cdot 0.04 = 0.76$, $k_1 = 0.76/8.91 = 0.086$, $k_2 = 0.76/32.85 = 0.023$. Hence

$$\text{CONF}_{0.95}\{0.023 \leqq \sigma^2 \leqq 0.086\}.$$

18. $n - 1 = 7$ degrees of freedom, $F(c_1) = 0.025$, $c_1 = 1.69$, $F(c_2) = 0.975$, $c_2 = 16.01$ from Table A10. From the sample,

$$\bar{x} = 17.7625, \qquad (n - 1)s^2 = 7s^2 = 0.73875.$$

Hence $k_1 = 0.437$, $k_2 = 0.046$. The *answer* is

$$\text{CONF}_{0.95}\ \{0.046 \leqq \sigma^2 \leqq 0.437\}.$$

20. $n - 1 = 9$ degrees of freedom, $F(c_1) = 0.025$, $c_1 = 2.70$, $F(c_2) = 0.975$, $c_2 = 19.02$ from Table A10. From the sample,

$$\bar{x} = 253.5, \qquad 9s^2 = 54.5.$$

Hence $k_1 = 54.5/2.70 = 20.19$, $k_2 = 54.5/19.02 = 2.87$. From Table 25.3 we thus obtain the (rather long!) confidence interval

$$\text{CONF}_{0.95}\{2.8 \leqq \sigma^2 \leqq 20.2\}.$$

22. By Theorem 1 in this section and by the hint, the distribution of $4X_1 - X_2$ is normal with mean $4 \cdot 23 - 4 = 88$ and variance $16 \cdot 3 + 1 = 49$.

im25.qxd 9/21/05 2:06 PM Page 396

24. By Theorem 1, the load Z is normal with mean $40N$ and variance $4N$, where N is the number of bags. Now

$$P(Z \leqq 2000) = \Phi\left(\frac{2000 - 40N}{2\sqrt{N}}\right) = 0.95$$

gives the condition

$$\frac{2000 - 40N}{2\sqrt{N}} \geqq 1.645$$

by Table A8. The *answer* is $N = 49$ (since N must be an integer).

SECTION 25.4. Testing of Hypotheses. Decisions, page 1058

Purpose. Our third big task is testing of hypotheses. This section contains the basic ideas and the corresponding mathematical formalism. Applications to further tasks of testing follow in Secs. 25.5–25.7.

Main Content, Important Concepts

Hypothesis (null hypothesis)

Alternative (alternative hypothesis), one- and two-sided

Type I error (probability α = significance level)

Type II error (probability β; $1 - \beta$ = power of a test)

Test for μ with known σ^2 (Example 2)

Test for μ with unknown σ^2 (Example 3)

Test for σ^2 (Example 4)

Comparison of means (Example 5)

Comparison of variances (Example 6)

Comment on Content

Special testing procedures based on the present ideas have been developed for controlling the quality of production processes (Sec. 25.5), for assessing the quality of produced goods (Sec. 25.6), for determining whether some function $F(x)$ is the unknown distribution function of some population (Sec. 25.7), and for situations in which the distribution of a population need not be known in order to perform a test (Sec. 25.8).

SOLUTIONS TO PROBLEM SET 25.4, page 1067

2. If the hypothesis $p = 0.5$ is true, X = *Number of heads in* 4040 *trials* is approximately normal with $\mu = 2020$, $\sigma^2 = 1010$ (Sec. 24.8). Hence

$$P(X \leqq c) = \Phi([c - 2020]/\sqrt{1010}) = 0.95, \qquad c = 2072 > 2048,$$

do not reject the hypothesis.

4. Left-sided test, $\sigma^2/n = 4/10 = 0.4$. From Table A8 in App. 5 we obtain

$$P(\overline{X} \leqq c)_{\mu=30.0} = \Phi\left(\frac{c - 30.0}{\sqrt{0.4}}\right) = 0.05.$$

Hence

$$c = 30.0 - 1.645\sqrt{0.4} = 28.96$$

and we reject the hypothesis.

im25.qxd 9/21/05 2:06 PM Page 397

(b) Right-sided test. We get

$$\bar{x} < c = 31.04$$

and do not reject the hypothesis.

6. We obtain

$$\eta(28.5) = P(\bar{X} > 28.96)_{\mu=28.5} = 1 - P(\bar{X} \leqq 28.96)_{\mu=28.5}$$
$$= 1 - \Phi\left(\frac{28.96 - 28.50}{\sqrt{0.4}}\right)$$
$$= 1 - \Phi(0.73) = 1 - 0.7673 = 0.2327.$$

8. The test is two-sided. The variance is unknown, so we have to proceed as in the case of Example 3. From the sample we compute

$$t = \sqrt{10}\,(0.811 - 0.800)/\sqrt{0.000\,054} = 4.73.$$

Now from Table A9 in App. 5 with $n - 1 = 9$ degrees of freedom and the condition

$$P(-c \leqq T \leqq c) = 0.95 \qquad \text{we get} \qquad c = 2.26.$$

Since $t > c$, we reject the hypothesis.

10. Hypothesis $\mu_0 = 30\,000$, alternative $\mu > 30\,000$. Using the given data and Table A9, we obtain

$$t = \sqrt{50}\,(32\,000 - 30\,000)/4000 = 3.54 > c = 1.68.$$

Hence we reject the hypothesis and assert that the manufacturer's claim is justified.

12. Hypothesis H_0: Not better. Alternative H_1: Better. Under H_0 the random variable

$$X = \textit{Number of cases cured in } 200 \textit{ cases}$$

is approximately normal with mean $\mu = np = 200 \cdot 0.7 = 140$ and variance $\sigma^2 = npq = 42$. From Table A8 and $\alpha = 5\%$ we get

$$(c - 140)/\sqrt{42} = 1.645, \qquad c = 140 + 1.645\sqrt{42} = 150.7.$$

Since the observed value 148 is not greater than c, we do not reject the hypothesis. This indicates that the results obtained so far do not establish the superiority.

14. We test the hypothesis ${\sigma_0}^2 = 25$ against the alternative that $\sigma^2 < 25$. As in Example 4, we now get

$$Y = (n - 1)S^2/{\sigma_0}^2 = 27S^2/25 = 1.08S^2.$$

From Table A10 with 27 degrees of freedom and the condition

$$P(Y < c) = \alpha = 5\% \qquad \text{we get} \qquad c = 16.2.$$

As in Example 4 we compute the corresponding

$$c^* = 16.2/1.08 = 15.00.$$

Now the observed value of S^2 is $s^2 = 3.5^2 = 12.25$. Since this is less than c^* and the test is left-sided, we reject the hypothesis and assert that it will be less expensive to replace all batteries simultaneously.

16. We test the hypothesis ${\sigma_x}^2 = {\sigma_y}^2$ against the alternative ${\sigma_x}^2 > {\sigma_y}^2$. We proceed as in Example 6. By computation,

$$v_0 = {s_x}^2/{s_y}^2 = 350/61.9 = 5.65.$$

im25.qxd 9/21/05 2:06 PM Page 398

For $\alpha = 5\%$ and (5, 6) degrees of freedom. Table A11 in App. 5 gives 4.39. Since 5.65 is greater, we reject the hypothesis and assert that the variance of the first population is greater than that of the second.

18. The test is two-sided. As in Example 5 we compute from (12)

$$t_0 = \sqrt{9}\,\frac{12 - 15}{\sqrt{4 + 4}} = -3.18.$$

Now Table A9 with $9 + 9 - 2 = 16$ degrees of freedom gives from $P(-c < T < c) = 0.95$ the value $c = 2.12$. Since $-3.18 < -2.12$, we reject the hypothesis.

SECTION 25.5. Quality Control, page 1068

Purpose. Quality control is a testing procedure performed every hour (or every half hour, etc.) in an ongoing process of production in order to see whether the process is running properly ("is under control," is producing items satisfying the specifications) or not ("is out of control"), in which case the process is being halted in order to search for the trouble and remove it. These tests may concern the mean, variance, range, etc.

Main Content

Control chart for the mean

Control chart for the variance

Comment on Content

Control charts have also been developed for the range, the number of defectives, the number of defects per unit, for attributes, etc. (see the problem set).

SOLUTIONS TO PROBLEM SET 25.5, page 1071

2. The assertion follows from (6c) in Sec. 24.8. As the numeric values we obtain

$$\mu \pm 3\sigma/\sqrt{n} = 1 \pm 0.09/\sqrt{6} = 1 \pm 0.037,$$

so that LCL = 0.963 and UCL = 1.037.

4. LCL and UCL will correspond to a significance level α, which, in general, is not equal to 1%.

6. $\text{LCL} = n\mu_0 - 2.58\sigma\sqrt{n}$, $\text{UCL} = n\mu_0 + 2.58\sigma\sqrt{n}$, as follows from Theorem 2 in Sec. 24.6.

8. $\text{LCL} = 5.00 - 2.58 \cdot 1.55/\sqrt{4} = 3$, UCL = 7

10. Decrease by a factor $\sqrt{2} = 1.41$. By a factor $2.58/1.96 = 1.32$ (see Table 25.1 in Sec. 25.3). Hence the two operations have almost the same effect.

12. The sample range tends to increase with increasing n, whereas σ remains unchanged.

14. Trend of sample means to increase. Abrupt change of sample means.

16. The random variable Z = *Number of defectives in a sample of size n* has the variance npq. Hence $\overline{X} = Z/n$ has the variance $\sigma^2 = npq/n^2 = 0.05 \cdot 0.95/100 = 0.000\,475$. This gives

$$\text{UCL} = 0.05 + 3\sigma = 0.115.$$

From the given values we see that the process is out of control.

im25.qxd 9/21/05 2:06 PM Page 399

SECTION 25.6. Acceptance Sampling, page 1073

Purpose. This is a test for the quality of a produced lot designed to meet the interests of both the producer and the consumer of the lot, as expressed in the terms listed below.

Main Content, Important Concepts

Sampling plan, acceptance number, fraction defective

Operating characteristic curve (OC curve)

Acceptable quality level (AQL)

Rejectable quality level (RQL)

Rectification

Average outgoing quality limit (AOQL)

Comments on Content

Basically, acceptance sampling first leads to the hypergeometric distribution, which, however, can be approximated by the simpler Poisson distribution and simple formulas resulting from it, or in other cases by the binomial distribution, which can in turn be approximated by the normal distribution. Typical cases are included in the problem set.

SOLUTIONS TO PROBLEM SET 25.6, page 1076

2. We expect a decrease of values because of the exponential function in (3), which involves n. The probabilities are 0.9098 (down from 0.9825), 0.7358, 0.0404.

4. $P(A;\ \theta) = e^{-20\theta}(1 + 20\theta)$ from (3). From Fig. 539 we find α and β. For $\theta = 1.5\%$ we obtain $P(A;\ 0.015) = 96.3\%$, hence $\alpha = 3.7\%$. Also $\beta = P(A;\ 0.075) = 55.8\%$, which is very poor.

6. $\mathrm{AOQ}(\theta) = \theta e^{-30\theta}(1 + 30\theta)$, $\mathrm{AOQ}' = 0$, $\theta_{\max} = 0.0539$, $\mathrm{AOQ}(\theta_{\max}) = 0.0280$

8. The approximation is $\theta^0(1 - \theta)^2$ and is fairly accurate, as the following values show:

θ	Exact (2D)	Approximate
0.0	1.00	1.00
0.2	0.63	0.64
0.4	0.35	0.36
0.6	0.15	0.16
0.8	0.03	0.04
1.0	0.00	0.00

10. From the definition of the hypergeometric distribution we now obtain

$$P(A;\ \theta) = \binom{20\theta}{0}\binom{20 - 20\theta}{3} \Big/ \binom{20}{3}$$

$$= \frac{(20 - 20\theta)(19 - 20\theta)(18 - 20\theta)}{6840}.$$

This gives $P(A;\ 0.1) = 0.72$ (instead of 0.81 in Example 1) and $P(A;\ 0.2) = 0.49$ (instead of 0.63), a decrease in both cases, as had to be expected.

12. $1 - 0.99^5 = 0.05$, $0.85^5 = 0.44$

im25.qxd 9/21/05 2:06 PM Page 400

14. For $\theta = 0.05$ we should get $P(A;\ \theta) = 0.98$. (Figure 539 illustrates this, for different values.) Since $n = 100$, we get $np = 5$ and the variance $npq = 5 \cdot 0.95 = 4.75$. Using the normal approximation of the binomial distribution, we thus obtain, with c to be determined,

$$\sum_{x=0}^{c} \binom{100}{x} 0.05^x 0.95^{100-x} \approx \Phi\left(\frac{c - 5 + 0.5}{\sqrt{4.75}}\right) - \Phi\left(\frac{0 - 5 - 0.5}{\sqrt{4.75}}\right) = 0.9800.$$

The second Φ-term equals $\Phi(-5.5/\sqrt{4.75}) = \Phi(-2.52) = 0.0059$ (Table A7). From this, $\Phi((c - 4.5)/\sqrt{4.75}) = 0.9859$, so that Table A8 gives

$$c = 4.50 + 2.19\sqrt{4.75} = 9.27.$$

Hence choose 9 or 10 as c.

16. By the binomial distribution,

$$\begin{aligned} P(A;\ \theta) &\approx \sum_{x=0}^{1} \binom{n}{x} \theta^x (1 - \theta)^{n-x} \\ &= (1 - \theta)^{n-1}[1 + (n - 1)\theta], \end{aligned}$$

which in those special cases gives

$$(1 - \theta)(1 + \theta) = 1 - \theta^2 \qquad (n = 2)$$

$$(1 - \theta)^2(1 + 2\theta) \qquad (n = 3)$$

$$(1 - \theta)^3(1 + 3\theta) \qquad (n = 4).$$

18. We have

$$P(A;\ \theta) \approx (1 - \theta)^5,$$

hence

$$\text{AOQ}(\theta) \approx \theta(1 - \theta)^5.$$

Now

$$[\theta(1 - \theta)^5]' = 0$$

gives $\theta = 1/6$, and from this,

$$\text{AOQL} = \text{AOQ}(\tfrac{1}{6}) = 0.067.$$

SECTION 25.7. Goodness of Fit. χ^2-Test, page 1076

Purpose. The χ^2-test is a test for a whole unknown distribution function, as opposed to the previous tests for unknown parameters in known types of distributions.

Main Content

Chi-square (χ^2) test

Test of normality

Comments on Content

The present method includes many practical problems, some of which are illustrated in the problem set.

Recall that the chi-square distribution also occurred in connection with confidence intervals and in our basic section on testing (Sec. 25.4).

im25.qxd 9/21/05 2:06 PM Page 401

SOLUTIONS TO PROBLEM SET 25.7, page 1079

2. The hypothesis that the coin is fair is accepted, in contrast with Prob. 1, because we now obtain

$$\chi_0^2 = \frac{(3-5)^2}{5} + \frac{(7-5)^2}{5} = 1.6 < 3.84.$$

4. From the sample and from Table A10 with $n - 1 = 5$ degrees of freedom we obtain

$$\chi_0^2 = (9^2 + 8^2 + 11^2 + 4^2 + 10^2 + 2^2)/30 = 12.87 > c = 11.07.$$

Accordingly, we reject the hypothesis that the die is fair.

6. $K = 2$ classes (dull, sharp). Expected values 10 dull, 390 sharp; 1 degree of freedom; hence

$$\chi_0^2 = \tfrac{49}{10} + \tfrac{49}{390} = 5.03 > 3.84.$$

Reject the claim. Here, two things are interesting. First, 16 dull knives (an excess of 60% over the expected value!) would not have been sufficient to reject the claim at the 5% level. Second, 49/10 contributes much more to χ_0^2 than 49/390 does; in other applications the situation will often be qualitatively similar.

8. The maximum likelihood estimates for the two parameters are $\bar{x} = 59.87$, $\hat{s} = 1.504$. $K - 1 - 2 = 2$ degrees of freedom. From Table A10 we get the critical value $9.21 > \chi_0^2 = 6.22$. Accept the hypothesis that the population from which the sample was taken is normally distributed. χ_0^2 is obtained as follows.

x	$\frac{x-\bar{x}}{s}$	$\Phi\left(\frac{x-\bar{x}}{s}\right)$	Expected	Observed	Terms in (1)
58.5	−0.91	0.181	14.31	14	0.01
59.5	−0.25	0.402	17.51	17	0.01
60.5	0.42	0.662	20.50	27	2.06
61.5	1.08	0.860	15.68	8	3.78
∞		1.000	11.00	13	0.36
					$\chi_0^2 = 6.22$

Slightly different results due to rounding are possible.

10. Let $50 + b$ be that number. Then $2b^2/50 > c$, $b > 5\sqrt{c}$, $50 + b = 60, 63, 64$.

12. $\hat{\mu} = \bar{x} = 23/50 = 0.46$, 1 degree of freedom, since we estimated μ. We thus obtain

$$\chi_0^2 = \frac{(33-31.56)^2}{31.56} + \frac{(11-14.52)^2}{14.52} + \frac{(6-3.34)^2}{3.34} = 3.04 < 3.84.$$

Hence we accept the hypothesis.

14. Expected $2480/3 = 827$ cars per lane; accordingly,

$$\chi_0^2 = \tfrac{1}{827}(83^2 + 23^2 + 107^2) = 22.81 > 5.99$$

(2 degrees of freedom, $\alpha = 5\%$). Hence we reject the hypothesis. (Note that even $\alpha = 1\%$ or 0.5% would lead to the same conclusion.)

16. We test the hypothesis H_0 that the number of defective rivets is the same for all three machines. Since

$$(7 + 8 + 12)/600 = 0.045$$

im25.qxd 9/21/05 2:06 PM Page 402

the expected number of defective rivets in 200 should be 9. Hence

$$\chi_0^2 = [(7-9)^2 + (8-9)^2 + (12-9)^2]/9 = 1.56.$$

Now from Table A10 with 2 degrees of freedom we get $c = 5.99$ and conclude that the difference is not significant.

18. $\bar{x} = 107$, $\chi_0^2 = \frac{1}{107}(13^2 + 12^2 + 3^2 + 1^2 + 5^2) = 3.252 < 9.49$ (4 degrees of freedom), so that we accept the hypothesis of equal time-efficiency.

20. Team Project. $n = 3 \cdot 77 = 231$.

(a) $a_j = 231/20 = 11.55$, $K = 20$, $\chi_0^2 = 24.32 < c = 30.14$ ($\alpha = 5\%$, 19 degrees of freedom). Accept the hypothesis.

(b) $\chi_0^2 = 13.10 > c = 3.84$ ($\alpha = 5\%$, 1 degree of freedom). Reject the hypothesis.

(c) $\chi_0^2 = 14.7 > c = 3.84$ ($\alpha = 5\%$, 1 degree of freedom). Reject the hypothesis.

SECTION 25.8. Nonparametric Tests, page 1080

Purpose. To introduce the student to the ideas of nonparametric tests in terms of two typical examples selected from a wide variety of tests in that field.

Main Content

Median, a test for it

Trend, a test for it

Comment on Content

Both tasks have not yet been considered in the previous sections. Another approach to trend follows in the next section.

SOLUTIONS TO PROBLEM SET 25.8, page 1082

2. Under the hypothesis that no adjustment is needed, shorter and longer pipes are equally probable. We drop the 4 pipes of exact length from the sample. Then the probability that under the hypothesis one gets 3 or fewer longer pipes among 18 pipes is, since $np = 9$ and $\sigma^2 = npq = 4.5$,

$$\sum_{x=0}^{3} \binom{18}{x} \left(\frac{1}{2}\right)^{18} \approx \Phi\left(\frac{3 - 9 + \frac{1}{2}}{\sqrt{4.5}}\right) - \Phi\left(\frac{0 - 9 - \frac{1}{2}}{\sqrt{4.5}}\right)$$
$$= \Phi(-2.6) - \Phi(-4.5) = 0.0047$$

and we reject the hypothesis and assert that the process needs adjustment.

4. Let $X =$ *Number of positive values among* 9 *values*. If the hypothesis is true, a value greater than 20°C is as probable as a value less than 20°C, and thus has probability 1/2. Hence, under the hypothesis the probability of getting at most 1 positive value is

$$P = (\tfrac{1}{2})^9 + 9 \cdot (\tfrac{1}{2})^9 = 2\%.$$

Hence we reject the hypothesis and assert that the setting is too low.

6. We drop 0 from the sample. Let $X =$ *Number of positive values.* Under the hypothesis we get the probability

$$P(X = 9) = \binom{9}{9} \left(\frac{1}{2}\right)^9 = 0.2\%.$$

im25.qxd 9/21/05 2:06 PM Page 403

Accordingly, we reject the hypothesis that there is no difference between A and B and assert that the observed difference is significant.

8. Under the hypothesis the probability of obtaining at most 3 negative differences (80 − 85, 90 − 95, 60 − 75) is

$$\left(\frac{1}{2}\right)^{15}\left[1+\binom{15}{1}+\binom{15}{2}+\binom{15}{3}\right]=1.76\%.$$

We reject the hypothesis and assert that B is better.

10. Hypothesis H_0: $q_{25}=0$. Alternative H_1, say, $q_{25}>0$. If H_0 is true, a negative value has probability $p=0.25$. Reject H_0 if fewer than c negative values are observed, where c results from $P(X \leqq c)_{H_0}=\alpha$.

14. $n=5$ values, with 2 transpositions, namely,

101.1 before 100.4 and 100.8,

so that from Table A12 we obtain

$$P(T \leqq 2)=0.117$$

and we do not reject the hypothesis.

16. We order by increasing x. Then we have 10 transpositions:

418 > 301, 352, 395, 375, 388

395 > 375, 388

465 > 455

521 > 455, 490.

Hypothesis *no trend,* alternative *positive trend,* $P(T \leqq 10)=1.4\%$ by Table A12 in App. 5. Reject the hypothesis.

18. $n=8$ values, with 4 transpositions, namely,

41.4 before 39.6

43.3 before 39.6, 43.0

45.6 before 44.5.

Table A12 gives

$$P(T \leqq 4)=0.007.$$

Reject the hypothesis that the amount of fertilizer has no effect and assert that the yield increases with increasing amounts of fertilizer.

SECTION 25.9. Regression. Fitting Straight Lines. Correlation, page 1083

Purpose. This is a short introduction to regression analysis, restricted to linear regression, and to correlation analysis; the latter is presented without proofs.

Main Content, Important Concepts

Distinction between regression and correlation

Gauss's least squares method

Sample regression line, sample regression coefficient

Population regression coefficient, a confidence interval for it

im25.qxd 9/21/05 2:06 PM Page 404

Sample covariance s_{xy}

Sample correlation coefficient r

Population covariance σ_{XY}

Population correlation coefficient ρ

Independence of X and Y implies $\rho = 0$ ("uncorrelatedness")

Two-dimensional normal distribution

If (X, Y) is normal, $\rho = 0$ implies independence of X and Y.

Test for $\rho = 0$

SOLUTIONS TO PROBLEM SET 25.9, page 1091

2. $\Sigma x_i = 24$, $\Sigma y_i = 13$, $n = 4$, $\Sigma x_i y_i = 79$, $(n-1)s_x^2 = 20$, by (9a). Hence we obtain from (11)

$$k_1 = \frac{4 \cdot 79 - 24 \cdot 13}{4 \cdot 20} = 0.05.$$

This gives the *answer*

$$y - 3.25 = 0.05(x - 6), \qquad \text{hence} \qquad y = 2.95 + 0.05x.$$

4. $n = 5$, $\Sigma x_i = 85$, $\bar{x} = 17$, $\Sigma y_i = 75$, $\bar{y} = 15$, $\Sigma x_i y_i = 1184$, hence

$$(n-1)s_x^2 = 4s_x^2 = 74.$$

Hence (11) gives

$$k_1 = \frac{5 \cdot 1184 - 85 \cdot 75}{5 \cdot 74} = -1.230.$$

The *answer* is

$$y - 15 = -1.230(x - 17), \qquad \text{hence} \qquad y = 35.91 - 1.230x.$$

6. $n = 9$, $\Sigma x_i = 183$, $\bar{x} = 20.33$, $\Sigma y_i = 440$, $\bar{y} = 48.89$, $\Sigma x_i y_i = 7701$, $(n-1)s_x^2 = 8s_x^2 = 944$. From (11) we thus obtain

$$k_1 = \frac{9 \cdot 7701 - 183 \cdot 440}{9 \cdot 944} = -1.32.$$

This gives the *answer*

$$y - 48.89 = -1.32(x - 20.33), \qquad \text{hence} \qquad y = 75.72 - 1.32x.$$

8. Equation (5) is

$$y - 1.875 = 0.067(x - 25); \qquad \text{thus} \qquad y = 0.2 + 0.067x.$$

10. Equation (5) is

$$y - 10 = 1.98(x - 5); \qquad \text{thus} \qquad y = 0.1 + 1.98x.$$

The spring modulus is 1/1.98.

12. $c = \pm 3.18$ from Table A9 with $n - 2 = 3$ degrees of freedom (corresponding to $2\frac{1}{2}\%$ and $97\frac{1}{2}\%$, by the symmetry of the t-distribution). From the sample we compute

$$4s_x^2 = 82\,000, \qquad 4s_{xy} = 354\,100, \qquad 4s_y^2 = 1\,530\,080.$$

im25.qxd 9/21/05 2:06 PM Page 405

From this and (7) we get

$$k_1 = \frac{354\,100}{82\,000} = 4.31829.$$

Also $q_0 = 993$ and $K = 0.2$. The *answer* is

$$\text{CONF}_{0.95}\{4.1 \leqq \kappa_1 \leqq 4.5\}.$$

14. Multiplying out the square, we get three terms, hence three sums,

$$\sum (x_j - \bar{x})^2 = \sum x_j^2 - 2\bar{x}\sum x_j + n\bar{x}^2$$
$$= \sum x_j^2 - \frac{2}{n}\sum x_i \sum x_j + n\left(\frac{1}{n}\sum x_j\right)^2$$

and the last of these three terms cancels half of the second term, giving the result.

SOLUTIONS TO CHAP. 25 REVIEW QUESTIONS AND PROBLEMS, page 1092

22. From Table 25.1 in Sec. 25.3 we obtain $k = 1.96 \cdot 4/\sqrt{400} = 0.392$ and

$$\text{CONF}_{0.95}\{52.6 \leqq \mu \leqq 53.4\}.$$

24. $\bar{x} = 26.4$, $k = 2.576 \cdot 2.2/\sqrt{5} = 2.534$ by Table 25.1, Sec. 25.3. This gives the *answer*

$$\text{CONF}_{0.99}\{23.86 \leqq \mu \leqq 28.94\}.$$

26. $n - 1 = 3$ degrees of freedom, $F(c_1) = 0.025$, $c_1 = 0.22$, $F(c_2) = 0.975$, $c_2 = 9.35$ from Table A10 in App. 5; hence $k_1 = 0.7/0.22 = 3.182$, $k_2 = 0.7/9.35 = 0.075$ by Table 25.3 in Sec. 25.3. The *answer* is

$$\text{CONF}_{0.95}\{0.075 \leqq \sigma^2 \leqq 3.182\}.$$

28. $k = 2.26 \cdot 0.157/\sqrt{10} = 0.112$; $\text{CONF}_{0.95}\{4.25 \leqq \mu \leqq 4.49\}$

30. $n = 41$ by trial and error, because $F(c) = 0.975$ gives $c = 2.02$ (Table A9 with 40 d.f.), so that $L = 2k = 2sc/\sqrt{n} = 0.099$ by Table 25.2.

32. From Table A10 in App. 5 and Table 25.3 in Sec. 25.3 we obtain

$$c_1 = \tfrac{1}{2}(\sqrt{253} - 2.58)^2 = 88.8,$$
$$c_2 = \tfrac{1}{2}(\sqrt{253} + 2.58)^2 = 170.9,$$

so that $k_1 = 244/c_1 = 2.76$ and $k_2 = 244/c_2 = 1.43$. The *answer* is

$$\text{CONF}_{0.99}\{1.42 \leqq \sigma^2 \leqq 2.75\}.$$

34. The test is two-sided. We have $\sigma^2/n = 0.025$, as before. Table A8 gives

$$P(\bar{X} < c)_{15.0} = \Phi\left(\frac{c - 15.0}{\sqrt{0.025}}\right) = 0.975, \qquad c = 15.31$$

and $15.0 - 0.31 = 14.69$ as the left endpoint of the acceptance region. Now $\bar{x} = 14.5 < 14.70$, and we reject the hypothesis.

36. The test is right-sided. From Table A9 with $n - 1 = 14$ degrees of freedom and

$$P(T > c)_{\mu_0} = 0.01, \qquad \text{thus} \qquad P(T \leqq c)_{\mu_0} = 0.99$$

im25.qxd 9/21/05 2:06 PM Page 406

we get $c = 2.62$. From the sample we compute

$$t = \sqrt{15}\,\frac{36.2 - 35.0}{\sqrt{0.9}} = 4.90 > c$$

and reject the hypothesis.

38. The hypothesis is $\mu_0 = 1000$, the alternative $\mu \neq 1000$. Because of the symmetry of the t-distribution, from Table A9 with 19 degrees of freedom we get for this two-sided test and the percentages 2.5% and 97.5% the critical values ± 2.09. From the sample we compute

$$t = \sqrt{20}(991 - 1000)/8 = -5.03 < c = -2.09$$

and reject the hypothesis.

40. $2.58 \cdot \sqrt{0.00024}/\sqrt{2} = 0.028$, LCL = 2.722, UCL = 2.778

42. $2.58\sqrt{0.0004}/\sqrt{2} = 0.036$, UCL = 3.536, LCL = 3.464

44. $P(T \leqq 3) = 6.8\%$ (Table A12). No.

THE SIGNS BEFORE THE DAY OF JUDGEMENT

Author: Al-Haafidh Ibn Katheer Hadeeth
Checking: Abu Talhah Daawood Burbank

Ayaat and Ahaadeeth about the Hour

“My Lord! Increase me in knowledge!" - Qur'an 20:114”

Allaah (subhaanahu wa ta'aala) said:
"They ask you (O Muhammad sal-Allaahu 'alayhe wa sallam) about the Hour, - when will be its appointed time? You have no knowledge to say anything about it, To your Lord belongs (the knowledge of) the term thereof? You (O Muhammad sal-Allaahu 'alayhe wa sallam) are only a warner for those who fear it, The Day they see it, (it will be) as if they had not tarried (in this world) except an afternoon or a morning." [An-Nazi'aat (79):42-46]

"They ask you about the Hour (Day of Resurrection): 'When will be its appointed time?' Say: 'The knowledge thereof is with my Lord (Alone). None can reveal its time but He. Heavy is its burden through the heavens and the earth. It shall not come upon you except all of a sudden.' They ask you as if you have a good knowledge of it. Say: 'The knowledge thereof is with Allaah (Alone) but most of mankind know not."" [Al-A'raaf (7):187]

There are many Ayaat and Ahaadeeth concerning this subject: Allaah said:
"The Hour has drawn near, and the moon has been cleft asunder." [Al-Qamar (54):1]
The Prophet (sal-Allaahu 'alayhe wa sallam) said, whilst pointing with his index and middle fingers,
"The time of my advent and the Hour are like these two fingers." [1]
In another report he said,
"The Hour almost came before me."

This indicates how close we are, relatively speaking, to the Hour.
Allaah said:
"Draws near for mankind their reckoning, while they turn away in heedlessness." [Al-Anbiyaa' (21):1]
"The Event (the Hour or the punishment of disbelievers and polytheists or the Islaamic laws or commandments), ordained by Allaah will come to pass, so seek not to hasten it. Glorified and Exalted be He above all that they associate as partners with Him." [An-Nahl (16):1]

"Those who believe not therein seek to hasten it, while those who believe are fearful of it, and know that it is the very truth. Verily, those who dispute concerning the Hour are certainly in error far away." [Ash-Shooraa (42):18]
In Saheeh al-Bukhaaree, there is a Hadeeth which states that a Bedouin asked the Prophet (sal-Allaahu 'alayhe wa sallam) about the Hour.

He (sal-Allaahu 'alayhe wa sallam) said,
"It will surely come to pass. What have you prepared for it?" The man said, "O Messenger of Allaah, I have not prepared much in the way of prayer and good works, but I love Allaah and His Messenger." The Prophet (sal-Allaahu 'alayhe wa sallam) said, "You will be with those you love." The Muslims had never rejoiced as much they did when they heard this Hadeeth. [2]
Some Ahaadeeth report that the Prophet (sal-Allaahu 'alayhe wa sallam) was asked about the Hour. He looked towards a young boy and said, "If he lives, he will not grow very old before he sees your Last Hour coming to you." [3]

By this he meant their death and entering the Hereafter, because everyone who dies enters the Hereafter; some people say that when a person has died, his judgment has begun. This Hadeeth with this meaning is "correct" (Saheeh).
Some heretics comment on this Hadeeth and give it an incorrect meaning. The exact timing of the Great Hour (as-Saa'at al-'Uzmaa) is something which Allaah alone knows and which He has not revealed to anyone, as is clear from the Hadeeth in which the Prophet (sal-Allaahu 'alayhe wa sallam) said:
"There are five things which nobody knows except Allaah;" then he recited, "Verily, Allaah! With Him (Alone) is the knowledge of the Hour, He sends down the rain, and knows that which is in the wombs. No person knows what he will earn tomorrow, and no person knows in what land he will die. Verily, Allaah is All Knower, All Aware (of things)."" [Luqman (31):34] [4]
When Gabriel (Jibreel) (alayhi-salaam) came to the Prophet (sal-Allaahu 'alayhe wa sallam) in the guise of a Bedouin, he asked him about Islaam, Eemaan (faith) and Ihsaan (excellence of faith); and the Prophet (sal-Allaahu 'alayhe wa sallam) answered his questions. But when he asked him about the Hour, he said,

"The one questioned about it knows no better than the questioner." Jibreel said, "Tell me about its signs." Then the Prophet (sal-Allaahu 'alayhe wa sallam) described them, as we shall see later when we quote this Hadeeth and others in full.
Hudhayfah said:
"The Prophet (sal-Allaahu 'alayhe wa sallam) stood up one day to speak to us, and told us everything that was going to happen until the Hour, and left nothing unsaid. Some of the listeners learnt it by heart, and some forgot it; these friends of mine learnt it. I do not remember it completely, but sometimes it springs to mind, just as one might remember and recognise the face of a man whom one had forgotten, when one sees him." [Abu Daawood, Muslim] [5]
Imaam Ahmad reported via Abu Nudrah that Abu Sa'eed said:
"One day the Prophet (sal-Allaahu 'alayhe wa sallam) led us in praying the afternoon prayer (Salaat al-'Asr). Then he stood and addressed us until sunset. He mentioned everything that was to happen until the Day of Resurrection, and left nothing unsaid. Some of us remembered it, and some of us forgot it. One of the things he said was:
'O people, this world is full of attractive temptations. Allaah has appointed you as vicegerents (Khaleefah) in this world, and He will see how you will act. So guard yourselves against the temptations of this world and of women.'
Towards the end of this speech, he said,
'The sun is about to set, and what remains of this world, compared to what has passed, is like what remains of this day compared to what has passed.' [6]"
'Alee ibn Zayd ibn Jad'an al-Timi narrated some Gharib and Munkar Ahaadeeth - which could bring into question the validity of this Hadeeth. But there are some reports which are similar to this Hadeeth, and which were transmitted with different isnaads. Part of this Hadeeth is in Saheeh Muslim, through Abu Nudrah on the authority of Abu Sa'eed. This Hadeeth refers to something which is beyond any doubt: what remains of this world, compared to what has passed, is very little. In spite of that, no-one can know exactly how much time is left except Allaah, and no-one can know exactly how much time has passed, except Allaah.

[2] A similar Hadeeth was narrated by Bukhaaree in Kitaab al-Adab.
[3] See Bukhaaree, Kitaab al-Adab; Muslim, Kitaab al-Fitan wa Ashraat

al-Sa'ah.
[4] Bukhaaree, Kitaab at-Tafsir, commentary on Luqman 31:34. A longer Hadeeth is narrated by Muslim in Kitaab al-Eemaan.
[5] Muslim, Kitaab al-Fitan wa Ashraaat al-Sa'ah; Abu Daawood, Kitaab al-Fitan wa'l-Malahim.
[6] The whole speech is narrated by Imaam Ahmad in his Musnad, 2/61. Checker's Note: Da`eef, al-Musnad (3/61) [or 2/61 as stated in the book??], at-Tirmidhee and al-Hakim (4/505). Da`eef due to `Alee ibn Zayd ibn Jad'an. al-Mishkat: 5145 of al-Albaanee. Parts of the complete speech are authentic, see Ibn Kathir's comments.
General Description of the Fitan (Tribulations)
Hudhayfah ibn al-Yaman said,
"People used to ask the Prophet (sal-Allaahu 'alayhe wa sallam) about good things, but I used to ask him about bad things because I was afraid that they might overtake me. I said, 'O Messenger of Allaah, we were lost in ignorance (Jahiliyyah) and evil, then Allaah brought this good (i.e. Islaam). Will some evil come after this good thing?' He said, 'Yes' I asked, 'And will some good come after that evil?' He said, 'Yes, but it will be tainted with some evil' I asked, 'How will it be tainted?' He said, 'There will be some people who will lead others on a path different from mine. You will see good and bad in them." I asked, 'Will some evil come after that good?' He said, 'Some people will be standing and calling at the gates of Hell; whoever responds to their call, they will throw him into the Fire.' I said, 'O Messenger of Allaah, describe them for us.' He said, 'They will be from our own people, and will speak our language.' I asked, 'What do you advise me to do if I should live to see that?' He said, 'Stick to the main body (jamaa'ah) of the Muslims and their leader (Imaam). I asked, What if there isno main body and no leader?' He said 'Isolate yourself from all of these sects, even if you have to eat the roots of trees until death overcomes you while you are in that state.' [1]"
'Abd Allaah ibn Mas'ood said:
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Islaam began as something strange, and it will revert to being strange as it was in the beginning, so good tidings for the strangers.' Someone asked, 'Who are the strangers?' He said, 'The ones who break away from their people (literally, 'tribes') for the sake of Islaam.'" This Hadeeth was narrated by Ibn Majah on the authority of Anas and Abu Hurairah. [2]

Divisions Within the Main Religious Groups

Abu Hurairah reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said:

"The Jews have split into seventy-one sects, and my Ummah will divide into seventy-three." [1]

'Awf ibn Malik reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said:

"The Jews split into seventy-one sects: one will enter Paradise and seventy will enter Hell. The Christians split into seventy-two sects: seventy-one will enter Hell and one will enter Paradise. By Him in Whose hand is my soul, my Ummah will split into seventy-three sects: one will enter Paradise and seventy-two will enter Hell." Someone asked, "O Messenger of Allaah, who will they be?" He replied, "The main body of the Muslims (al-Jamaa'ah)."

'Awf ibn Malik is the only one who reported this Hadeeth, and its isnaad is acceptable. [2]

Anas ibn Malik said,

"I shall tell you a Hadeeth which I heard from the Messenger of Allaah, and which no-one will tell you after me. I heard him say, 'Among the signs of the Hour will be the disappearance of knowledge and the appearance of ignorance. Adultery will be prevalent and the drinking of wine will be common. The number of men will decrease and the number of women will increase until there will be fifty women to be looked after by one man.'" This Hadeeth was reported in the two Saheehs from the Hadeeth of 'Abd Rabbihi. [3]

'Abd Allaah said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Just before the Hour, there will be days in which knowledge will disappear and ignorance will appear, and there will be much killing.' " [Ibn Maajah; also narrated by Bukhaaree and Muslim, from the Hadeeth of al-A'mash] [4]

Hudhayfah ibn al-Yaman said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Islaam will become worn out like clothes are, until there will be no-one who knows what fasting, prayer, charity and rituals are. The Qur'aan will disappear in one night, and no Ayah will be left on earth. Some groups of old people will be left who will say, 'We heard our fathers saying La ilaha illa Allaah, so we repeated it.' Silah asked Hudhayfah, "What will saying La ilaha illa Allaah do for them when they do not know what prayer, fasting, ritual and charity

are?" Hudhayfah ignored him; then Silah repeated his question three times, and each time Hudayfah ignored him. Finally he answered, "O Silah, it will save them from Hell", and said it three times. [Ibn Maajah] [5]
This indicates that in the last days, knowledge will be taken from the people, and even the Qur'aan will disappear from the Mushafs and from people's hearts. People will be left without knowledge. Only the old people will tell them that they used to hear people saying La ilaha illa Allaah; and they will repeat it to feel close to Allaah, so it will give them some blessing, even if they do not have any good deeds or beneficial knowledge. Knowledge will be taken away from men and ignorance will increase during the last days, and their ignorance and misguidance will increase until the end, as in the Hadeeth of the Prophet (sal-Allaahu 'alayhe wa sallam):
"The Hour will not come upon anyone who says, 'Allaah, Allaah'; it will only come upon the most evil of men." [6]

Footnotes

Checker's Note: Saheeh, Saheeh Ibn Maajah: 3225
[2] Abu Daawood, Kitaab as-Sunnah, (Hadeeth 4572, 4573), 12/1340-2.
"The main body of the Muslims (al-Jamaa'ah)" means the people of the Qur'aan, Hadeeth, Fiqh and other sciences, who have agreed to follow the Traditions of the Prophet (sal-Allaahu 'alayhe wa sallam) in all circumstances without introducing any changes or imposing their own confused ideas.
Checker's Note: Saheeh, Saheeh al-Jami as-Sagheer: 1082, the narration of `Awf ibn Malik is also reported by Ibn Maajah (no. 4992), Ibn Abee `Asim in as-Sunnah (no. 63) and al-Lalikai in Sharh us-Sunnah (no. 1492).
[3] A similar Hadeeth was narated by al-Bukhaaree in Kitaab al-'Ilm, 1/30,31; and by Muslim.
Checker's Note: Saheeh, al-Bukhari and Muslim.
[4] Bukhaaree, Kitaab al-Fitan, 9/61; Msulim, Kitaab al-'Ilm, 8/58.
[5] Checker's Note: Saheeh, Silsilatul Ahadeeth as-Saheehah: 87.
[6]The first part of it was related by Muslim in Kitab al-Eemaan, 1/91, and the second part in Kitab al-Fitan wa Ashraat al-Sa'ah, 8/208.
The Evils Which Will Befall the Muslim Ummah During The Last Days
'Abd Allaah ibn 'Umar said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) came to us and said, 'O Muhaajiroon, (emigrants from Makkah to al-Madinah) you may be

afflicted by five things; God forbid that you should live to see them. If fornication should become widespread, you should realise that this has never happened without new diseases befalling the people which their forebears never suffered. If people should begin to cheat in weighing out goods, you should realise that this has never happened without drought and famine befalling the people, and their rulers oppressing them. If people should withhold Zakaat, you should realise that this has never happened without the rain being stopped from falling; and were it not for the animals' sake, it would never rain again. If people should break their covenant with Allaah and His Messenger, you should realise that his has never happened without Allaah sending an enemy against them to take some of their possessions by force. If the leaders do not govern according to the Book of Allaah, you should realise that this has never happened without Allaah making them into groups and making them fight one another.'" [Ibn Maajah] [1]

'Alee ibn Abee Taalib said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said: 'If my Ummah bears fifteen traits, tribulation will befall it.' Someone asked, 'What are they, O Messenger of Allaah?' He said, 'When any gain is shared out only among the rich, with no benefit to the poor; when a trust becomes a means of making a profit; when paying Zakaat becomes a burden; when a man obeys his wife and disobeys his mother; and treats his friend kindly whilst shunning his father; when voices are raised in the mosques; when the leader of a people is the worst of them; when people treat a man with respect because they fear some evil he may do; when much wine is drunk; when men wear silk; when female singers and musical instruments become popular; when the last ones of this Ummah curse the first ones - then let them expect a red wind, or the earth to swallow them, or to be transformed into animals.'" [Tirmidhee] [2]

'Alee ibn Abee Taalib said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) led us in praying Salaat al-Fajr (the morning prayer). When he had finished, a man called to him: 'When will the Hour be? The Prophet (sal-Allaahu 'alayhe wa sallam) reprimanded him and said 'Be quiet!' After a while he raised his eyes to the sky and said, 'Glorified be the One Who raised it and is taking care of it.' Then he lowered his gaze to the earth and said, 'Glory be to the One Who has outspread it and has created it.' Then the Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Where is the one who asked me about the Hour?' The man knelt down and said, 'I asked you.' The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Hour will come when leaders are

oppressors, when people believe in the stars and reject al-Qadar (the Divine Decree of destiny) when a trust becomes a way of making a profit, when people give to charity (Sadaqah) reluctantly, when adultery becomes widespread - when this happens, then your people will perish.'" [3]
'Imran ibn Husayn said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Some people of this Ummah will be swallowed up by the earth, some will be transformed into animals, and some will be bombarded with stones.' One of the Muslims asked, 'When will that be, O Messenger of Allaah?' He said, 'When singers and musical instruments will become popular, and much wine will be drunk.'"[4]

The Greater Signs of the Hour
After the lesser signs of the Hour appear and increase, mankind will have reached a stage of great suffering. Then the awaited Mahdee will appear; he is the first of the greater, and clear, signs of the Hour. There will be no doubt about his existence, but this will only be clear to the knowledgeable people. The Mahdee will rule until the False Messiah (al-Maseeh ad-Dajjaal) appears, who will spread oppression and corruption. The only ones who will know him well and avoid his evil will be those who have great knowledge and Eemaan (faith).
The false Messiah will remain for a while, destroying mankind completely, and the earth will witness the greatest Fitnah (tribulation) in its history. Then the Messiah Jesus (alayhi salam) will descend, bringing justice from heaven. He will kill the Dajjaal, and there will be years of safety and security.
Then the appearance of Ya'jooj and Ma'jooj (Gog and Magog) will take mankind by surprise, and corruption will overtake them again. In answer

to Jesus' faithful prayer to Allaah (subhanahu wa ta'aala), they will die, and safety, security, justice and stability will return.
This state of affairs will continue for some years, until the death of Jesus.
The Ulamaa differ concerning the order in which the other greater signs of the Hour will come about. They are:

- The destruction of the Ka'bah and the recovery of its treasure.
- The rising of the sun from the west.
- The emergence of the Beast from the earth.
- The smoke.
- A wind will take the souls of the believers.
- The Qur'aan will be taken up into heaven.
- A fire will drive the people to their last gathering place.
- The Trumpet will be sounded: at the first sound everyone will feel terror; at the second sound all will be struck down; at the last sound all will be resurrected.

The Mahdee
The Mahdee will come at the end of time; he is one of the Rightly-Guided Caliphs and Imaams. He is not the Mahdee who is expected by the Shee'ah, who they claim will appear from a tunnel in Saamarraa. This claim of theirs has no basis in reality nor in any reliable source. They allege that his name is Muhammad ibn al-Hasan ibn al-Askaree, and that he went into the tunnel when he was five years old.
The matter we intend to discuss has been proven by Ahaadeeth narrated from the Prophet (sal-Allaahu 'alayhe wa sallam): that the Mahdee will appear at the end of time. I believe that he will appear before Jesus the son of Mary comes down, as the Ahaadeeth indicate.
Hajjaaj said that he heard Alee say,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, "Even if there were only one day left for the world, Allaah would send a man from among us to fill the world with justice, just as it had been filled with oppression and justice." [Ahmad] [1]
Alee said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, "The Mahdee is one of us, from among the people of my household. In one night Allaah will inspire him and prepare him to carry out his task successfully." [Ahmad and Ibn Maajah] [2]
Alee said, whilst looking at his son al-Hasan,
This son of mine is a Sayyid (master), as the Prophet (sal-Allaahu 'alayhe wa sallam) named him. Among his descendants there will be man named after your Prophet (sal-Allaahu 'alayhe wa sallam). He will resemble him

in behaviour but not in looks. Then he told them the report which mentions that the earth will be filled with justice. [Abu Daawood] [3]
Abu Daawood devoted a chapter of his Sunan to the subject of the Mahdee. At the beginning of this chapter he quoted the Hadeeth of Jaabir ibn Samrah, in which the Prophet (sal-Allaahu 'alayhe wa sallam) said, "This religion will remain steadfast until twelve caliphs have ruled over you." (According to another report he said, "This religion will remain strong until twelve caliphs have ruled over you.") Jaabir said, "The people cheered and shouted Allaahu Akbar! Then the Prophet (sal-Allaahu 'alayhe wa sallam) whispered something. I asked my father 'What did he say?' My father said, 'He said, All ofthem will be from Quraysh.'" Another report says that when the Prophet (sal-Allaahu 'alayhe wa sallam) returned to his house, Quraysh came to him and asked, "What will happen after that?" He said, "Then there will be tribulation and killing." [4]
Abu Daawood reported a Hadeeth from Abd Allaah ibn Masood:
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, "If there were only one day left for the world, that day would be lengthened until a man from among my descendants or from among the people of my household, was sent; his name will be the same as my name, and his fathers name will be the same as my fathers name. He will fill the earth with justice and fairness, just as it will have been filled with injustice and oppression. The world will not end until a man of my household, whose name is the same as mine, holds sway." [5]
Abd Allaah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'A man from my household, whose name is like mine, will take power.'" [Tirmidhee] [6]
In another report, from Abu Hurairah, the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"If there were only one day left for this world, Allaah would lengthen it until he took power." [7]
Aboo Sa'eed said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Mahdee will be one of my descendants; he will have a high forehead and a hooked nose. He will fill the earth with justice and fairness just as it was filled with injustice and oppression, and he will rule for seven years.'" [Abu Daawood] [8]
Umm Salamah said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say,'The Mahdee will be one of my descendants, from the children of Faatimah.'" [Abu Daawood] [9]

Umm Salamah reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"People will begin to differ after the death of a Khaleefah. A man from the people of Madinah will flee to Makkah. Some of the people of Makkah will come to him and drag him out against his will; they will swear allegiance to him between al-Rukn and al-Maqam. An army will be sent against him from Syria; it will be swallowed up in the desert between Makkah and Madinah. When the people see this, groups of people from Syria and Iraq will come and swear allegiance to him. Then a man from Quraysh whose mother is from Kalb will appear and send an army against them, and will defeat them; this will be known as the Battle of Kalb. Whoever does not witness the spoils of this battle will miss much! The Mahdee will distribute the wealth, and will rule the people according to the Sunnah of the Prophet (sal-Allaahu 'alayhe wa sallam). Then he will die, and the Muslims will pray for him." [Abu Daawood] [10]
Alee said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'A man named al-Haarith ibn Hirath will come from Transoxania. His army will be led by a man named Mansoor. He will pave the way for and establish the government of the family of Muhammad, just as Quraysh established the government of the Messenger of Allaah. Every believer will be obliged to support him.'" [Abu Daawood] [11]
Abd Allaah ibn al-Haarith ibn Juz' al-Zubaydee said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'A people will come out of the East who will pave the way for the Mahdee.'" [Ibn Maajah] [12]
Abd Allaah said,
"Whilst we were with the Prophet (sal-Allaahu 'alayhe wa sallam), some young men from Banu Hashim approached us. When the Prophet (sal-Allaahu 'alayhe wa sallam) saw them, his eyes filled with tears and the colour of his face changed. I said, 'We can see something has changed in your face, and it upsets us.' The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'We are the people of a Household for whom Allaah has chosen the Hereafter rather than this world. The people of my Household (Ahl al-Bayt) will suffer a great deal after my death, and will be persecuted until a people carrying black banners will come out of the east. They will instruct the people to do good, but the people will refuse; they will fight until they are victorious, and the people do as they asked, but they will not accept it from them until they hand over power to a man from my household. Then the earth will be filled with fairness, just as it had been filled with injustice. If any of you live to see this, you should go

to him even if you have to crawl across ice.'" [13]
This text refers to the rule of the Abbasids, as we have mentioned above in the text referring to the beginningof their rule in 132 AH. It also indicates that the Mahdee will appear after the Abbasids, and that he will be one of the Ahl al-Bayt, a descendant of Faatimah, the daughter of the Prophet (sal-Allaahu 'alayhe wa sallam), through Hasan, not Husayn, as mentioned in the Hadeeth from Alee ibn Abee Taalib; and Allaah knows best. [14]
Thwaban said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said,'Three men will be killed at the place where your treasure is. Each of them will be the son of a Khaleefah, and none of them will get hold of the treasure. Then the black banners will come out of the East, and they will slaughter you in a way which has never been seen before.' Then he said something which I do not remember; then, 'If you see him, go and give him your allegiance, even if you have to crawl over ice, because he is the Khaleefah of Allaah, the Mahdee.'" [Ibn Maajah] [15]
The treasure referred to in this text is the treasure of the Ka'bah. Towards the end of time, three of the sons of the Khaleefahs will fight to get hold of it, until the Mahdee appears. He will appear from the East, not from the tunnel of Saamarraa, as the Shee'ah claim; they believe that he is in this tunnel now, and they are waiting for him to emerge at the end of time. There is no evidence for it in any book or Saheeh tradition, and there is no benefit in believing this.
The truth of the matter is that the Mahdee whose coming is promised at the end of time will appear from the East,and people will swear allegiance to him at the Ka'bah, as some Ahaadeeth indicate.
At the time of the Mahdee, there will be peace and prosperity, with abundant crops and wealth, strong rulers, and Islaam will be well-established.
Aboo Sa'eed said,
"By Allaah every ruler we have had has been worse than the previous one, and every year has been worse than the year before, but I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'Among your rulers will be one who will give out wealth freely, without counting it. A man will come and ask him for money, and he will say, "Take"; the man will spread his cloak out and the ruler will pour money into it.' The Prophet (sal-Allaahu 'alayhe wa sallam) spread out a thick cloak he had been wearing, to demonstrate the mans actions; then he gathered it up by its corners and said, 'Then the man will take it and leave.'" [Ahmad] [16]

Different Kinds of Fitan (Tribulations)
Zaynab bint Jahsh said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) got up from his sleep; his face was flushed and he said, 'There is no god but Allaah. Woe to the Arabs, for a great evil which is nearly approaching them. Today a gap has been made in the wall of Gog and Magog like this (Sufyan illustrated this by forming the number of 90 or 100 with his fingers).' Someone asked, 'Shall we be destroyed even though there are righteous people among us?' The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Yes, if evil increases.'" [Bukhaaree] [1]
Umm Salamah, the wife of the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"One night the Prophet (sal-Allaahu 'alayhe wa sallam) got up and said, 'SubhanAllaah! How many tribulations have come down tonight, and how many treasures have been disclosed! Go and wake the dwellers of these apartments (i.e. his wives) for prayer. A well-dressed soul in this world may be naked in the Hereafter.'" [Bukhaaree] [2]
Usamah ibn Zayd said,
"Once the Prophet (sal-Allaahu 'alayhe wa sallam) stood over one of the battlements of al-Madinah and asked the people, 'Do you see what I see?' They said, 'No.' He said, 'I see afflictions falling upon your houses as rain drops fall.'" [Bukhaaree and Muslim] [3]
Abu Hurairah (radiallahu anhu) said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Time will pass rapidly, knowledge will decrease, miserliness will become widespread in peoples hearts, afflictions will appear, and there will be much Harj.' The people asked, 'O Messenger of Allaah, what is Harj?' He said, 'Killing, killing!'" [Bukhaaree] [4]
Al-Zubayr ibn Adee narrated,
"We went to Anas ibn Malik and complained about the wrong we were suffering at the hands of al-Hajjaaj. Anas ibn Malik said, 'Be patient, "For no time will come but that the time following it will be worse, until you meet your Lord." I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say that.'" [Bukhaaree]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'There will come a time of afflictions when one who sits will be better than one who stands; one who stands will be better than one who walks; and one who walks

will be better than one who runs. Whoever exposes himself to these afflictions, they will destroy him. So whoever can find a place of protection or refuge from them, should take shelter in it.'" [Bukhaaree and Muslim] [5]

Hudhayfah said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) told us two Hadeeth, one of which I have seen fulfilled, and I am waiting for the fulfilment of the other. The Prophet (sal-Allaahu 'alayhe wa sallam) told us that honesty came down into mens hearts (from Allaah); then they learnt it from the Qur'aan, and then from the Sunnah. The Prophet (sal-Allaahu 'alayhe wa sallam) told us that honesty would be taken away. He said, 'Man will be overtaken by sleep, during which honesty will be taken away from his heart, and only its trace will remain, like traces of a dark spot. Then man will be overtaken by slumber again, during which honesty will decrease still further, until its trace will resemble a blister such as is caused when an ember is dropped onto ones foot: it swells, but there is nothing inside. People will be carrying on with their trade, but there will hardly be any trustworthy persons. People will say, There is an honest man in such-and-such a tribe. Later they will say about some man, What a wise, polite and strong man he is! - although he will not have faith even the size of a mustard-seed in his heart.' Indeed, there came a time when I did not mind dealing with any one of you, for if he were a Muslim his Islaam would compel him to pay whatever he owed me, and if he were a Christian, the Muslim official would compel him to pay it. But now I do not deal with anyone except so-and-so and so-and-so." [Bukhaaree] [6]

Ibn Umar said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) stood beside the pulpit, facing the east, and said, 'Afflictions will verily emerge from here, where the top of Satans head will appear.'" [Bukhaaree] [7]

Abu Hurairah said that he had heard the Prophet (sal-Allaahu 'alayhe wa sallam) say,

"The Hour will not come until a man passes by someone's grave and says, 'Would that I were in his place!'" [Bukhaaree] [8]

Abu Hurairah said,

"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'The Hour will not come until the buttocks of the women of Daws move whist going around Dhoo l-Khalasah.'" Dhoo l-Khalasah was an idol worshipped by the tribe of Daws during the Jaahiliyyah. [Hadeeth from Bukhaaree] [9]

Abu Hurairah also said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Euphrates will

disclose a golden treasure. Whoever is present at that time should not take anything of it.'" [10]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Hour will not come before the Euphrates uncovers a mountain of gold, for which people will fight. Ninety-nine out of every hundred will die, but every one among them will say that perhaps he will be the one who will survive (and thus possess the gold).'" [Muslim] [11]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam)said, 'The Hour will not come until the following events have come to pass: two large groups will fight the another, and there will be many casualties; they will both be following the same religious teaching. Nearly thirty Dajjaals will appear, each of them falsely claiming to be a Messenger from Allaah. Knowledge will disappear, earthquakes will increase, time will pass quickly, afflictions will appear, and Harj (ie killing) will increase. Wealth will increase, so that a wealthy man will worry lest no-one accept his Zakaat, and when he offers it to anyone, that person will say, "I am not in need of it." People will compete in constructing high buildings. When a man passes by someones grave, he will say, "Would that I were in his place!" The sun will rise from the west; when it rises and the people see it, they will believe, but,
"No good will it do to a soul to believe in them then, if it believed not before nor earned righteousness through its faith..." [Al-An'aam (6):158]
"The Hour will come suddenly: when a man has milked his she-camel and taken away the milk, but he will not have time to drink it; before a man repairing a tank for his livestock will be able to put water in it for his animals; and before a man who has raised a morsel of food to his mouth will be able to eat it." [Bukhaaree] [12]
Hudhayfah ibn al-Yaman said,
"Of all the people, I know most about every tribulation which is going to happen between now and the Hour. This is not because the Prophet (sal-Allaahu 'alayhe wa sallam) told me something in confidence which he did not tell anyone else; it is because I was present among a group of people to whom he spoke about the tribulations (al-Fitan). The Prophet (sal-Allaahu 'alayhe wa sallam) mentioned three tribulations which would hardly spare anybody, and some which would be like storms in summer; some would be great and some would be small. Everyone who was present at that gathering has passed away, except me." [Muslim] [13]
Abu Hurairah said,

"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, "If you live for a while, you will see people go out under the wrath of Allaah and come back under His curse, and they will have in their hands whips like the tail of an ox.'" [Ahmad, Muslim] [14]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'There are two types among the people of Hell whom I have not yet seen. The first are people who have whips like the tails of oxen, with which they beat people, and the second are women who are naked in spite of being dressed; they will be led astray and will lead others astray, and their heads will look like camels humps. These women will not enter Paradise; they will not even experience the faintest scent of it, even though the fragrance of Paradise can be perceived from such a great distance.'" [15]
Anas ibn Malik said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) was asked, 'O Messenger of Allaah, (what will happen) when we stop enjoining good and forbidding evil?' He said, 'When what happened to the Israelites happens among you: when fornication becomes widespread among your leaders, knowledge is in the hands of the lowest of you, and power passes into the hands of the least of you.'" [Ibn Maajah] [16]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Woe to the Arabs from the great evil which is nearly approaching them: it will be like patches of dark night. A man will wake up as a believer, and be a kafir (unbeliever) by nightfall. People will sell their religion for a small amount of worldly goods. The one who clings to his religion on that day will be as one who is grasping an ember - or thorns.'" [Ahmad] [17]
Abu Hurairah said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) saying to Thawbaan, 'O Thawban, what will you do when the nations call one another to invade you as people call one another to come and eat from one bowl?' Thawbaan said, 'May my father and my mother be sacrificed for you, O Messenger of Allaah! Is it because we are so few?' The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'No, on that day you (Muslims) will be many, but Allaah will put weakness (wahn) in your hearts.' The people asked, 'What is that weakness, O Messenger of Allaah?' He said, 'It is love for this world and dislike of fighting.'" [Ahmad] [18]
The Prophet (sal-Allaahu 'alayhe wa sallam) said,
"There will be a tribulation in which one who is sleeping will be better than one who is lying down, one who is lying will be better than one who is

sitting, one who is sitting will be better than one who is standing, one who is standing will be better than one who is walking, one who is walking will be better than one who is riding, and one who is riding will be better than one who is running; all of their dead will be in Hell." The Companion of the Prophet (sal-Allaahu 'alayhe wa sallam) who narrated this Hadeeth said, "O Messenger of Allaah, when will that be?" He said, "That will be the days of Harj." He asked, "When will the days of Harj be?" The Prophet (sal-Allaahu 'alayhe wa sallam) said, "When a man will not trust the person to whom he is speaking." The Companion asked, "What do you advise me to do if I live to see that?" He said, "Restrain yourself, and go back to your place of residence." The Companion then asked, "O Messenger of Allaah, what should I do if someone enters my neighbourhood to attack me?" He said, "Go into your house." The Companion asked, "What if he enters my house?" He said, "Go into the place where you pray and do this - and he folded his arms, - and say 'My Lord is Allaah', until you die." [19]

Abu Bakrah said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'There will be a tribulation during which one who is lying down will be better than one who is sitting, one who is sitting will be better than one who is standing, one who is standing will be better than one who is walking, and one who is walking will be better than one who is running.' Someone asked, 'O Messenger of Allaah, what do you advise me to do?' He said, 'Whoever has camels, let him stay with them, and whoever has land, let him stay in his land.' Someone asked, 'What about someone who does not have anything like that?' He said, 'Then let him take his sword and strike its edge against a stone, then go as far away as possible.'" [Abu Daawood; similar Hadeeth in Muslim] [20]

At the time of the Fitnah of Uthmaan ibn Affaan's Khilaafah (Caliphate), Sa'd ibn Abee Waqqaas said,

"I bear witness that the Prophet (sal-Allaahu 'alayhe wa sallam) said, 'There will come a tribulation during which one who sits will be better than one who stands, one who stands will be better than one who walks, and one who walks will be better than one who runs.' Someone asked, 'What do you advise if someone enters my house to kill me?' He said, 'Be like the son of Adam (i.e. resign yourself).'" [Muslim, Tirmidhee] [21]

Abu Moosaa al-Asharee said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Before the Hour comes, there will be a tribulation like patches of dark night. A man will get up a believer and go to sleep a kaafir, or will go to sleep a believer and

get up a kaafir. The one who sits will be better than one who stands, and one who walks will be better than one who runs. Break your bows, cut their strings, and strike your swords against stones. If someone comes to kill any of you, then be like the better of the twos ons of Adam.'" [Abu Daawood] [22]

Abu Dharr said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) was riding a donkey and sat me behind him. He said, 'O Abu Dharr, if the people were suffering from such severe hunger that you could not even get up from your bed to go to the mosque, what would you do?' I said, 'Allaah and His Messenger know best.' He said, 'Be decent and restrain yourself.' Then he said, 'O Abu Dharr, if the people were suffering from severe death (i.e. if a man were worth no more than a grave), what would you do? If the people were killing one another, until Hajarat al-Zayt (an area of Madinah) were submerged in blood, what would you do?' I said, 'Allaah and His Messenger know best.' He said, 'Stay in your house and lock the door.' I asked, 'What if I am not left alone?' He said, 'Then be one of them.' I said, 'Should I take up my sword?' He said, 'If you did that, you would be joining them in their activities. No - if you fear that the brightness of the shining sword will disturb you, then cover your face with part of your clothing, and let him carry his own sin and your sin.'" [Ahmad] [23]

Abd Allaah ibn Amr said,

"We were on a journey with the Prophet (sal-Allaahu 'alayhe wa sallam)...When the Prophet (sal-Allaahu 'alayhe wa sallam)'s caller called for prayer, I went there. The Prophet (sal-Allaahu 'alayhe wa sallam) was addressing the people, saying: "O people, it has been the duty of every Prophet before me to guide his people to whatever he knew was good for them, and to warn them against whatever he knew was bad for them, but this Ummah has its time of peace and security at the beginning; at the end of its existence it will suffer trials and tribulations, one after the other. Tribulation will come, and the believer will say, "This will finish me", but it will pass. Another tribulation will come, and he will say, "This is it", but it will pass, and a third will come and go likewise. Whoever wishes to be rescued from Hell, and enter Paradise, let him die believing in Allaah and the Last Day, and treat the people as he himself wishes to be treated. If anyone gives allegiance to an Imaam, then let him obey him if he can (or on one occasion he said: as much as you can).'"

Abd al-Rahman (one of the narrators of this Hadeeth) said,

"When I heard that, I put my head between my knees and said, 'But your cousin Mu'aawiyah is ordering us to squander our wealth among

ourselves in vanity, and to kill each other, although Allaah has said, "O you who believe! Squander not your wealth among yourselves in vanity..." ' [an-Nisaa (4):29]
Abd Allaah (another narrator) put his head in his hands and paused a while, then he raised his head and said,
"Obey him in that which is obedience to Allaah and disobey that which is disobedience to Allaah." I asked him, "Did you hear that from the Prophet (sal-Allaahu 'alayhe wa sallam)?" He said, "Yes, I heard it with my ears and understood it in myheart." [Ahmad, Abu Daawood, an-Nasaa'ee, Ibn Maajah] [24]
Abd Allaah ibn Amr said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'If you see my Ummah fearing a tyrant so much that they dare not tell him that he is a tyrant, then there will be no hope for them.'"
The Prophet (sal-Allaahu 'alayhe wa sallam) said,
"Among my Ummah, some will be swallowed up by the earth, some bombarded with stones, and some transformed into animals." [Ahmad] [25]

Daws: a tribe in Yemen; Dhoo l-Khalasah: a house full of idols - it is so called because they believed that whoever worshipped it or went around it would be purified (khallasa). This Hadeeth means that the tribe of Daws will become apostates from Islaam and will go back to idol worshipping; even their women will exert themselves in worshipping the idol and running around it, so that their flesh will quiver.

The Signs and Portents of the Hour
'Abd Allaah ibn 'Amr said,
"I went to the Prophet (sal-Allaahu 'alayhe wa sallam) one day whilst he was performing Wudoo' (ablution) slowly and carefully. He raised his head, looked at me and said, 'Six things will happen to this Ummah: the death of your Prophet - 'and when I heard that I was aghast,' - this is the first. The second is that your wealth will increase so much that if a man were given ten thousand, he would still not be content with it. The third is that tribulation will enter the house of every one of you. The fourth is that sudden death will be widespread. The fifth is a peace-treaty between you and the Romans: they will gather troops against you for nine months - like a woman's period of childbearing - then they will be the first to break the treaty. The sixth is the conquest of a city.' I asked, 'O Messenger of Allaah, which city?' He said, 'Constantinople.' " [Ahmad] [1]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Hasten to do good deeds before six things happen: the rising of the sun from the West, the smoke, the Dajjaal, the beast, the (death) of one of you, or general tribulation.' " [Ahmad, Muslim] [2]
Hudhayfah ibn 'Ubayd said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) came upon us whilst, we were busy in discussion. He asked us, 'What are you talking about?' We said, 'We are discussing the Hour.' He said, 'It will not come until you see ten signs: the smoke, the Dajjaal, the beast, the sun rising from the West, the descent of Jesus son of Mary, Gog and Magog, and three land-slides - one in the East, one in the West, and one in Arabia, at the end of which fire will burst forth from the direction of Aden (Yemen) and drive peopl eto the place of their final assembly.' " [Ahmad] [3]

[3] Muslim, Kitaab al-Fitan, 8/179.
Checker's Note: Wrong spelling, Ibn `Ubayd should be Ibn Usayd. Reported by Muslim, not by Ahmad as main text states.
The Battle with the Romans
After the battle with the Romans, which ended with the conquest of Constantinople, the Dajjaal will appear, and Jesus son of Mary will

descend from Heaven to the earth, to the white minaret in the east of Damascus, at the time of Salaat al-Fajr (the morning prayer), as we shall see in the Saheeh Traditions.
Dhoo Mukhammar said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'You will make a peace-treaty with the Romans, and together you will invade an enemy beyond Rome. You will be victorious and take much booty. Then you will camp in a hilly pasture; one of the Roman men will come and raise a cross and say "Victory to the Cross", so one of the Muslims will come and kill him. Then the Romans will break the treaty, and there will be a battle. They will gather an army against you and come against you with eighty banners, each banner followed by 10,000 men.' " [Ahmad, Abu Daawood, Ibn Maajah] [1]
Yusayr ibn Jaabir said,
"Once there was a red storm in Kufah. A man came who had nothing to say except, 'O 'Abd Allaah ibn Mas'ood, has the Hour come?' 'Abd Allaah was sitting reclining against something, and said, 'The Hour will not come until people will not divide inheritance, nor rejoice over booty.' Pointing towards Syria, he said, 'An enemy will gather forces against the Muslims and the Muslims will gather forces against them.' I asked, 'Do you mean the Romans?' He said, 'Yes. At that time there will be very heavy fighting. The Muslims will prepare a detachment to fight to the death; they will not return unless they are victorious. They will fight until night intervenes. Both sides will return without being victorious; then many will be killed on both sides. On the fourth day, the Muslims who are left will return to the fight, and Allaah will cause the enemy to be routed. There will be a battle the like of which has never been seen, so that even if a bird were to pass their ranks, it would fall down dead before it reached the end of them. Out of a family of one hundred, only one man will survive, so how could he enjoy the booty or divide any inheritance? While they are in this state, they will hear of an even worse calamity. A cry will reach them: "The Dajjaal has taken your place among your offspring." So they will throw away whatever is in their hands and go forward, sending 10 horsemen as a scouting party. The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'I know their names, and the names of their fathers, and the colours of their horses. They will be the best horsemen on the face of the earth on that day.' " [Ahmad, Muslim] [2]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Hour will not come until the Romans camp at al-A'mash or Dabeeq. An army,

composed of the best people on earth at that time, will come out from Madinah to meet them. When they have arranged themselves in ranks, the Romans will say, 'Do not stand between us and those who took prisoners from amongst us. Let us fight with them.' The Muslims will say, 'No, by Allaah, we will never stand aside from you and our brothers.' Then they will fight. One-third will runaway, and Allaah will never forgive them. One-third will be killed, and they will be the best of martyrs in Allaah's sight. One-third, who will never be subjected to trials or tribulations, will win, and will conquer Constantinople. Whilst they are sharing out the booty, after hanging their swords on the olive-trees, Satan will shout to them that the Dajjaal has taken their place among their families. When they come to Syria, the Dajjaal will appear, while they are preparing for battle and drawing up the ranks. When the time for prayer comes, Jesus the son of Mary will descend and lead them in prayer. When the enemy of Allaah (i.e. the Dajjaal) sees him, he will start to dissolve like salt in water, but Allaah will kill him.' " [Muslim] [3]

The Prophet (sal-Allaahu 'alayhe wa sallam) said,

"The Hour will not come until the furthest border of the Muslims will be in Bulaa." Then he said, "O 'Alee!" 'Alee said, "May my father and mother be sacrificed for you!" The Prophet (sal-Allaahu 'alayhe wa sallam) said, "You will fight the Romans, and those who come after you will fight them, until the best people among the Muslims, the people of al-Hijaaz, will go out to fight them, fearing nothing but Allaah. They will conquer Constantinople with Tasbeeh and Takbeer (saying "Subhaan Allaah" and "Allaahu Akbar"), and they will obtain booty the like of which has never been seen - they will share it out by scooping it up with their sheilds. Someone will come and say, 'The Dajjaal has appeared in your land', but he will be lying. Anyone who takes notice of him will regret it, and anyone who ignores him will regret it." [Ibn Maajah] [4]

Naafi' ibn 'Utbah said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'You will attack Arabia, and Allaah will enable you to conquer it. Then you will attack Persia, and Allaah will enable you to conquer it. Then you will attack Rome, and Allaah will enable you to conquer it. Then you will attack the Dajjaal, and Allaah will enable you to conquer him.' " [Muslim] [5]

When Mustawrid al-Qurashee was sitting with 'Amr ibn al-'Aas, he said, "I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'The Hour will come when the Romans will be in the majority.' 'Amr asked him, "What are you saying?" He said, "I am repeating that which I heard from the Prophet (sal-Allaahu 'alayhe wa sallam)." 'Amr said, "If you say this, it is

true, because they have four good characteristics: they are the most able to cope with tribulation, the quickest to recover after disaster and to return to the fight after disaster, and are the best as far as treating the poor, weak and orphans is concerned. They have a fifth characteristic which is very good; they do not allow themselves to be oppressed by their kings." [6]
The Prophet (sal-Allaahu 'alayhe wa sallam) said,
"You will fight the Romans, and Believers from the Hijaaz will fight them after you, until Allaah enables them to conquer Constantinople and Rome with Tasbeeh and Takbeer ("Subhaan Allaah" and "Allaahu Akbar"). Its fortifications will collapse, and they will obtain booty the like of which has never been seen, so that they will share it out by scooping it up with their shields. Then someone will cry, 'O Muslims! The Dajjaal is in your country, with your families', and the people will leave the wealth. Anyone who takes notice will regret it and anyone who ignores it will regret it. They will ask, 'Who shouted?' but they will not know who he is. They will say, 'Send a vanguard to Ilyaa.' If the Dajjaal has appeared, you will hear about his deeds.' So they will go and see, and if they see that everything is normal, they will say, 'No-one would give a shout like that for no reason, so let us go together to Ilyaa'.' If we find the Dajjaal there we will fight him together, until Allaah decides between us and him. If we do not find the Dajjaal, we will go back to our country and our families.' " [7]
Mu'aadh ibn Jabal said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The building of Bayt al-Maqdis (in Jerusalem) will be followed by the destruction of Yathrib (Madeenah), which will be followed by the conquest of Constantinople, which will be followed by the appearance of the Dajjaal.' Then he put his hand on the thigh or the shoulder of the one with whom he was speaking (i.e. Mu'aadh), and said, 'This is as true as the fact that you are here (or as true as you are sitting here).' " [8]
This does not mean that Madeenah will be destroyed completely before the appearance of the Day, but that will happen at the end of time, as we shall see in some authentic Ahaadeeth. But the building of Bayt al-Maqdis will be the cause of the destruction of Madeenah, as it was proven in the Hadeeth that the Dajjaal will not be able to enter Madinah. He will be prevented from doing so because it is surrounded by angles bearing unsheathed swords. [9]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said about Madeenah: 'Neither plague nor the Dajjaal can enter it.' " [Bukhaaree] [10]

The Appearance of the Dajjaal
First of all, we will quote the reports which mention the liars and "dajjaals" who will precede the coming of the Dajjaal, or Antichrist, who will be the last of them; may Allaah curse them and punish them with Hell-fire.
Jaabir ibn Samurah said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'Just before the Hour there will be many liars.' " Jaabir said, "Be on your guard against them." [Muslim] [1]
Jaabir said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'Just before the Hour there will be many liars; among them is the one in al-Yamamah, the

'Ansi in San'a', the one in Himyar, and the Dajjaal. This will be the greatest fitnah.' " [Ahmad] [2]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Hour will not come ... until nearly 30 "dajjaals" (liars) appear, each one claiming to be a messenger from Allaah.' " [Bukhaaree and Muslim] [3]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Hour will not come until 30 "dajjaals" appear, each of them claiming to be a messenger from Allaah, wealth increases, tribulations appear and al-Harj increases.' Someone asked, 'What is al-Harj?' He said, 'Killing, killing.' " [Ahmad] [4]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Hour will not come until 30 "dajjaals" appear, all of them lying about Allaah and His Messenger.' " [Abu Daawood] [5]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Just before the Hour, there will be thirty "dajjaals", each of whom will say, I am a Prophet.' " [Ahmad] [6]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'There will be "dajjaals" and liars among my Ummah. They will tell you something new, which neither you nor your forefathers have heard. Be on your guard against them, and do not let them lead you astray.' " [Ahmad] [7]
Thawbaan said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'There will be thirty liars among my Ummah. Each one will claim that he is a prophet; but I am the last of the Prophets (Seal of the Prophets), and there will be no Prophet after me.' " [Ahmad] [8]
The Prophet (sal-Allaahu 'alayhe wa sallam) said,
"Verily before the Day of Resurrection there will appear the Dajjaal, and thirty or more liars." [Ahmad] [9]
Ibn 'Umar said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'Among my Ummah there will be more than seventy callers, each of whom will be calling people to Hell-fire. If I wished, I could tell you their names and tribes.' " [10]
Abu Bakrah said,
"The people spoke a great deal against Musaylimah before the Prophet

(sal-Allaahu 'alayhe wa sallam) said anything about him. Then the Prophet (sal-Allaahu 'alayhe wa sallam) got up to give a speech and said: '...as for this man about whom you have spoken so much - he is one of the thirty liars who will appear before the Hour, and there is no town which will not feel the fear of the Antichrist.' " [Ahmad] [11]
In another version of this report, the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"He is one of the thirty liars who will appear before the Dajjaal. There is no town which will escape the fear of the Dajjaal, apart from Madeenah. At that time there will be two angels at every entrance of Madeenah, warding off the fear of the Antichrist." [12]
Anas ibn Malik said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The time of the Dajjaal will be years of confusion. People will believe a liar, and disbelieve one who tells the truth. People will distrust one who is trustworthy, and trust one who is treacherous; and the Ruwaybidah will have a say.' Someone asked, 'Who are the Ruwaybidah?' He said, 'Those who rebel against Allaah and will have a say in general affairs.' " [Ahmad] [13]

Ahaadeeth about the Dajjaal
'Abd Allaah ibn 'Umar said,
"'Umar ibn al-Khattab went along with the Prophet (sal-Allaahu 'alayhe wa sallam) and a group of people to Ibn Sayyaad, and found him playing with some children near the battlement of Banoo Maghaalah. At that time Ibn Sayyaad was on the threshold of adolescence; he did not realise that anybody was near until the Prophet (sal-Allaahu 'alayhe wa sallam) struck him on the back. The Prophet (sal-Allaahu 'alayhe wa sallam) said to him: 'Do you bear witness than I am the Messenger of Allaah?' Ibn Sayyaad looked at him and said, 'I bear witness that you are the Prophet (sal-Allaahu 'alayhe wa sallam) of the unlettered.' Then Ibn Sayyaad said to the Prophet (sal-Allaahu 'alayhe wa sallam), 'Do you bear witness that I am the Messenger of Allaah?' The Prophet (sal-Allaahu 'alayhe wa sallam) dismissed this and said, 'I believe in Allaah and His Messengers.' Then the Prophet (sal-Allaahu 'alayhe wa sallam) asked him, 'What do you see?' Ibn Sayyaad said, 'Sometimes a truthful person comes to me, and sometimes a liar.' The Prophet (sal-Allaahu 'alayhe wa sallam) said to him, 'You are confused', then he said, 'I am hiding something from you.' Ibn Sayyaad said, 'It is Dukh.' The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Silence! You will not be able to go beyond your rank.' 'Umar ibn al-Khattab said, 'O Messenger of Allaah, shall I cut off his head?' The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'If he is (the Dajjaal) you will not be able to overpower him, and if he is not, then killing will not do you any good.' "
Saleem ibn 'Abd Allaah said,

"I heard 'Abd Allaah ibn 'Umar say, 'After that, the Prophet (sal-Allaahu 'alayhe wa sallam) and Ubayy ibn Ka'b went along to the palm trees where Ibn Sayyaad was. The Prophet (sal-Allaahu 'alayhe wa sallam) started to hide behind a tree, with the intention of hearing something from Ibn Sayyaad before Ibn Sayyaad saw him. The Prophet (sal-Allaahu 'alayhe wa sallam) saw him lying on a bed, murmuring beneath a blanket. Ibn Sayyaad's mother saw the Prophet (sal-Allaahu 'alayhe wa sallam) hiding behind a tree, and said to her son, "O Saf (Ibn Sayyaad's first name), here is Muhammad!" Ibn Sayyad jumped up, and the Prophet (sal-Allaahu 'alayhe wa sallam) said, "If you had left him alone, he would have explained himself." "
Saleem said,
"Abd Allaah ibn'Umar said, The Prophet (sal-Allaahu 'alayhe wa sallam) stood up to address the people. He praised Allaah as He deserved to be praised, then he spoke about the Dajjaal: 'I warn you against him; there is no Prophet who has not warned his people against him, even Noah warned his people against him. But I will tell you something which no other Prophet has told his people. You must know that the Dajjaal is one-eyed, and Allaah is not one-eyed.' "
Ibn Shihaab said:
"'Umar ibn Thaabit al-Ansaaree told me that some of the Companions of the Prophet (sal-Allaahu 'alayhe wa sallam) told him that on the day when he warned the people about the Dajjaal, the Prophet (sal-Allaahu 'alayhe wa sallam) said: 'There will be written between his eyes the word Kaafir (unbeliever). Everyone who resents his bad deeds - or every believer - will be able to read it.' He also said, 'You must know that no one of you will be able to see his Lord until he dies.' " [Muslim, Bukhaaree] [1]
Ibn 'Umar said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) mentioned the Dajjaal to the people. He said, 'Allaah is not one-eyed, but the Dajjaal is blind in his right eye, and his eye is like a floating grape.' " [Muslim] [2]
Anas ibn Malik said,
"TheProphet (sal-Allaahu 'alayhe wa sallam) said, 'There has never been a Prophet who did not warn his people against that one-eyed liar. Verily he is one-eyed and your Lord is not one-eyed. On his forehead will be written the letter Kaf, Fa, Ra (Kaafir).' " [Muslim, Bukhaaree] [3]
Hudhayfah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'I know more about the powers which the Dajjaal will have than he will know himself. He will have two flowing rivers: one will appear to be pure water, and the other

will appear to be flaming fire. Whosoever lives to see that, let him choose the river which seems to be fire, then let him close his eyes, lower his head and drink from it, for it will be cold water. The Dajjaal will be one-eyed; the place where one eye should be will be covered by a piece of skin. On his forehead will be written the word Kaafir,and every believer, whether literate or illiterate, will be able to read it.' " [Muslim] [4]
Abu Hurayrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Shall I tell you something about the Dajjaal which no Prophet has ever told his people before me? The Dajjaal is one-eyed and will bring with him something which will resemble Paradise and Hell; but that which he calls Paradise will in fact be Hell. I warn you against him as Noah warned his people against him.' " [Bukhaaree, Muslim] [5]
Muhammad ibn Munkadir said:
"I saw Jaabir ibn 'Abd Allaah swearing by Allaah that Ibn Sayyaad was the Dajjaal, so I asked him, 'Do you swear by Allaah?' He said, 'I heard 'Umar swear to that effect in the presence of the Prophet (sal-Allaahu 'alayhe wa sallam), and the Prophet (sal-Allaahu 'alayhe wa sallam) did not disapprove of it.' " [6]
Some 'ulamaa' (scholars) say that some of the Sahaabah (Companions of the Prophet) believed Ibn Sayyaad to be the greater Dajjaal, but that is not the case: Ibn Sayyaad was a lesser dajjal.
Ibn Sayyaad travelled between Makkah and Madeenah with Abu Sa'eed, and complained to him about the way that people were saying that he was the Dajjaal. Then he said to Abu Sa'eed,
"Did not the Prophet (sal-Allaahu 'alayhe wa sallam) say that the Dajjaal would not enter Madinah? I was born there. Did not he say that he would not have any children? - I have children. Did not he say that he would be a Kaafir? - I have embraced Islaam. Of all the people, I know the most about him: I know where he is now. If I were given the opportunity to be in his place, I would not resent it.' " [Bukhaaree, Muslim]
There are many Ahaadeeth about Ibn Sayyaad, some of which are not clear as to whether he was the Dajjaal or not. We shall see Ahaadeeth which indicates that the Dajjaal is not Ibn Sayyaad, as in the Hadeeth of Faatimah Bint Qays al-Fahriyyah, although this does not mean that he was not one of the lesser Dajjaal; but Allaah knows best.

Footnotes
[1] Bukhaaree, Kitaab al-Adab, 8/49, 50. Muslim, Kitaab al-Fitan, 8/192, 193.

Ibn Sayyaad's [or Ibn Sa'eed's] first name was Saaf. He had some characteristics similar to those ascribed to the Dajjaal. When he was young, he was like a Kaahin (soothsayer) - sometimes he spoke the truth, sometimes he lied. When he grew up, he embraced Islaam and displayed some good characteristics, but later he changed, and it was said that his behaviour might indicate that he was the Dajjaal. But the Prophet (sal-Allaahu 'alayhe wa sallam) had not received any Wahy (revelation) to that effect, so he told 'Umar: "If he is [the Dajjaal] you will not be able to overpower him."
Banoo Maghaalah: if you stand facing the Masjid al-Nabawee, (the Prophet's Mosque in Madeenah), everything on your right is the territory of Banoo Maghaalah.
Dukh: i.e. al-Dukhaan (smoke). The Prophet (sal-Allaahu 'alayhe wa sallam) was thinking of the Aayah,
"Then wait you for the Day when the sky will bring forth a visible smoke." [ad-Dukhaan (44):10]
"… with the intention of hearing something…" in other words, the Prophet (sal-Allaahu 'alayhe wa sallam) wanted to eavesdrop on Ibn Sayyaad so that he and his companions could find out whether he was a soothsayer (kaahin) or a sorcerer.
"if you had left him alone, he would have had explained himself": i.e., if his mother had not told him that the Prophet (sal-Allaahu 'alayhe wa sallam) was there, then the Prophet (sal-Allaahu 'alayhe wa sallam) would have found out what he was - a soothsayer or a sorcerer.
[2] Muslim, Kitaab al-Fitan, 8/194, 195.
"His eye is like a floating grape" - this means that, his eye will protrude and there will be some kind of brightness in it.
[3] Muslim, ibid. Bukhaaree, Kitaab al-Fitan, 9/75, 76.
"On his forehead will be written the letters Kaaf, Faa', Raa' " - this indicates that he will call people to Kufr, not the right path, so we must avoid him. The fact that Muslims will be able to identify him as a Kaafir is a great blessing from Allaah to this Ummah.
[4] Muslim, ibid. Shorter version in Bukhaaree, Kitaab al-Fitan, 9/75.
[5] Bukhaaree, Kitaab al-Anbiyaa, 4/75. Muslim, Kitaab al-Fitan, 8/196.

The Hadeeth of Faatimah bint Qays
'Aamir ibn Sharaaheel Sha'bi Sha'b Hamdaan reported that he asked Faatimah bint Qays, the sister of Dahhaak ibn Qays,who was one of the first Muhaajiraat,
"Tell me a Hadeeth which you heard directly from the Prophet (sal-

Allaahu 'alayhe wa sallam) with no narrator in between." She said, "I can tell you if you like." He said, "Yes, please tell me." She said,
"I married Ibn al-Mugheerah, who was one of the best of the youth of Quraysh in those days. But he fell in the first Jihaad on the side of the Prophet (sal-Allaahu 'alayhe wa sallam).
"When I became a widow, 'Abd al-Rahmaan ibn 'Awf, one of the companions of the Prophet (sal-Allaahu 'alayhe wa sallam) sent me a proposal of marriage. The Prophet (sal-Allaahu 'alayhe wa sallam) also sent me a proposal of marriage on behalf of his freedman Usaamah ibn Zayd. I had been told that the Prophet (sal-Allaahu 'alayhe wa sallam) had said, 'He who loves me should also love Usaamah.' When the Prophet (sal-Allaahu 'alayhe wa sallam) spoke to me, I said, 'It is up to you: marry me to whomever you wish.'
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Go and stay with Umm Shareek.' Umm Shareek was a rich Ansaaree (Muslim originally from Madeenah) woman, who spent much in the way of Allaah ande ntertained many guests. I said, 'I will do as you wish.' Then he said, 'Don't go. Umm Shareek has many guests, and I would not like it if your head or leg were to become uncovered accidentally and people saw something you would not wish them to see. It is better if you go and stay with your cousin 'Abd Allaah ibn 'Amr ibn Umm Maktoom' (Abd Allaah was of the Banoo Fihr of Quraysh, the same tribe as that to which Faatimah belonged).
"So I went to stay with him, and when I had completed my 'Iddah (period of waiting), I heard the Prophet's (sal-Allaahu 'alayhe wa sallam) announcer calling for congregational prayer. I went out to the mosque, and prayed behind the Prophet (sal-Allaahu 'alayhe wa sallam). I was in the women's row, which was at the back of the congregation. When the Prophet (sal-Allaahu 'alayhe wa sallam) had finished his prayer, he sat on the pulpit, smiling, and said, 'Everyone should stay in his place.' Then he said, 'Do you know why I had asked you to assemble?' The people said, 'Allaah and His Messenger know best.'
"He said, 'By Allaah, I have not gathered you here to give you an exhortation or a warning. I have kept you here because Tameem ad-Daaree, a Christian man who has come and embraced Islaam, told me something which agrees with that which I have told you about the Dajjaal. He told me that he had sailed in a ship with thirty men from Banoo Lakhm and Banoo Judhaam. The waves had tossed them about for a month, then they were brought near to an island, at the time of sunset. They landed on the island, and were met by a beast who was so hairy that they

could not tell its front from its back. They said, "Woe to you! What are you?" It said, "I am al-Jassaasah." They said, "What is al-Jassaasah?" It said, "O people, go to this man in the monastery, for he is very eager to know about you." Tameem said that when it named a person to us, we were afraid lest it be a devil.
"Tamim said, 'We quickly went to the monastery. There we found a huge man with his hands tied up to his neck and with iron shackles between his legs up to the ankles. We said, "Woe to you, who are you?" He said, "You will soon know about me. Tell me who you are." We said, "We are people from Arabia. We sailed in a ship, but the waves have been tossing us about for amonth, and they brought us to your island, where we met a beast who was so hairy that we could not tell its front from its back. We said to it, "Woe to you! What are you?" and it said, "I am al-Jassaasah." We asked, "Whatis al-Jassaasah?" and it told us, "Go to this man in the monastery, for he is very eager to know about you." So we came to you quickly, fearing that it might be a devil.'
"The man said, 'Tell me about the date-palms of Baysaan.' We said, 'What do you want to know about them?' He said, 'I want to know whether these trees bear fruit or not.' We said, 'Yes.' He said, 'Soon they will not bear fruit.' Then he said, 'Tell me about the lake of at-Tabariyyah [Tiberias, in Palestine].' We said, 'What do you want to know about it?' He asked, 'Is there water in it?' We said, 'There is plenty of water in it.' He said, 'Soon it will become dry.' Then he said, 'Tell me about the spring of Zughar.' We said, 'What do you want to know about it?' He said, 'Is there water in it, and does it irrigate the land?' We said, 'Yes, there is plenty of water in it, and the people use it to irrigate the land.'
"Then he said, 'Tell me about the unlettered Prophet - what has he done?' We said, 'He has left Makkah and settled in Yathrib.' He asked, 'Do the Arabs fight against him?' We said, 'Yes.' He said, 'How does he deal with them?' So we told him that the Prophet (sal-Allaahu 'alayhe wa sallam) had overcome the Arabs around him and that they had followed him. He asked, 'Has it really happened?' We said, 'Yes.' He said, 'It is better for them if they follow him. Now I will tell you about myself. Iam the Dajjaal. I will soon be permitted to leave this place: I will emerge and travel about the earth. In forty nights I will pass through every town, except Makkah and Madeenah, for these have been forbidden to me. Every time I try to enter either of them, I will be met by an angel bearing an unsheathed sword, who will prevent me from entering. There will be angels guarding them at every passage leading to them.'
Faatimah said, "The Prophet (sal-Allaahu 'alayhe wa sallam), striking the

pulpit with his staff, said: 'This is Tayyibah, this is Tayyibah, this is Tayyibah, [i.e. Madeenah]. Have I not told you something like this?' The people said, 'Yes.' He said, 'I liked the account given to me by Tameem because it agrees with that which I have told you about the Dajjaal, and about Makkah and Madeenah. Indeed he is in the Syrian sea or the Yemen sea. No, on the contrary, he is in the East, he is in the East, he is in the East' and he pointed towards the East. Faatimah said: I memorised this from the Prophet (sal-Allaahu 'alayhe wa sallam)." [Muslim] [1]

'Abd Allaah ibn 'Umar said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'While I was asleep, I saw myself in a dream performing Tawaaf (circumambulation) around the Ka'bah. I saw a ruddy man with lank hair and water dripping from his head. I said, "Who is he?" and they said, "The son of Mary." Then I turned around and saw another man with a huge body, red complexion, curly hair and one eye. His other eye looked like a floating grape. They said, "This is the Dajjaal." The one who most resembles him is Ibn Qatan, a man from the tribe of al-Khuzaa'ah'.' " [Bukhaaree, Muslim] [2]

Jaabir ibn 'Abd Allaah said,

"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Dajjaal will appear at the end of time, when religion is taken lightly. He will have forty days in which to travel throughout the earth. One of these days will be like a year, another will be like a month, a third will be like a week, and the rest will be like normal days. He will be riding a donkey; the width between its ears will be forty cubits. He will say to the people: "I am your lord." He is one-eyed, but your Lord is not one-eyed. On his forehead will be written the word Kaafir, and every believer, literate or illiterate, will be able to read it. He will go everywhere except Makkah and Madeenah, which Allaah has forbidden to him; angels stand at their gates. He will have a mountain of bread, and the people will face hardship, except for those who follow him. He will have two rivers, and I know what is in them. He will call one Paradise and one Hell. Whoever enters the one he calls Paradise will find that it is Hell, and whoever enters the one he calls Hell will find that it is Paradise. Allaah will send with him devils who will speak to the people. He will bring a great tribulation; he will issue a command to the sky and it will seem to the people as if it is raining. Then he will appear to kill someone and bring him back to life. After that he will no longer have this power. The people will say, "Can anybody do something like this except the Lord?" The Muslims will flee to Jabal al-Dukhaan in Syria, and the Dajjaal will come and besiege them. The siege will intensify and they will suffer great hardship. Then Jesus son of Mary will

descend, and will call the people at dawn: "O people, what prevented you from coming out to fight this evil liar?" They will answer, "He is a Jinn." Then they will go out, and find Jesus son of Mary. The time for prayer will come, and the Muslims will call on Jesus to lead the prayer, but he will say, "Let your Imaam lead the prayer." Their Imaam will lead them in praying Salaat al-Subh (Morning prayer), then they will go out to fight the Dajjaal. When the liar sees Jesus, he will dissolve like salt in water. Jesus will go to him and kill him, and he will not let anyone who followed him live.' " [Ahmad] [3]

Footnotes

The Hadeeth of Al-Nuwas Ibn Sam'an Al-Kilabi
Al-Nuwas ibn Saman said,
"One morning the Prophet (sal-Allaahu 'alayhe wa sallam) spoke about the Dajjaal. Sometimes he described him as insignificant, and sometimes he described him as so dangerous that we thought he was in the clump of date-palms nearby. When we went to him later on, he noticed that fear in our faces, and asked, 'What is the matter with you?' We said, 'O Messenger of Allaah, this morning you spoke of the Dajjaal; sometimes you described him as insignificant, and sometimes you described him as being so dangerous that we thought he was in the clump of date-palms nearby.
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'I fear for you in other matters besides the Dajjaal. If he appears whilst I am among you, I will contend with him on your behalf. But if he appears while I am not among you, then each man must contend with him on his own behalf, and Allaah will take care of every Muslim on my behalf. The Dajjaal will be a young man, with short, curly hair, and one eye floating. I would liken him to 'Abd al-Uzzaa ibn Qatan. Whoever amongst you lives to see him should recite the opening Ayaat of Surat al-Kahf. He will appear on the way between

Syria and Iraq, and will create disaster left and right. O servants of Allaah, adhere to the Path of Truth.' "
"We said, 'O Messenger of Allaah, for the day which is like a year, will one days prayers be sufficient?' He said, 'No, you must make an estimate of the time, and then observe the prayers.' "
"We asked, 'O Messenger of Allaah, how quickly will he walk upon the earth?' He said, 'Like a cloud driven by the wind. He will come to the people and call them (to a false religion), and they will believe in him and respond to him. He will issue a command to the sky, and it will rain; and to the earth, and it will produce crops. After grazing on these crops, their animals will return with their udders full of milk and their flanks stretched. Then he will come to another people and will call them (to a false religion), but they will reject his call. He will depart from them; they will suffer famine and will possess nothing in the form of wealth. Then he will pass through the wasteland and will say, Bring forth your treasures, and the treasures will come forth, like swarms of bees. Then he will call a man brimming with youth; he will strike him with a sword and cut him in two, then place the two pieces at the distance between an archer and his target. Then he will call him, and the young man will come running and laughing.' "
"At that point, Allaah will send the Messiah, son of Mary, and he will descend to the white minaret in the east of Damascus, wearing two garments dyed with saffron, placing his hands on the wings of two angels. When he lowers his head, beads of perspiration will fall from it, and when he raises his head, beads like pearls will scatter from it. Every Kaafir who smells his fragrance will die, and his breath will reach as far as he can see. He will search for the Dajjaal until he finds him at the gate of Ludd, where he will kill him."
"Then a people whom Allaah has protected will come to Jesus son of Mary, and he will wipe their faces (i.e. wipe the traces of hardship from their faces) and tell them of their status in Paradise. At that time Allaah will reveal to Jesus: "I have brought forth some of My servants whom no-one will be able to fight. Take My servants safely to at-Toor."
"Then Allaah will send Gog and Magog, and they will swarm down from every slope. The first of them will pass by the Lake of Tiberias, and will drink some of its water; the last of them will pass by it and say, "There used to be water here." Jesus, the Prophet of Allaah, and his Companions will be besieged until a bull's head will be dearer to them than one hundred dinars are to you nowadays."
"Then Jesus and his Companions will pray to Allaah, and He will send

insects who will bite the people of Gog and Magog on their necks, so that in the morning they will all perish as one. Then Jesus and his Companions will come down and will not find any nook or cranny on earth which is free from their putrid stench. Jesus and his Companions will again pray to Allaah, Who will send birds like the necks of camels; they will seize the bodies of Gog and Magog and throw them wherever Allaah wills. Then Allaah will send rain which no house or tent will be able to keep out, and the earth will be cleansed, until it will look like a mirror. Then the earth will be told to bring forth its fruit and restore its blessing. On that day, a group of people will be able to eat from a single pomegranate and seek shelter under its skin (i.e. the fruit would be so big). A milch camel will give so much milk that a whole party will be able to drink from it; a cow will give so much milk that a whole tribe will be able to drink from it; and a milch-sheep will give so much milk that a whole family will be able to drink from it. At that time, Allaah will send a pleasant wind which will soothe them even under their armpits, and will take the soul of every Muslim. Only the most wicked people will be left, and they will fornicate like asses; then the Last Hour will come upon them." " [Muslim] [1]

Ludd: the biblical Lydda, now known as Lod, site of the zionist state's major airport
Hadeeth narrated from Abu Umaamah Al-Baahilee
Abu Umaamah al-Baahilee said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) delivered a speech to us, most of which dealt with the Dajjaal and warned us against him. He said, 'No tribulation on earth since the creation of Adam will be worse than the tribulation of the Dajjaal. Allaah has never sent a Prophet who did not warn his Ummah against the Dajjaal. I am the last of the Prophets, and you are the last Ummah. The Dajjaal is emerging among you and it is inevitable. If he appears while I am still among you, I will contend with him on behalf of every Muslim. But if he appears after I am gone, then every person must contend with him on his own behalf. He will appear on the way between Syria and Iraq, and will spread disaster right and left. O servants of Allaah adhere to the path of Truth. I shall describe him for you in a way that no Prophet has ever done before.
He will start by saying that he is a Prophet, but there will be no Prophet after me. Then he will say, "I am your Lord," but you will never see your

Lord until you die. The Dajjaal is one-eyed, but your Lord, glorified be He, is not one-eyed. On his forehead will be written the word Kaafir, which every Muslim, literate or illiterate, will be able to read. Among that which he will bring will be the Paradise and Hell he will offer; but that which he calls Hell will be Paradise, and that which he calls Paradise will be Hell. Whoever enters his Hell, let him seek refuge with Allaah and recite the opening Ayaat of Surat ul-Kahf, and it will become cool and peaceful for him, as the fire became cool and peaceful for Abraham.
"He will say to a Bedouin, What do you think if I bring your father and mother back to life for you? Will you bear witness that I am your lord? The Bedouin will say Yes, so two devils will assume the appearance of his father and mother, and will say, "O my son, follow him for he is your lord."
"He will be given power over one person, whom he will kill and cut in two with a saw. Then he will say, Look at this slave of mine, now I will resurrect him, but he will still claim that he has a Lord other than me. Allaah will resurrect him, and this evil man (the Dajjaal) will say to him, Who is your Lord? The man will answer, 'My Lord is Allaah, and you are the enemy of Allaah. You are the Dajjaal. By Allaah, I have never been more sure of this than I am today.' "
Aboo Sa'eed said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'That man will have the highest status among my Ummah in Paradise.' "
Abu Sa'eed said,
"By Allaah, we never thought that that man would be any other than 'Umar ibn al-Khattab, until he passed away."
Al-Muhaaribee said:
"Then we referred to the Hadeeth of Abu Raafi'ee, which said, 'Part of his Fitnah will be the fact that he will pass through an area whose people will deny him, and none of their livestock will remain alive. Then he will pass through a second area whose people will believe in him; he will order the sky to rain and the earth to bring forth crops, and their flocks will return from grazing fatter than they have ever been, with their flanks stretched, their udders full. He will pass through every place on earth - except Makkah and Madeenah, which he will never enter, for there are angels guarding every gate of them with unsheathed swords - until he reaches al-Zareeb al-Ahmar and camps at the edge of the salt-marsh. Madeenah will be shaken by three tremors, after which every Munaafiq (hypocrite) will leave it, and it will be cleansed of evil, as iron is cleansed of dross. That day will be called Yawm al-Khalaas (The Day of Purification).' "

Umm Shareek bint Abee'l-'Akr said,
"O Messenger of Allaah, where will the Arabs be at that time?" He said, "At that time they will be few; most of them will be in Bayt al-Maqdis (Jerusalem), and their Imaam will be a righteous man. Whilst their Imaam is going forward to lead the people in praying Salaat al-Subh (themorning prayer), Jesus son of Mary will descend. The Imaam will step back, to let Jesus lead the people in prayer, but Jesus will place his hand between the man's shoulders and say, 'Go forward and lead the prayer, for the Iqaamah was made for you.' So the Imaam will lead the people in prayer, and afterwards Jesus (alayhi-salam) will say, 'Open the gate.' The gate will be opened, and behind it will be the Dajjaal and a thousand Jews, each of them bearing a sword and shield. When the Dajjaal sees Jesus, he will begin to dissolve like salt in water, and will run away. Jesus will say, 'You will remain alive until I strike you with my sword.' He will catch up with him at the eastern gate of Ludd and will kill him. The Jews will be deflated with the help of Allaah. There will be no place for them to hide; they will not be able to hide behind any stone, wall, animal or tree - except the boxthorn (al-Gharqarah) - without it saying, 'O Muslim servant of Allaah! here is a Jew, come and kill him!' " The Prophet (sal-Allaahu 'alayhe wa sallam) said, "The time of the Dajjaal will be forty years; one year like half a year, one year like a month, and one month like a week. The rest of his days will pass so quickly that if one of you were at one of the gates of Madeenah, he would not reach the other gate before evening fell."
Someone asked,
"O Messenger of Allaah, how will wepray in those shorter days?" He said, "Workout the times of prayer in the same way that you do in these longer days, and then pray." The Prophet (sal-Allaahu 'alayhe wa sallam) said, "Jesus son of Mary will be a just administrator and leader of my Ummah. He will break the cross, kill the pigs, and abolish the Jizyah (tax on non-Muslims). He will not collect the Sadaqah, so he will not collect sheep and camels. Mutual enmity and hatred will disappear. Every harmful animal will be made harmless, so that a small boy will be able to put his hand into a snakes mouth without being harmed,a small girl will be able to make a lion run away from her, and a wolf will go among sheep as if he were a sheepdog. The earth will be filled with peace as a container is filled with water. People will be in complete agreement, and only Allaah will be worshipped. Wars will cease, and the authority of Quraysh will be taken away. The earth will be like a silver basin, and will produce fruits so abundantly that a group of people will gather to eat a bunch of grapes or

on epomegranate and will be satisfied. A bull will be worth so much money, but a horse will be worth only a few dirhams."
Someone asked,
"O Messenger of Allaah, why will a horse be so cheap?" He said, "Because it will never be ridden in war." He was asked, "Why will the bull be so expensive?" He said, "Because it will plough the earth. For three years before the Dajjaal emerges, the people will suffer severe hunger. In the first year, Allaah will order the sky to withhold a third of its rain, and the earth to withhold two-thirds of its fruits. In the third year, He will order the sky to withhold all of its rain, and the earth to withhold all of its fruits, so that nothing green will grow. Every cloven-hoofed creature will die except for whatever Allaah wills." Someone asked, "How will the people live at that time?" He said, "By saying Laa ilaaha illaa Allaah, Allaahu Akbar, Subhaan Allaah and Al-Hamdu-lillaah. This will be like food for them." [1]
The Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Dajjaal will come forth, and one of the Believers will go towards him. The armed men of the Dajjaal will ask him, 'Where are you going?' He will say, 'I am going to this one who has come forth.' They will say, 'Kill him!' Then some of them will say to the others, 'Hasn't your lord [ie the Dajjaal] forbidden you to kill anyone without his permission?' So they will take him to the Dajjaal, and when the Believer sees him, he will say, 'O People, this is the Dajjaal whom the Prophet (sal-Allaahu 'alayhe wa sallam) told us about.' Then the Dajjaal will order them to seize him and wound him in the head; they will inflict blows all over, even in his back and stomach. The Dajjaal will ask him, 'Don't you believe in me?' He will say, 'You are a false Messiah.' The Dajjaal will order that he be sawn in two from the parting of his hair to his legs; then he will walk between the two pieces. Then he will say 'Stand!' and the man will stand up. The Dajjaal will say to him, 'Don't you believe in me?' The believer will say, 'It has only increased my understanding that you are the Dajjaal.' Then he will say, 'O people! he will not treat anyone else in such a manner after me.' The Dajjaal will seize him to slaughter him, but the space between his neck and collar-bone will be turned into copper, and the Dajjaal will not be able to do anything to him. He will take the man by his arms and legs and throw him away; the people will believe that he has been thrown into Hell, whereas in fact he will have been thrown into Paradise." The Prophet (sal-Allaahu 'alayhe wa sallam) said, "He will be the greatest of martyrs in the sight of Allaah, the Lord of the Worlds." [Muslim] [2]

Footnotes
[1] Ibn Maajah, Kitaab al-Fitan, (Hadeeth 4077), 2:1363.
"He will break the cross and kill pigs", i.e. Christianity will be annulled.
"He will not collect the Sadaqah" (i.e. Zakaat) - because there will be so much wealth, and no-one will be in need of Sadaqah.

[2] Muslim, Kitaab al-Fitan wa Ashtaar al-Saa'ah, 8/199, 200
The Hadeeth of Al-Mugheerah Ibn Shu'bah
Al-Mugheerah ibn Shu'bah said,
"No-one asked the Prophet (sal-Allaahu 'alayhe wa sallam) more questions about the Dajjaal than I did. He said, 'You should not worry about him, because he will not be able to harm you.' I said, 'But they say that he will have much food and water!' He said, 'He is too insignificant in the sight of Allaah to have all that.' " [Muslim]
Al-Mugheerah ibn Shu'bah said,
"No-one asked the Prophet (sal-Allaahu 'alayhe wa sallam) more questions about the Dajjaal than I did." One of the narrators said, "What did you ask him?" Al-Mugheerah said, "I said, 'They say that the Dajjaal will have a mountain of bread and meat, and a river of water. The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'He is too insignificant in the sight of Allaah to have all that.' " [Muslim]
From these Ahaadeeth, we can see that Allaah will test His servants with the Dajjaal and by the miracles which he will be permitted to perform: as we have already mentioned, the Dajjaal will order the sky to rain for those who accept him, and will order the earth to bring forth its fruits so that they and their livestock will eat of it, and their flocks will return fat and with their udders full of milk. Those who reject the Dajjaal and refuse to believe in him will suffer drought and famine; people and livestock will die, and wealth and supplies of food will be depleted. People will follow the Dajjaal like swarms of bees, and he will kill a young man and bring him back to life.
This is not a kind of magic; it will be something real with which Allaah will test His servants at the end of time. Many will be led astray, and many will be guided by it. Those who doubt will disbelieve, but those who believe will be strengthened in their faith.
Al-Qaadi 'Iyaad and others interpreted the phrase "He is too insignificant in the sight of Allaah to have all that" as meaning that the Dajjaal is too insignificant to have anything that could lead the true believers astray, because he is obviously evil and corrupt. Even if he brings great terror, the word Kaafir will be clearly written between his eyes; one report

explains that it will be written "Kaaf, Faa, Raa," from which we can understand that it will be written perceptibly, not abstractly, as some people say.
One of his eyes will be blind, protruding and repulsive; this is the meaning of the Hadeeth: "...as if it were a grape floating on the surface of the water." Other reports say that it is "dull, with no light in it," or "like white spittle on a wall," i.e. it will look ugly.
Some reports say that it is his right eye which will be blind; others say that it is his left eye.
He could be partly blind in both eyes, or there could be a fault in both eyes. This interpretation could be supported by the Hadeeth narrated by at-Tabaraanee, in which he reports that Ibn 'Abbaas said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Dajjaal is curly-haired and white-skinned. His head is like the branch of a tree; his left eye is blind, and the other eye looks like a floating grape.' "
One may ask: if the Dajjaal is going to cause such widespread evil and his claim to be a "lord" will be so widely believed - even though he is obviously a liar, and all the Prophet's have warned against him - why does the Qur'aan not mention him by name and warn us against his lies and stubbornness?
The answer is:-
The Dajjaal was referred to in the Ayah:
"...The day that some of the Signs of your Lord do come, no good will it do to a person to believe then, if he believed not before, nor earned good (by performing deeds of righteousness) through his Faith..." [al-An'aam (6):158]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'There are three things which, when they appear, no good will it do a soul to believe in them then, if it believed not before nor earned righteousness through its Faith. They are: The Dajjaal, the Beast, and the rising of the sun from the west.' "
Jesus son of Mary will descend from Heaven and kill the Dajjaal, as we have already mentioned. The descent of Jesus is mentioned in the Ayaat:
"And because of their saying (in boast), "We killed Messiah 'Eesaa (Jesus), son of Maryam (Mary), the Messenger of Allaah," - but they killed him not, nor crucified him, but the resemblance of 'Eesaa (Jesus) was put over another man (and they killed that man), and those who differ therein are full of doubts. They have no (certain) knowledge, they follow nothing but conjecture. For surely; they killed him not [i.e. 'Eesaa

(Jesus), son of Maryam (Mary) alayhi-salam]:
But Allaah raised him ['Eesaa (Jesus)] up (with his body and soul) unto Himself (and he alayhi-salam is in the heavens). And Allaah is Ever All Powerful, All Wise.
And there is none of the people of the Scripture (Jews and Christians), but must believe in him ['Eesaa (Jesus), son of Maryam (Mary), as only a Messenger of Allaah and a human being], before his ['Eesaa (Jesus) alayhi-salam or a Jew's or a Christian's] death (at the time of the appearance of the angel of death). And on the Day of Resurrection, he ['Eesaa (Jesus)] will be a witness against them." [an-Nisaa' (4):157-9]
We think that the Tafseer (interpretation) of this Aayah is that the pronoun in "before his death" (qabla mawtihi) refers to Jesus; i.e, he will descend and the People of the Book who differed concerning him will believe in him. The Christians claimed that he was divine, while the Jews made a slanderous accusation, i.e. that he was born from adultery. When Jesus descends before the Day of Judgment, he will correct all these differences and lies.
On this basis, the reference to the descent of the Messiah Jesus son of Mary also includes a reference to the Dajjaal (false Mesor Antichrist), who is the opposite of the true Messiah, because sometimes the Arabs refer to one of two opposites and not the other, but mean both.
The Dajjaal is not mentioned by name in the Qur'aan because he is so insignificant: he claims to be divine, but he is merely a human being. His affairs are too contemptible to be mentioned in the Qur'aan. But the Prophet's, out of loyalty to Allaah, warned their people about the Dajjaal and the tribulations and misguiding miracles he would bring. It is enough for us to know the reports of the Prophet's and the many reports from the Prophet Muhammad (sal-Allaahu 'alayhe wa sallam).
One could argue that Allaah has mentioned Pharaoh and his false claims, such as:
"I am your lord, most high" [an-Nazi'aat (79):24] and "O chiefs! I know not that you have an ilaah (a god) other than me..." [al-Qasas (28):38]
This can be explained by the fact that Pharaoh and his deeds are in the past, and his lies are clear to every believer. But the Dajjaal is yet to come, in the future; it will be a Fitnah and a test for all people. So the Dajjaal is not mentioned in the Qur'aan because he is contemptible; and the fact that he is not mentioned means that it will be a great test.
The facts about the Dajjaal and his lies are obvious and do not need further emphasis. This is often the case when something is very clear. For example, when the Prophet (sal-Allaahu 'alayhe wa sallam) was

terminally ill, he wanted to write a document confirming that Abu Bakr would be the Khaleefah after him. Then he abandoned this idea, and said,
"Allaah and the believers will not accept anyone other than Abu Bakr."
He decided not to write the document because he knew of Abu Bakr's high standing among the Sahaabah (Companions) and was sure that they would not choose anyone else. Similarly, the facts about the Dajjaal are so clear that they did not need to be mentioned in the Qur'aan. Allaah did not mention the Dajjaal in the Qur'aan because He (subhaanahu wa ta'aala) knew that the Dajjaal would not be able to lead His true servants astray; he would only increase their faith, their submission to Allaah and His Messenger, their belief in the Truth, and their rejection of falsehood. For this reason the believer whom the Dajjaal overpowers will say, when he revives him,
"By Allaah, it has only increased my understanding that you are the one-eyed liar about whom the Prophet (sal-Allaahu 'alayhe wa sallam) spoke."
More Ahaadeeth about the Dajjaal
The Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Dajjaal will emerge in a land in the east called Khurasan. His followers will be people with faces like hammered shields." [1]
Asmaa' bint Yazeed al-Ansaariyyah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'During the three years just before the Dajjaal comes, there will be one year when the sky will withhold one third of its rain and the earth one-third of its fruits. In the second year the sky will withhold two-thirds of its rain, and the earth two-thirds of its fruits. In the third year the sky will withhold all of its rain, and the earth all of its fruits, and all the animals will die. It will be the greatest tribulation: the Dajjaal will bring a Bedouin and say to him, "What if I bring your camels to life for you? Will you agree that I am your lord?" The Bedouin will say "Yes." So devils will assume the forms of his camels, with the fullest udders and the highest humps. Then he will bring a man whose father and brother have died, and will ask him, "What do you think if I bring your father and brother back to life? Will you agree that I am your lord?" The man will say "Yes," so the devils will assume the forms of his father and brother.' Then the Prophet (sal-Allaahu 'alayhe wa sallam) went out for something, and then returned. The people were very concerned about what he had told them. He stood in the doorway and asked, 'What is wrong, Asma'? I said, 'O Messenger of Allaah, you have terrified us with what you said about the Dajjaal.' He said, 'He will

certainly appear. If I am still alive, I will contend with him on your behalf; otherwise Allaah will take care of every Muslim on my behalf.' I said, 'O Messenger of Allaah, we do not bake our dough until we are hungry, so how will it be for the believers at that time?' The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The glorification of Allaah which suffices the people of Heaven will be sufficient for them.' " [2]
Abu Hurairah (radi-Allahu 'anhu) said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Hour will not come until the Muslims fight the Jews and kill them. When a Jew hides behind a rock or a tree, it will say, "O Muslim, O servant of Allaah! There is a Jew behind me, come and kill him!" All the trees will do this except the box-thorn (al-Gharqad), because it is the tree of the Jews.' " [Ahmad] [3]

Protection Against The Dajjaal
1. Seeking refuge with Allaah from his tribulation.
It is proven in the Saheeh (authentic) Ahaadeeth that the Prophet (sal-Allaahu 'alayhe wa sallam) used to seek refuge with Allaah from the tribulation of the Dajjaal in his prayers, and that he commanded his Ummah to dol ikewise:
"Allaahumma innaa na'oodhu bika min 'adhaabi jahannam, wa min 'adhaabi 'l-qabr, wa min fitnatee 'l-mahyaa'i wa'l-mamaat, wa min fitnatee' l-maseehi 'd-dajjaal."
"O Allaah! We seek refuge with You from the punishment of Hell, from the punishment of the grave, from the tribulations of life and death, and from the tribulation of the False Messiah (Dajjaal)." [1]
This Hadeeth was narrated by many Sahabah, including Anas, Abu Hurairah, 'Aa'ishah, Ibn 'Abbaas, and Sa'd (radi-Allaahu 'anhum).
2. Memorising certain Aayaat from Surat al-Kahf.
Al-Haafidh ad-Dhahabee said,
"Seeking refuge with Allaah from the Dajjaal is mentioned in many

Mutawaatir Ahaadeeth (those with numerous lines of narrators). One way of doing this is to memorise ten Ayaat from Surat al-Kahf."
Abul-Diraa reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said, "Whoever memorises the first ten Aayaat of Surat al-Kahf will be protected from the Dajjaal." [Abu Daawood] [2]
3. Keeping away from the Dajjaal.
One way to be protected from the tribulation of the Dajjaal is to live in Madeenah or Makkah.
Abu Hurairah reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"There are angels standing at the gates of Madeenah; neither plague nor the Dajjaal can enter it." [Bukhaaree, Muslim]
Abu Bakr reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said, "The terror caused by the Dajjaal will not enter Madeenah. At that time it will have seven gates; there will be two angels guarding every gate." [Bukhaaree] [3]
Anas said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Dajjaal will come to Madeenah, and he will find angels guarding it. Neither plague nor the Dajjaal will enter it, inshaa-Allaah.' " [Tirmidhee, Bukhaaree]
It has been proven in the Saheeh Ahaadeeth that the Dajjaal will not enter Makkah or Madeenah, because the angels will prevent him from entering these two places which are sanctuaries and are safe from him. When he camps at the salt-marsh (Sabkhah) of Madeenah, it will be shaken by three tremors - either physically or metaphorically - and every hypocrite will go out to join the Dajjaal. On that day, Madeenah will be cleansed of its dross and will be refined and purified; and Allaah knows best.

The Life And Deeds Of The Dajjaal
The Dajjaal will be a man, created by Allaah to be a test for people at the end of time. Many will be led astray through him, and many will be guided through him; only the sinful will be led astray.
Al-Haafidh Ibn 'Alee al-Aabaar wrote in his book of history (at-Taareekh)

that the Dajjaal's Kunyah (nickname or paternal title) would be Abu Yoosuf. [1]
Abu Bakrah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Dajjaal's parents will remain childless for thirty years, then a one-eyed child will be born to them. He will be very bad and will cause a great deal of trouble. When he sleeps, his eyes will be closed but his heart (or mind) will still be active.' Then he described his parents: 'His father will be a tall and bulky man, with a long nose like a beak; his mother will be a huge, heavy-breasted woman.' " [2]
Abu Bakrah said,
"We heard that a child had been born to some of the Jews in Madeenah. Az-Zubayr ibn al-'Awaam and I went see his parents, and found that they matched the description given by the Prophet (sal-Allaahu 'alayhe wa sallam). We saw the boy lying in the sun, covered with a blanket, murmuring to himself. We asked his parents about him, and they said, 'We remained childless for thirty years, then this one-eyed boy was born to us. He is very bad and causes a great deal of trouble.' When we went out, we passed the boy. He asked us, 'What were you doing?' We said, 'Did you hear us?' He said, 'Yes; when I sleep, my eyes are closed but my heart (mind) is still active.' That boy was Ibn Sayyaad." [Ahmad, Tirmidhee; this Hadeeth is not very strong] [3]
As we have already seen in the Saheeh Ahaadeeth, Maalik and others think that Ibn Sayyaad was not the Dajjaal; he was one of a number of "lesser dajjaals." Later he repented and embraced Islaam; Allaah knows best his heart and deeds.
The "greater" Dajjaal is the one mentioned in the Hadeeth of Faatimah bint Qays, which she narrated from the Prophet (sal-Allaahu 'alayhe wa sallam), from Tameem ad-Daaree, and which includes the story of the Jassaasah. The Dajjaal will be permitted to appear at the end of time, after the Muslims have conquered a Roman city called Constantinople. He will first appear in Isfahaan, in an area known as the Jewish quarter (al-Yahoodiyyah). He will be followed by seventy thousand Jews from that area, all of them armed. Seventy thousand Tatars and many people from Khuraasaan will also follow him. At first he will appear as a tyrannical king, then he will claim to be a prophet, then a lord. Only the most ignorant of men will follow him; the righteous and those guided by Allaah will reject him. He will start to conquer the world country by country, fortress by fortress, region by region, town by town; no place will remain unscathed except Makkah and Madeenah. The length of his stay

on earth will be forty days: one day like a year, one day like a month, one day like a week, and the rest of the days like normal days, i.e. his stay will be approximately one year and two and a half months. Allaah will grant him many miracles, through which whoever He wills will be astray, and the faith of the believers will be strengthened. The descent of Jesus son of Mary, the true Messiah, will happen at the time of the Dajjaal, the false messiah. He will descend to the minaret in the east of Damascus. The believers and true servants of Allaah will gather to support him, and the Messiah Jesus son of Mary will lead them against the Dajjaal, who at that time will be heading for Bayt al-Maqdis (Jerusalem). He will catch up with him at 'Aqabah 'Afeeq. The Dajjaal will runaway from him, but Jesus will catch up with him at the gate of Ludd, and will kill him with his spear just as he is entering it. He will say to him, "I have to deal you a blow; you cannot escape." When the Dajjaal faces him, he will begin to dissolve like salt in water. So Jesus will kill him with his spear at the gate of Ludd, and he will die there, as many Saheeh Ahaadeeth indicate.
Majma' ibn Jaariyah is reported to have said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) saying, 'The son of Mary will kill the Dajjaal at the gate of Ludd.' " [Tirmidhee] [4]

The Descent of Jesus at the End of Time
Abd Allaah ibn 'Amr said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Dajjaal will appear in my Ummah, and will remain for forty - "I cannot say whether he meant forty days, forty months or forty years." - Then Allaah will send Jesus (alayhi-salam), the son of Mary, who will resemble 'Urwah ibn Mas'ood. He will chase the Dajjaal and kill him. Then the people will live for seven years during which there will be no enmity between any two

persons. Then Allaah will send a cold wind from the direction of Syria, which will take the soul of everyone who has the slightest speck of good or faith in his heart. Even if one of you were to enter the heart of a mountain, the wind would reach him there and take his soul. Only the most wicked people will be left; they will be as careless as birds, with the characteristics of beasts, and will have no concern for right and wrong. Satan will come to them in the form of man and will say, "Don't you respond?" They will say, "What do you order us to do?" He will order them to worship idols, and in spite of that they will have sustenance in abundance, and lead comfortable lives.
"Then the Trumpet will be blown, and everyone will tilt their heads to hear it. The first one to hear it will be a man busy repairing a trough for his camels. He and everyone else will be struck down. Then Allaah will send (or send down) rain like dew, and the bodies of the people (i.e. the dead) will grow out of it. Then the trumpet will be sounded again, and the people will get up and look around. Then it will be said, "O people, go to your Lord and account for yourselves." It will be said, "Bring out the people of Hell," and it will be asked, "How many are there?" - the answer will come: "Nine hundred and ninety-nine out of every thousand." "On that day a child will grow old and the shin will be laid bare." [al-Qalam (68):42] " [Muslim] [1]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The son of Mary will come down as a just leader. He will break the cross, and kill the pigs. Peace will prevail and people will use their swords as sickles. Every harmful beast will be made harmless; the sky will send down rain in abundance,and the earth will bring forth its blessings. A child will play with a fox and not come to any harm; a wolf will graze with sheep and a lion with cattle, without harming them.' " [Ahmad] [2]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'By Him in Whose hand is my soul, surely the son of Mary will come down among you as a just ruler. He will break the cross, kill the pigs and abolish the Jizyah. Wealth will be in such abundance that no-one will care about it, and a single prostration in prayer will be better than the world and all that is in it.' "
Abu Hurairah said,
'If you wish, recite the Aayah: "And there is none of the People of the Book but must believe in him before his death; and on the Day of Judgement he will be a witness against them..." [an-Nisaa' (4):159] '

[Bukhaaree, Muslim] [3]
Abu Hurairah reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Prophets are like brothers; they have different mothers but their religion is one. I am the closest of all the people to Jesus son of Mary, because there is no other Prophet between him and myself. He will come again, and when you see him, you will recognise him. He is of medium height and his colouring is reddish-white. He will be wearing two garments, and his hair will look wet. He will break the cross, kill the pigs, abolish the Jizyah and call the people to Islaam. During his time, Allaah will end every religion and sect other than Islaam, and will destroy the Dajjaal. Then peace and security will prevail on earth, so that lions will graze with camels, tigers with cattle, and wolves with sheep; children will be able to play with snakes without coming to any harm. Jesus will remain for forty years, then die, and the Muslims will pray for him."
[Ahmad] [4]
Ibn Masood reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"On the night of the Israa' (night journey), I met my father Abraham, Moses and Jesus, and they discussed the Hour. The matter was referred first to Abraham, then to Moses, and both said, 'I have no knowledge of it.' Then it was referred to Jesus, who said, 'No-one knows about its timing except Allaah; what my Lord told me was that the Dajjaal will appear, and when he sees me he will begin to melt like lead. Allaah will destroy him when he sees me. The Muslims will fight against the Kaafirs, and even the trees and rocks will say, "O Muslim, there is a Kaafir hiding beneath me - come and kill him!" Allaah will destroy the Kaafirs, and the people will return to their own lands. Then Gog and Magog will appear from all directions, eating and drinking everything they find. The people will complain to me, so I will pray to Allaah and He will destroy them, so that the earth will be filled with their stench. Allaah will send rain which will wash their bodies into the sea. My Lord has told me that when that happens, the Hour will be very close, like a pregnant woman whose time is due, but her family do not know exactly when she will deliver.' "
[Ahmad, Ibn Maajah] [5]

Description of the Messiah Jesus son of Mary, Messenger of Allaah
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'On the night of the Israa' (miraculous journey to Jerusalem) I met Moses - he was a slim man with wavy hair, and looked like a man from the Shanoo'ah tribe. I also met Jesus - he was of medium height and of a red complexion, as if he had just come out of the bath' " [Bukhaaree, Muslim] [1]
The Prophet (sal-Allaahu 'alayhe wa sallam) said,
"Whilst I was asleep, I saw myself (in a dream) making Tawaaf around the Ka'bah. I saw a brown-skinned man, with straight hair, being supported by two men, and with water dripping from his head. I said, 'Who is this?' They said, 'The son of Mary' I turned around and saw a fat, ruddy man, with curly hair, who was blind in his right eye; his eye looked like a floating grape. I asked, 'Who is this?' They said, 'The Dajjaal.' The one who most resembles him is Ibn Qatan." Az-Zuhri explained: Ibn Qatan was a man from Khuzaa'ah who died during the Jaahiliyyah (before the coming of Islaam). [Bukhaaree] [2]

The Appearance of Gog and Magog
They (two tribes or peoples) will appear at the time of Jesus son of Mary, after the Dajjaal. Allaah will destroy them all in one night, in response to the supplication of Jesus.
Abu Hurairah reported that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"Everyday, Gog and Magog are trying to dig a way out through the

barrier. When they begin to see sunlight through it, the one who is in charge of them says, 'Go back; you can carry on digging tomorrow,' and when they come back, the barrier is stronger than it was before. This will continue until their time comes and Allaah wishes to send them forth. They will dig until they begin to see sunlight, then the one who is in charge of them will say, 'Go back; you can carry on digging tomorrow, inshaa'-Allaah.' In this case he will make an exception by saying inshaa'-Allaah, thus relating the matter to the Will of Allaah. They will return on the following day, and find the hole as they left it. They will carry on digging and come out against the people. They will drink all the water, and the people will entrench themselves in their fortresses. Gog and Magog will fire their arrows into the sky, and they will fall back to earth with something like blood on them. Gog and Magog will say, 'We have defeated the people of earth, and overcome the people of heaven.' Then Allaah will send a kind of worm in the napes of their necks, and they will be killed by it...' 'By Him in Whose hand is the soul of Muhammad, the beasts of the earth will become fat.' " [1]

Gog and Magog are two groups of Turks, descended from Yaafith (Japheth), the father of the Turks, one of the sons of Noah. At the time of Abraham (alayhi-salam), there was a king called Dhu'l-Qarnayn. He performed Tawaaf around the Ka'bah with Abraham (alayhi-salam) when he first built it; he believed and followed him. Dhu'l-Qarnayn was a good man and a great king; Allaah gave him great power and he ruled the east and west. He held sway over all kings and countries, and travelled far and wide in both east and west. He travelled eastwards until he reached a pass between two mountains, through which people were coming out. They did not understand anything, because they were so isolated; they were Gog and Magog. They were spreading corruption through the earth, and harming the people, so the people sought help from Dhu'l-Qarnayn. They asked him to build a barrier between them and Gog and Magog. He asked them to help him to build it, so together they built a barrier by mixing iron, copper and tar.

Thus Dhu'l-Qarnayn restrained Gog and Magog behind the barrier. They tried to penetrate the barrier, or to climb over it, but to no avail. They could not succeed because the barrier is so huge and smooth. They began to dig, and they have been digging for centuries; they will continue to do so until the time when Allaah decrees that they come out. At that time the barrier will collapse, and Gog and Magog will rush out in all directions, spreading corruption, uprooting plants, killing people. When Jesus (alayhi-salam) prays against them, Allaah will send a kind of worm

in the napes of their necks, and they will be killed by it.

The destruction of the Ka'bah
At the end of time, Dhu'l-Suwayqatayn, who will come from Abyssinia (al-Habash), will destroy the Ka'bah in order to steal its treasure and Kiswah (cloth covering). The Ka'bah is the ancient building which was built by Abraham, and whose foundations were laid by Adam.
As Tafseer (interpretation) of the Aayah "Until the Gog and Magog (people) are let through (their barrier)" [al-Anbiyaa' (21):96], it was reported from Ka'b al-Ahbar that Dhu'l-Suwayqatayn will first emerge at the time of Jesus, son of Mary. Allaah will send Jesus at the head of a vanguard of between seven and eight hundred. While they are marching towards Dhu'l-Suwayqatayn, Allaah will send a breeze from the direction of Yemen, which will take the soul of every believer. Only the worst of people will be left, and they will begin to copulate like animals. Ka'b said: "At that time, the Hour will be close at hand." [1]
'Abd Allaah ibn 'Amr said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'Dhu'l-Suwayqatayn from Abyssinia will destroy the Ka'bah and steal its treasure and Kiswah. It is as if I could see him now: he is bald-headed and has a distortion in his wrists. He will strike the Ka'bah with his spade and pick-axe.' " [Ahmad] [2]
It was reported from 'Abd Allaah ibn 'Umar that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"Leave the Abyssinians alone so long as they do not disturb you, for no-one will recover the treasure of the Ka'bah except Dhu'l-Suwayqatayn from Abyssinia." [Abu Daawood, in the chapter on the prohibition of provoking the Abyssinians] [3]
Ibn 'Abbaas narrated that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"It is as if I can see him now: he is black and his legs are widely spaced. He will destroy the Ka'bah stone by stone." [Ahmad] [4]
The Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Hour will not come until a man from Qahtaan appears and rules the people." [Muslim; similar Hadeeth in Bukhaaree]

This man could be Dhu'l-Suwayqatayn, or someone else, because this man comes from Qahtaan, while other reports say that Dhu'l-Suwayqatayn comes from Abyssinia; and Allaah knows best.
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Day and night will not come to an end until a freed man called Jahjaah holds sway.' " [Ahmad] [5]
This could be the name of Dhul-Suwayqatayn from Abyssinia; and Allaah knows best.
'Umar ibn al-Khattab reported that he heard the Prophet (sal-Allaahu 'alayhe wa sallam) say:
"The people of Makkah will leave, and only a few people will pass through it. Then it will be resettled and rebuilt; then the people will leave it again, and no-one will ever return." [6]

Footnotes
[1] Concerning Dhu'l-Suwayqatayn, see: Bukhaaree: Kitaab al-Hajj, Baab Hadam al-Ka'bah (The Book of Pilgrimage, Chapter of the Destruction of the Ka'bah), 2/183. Muslim, Kitaab al-Fitan wa Ashraat al-Saa'ah, 8/183.
Dhu'l-Suwayqatayn: al-Suwayqatayn is the dimunitive of al-Saaqayn (legs); his legs are described as being "small" because they are thin. Thin legs are, in general, a characteristic of the Sudanese and people of the Horn of Africa.

Madeenah will remain inhabited at the time of the Dajjaal
It has been proven in the Saheeh Ahaadeeth, as already stated, that the Dajjaal will not be able to enter Makkah and Madeenah, and that there will be angels at the gates of Makkah to ward him off and prevent him

from entering.
It was reported from Abu Hurairah that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"Neither the Dajjaal nor plague will be able to enter Madeenah."
As mentioned above, the Dajjaal will camp outside Madeenah, and it will be shaken by three tremors. Every hypocrite and sinner will go out to join the Dajjaal, and every believer and Muslim will stay. That day will be called the Day of Purification (Yawm al-Khalaas). Most of those who go out to join the Dajjaal will be women. As the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"Verily it (Madeenah) is good; its evil will be eliminated and its goodness will be obvious."
Allaah (subhaanahu wa ta'aala) said:
"Women impure are for men impure, and men impure for women impure, and women of purity are for men of purity, and men of purity are for women of purity..." [an-Noor (24):26)
Madeenah will remain inhabited during the days of the Dajjaal, and during the time of Jesus son of Mary (alayhi-salam), until he dies and is buried there. Then it will be destroyed.
'Umar ibn al-Khattab said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'A rider will go around Madeenah and say, There used to be many Muslims here.' " [Ahmad] [1]

Footnotes

Checker's Note: Da`eef isnaad due to Ibn Lahi'ah and `an`anah of Abu Zubair. The fact that Madinah will be deserted is reported from Abu Hurairah by al-Bukhaaree.
The Emergence of the Beast
Among the signs of the Hour will be the emergence of a beast from the earth. It will be very strange inappearance, and extremely huge; one cannot even imagine what it will look like. It will emerge from the earth and shake the dust from its head. It will have with it the ring of Solomon and the rod of Moses. People will be terrified of it and will try to run away, but they will not be able to escape, because such will be the decree of Allaah. It will destroy the nose of every unbeliever with the rod, and write the word "Kaafir" on his forehead; it will adorn the face of every believer and write the word "Mu'min" (true believer) on his forehead, and it will speak to people.

Allaah (subhaanahu wa ta'aala) said:
"And when the Word is fulfilled against them (the unjust), We shall produce from the earth a Beast to (face) them: it will speak to them..." [an-Naml (27):82]
Ibn 'Abbaas, al-Hasan and Qataadah said that "It will speak to them" (tukallimuhum) means that it will address them. Ibn Jareer suggested that it means that the Beast will address them with the words "...for that mankind did not believe with assurance in Our Signs..." [an-Naml (27):82 - latter part of the Ayah]
Ibn Jareer reported this from 'Alee and 'Ata'. It was reported from Ibn 'Abbaas that tukallimuhum means that the Beast will cut them, i.e., it will write the word "Kaafir" on the forehead of the unbeliever. It was also reported from Ibn 'Abbaas that he will both address them and cut them; this suggestion incorporates both of the previous suggestions; and Allaah knows best.
We have already mentioned the Hadeeth of Hudhayfah ibn Usayd, in which the Prophet (sal-Allaahu 'alayhe wa sallam) is reported to have said,
"The Hour will not come until you see ten signs: the smoke; the Dajjaal; the Beast; the sun rising from the West; the descent of Jesus son of Mary; Gog and Magog; and three land-slides - one in the East, one in the West, and one in Arabia, at the end of which fire will burst forth from the direction of Aden (Yemen) and drive people to the place of their final assembly."
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Hasten to do good deeds before six things happen: the rising of the sun from the West, the smoke, the Dajjaal, the Beast, the (death) of one of you or general tribulation.' " [Muslim]
Bareedah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) took me to a place in the desert, near Makkah. It was a dry piece of land surrounded by sand. The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Beast will emerge from this place.' It was a very small area." [Ibn Maajah] [1]
It was reported from Abu Hurairah that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Beast of the Earth will emerge, and will have with it the rod of Moses and the ring of Solomon."
It was also reported that he said,
"(The Beast) will destroy the noses of the unbelievers with the ring, - so

that people seated around one table will begin to address one another with the words "O Believer!" or "O Unbeliever!" (i.e., everyone's status will become clear) [Ibn Maajah] [2]
'Abd Allaah ibn 'Amr said,
"I memorised a Hadeeth from the Prophet (sal-Allaahu 'alayhe wa sallam) which I have not forgotten since. I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'The first of the signs (of the Hour) to appear will be the rising of the sun from the West and the appearance of the Beast before the people in the forenoon. Whichever of these two events happens first, the other will follow immediately.' " [Muslim] [3]
That is to say, these will be the first extraordinary signs. The Dajjaal, the descent of Jesus (alayhi-salam), the emergence of Gog and Magog, are less unusual in that they are all human beings. But the emergence of the Beast, whose form will be very strange, its addressing the people and classifying them according to their faith or unbelief, is something truly extraordinary. This is the first of the earthly signs, as the rising of the sun from the West is the first of the heavenly signs.

The Rising of the Sun from the West
Allaah (subhaanahu wa ta'aala) says:
"Do they then wait for anything other than that the angels should come to them, or that your Lord should come, or that some of the Signs of your Lord should come (i.e. portents of the Hour e.g., arising of the sun from the west)! The day that some of the Signs of your Lord do come, no good will it do to a person to believe then, if he believed not before, nor earned good (by performing deeds of righteousness) through his Faith. Say: 'Wait you! we (too) are waiting.'" [al-An'aam (6):158]
It was reported from Abu Sa'eed al-Khudree that the Prophet (sal-Allaahu 'alayhe wa sallam) explained,
"The day that some of the Signs of your Lord do come, no good will it do to a person to believe then...", referring to the rising of the sun from the West. [Ahmad] [1]

Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'The Hour will not come until the sun rises from the West. When the people see it, whoever is living on earth will believe, but that will be the time when - No good will it do to a person to believe then, if he believed not before then' " [Bukhaaree] [2]
It was also reported from Abu Hurairah that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Hour will not come until the sun rises from the West. When it rises and the people see it, they will all believe. But that will be the time when 'No good will it do to a person to believe then.' " [Bukhaaree] [3]
It was reported from Abu Hurairah that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"There are three things which, if they appear, 'No good will it do to a person to believe then, if he believed not before, nor earned good (by performing deeds of righteousness) through his Faith' They are: the rising of the sun from the West, the Dajjaal, and the Beast of the Earth." [Ahmad, Muslim, Tirmidhee] [4]
Abu Dharr said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) asked me, 'Do you know where the sun goes when it sets?' I said, 'I do not know' He said, 'It travels until it prostrates itself beneath the Throne, and asks for permission to rise again. But a time will come when it will be told, 'Go back whence you came.' That will be the time when 'No good will it do to a person to believe then, if he believed not before, nor earned good (by performing deeds of righteousness) through his Faith' " [Bukhaaree] [5]
'Amr ibn Jareer said,
"Three Muslims were sitting with Marwaan in Madeenah, and heard him say, whilst talking about the Signs of the Hour, that the first of them would be the appearance of the Dajjaal. The three went to 'Abd Allaah ibn 'Amr, and told him what they had heard Marwaan say concerning the Signs. 'Abd Allaah said, 'Marwan has not said much. I memorised a Hadeeth like that from the Prophet (sal-Allaahu 'alayhe wa sallam) which I have not forgotten since. I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say:
"The first of the signs will be the rising of the sun from the West, and the emergence of the Beast in the forenoon. Whichever of the two comes first, the other will follow immediately"
Then 'Abd Allaah, who was widely-read, said,
"I think that the first to happen will be the rising of the sun from the West.

Every time it sets, it goes beneath the Throne, prostrates itself, and seeks permission to rise again. A time will come when three times it will seek permission and will receive no reply, until, when part of the night has passed and it realises that even if it were given permission, it would not be able to rise on time, it will say: 'O my Lord, how far the rising-point is from me! What can I do for the people now?' Then it will seek permission to go back, and it will be told: 'Rise from where you are now' - and it will rise from the West." Then 'Abd Allaah recited the Aayah: "No good will it do to a person to believe then, if he believed not before, nor earned good (by performing deeds of righteousness) through his Faith." [Ahmad] [6]

The Smoke which will appear at the End of Time
Masrooq said:
"While a man was giving a speech among the people of Kindah, he said, 'There will be smoke on the Day of Resurrection which will deprive the hypocrites of their hearing and sight, but the believers will only suffer something like a cold.' We were terrified, so we went to Ibn Masood, who was reclining. When he heard about this, he became angry and sat up, and said: 'O people, whoever knows a thing, let him say it; but whoever does not know, let him say, "Allaah knows best." It is a part of knowledge, when one does not know something, to say "Allaah knows best." Allaah (subhaanahu wa ta'aala) said to His Prophet Muhammad (sal-Allaahu 'alayhe wa sallam):
"Say (O Muhammad sal-Allaahu 'alayhe wa sallam): 'No wage do I ask of you for this (the Qur'aan), nor am I one of the Mutakallifoon (those who pretend and fabricate things which do not exist).'" [Saad (38):86]
"Quraysh were being slow in embracing Islaam, so the Prophet (sal-Allaahu 'alayhe wa sallam) prayed against them, saying, 'O Allaah, help

me against them by sending seven years of famine like those of Joseph.' They were afflicted by a year of famine in which they were destroyed, and ate dead animals and bones. They began to see something like smoke between the sky and the earth. Abu Sufyan came and said, 'O Muhammad! You came to command us to keep good relations with our relatives, and your people have perished, so pray that Allaah may relieve them.'"

Then Ibn Mas'ood recited,

"Then wait you for the Day when the sky will bring forth a visible smoke. Covering the people, this is a painful torment. (They will say): "Our Lord! Remove the torment from us, really we shall become believers!" How can there be for them an admonition (at the time when the torment has reached them), when a Messenger explaining things clearly has already come to them. Then they had turned away from him (Messenger Muhammad sal-Allaahu 'alayhe wa sallam) and said: "One (Muhammad sal-Allaahu 'alayhe wa sallam) taught (by a human being), a madman!" Verily, We shall remove the torment for a while. Verily! You will revert." [ad-Dukhaan (44):10-15]

Ibn Masood asked:

"Will their punishment in the Hereafter be removed so they can go back to their Kufr?"

Allaah (subhaanahu wa ta'aala) said:

"On the Day when We shall seize you with the greatest grasp. Verily, We will exact retribution." [ad-Dukhaan (44):16]

...and soon will come the inevitable (punishment)!" [al-Furqaan (25):77]

These Ayaat refer to the Day (Battle) of Badr. Allaah (subhaanahu wa ta'aala) said:

"Alif Laam Meem. The Romans have been defeated. In the nearer land (Syria, Iraq, Jordan, and Palestine), and they, after their defeat, will be victorious. Within three to nine years." [ar-Room (30): 1-4] [Bukhaaree] [1]

This speaker's suggestion - that the idea that the smoke would be on the Day or Resurrection was not a good one - made Ibn Masood react angrily. But the smoke will appear before the Day of Resurrection; it will be one of the signs, which are: the Beast, the Dajjaal, the Smoke, and Gog and Magog, as the Ahaadeeth narrated from Abu Sareehah, Abu Hurairah and other Sahaabah indicate.

As mentioned in the Saheeh Ahaadeeth, the fire which will appear before the Day of Resurrection will burst forth from the direction of Aden, and drive the people to the place of their final assembly. It will move with

them and halt with them, and will devour any who lag behind.

Other Events which will precede the Hour
It was reported from Abu Sa'eed al-Khudree that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"Thunderbolts will increase so much as the Hour approaches that when a man comes to a people, he will ask, 'Who amongst you was struck by a thunderbolt this morning?' and they will say, 'So-and-so and so-and-so was struck.' " [Ahmad] [1]
Heavy rain before the Day of Resurrection
It was reported from Abu Hurairah that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The hour will not come until there has been rain which will destroy all dwellings except tents." [2]
We have already mentioned many Ahaadeeth about the signs of the Hour. Now we will turn our attention to some Ahaadeeth which could indicate that the Hour is close at hand.
It was reported from Abu Hurairah that the Prophet (sal-Allaahu 'alayhe wa sallam) said:
"The Hour will not come until the following events have come to pass: people will compete with one another in constructing high buildings; two big groups will fight one another, and there will be many casualties - they will both be following the same religious teaching; earthquakes will increase; time will pass quickly; afflictions and killing will increase; nearly thirty dajjals will appear, each of them claiming to be a messenger from Allaah; a man will pass by a grave and say, 'Would that I were in your place'; the sun will rise from the West; when it rises and the people see it, they will all believe, but that will be the time when 'No good will it do to a person to believe then, if it believed not before...' [al-An'aam (6):158]; and a wealthy man will worry lest no-one accept his Zakaat." [Bukhaaree, Muslim]
It was reported from Anas that the Prophet (sal-Allaahu 'alayhe wa sallam) said:
"Among the signs of the Hour are the following: knowledge will decrease and ignorance will prevail; fornication and the drinking of wine will be common; the number of men will decrease and the number of women will increase, until one man will look after fifty women." [Bukhaaree] [3]
'Aa'ishah said,

"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say, 'Day and night will not pass away until people begin to worship Laat and 'Uzzaa' (two goddesses of pre-Islaamic Arabic). I said, 'O Messenger of Allaah, I thought that when Allaah revealed the Aayah "It is He Who has sent His Messenger (Muhammad sal-Allaahu 'alayhe wa sallam) with guidance and the religion of truth (Islaam), to make it superior over all religions even though the Mushrikoon (polytheists, pagans, idolaters, disbelievers in the Oneness of Allaah) hate (it)" [at-Tawbah (9):33], it implied that (this promise) would be fulfilled.' The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'It will happen as Allaah wishes. Then Allaah will send a pleasant breeze, which will take everyone who has as much faith as a grain of mustard-seed in his heart. Only those with no goodness in them will be left, and they will revert to the religion of their forefathers.' " [Muslim] [4]

It was reported from Abu Hurairah that one day, while the Prophet (sal-Allaahu 'alayhe wa sallam) was sitting with the people, a Bedouin came to him and asked him about Eemaan and Islaam, then he asked, "O Messenger of Allaah, when will the Hour be?" He said, "The one who is asked about it does not know more than the one who asks, but I tell you about its signs. When a slave gives birth to her mistress, and when the bare-footed and naked become the chiefs of the people - these are among the signs of the Hour. There are five things which no-one knows except Allaah." Then he recited:

"Verily the knowledge of the Hour is with God (alone). It is He Who sends down rain, and He Who knows what is in the wombs. Nor does anyone know what it is that he will earn on the morrow: nor does anyone know in what land he is to die. Verily God is All-Knowing, All Aware." [Luqman (31):34]

Then the man went away, and the Prophet (sal-Allaahu 'alayhe wa sallam) said, "Call him back to me," but when the people went to call him, they could not see anything. The Prophet (sal-Allaahu 'alayhe wa sallam) said, "That was Gabriel, who came to teach the people their religion." [Bukhaaree, Muslim] [5]

"The bare-footed and naked paupers will compete with one another in constructing high buildings" means that they will become the chiefs of people. They will become rich, and their only concern will be to compete in constructing high buildings. This is as in the Hadeeth we shall see later:

"The Hour will not come until the happiest people in the world will be the depraved sons of the depraved."

It was reported from Abu Sa'eed that the Prophet (sal-Allaahu 'alayhe wa

sallam) said:
"The Hour will not come until the time when a man will leave his home, and his shoes or whip or stick will tell what is happening to his family." [Ahmad] [6]
It was reported from Abu Sa'eed that the Prophet (sal-Allaahu 'alayhe wa sallam) said:
"By Him in Whose hand is my soul, the Hour will not come until wild animals talk to men, and a man speaks to his whip or his shoe, and his thigh will tell him about what happened to his family after he left." [7]
Anas said,
"We were discussing the fact that the Hour would not come until there is no rain, the earth does not produce crops, and fifty women will be cared for by one man; and if a woman passes by a man, he will look at her and say, 'This woman once had a husband.' " [Ahmad] [8]
Abu Hurairah said:
"The Prophet (sal-Allaahu 'alayhe wa sallam) said: 'The Hour will not come until time passes so quickly that a year will be like a month, a month like a week, a week like a day, a day like an hour, and an hour like the time it takes for a palm-leaf to burn.' " [Ahmad] [9]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said: 'The world will not pass away until the one who enjoys it the most is the depraved son of the depraved.' " [Ahmad] [10]
Abu Hurairah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) said, 'Before the Hour comes, there will be years of deceit, in which a truthful person will be disbelieved and a liar will be believed; and the insignificant will have a say.' " [Ahmad] [11]
Abu Hurairah said:
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say: 'The Hour will not come until the sheep with horns no longer fights the sheep without horns.' " [Ahmad] [12]
It was reported from Abu Hurairah that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Hour will not come until wealth increases so much that a wealthy man will be worried lest no-one accept his Sadaqah; knowledge will be taken away; time will pass quickly; tribulations will appear; and there will be much Harj." The people asked, "What is Harj, O Messenger of Allaah?" He said, "Killing, killing." [Ahmad] [13]
It was reported from Abu Hurairah that the Prophet (sal-Allaahu 'alayhe

wa sallam) said,
"By Him Who sent me with the Truth, this earth will not pass away until people are afflicted with landslides, are pelted with stones, and are transformed into animals." The people asked, "When will that be, O Messenger of Allaah?" He said, "When you see women riding in the saddle, when singers are common, when bearing false witness becomes widespread, and when men lie with men and women with women." [14]
Taariq ibn Shihaab said,
"We were sitting with 'Abd Allaah ibn Mas'ood, when a man came and told us that the time for prayer had come. So we got up and went to the mosque... After the prayer, a man came to 'Abd Allaah ibn Mas'ood and said, 'As-salaam 'alayka (Peace be upon you), O Abu 'Abd ar-Rahmaan'. 'Abd Allaah answered, 'Allaah and His Messenger have spoken the truth.' When we went back, we asked one another, 'Did you hear the answer he gave? Who is going to ask him about it?' I said, 'I will ask him'; so I asked him when he came out. He narrated from the Prophet (sal-Allaahu 'alayhe wa sallam):
'Before the Hour comes, there will be a special greeting for the people of distinction; trade will become so widespread that a woman will help her husband in business; family ties will be cut; the giving of false witness will be common, while truthful witness will be rare; and writing will be widespread.' [Ahmad] [15]

Description of the People who will be Alive at the End of Time
It was reported from 'Abd Allaah ibn 'Amr that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Hour will not come until Allaah takes away the best people on earth; only the worst people will be left; they will not know any good or forbid any evil." [Ahmad] [1]
'Abd Allaah ibn Mas'ood said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say: 'Eloquence can be bewitching; the worst of the people are those upon whom the Hour will come while they are still alive, and those who turn graves into mosques.' " [Ahmad] [2]
It was reported from Anas that the Prophet (sal-Allaahu 'alayhe wa sallam) said,
"The Hour will not come until no-one on earth says 'Laa ilaaha illaa Allaah.'" [Ahmad] [3]
It was also reported from Anas that the Prophet (sal-Allaahu 'alayhe wa sallam) said:
"The Hour will not come until no-one on earth says, 'Allaah, Allaah.'" [Ahmad] [4]
There are two suggestions as to the meaning of the phrase, "until no-one on earth says 'Allaah, Allaah'":

It could mean that no-one will forbid evil, or try to correct another if he sees him doing something wrong. We have already come across this in the Hadeeth of 'Abd Allaah ibn 'Amr:
"Only the worst people will be left; they will not know any good or forbid any evil."
It could mean that Allaah will no longer be mentioned, and His Name will not be known; this will be part of the prevalent corruption and Kufr, as in the previous Hadeeth,
"Until no-one on earth says 'Laa ilaaha illaa Allaah."
'Aa'ishah said,
"The Prophet (sal-Allaahu 'alayhe wa sallam) came in, saying 'O 'Aa'ishah, your people will be the first of my Ummah to join me.' When he sat down, I said, 'O Messenger of Allaah, may I be sacrificed for you! When you came in, you were saying something which scared me.' He asked, 'What was that?' I said, 'You said that my people would be the first of your Ummah to join you.' He said, 'Yes.' I asked, 'Why is that?' He said, 'Death will be widespread among them, and their relatives will be jealous of them.' I said, 'How will people be after that?' He said, 'Like locusts: the strong will devour the weak, until the Hour comes.' " [Ahmad] [5]
'Albaa' al-Salamee said,
"I heard the Prophet (sal-Allaahu 'alayhe wa sallam) say: 'The Hour will only come upon the worst of the people.' " [Ahmad] [6]
