Goal of the Book. Arrangement of Material

This new edition continues the tradition of providing instructors and students with a comprehensive and up-to-date resource for teaching and learning ***engineering mathematics,*** that is, ***applied mathematics*** for engineers and physicists, mathematicians and computer scientists, as well as members of other disciplines. A course in elementary calculus is the sole ***prerequisite.***

The subject matter is arranged into seven parts A–G:

A Ordinary Differential Equations (ODEs) (Chaps. 1–6)
B Linear Algebra. Vector Calculus (Chaps. 7–9)
C Fourier Analysis. Partial Differential Equations (PDEs) (Chaps. 11–12)
D Complex Analysis (Chaps. 13–18)
E Numeric Analysis (Chaps. 19–21)
F Optimization, Graphs (Chaps. 22–23)
G Probability, Statistics (Chaps. 24–25).

This is followed by five appendices:

App. 1 References (ordered by parts)
App. 2 Answers to Odd-Numbered Problems
App. 3 Auxiliary Material (see also inside covers)
App. 4 Additional Proofs
App. 5 Tables of Functions.

This book has helped to pave the way for the present development of engineering mathematics. By a modern approach to those areas A–G, this new edition will prepare the student for the tasks of the present and of the future. The latter can be predicted to some extent by a judicious look at the present trend. Among other features, this trend shows the appearance of more complex production processes, more extreme physical conditions (in space travel, high-speed communication, etc.), and new tasks in robotics and communication systems (e.g., fiber optics and scan statistics on random graphs) and elsewhere. This requires the refinement of existing methods and the creation of new ones.

It follows that students need solid knowledge of basic principles, methods, and results, and a clear view of what engineering mathematics is all about, and that it requires proficiency in all three phases of problem solving:

- **Modeling,** that is, translating a physical or other problem into a mathematical form, into a mathematical *model;* this can be an algebraic equation, a differential equation, a graph, or some other mathematical expression.
- **Solving** the model by selecting and applying a suitable mathematical method, often requiring numeric work on a computer.
- **Interpreting** the mathematical result in physical or other terms to see what it practically means and implies.

It would make no sense to overload students with all kinds of little things that might be of occasional use. Instead they should recognize that mathematics rests on relatively few basic concepts and involves powerful unifying principles. This should give them a firm grasp on the ***interrelations among theory, computing, and*** (physical or other) ***experimentation.***

PARTS AND CHAPTERS OF THE BOOK

PART A
Chaps. 1–6
Ordinary Differential Equations (ODEs)

Chaps. 1–4
Basic Material

Chap. 5
Series Solutions

Chap. 6
Laplace Transforms

PART B
Chaps. 7–10
Linear Algebra. Vector Calculus

Chap. 7
Matrices,
Linear Systems

Chap. 8
Eigenvalue Problems

Chap. 9
Vector Differential
Calculus

Chap. 10
Vector Integral Calculus

PART C
Chaps. 11–12
Fourier Analysis. Partial Differential
Equations (PDEs)

Chap. 11
Fourier Analysis

Chap. 12
Partial Differential Equations

PART D
Chaps. 13–18
Complex Analysis,
Potential Theory

Chaps. 13–17
Basic Material

Chap. 18
Potential Theory

PART E
Chaps. 19–21
Numeric Analysis

Chap. 19
Numerics in
General

Chap. 20
Numeric
Linear Algebra

Chap. 21
Numerics for
ODEs and PDEs

PART F
Chaps. 22–23
Optimization, Graphs

Chap. 22
Linear Programming

Chap. 23
Graphs, Optimization

PART G
Chaps. 24–25
Probability, Statistics

Chap. 24
Data Analysis. Probability Theory

Chap. 25
Mathematical Statistics

GUIDES AND MANUALS
Maple Computer Guide
Mathematica Computer Guide

Student Solutions Manual

Instructor's Manual

General Features of the Book Include:

- **Simplicity of examples,** to make the book teachable—why choose complicated examples when simple ones are as instructive or even better?
- **Independence of chapters,** to provide ***flexibility*** in tailoring courses to special needs.
- **Self-contained presentation,** except for a few clearly marked places where a proof would exceed the level of the book and a reference is given instead.
- **Modern standard notation,** to help students with other courses, *modern* books, and mathematical and engineering journals.

Many sections were rewritten in a more detailed fashion, to make it a ***simpler book.*** This also resulted in a ***better balance between theory and applications.***

Use of Computers

The presentation is ***adaptable to various levels of technology and use of a computer or graphing calculator:*** very little or no use, medium use, or intensive use of a graphing calculator or of an unspecified ***CAS*** (Computer Algebra System, ***Maple, Mathematica, or Matlab*** being popular examples). In either case texts and problem sets form an entity without gaps or jumps. And many problems can be solved by hand or with a computer or both ways. (For ***software,*** see the beginnings of *Part E* on Numeric Analysis and *Part G* on Probability and Statistics.)

More specifically, this new edition on the one hand gives more prominence to tasks the computer ***cannot*** do, notably, modeling and interpreting results. On the other hand, it includes ***CAS projects, CAS problems,*** and ***CAS experiments,*** which ***do require*** a computer and show its power in solving problems that are difficult or impossible to access otherwise. Here our goal is the combination of *intelligent* computer use with high-quality mathematics. This has resulted in a change from a formula-centered teaching and learning of engineering mathematics to a more quantitative, project-oriented, and visual approach. CAS experiments also exhibit the computer as an instrument for observations and experimentations that may become the beginnings of new research, for "proving" or disproving conjectures, or for formalizing empirical relationships that are often quite useful to the engineer as working guidelines. These changes will also help the student in discovering the ***experimental aspect of modern applied mathematics.***

Some ***routine and drill work*** is retained as a necessity for keeping firm contact with the subject matter. In some of it the computer can (but must not) give the student a hand, but there are plenty of problems that are more suitable for pencil-and-paper work.

Major Changes

1. New Problem Sets. Modern engineering mathematics is mostly ***teamwork.*** It usually combines analytic work in the process of modeling and the use of computer algebra and numerics in the process of solution, followed by critical evaluation of results. Our problems—some straightforward, some more challenging, some "thinking problems" not accessible by a CAS, some open-ended—reflect this modern situation with its increased emphasis on qualitative methods and applications, and the problem sets take care of this novel situation by including team projects, CAS projects, and writing projects. The latter will also help the student in writing general reports, as they are required in engineering work quite frequently.

2. Computer Experiments, using the computer as an instrument of **"experimental mathematics"** for exploration and research (see also above). These are mostly open-ended

experiments, demonstrating the use of computers in experimentally finding results, which may be provable afterward or may be valuable heuristic qualitative guidelines to the engineer, in particular in complicated problems.

3. **More on modeling and selecting methods,** tasks that usually cannot be automated.

4. **Student Solutions Manual and Study Guide enlarged,** upon explicit requests of the users. This Manual contains worked-out solutions to carefully selected odd-numbered problems (to which App. 1 gives only the final answers) as well as general comments and hints on studying the text and working further problems, including explanations on the significance and character of concepts and methods in the various sections of the book.

Further Changes, New Features

- Electric circuits moved entirely to Chap. 2, to avoid duplication and repetition
- Second-order ODEs and Higher Order ODEs placed into two separate chapters (2 and 3)
- In Chap. 2, applications presented before variation of parameters
- Series solutions somewhat shortened, without changing the order of sections
- Material on Laplace transforms brought into a better logical order: partial fractions used earlier in a more practical approach, unit step and Dirac's delta put into separate subsequent sections, differentiation and integration of transforms (not of functions!) moved to a later section in favor of practically more important topics
- Second- and third-order determinants made into a separate section for reference throughout the book
- Complex matrices made optional
- Three sections on curves and their application in mechanics combined in a single section
- First two sections on Fourier series combined to provide a better, more direct start
- Discrete and Fast Fourier Transforms included
- Conformal mapping presented in a separate chapter and enlarged
- Numeric analysis updated
- Backward Euler method included
- Stiffness of ODEs and systems discussed
- List of software (in Part E) updated; another list for statistics software added (in Part G)
- References updated, now including about 75 books published or reprinted after 1990

Suggestions for Courses: A Four-Semester Sequence

The material, when taken in sequence, is suitable for four consecutive semester courses, meeting 3–4 hours a week:

1st Semester.	*ODEs* (Chaps. 1–5 or 6)
2nd Semester.	*Linear Algebra. Vector Analysis* (Chaps. 7–10)
3rd Semester.	*Complex Analysis* (Chaps. 13–18)
4th Semester.	*Numeric Methods* (Chaps. 19–21)

Suggestions for Independent One-Semester Courses

The book is also suitable for various independent one-semester courses meeting 3 hours a week. For instance:

Introduction to ODEs (Chaps. 1–2, Sec. 21.1)
Laplace Transforms (Chap. 6)
Matrices and Linear Systems (Chaps. 7–8)
Vector Algebra and Calculus (Chaps. 9–10)
Fourier Series and PDEs (Chaps. 11–12, Secs. 21.4–21.7)
Introduction to Complex Analysis (Chaps. 13–17)
Numeric Analysis (Chaps. 19, 21)
Numeric Linear Algebra (Chap. 20)
Optimization (Chaps. 22–23)
Graphs and Combinatorial Optimization (Chap. 23)
Probability and Statistics (Chaps. 24–25)

Acknowledgments

I am indebted to many of my former teachers, colleagues, and students who helped me directly or indirectly in preparing this book, in particular, the present edition. I profited greatly from discussions with engineers, physicists, mathematicians, and computer scientists, and from their written comments. I want to mention particularly Y. Antipov, D. N. Buechler, S. L. Campbell, R. Carr, P. L. Chambre, V. F. Connolly, Z. Davis, J. Delany, J. W. Dettman, D. Dicker, L. D. Drager, D. Ellis, W. Fox, A. Goriely, R. B. Guenther, J. B. Handley, N. Harbertson, A. Hassen, V. W. Howe, H. Kuhn, G. Lamb, M. T. Lusk, H. B. Mann, I. Marx, K. Millet, J. D. Moore, W. D. Munroe, A. Nadim, B. S. Ng, J. N. Ong, Jr., D. Panagiotis, A. Plotkin, P. J. Pritchard, W. O. Ray, J. T. Scheick, L. F. Shampine, H. A. Smith, J. Todd, H. Unz, A. L. Villone, H. J. Weiss, A. Wilansky, C. H. Wilcox, H. Ya Fan, and A. D. Ziebur, all from the United States, Professors E. J. Norminton and R. Vaillancourt from Canada, and Professors H. Florian and H. Unger from Europe. I can offer here only an inadequate acknowledgment of my gratitude and appreciation.

Special cordial thanks go to Privatdozent Dr. M. Kracht and to Mr. Herbert Kreyszig, MBA, the coauthor of the Student Solutions Manual, who both checked the manuscript in all details and made numerous suggestions for improvements and helped me proofread the galley and page proofs.

Furthermore, I wish to thank John Wiley and Sons (see the list on p. iv) as well as GGS Information Services, in particular Mr. K. Bradley and Mr. J. Nystrom, for their effective cooperation and great care in preparing this new edition.

Suggestions of many readers worldwide were evaluated in preparing this edition. Further comments and suggestions for improving the book will be gratefully received.

ERWIN KREYSZIG

CONTENTS

PART A Ordinary Differential Equations (ODEs) 1

CHAPTER 1 First-Order ODEs 2
1.1 Basic Concepts. Modeling 2
1.2 Geometric Meaning of $y' = f(x, y)$. Direction Fields 9
1.3 Separable ODEs. Modeling 12
1.4 Exact ODEs. Integrating Factors 19
1.5 Linear ODEs. Bernoulli Equation. Population Dynamics 26
1.6 Orthogonal Trajectories. *Optional* 35
1.7 Existence and Uniqueness of Solutions 37
Chapter 1 Review Questions and Problems 42
Summary of Chapter 1 43

CHAPTER 2 Second-Order Linear ODEs 45
2.1 Homogeneous Linear ODEs of Second Order 45
2.2 Homogeneous Linear ODEs with Constant Coefficients 53
2.3 Differential Operators. *Optional* 59
2.4 Modeling: Free Oscillations. (Mass–Spring System) 61
2.5 Euler–Cauchy Equations 69
2.6 Existence and Uniqueness of Solutions. Wronskian 73
2.7 Nonhomogeneous ODEs 78
2.8 Modeling: Forced Oscillations. Resonance 84
2.9 Modeling: Electric Circuits 91
2.10 Solution by Variation of Parameters 98
Chapter 2 Review Questions and Problems 102
Summary of Chapter 2 103

CHAPTER 3 Higher Order Linear ODEs 105
3.1 Homogeneous Linear ODEs 105
3.2 Homogeneous Linear ODEs with Constant Coefficients 111
3.3 Nonhomogeneous Linear ODEs 116
Chapter 3 Review Questions and Problems 122
Summary of Chapter 3 123

CHAPTER 4 Systems of ODEs. Phase Plane. Qualitative Methods 124
4.0 Basics of Matrices and Vectors 124
4.1 Systems of ODEs as Models 130
4.2 Basic Theory of Systems of ODEs 136
4.3 Constant-Coefficient Systems. Phase Plane Method 139
4.4 Criteria for Critical Points. Stability 147
4.5 Qualitative Methods for Nonlinear Systems 151
4.6 Nonhomogeneous Linear Systems of ODEs 159
Chapter 4 Review Questions and Problems 163
Summary of Chapter 4 164

CHAPTER 5 Series Solutions of ODEs. Special Functions 166
5.1 Power Series Method 167
5.2 Theory of the Power Series Method 170

5.3 Legendre's Equation. Legendre Polynomials $P_n(x)$ 177
5.4 Frobenius Method 182
5.5 Bessel's Equation. Bessel Functions $J_\nu(x)$ 189
5.6 Bessel Functions of the Second Kind $Y_\nu(x)$ 198
5.7 Sturm–Liouville Problems. Orthogonal Functions 203
5.8 Orthogonal Eigenfunction Expansions 210
Chapter 5 Review Questions and Problems 217
Summary of Chapter 5 218

CHAPTER 6 Laplace Transforms 220
6.1 Laplace Transform. Inverse Transform. Linearity. s-Shifting 221
6.2 Transforms of Derivatives and Integrals. ODEs 227
6.3 Unit Step Function. t-Shifting 233
6.4 Short Impulses. Dirac's Delta Function. Partial Fractions 241
6.5 Convolution. Integral Equations 248
6.6 Differentiation and Integration of Transforms. 254
6.7 Systems of ODEs 258
6.8 Laplace Transform: General Formulas 264
6.9 Table of Laplace Transforms 265
Chapter 6 Review Questions and Problems 267
Summary of Chapter 6 269

PART B Linear Algebra. Vector Calculus 271

CHAPTER 7 Linear Algebra: Matrices, Vectors, Determinants. Linear Systems 272
7.1 Matrices, Vectors: Addition and Scalar Multiplication 272
7.2 Matrix Multiplication 278
7.3 Linear Systems of Equations. Gauss Elimination 287
7.4 Linear Independence. Rank of a Matrix. Vector Space 296
7.5 Solutions of Linear Systems: Existence, Uniqueness 302
7.6 For Reference: Second- and Third-Order Determinants 306
7.7 Determinants. Cramer's Rule 308
7.8 Inverse of a Matrix. Gauss–Jordan Elimination 315
7.9 Vector Spaces, Inner Product Spaces. Linear Transformations. *Optional* 323
Chapter 7 Review Questions and Problems 330
Summary of Chapter 7 331

CHAPTER 8 Linear Algebra: Matrix Eigenvalue Problems 333
8.1 Eigenvalues, Eigenvectors 334
8.2 Some Applications of Eigenvalue Problems 340
8.3 Symmetric, Skew-Symmetric, and Orthogonal Matrices 345
8.4 Eigenbases. Diagonalization. Quadratic Forms 349
8.5 Complex Matrices and Forms. *Optional* 356
Chapter 8 Review Questions and Problems 362
Summary of Chapter 8 363

CHAPTER 9 Vector Differential Calculus. Grad, Div, Curl 364
9.1 Vectors in 2-Space and 3-Space 364
9.2 Inner Product (Dot Product) 371
9.3 Vector Product (Cross Product) 377
9.4 Vector and Scalar Functions and Fields. Derivatives 384
9.5 Curves. Arc Length. Curvature. Torsion 389
9.6 Calculus Review: Functions of Several Variables. *Optional* 400
9.7 Gradient of a Scalar Field. Directional Derivative 403
9.8 Divergence of a Vector Field 410
9.9 Curl of a Vector Field 414
Chapter 9 Review Questions and Problems 416
Summary of Chapter 9 417

CHAPTER 10 Vector Integral Calculus. Integral Theorems 420
10.1 Line Integrals 420
10.2 Path Independence of Line Integrals 426
10.3 Calculus Review: Double Integrals. *Optional* 433
10.4 Green's Theorem in the Plane 439
10.5 Surfaces for Surface Integrals 445
10.6 Surface Integrals 449
10.7 Triple Integrals. Divergence Theorem of Gauss 458
10.8 Further Applications of the Divergence Theorem 463
10.9 Stokes's Theorem 468
Chapter 10 Review Questions and Problems 473
Summary of Chapter 10 474

PART C Fourier Analysis. Partial Differential Equations (PDEs) 477

CHAPTER 11 Fourier Series, Integrals, and Transforms 478
11.1 Fourier Series 478
11.2 Functions of Any Period $p = 2L$ 487
11.3 Even and Odd Functions. Half-Range Expansions 490
11.4 Complex Fourier Series. *Optional* 496
11.5 Forced Oscillations 499
11.6 Approximation by Trigonometric Polynomials 502
11.7 Fourier Integral 506
11.8 Fourier Cosine and Sine Transforms 513
11.9 Fourier Transform. Discrete and Fast Fourier Transforms 518
11.10 Tables of Transforms 529
Chapter 11 Review Questions and Problems 532
Summary of Chapter 11 533

CHAPTER 12 Partial Differential Equations (PDEs) 535
12.1 Basic Concepts 535
12.2 Modeling: Vibrating String, Wave Equation 538
12.3 Solution by Separating Variables. Use of Fourier Series 540
12.4 D'Alembert's Solution of the Wave Equation. Characteristics 548
12.5 Heat Equation: Solution by Fourier Series 552

12.6 Heat Equation: Solution by Fourier Integrals and Transforms 562
12.7 Modeling: Membrane, Two-Dimensional Wave Equation 569
12.8 Rectangular Membrane. Double Fourier Series 571
12.9 Laplacian in Polar Coordinates. Circular Membrane. Fourier–Bessel Series 579
12.10 Laplace's Equation in Cylindrical and Spherical Coordinates. Potential 587
12.11 Solution of PDEs by Laplace Transforms 594
Chapter 12 Review Questions and Problems 597
Summary of Chapter 12 598

PART D Complex Analysis 601

CHAPTER 13 Complex Numbers and Functions 602
13.1 Complex Numbers. Complex Plane 602
13.2 Polar Form of Complex Numbers. Powers and Roots 607
13.3 Derivative. Analytic Function 612
13.4 Cauchy–Riemann Equations. Laplace's Equation 618
13.5 Exponential Function 623
13.6 Trigonometric and Hyperbolic Functions 626
13.7 Logarithm. General Power 630
Chapter 13 Review Questions and Problems 634
Summary of Chapter 13 635

CHAPTER 14 Complex Integration 637
14.1 Line Integral in the Complex Plane 637
14.2 Cauchy's Integral Theorem 646
14.3 Cauchy's Integral Formula 654
14.4 Derivatives of Analytic Functions 658
Chapter 14 Review Questions and Problems 662
Summary of Chapter 14 663

CHAPTER 15 Power Series, Taylor Series 664
15.1 Sequences, Series, Convergence Tests 664
15.2 Power Series 673
15.3 Functions Given by Power Series 678
15.4 Taylor and Maclaurin Series 683
15.5 Uniform Convergence. *Optional* 691
Chapter 15 Review Questions and Problems 698
Summary of Chapter 15 699

CHAPTER 16 Laurent Series. Residue Integration 701
16.1 Laurent Series 701
16.2 Singularities and Zeros. Infinity 707
16.3 Residue Integration Method 712
16.4 Residue Integration of Real Integrals 718
Chapter 16 Review Questions and Problems 726
Summary of Chapter 16 727

CHAPTER 17 Conformal Mapping 728
17.1 Geometry of Analytic Functions: Conformal Mapping 729
17.2 Linear Fractional Transformations 734
17.3 Special Linear Fractional Transformations 737

17.4 Conformal Mapping by Other Functions 742
17.5 Riemann Surfaces. *Optional* 746
Chapter 17 Review Questions and Problems 747
Summary of Chapter 17 748

CHAPTER 18 Complex Analysis and Potential Theory 749
18.1 Electrostatic Fields 750
18.2 Use of Conformal Mapping. Modeling 754
18.3 Heat Problems 757
18.4 Fluid Flow 761
18.5 Poisson's Integral Formula for Potentials 768
18.6 General Properties of Harmonic Functions 771
Chapter 18 Review Questions and Problems 775
Summary of Chapter 18 776

PART E Numeric Analysis 777
Software 778

CHAPTER 19 Numerics in General 780
19.1 Introduction 780
19.2 Solution of Equations by Iteration 787
19.3 Interpolation 797
19.4 Spline Interpolation 810
19.5 Numeric Integration and Differentiation 817
Chapter 19 Review Questions and Problems 830
Summary of Chapter 19 831

CHAPTER 20 Numeric Linear Algebra 833
20.1 Linear Systems: Gauss Elimination 833
20.2 Linear Systems: LU-Factorization, Matrix Inversion 840
20.3 Linear Systems: Solution by Iteration 845
20.4 Linear Systems: Ill-Conditioning, Norms 851
20.5 Least Squares Method 859
20.6 Matrix Eigenvalue Problems: Introduction 863
20.7 Inclusion of Matrix Eigenvalues 866
20.8 Power Method for Eigenvalues 872
20.9 Tridiagonalization and QR-Factorization 875
Chapter 20 Review Questions and Problems 883
Summary of Chapter 20 884

CHAPTER 21 Numerics for ODEs and PDEs 886
21.1 Methods for First-Order ODEs 886
21.2 Multistep Methods 898
21.3 Methods for Systems and Higher Order ODEs 902
21.4 Methods for Elliptic PDEs 909
21.5 Neumann and Mixed Problems. Irregular Boundary 917
21.6 Methods for Parabolic PDEs 922
21.7 Method for Hyperbolic PDEs 928
Chapter 21 Review Questions and Problems 930
Summary of Chapter 21 932

PART F Optimization, Graphs 935

CHAPTER 22 Unconstrained Optimization. Linear Programming 936
22.1 Basic Concepts. Unconstrained Optimization 936
22.2 Linear Programming 939
22.3 Simplex Method 944
22.4 Simplex Method: Difficulties 947
Chapter 22 Review Questions and Problems 952
Summary of Chapter 22 953

CHAPTER 23 Graphs. Combinatorial Optimization 954
23.1 Graphs and Digraphs 954
23.2 Shortest Path Problems. Complexity 959
23.3 Bellman's Principle. Dijkstra's Algorithm 963
23.4 Shortest Spanning Trees. Greedy Algorithm 966
23.5 Shortest Spanning Trees. Prim's Algorithm 970
23.6 Flows in Networks 973
23.7 Maximum Flow: Ford–Fulkerson Algorithm 979
23.8 Bipartite Graphs. Assignment Problems 982
Chapter 23 Review Questions and Problems 987
Summary of Chapter 23 989

PART G Probability, Statistics 991

CHAPTER 24 Data Analysis. Probability Theory 993
24.1 Data Representation. Average. Spread 993
24.2 Experiments, Outcomes, Events 997
24.3 Probability 1000
24.4 Permutations and Combinations 1006
24.5 Random Variables. Probability Distributions 1010
24.6 Mean and Variance of a Distribution 1016
24.7 Binomial, Poisson, and Hypergeometric Distributions 1020
24.8 Normal Distribution 1026
24.9 Distributions of Several Random Variables 1032
Chapter 24 Review Questions and Problems 1041
Summary of Chapter 24 1042

CHAPTER 25 Mathematical Statistics 1044
25.1 Introduction. Random Sampling 1044
25.2 Point Estimation of Parameters 1046
25.3 Confidence Intervals 1049
25.4 Testing Hypotheses. Decisions 1058
25.5 Quality Control 1068
25.6 Acceptance Sampling 1073
25.7 Goodness of Fit. χ^2-Test 1076
25.8 Nonparametric Tests 1080
25.9 Regression. Fitting Straight Lines. Correlation 1083
Chapter 25 Review Questions and Problems 1092
Summary of Chapter 25 1093

INDEX I1

PART A

Ordinary Differential Equations (ODEs)

CHAPTER 1 First-Order ODEs

CHAPTER 2 Second-Order Linear ODEs

CHAPTER 3 Higher Order Linear ODEs

CHAPTER 4 Systems of ODEs. Phase Plane. Qualitative Methods

CHAPTER 5 Series Solutions of ODEs. Special Functions

CHAPTER 6 Laplace Transforms

Differential equations are of basic importance in engineering mathematics because many physical laws and relations appear mathematically in the form of a differential equation. In Part A we shall consider various physical and geometric problems that lead to differential equations, with emphasis on ***modeling,*** that is, the transition from the physical situation to a "mathematical model." In this chapter the model will be a differential equation, and as we proceed we shall explain the most important standard methods for solving such equations.

Part A concerns ***ordinary*** **differential equations (ODEs),** whose unknown functions depend on a *single* variable. *Partial* differential equations (PDEs), involving unknown functions of *several* variables, follow in Part C.

ODEs are very well suited for computers. ***Numeric methods for ODEs can be studied directly after Chaps.*** **1** ***or*** **2.** See Secs. 21.1–21.3, which are independent of the other sections on numerics.

CHAPTER 1

First-Order ODEs

In this chapter we begin our program of studying ordinary differential equations (ODEs) by deriving them from physical or other problems **(modeling),** solving them by standard methods, and interpreting solutions and their graphs in terms of a given problem. Questions of existence and uniqueness of solutions will also be discussed (in Sec. 1.7).

We begin with the simplest ODEs, called ODEs ***of the first order*** because they involve only the first derivative of the unknown function, no higher derivatives. Our usual notation for the unknown function will be $y(x)$, or $y(t)$ if the independent variable is time t.

If you wish, use your computer algebra system (CAS) for checking solutions, but make sure that you gain a conceptual understanding of the basic terms, such as ODE, direction field, and initial value problem.

COMMENT. ***Numerics for first-order ODEs can be studied immediately after this chapter.*** See Secs. 21.1–21.2, which are independent of other sections on numerics.

Prerequisite: Integral calculus.
Sections that may be omitted in a shorter course: 1.6, 1.7.
References and Answers to Problems: App. 1 Part A, and App. 2

1.1 Basic Concepts. Modeling

If we want to solve an engineering problem (usually of a physical nature), we first have to formulate the problem as a mathematical expression in terms of variables, functions, equations, and so forth. Such an expression is known as a mathematical **model** of the given problem. The process of setting up a model, solving it mathematically, and interpreting the result in physical or other terms is called *mathematical modeling* or, briefly, **modeling.** We shall illustrate this process by various examples and problems because modeling requires experience. (Your computer may help you in solving but hardly in setting up models.)

Since many physical concepts, such as velocity and acceleration, are derivatives, a model is very often an equation containing derivatives of an unknown function. Such a model is called a **differential equation.** Of course, we then want to find a solution (a function that satisfies the equation), explore its properties, graph it, find values of it, and interpret it in physical terms so that we can understand the behavior of the physical system in our given problem. However, before we can turn to methods of solution we must first define basic concepts needed throughout this chapter.

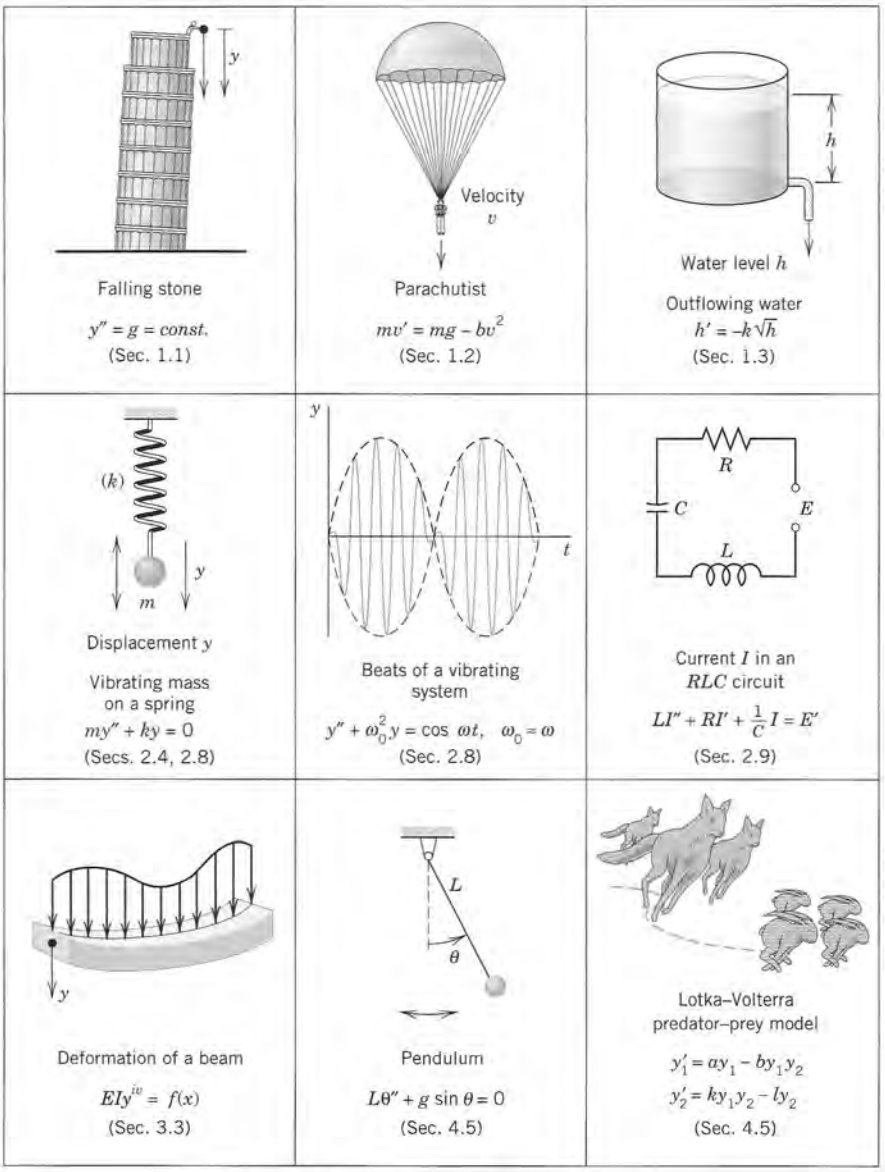

Fig. 1. Some applications of differential equations

An **ordinary differential equation (ODE)** is an equation that contains one or several derivatives of an unknown function, which we usually call $y(x)$ (or sometimes $y(t)$ if the independent variable is time t). The equation may also contain y itself, known functions of x (or t), and constants. For example,

$$y' = \cos x, \tag{1}$$

$$y'' + 9y = 0, \tag{2}$$

$$x^2y'''y' + 2e^xy'' = (x^2 + 2)y^2 \tag{3}$$

are ordinary differential equations (ODEs). The term *ordinary* distinguishes them from *partial differential equations* (PDEs), which involve partial derivatives of an unknown function of *two or more* variables. For instance, a PDE with unknown function u of two variables x and y is

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0.$$

PDEs are more complicated than ODEs; they will be considered in Chap. 12.

An ODE is said to be of **order** n if the nth derivative of the unknown function y is the highest derivative of y in the equation. The concept of order gives a useful classification into ODEs of first order, second order, and so on. Thus, (1) is of first order, (2) of second order, and (3) of third order.

In this chapter we shall consider **first-order ODEs.** Such equations contain only the first derivative y' and may contain y and any given functions of x. Hence we can write them as

$$F(x, y, y') = 0 \tag{4}$$

or often in the form

$$y' = f(x, y).$$

This is called the *explicit form*, in contrast with the *implicit form* (4). For instance, the implicit ODE $x^{-3}y' - 4y^2 = 0$ (where $x \neq 0$) can be written explicitly as $y' = 4x^3y^2$.

Concept of Solution

A function

$$y = h(x)$$

is called a **solution** of a given ODE (4) on some open interval $a < x < b$ if $h(x)$ is defined and differentiable throughout the interval and is such that the equation becomes an identity if y and y' are replaced with h and h', respectively. The curve (the graph) of h is called a **solution curve**.

Here, **open interval** $a < x < b$ means that the endpoints a and b are not regarded as points belonging to the interval. Also, $a < x < b$ includes *infinite intervals* $-\infty < x < b$, $a < x < \infty$, $-\infty < x < \infty$ (the real line) as special cases.

EXAMPLE 1 Verification of Solution

$y = h(x) = c/x$ (c an arbitrary constant, $x \neq 0$) is a solution of $xy' = -y$. To verify this, differentiate, $y' = h'(x) = -c/x^2$, and multiply by x to get $xy' = -c/x = -y$. Thus, $xy' = -y$, the given ODE.

EXAMPLE 2 Solution Curves

The ODE $y' = dy/dx = \cos x$ can be solved directly by integration on both sides. Indeed, using calculus, we obtain $y = \int \cos x \, dx = \sin x + c$, where c is an arbitrary constant. This is a ***family of solutions.*** Each value of c, for instance, 2.75 or 0 or -8, gives one of these curves. Figure 2 shows some of them, for $c = -3, -2, -1, 0, 1, 2, 3, 4$.

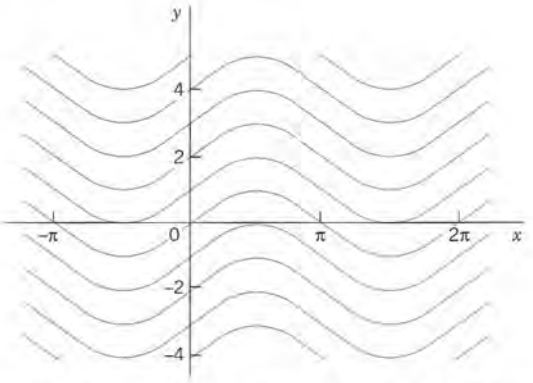

Fig. 2. Solutions $y = \sin x + c$ of the ODE $y' = \cos x$

EXAMPLE 3 Exponential Growth, Exponential Decay

From calculus we know that $y = ce^{3t}$ (c any constant) has the derivative (chain rule!)

$$y' = \frac{dy}{dt} = 3ce^{3t} = 3y.$$

This shows that y is a solution of $y' = 3y$. Hence this ODE can model **exponential growth,** for instance, of animal populations or colonies of bacteria. It also applies to humans for small populations in a large country (e.g., the United States in early times) and is then known as ***Malthus's law.***[1] We shall say more about this topic in Sec. 1.5.

Similarly, $y' = -0.2y$ (with a minus on the right!) has the solution $y = ce^{-0.2t}$. Hence this ODE models **exponential decay,** for instance, of a radioactive substance (see Example 5). Figure 3 shows solutions for some positive c. Can you find what the solutions look like for negative c?

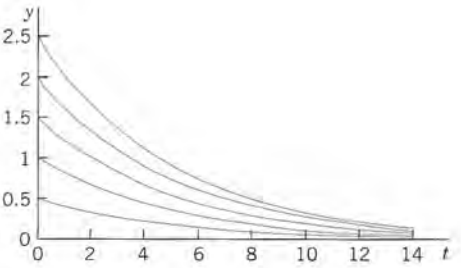

Fig. 3. Solutions of $y' = -0.2y$ in Example 3

[1]Named after the English pioneer in classic economics, THOMAS ROBERT MALTHUS (1766–1834).

We see that each ODE in these examples has a solution that contains an arbitrary constant c. Such a solution containing an arbitrary constant c is called a **general solution** of the ODE.

(We shall see that c is sometimes not completely arbitrary but must be restricted to some interval to avoid complex expressions in the solution.)

We shall develop methods that will give general solutions *uniquely* (perhaps except for notation). Hence we shall say ***the*** general solution of a given ODE (instead of ***a*** general solution).

Geometrically, the general solution of an ODE is a family of infinitely many solution curves, one for each value of the constant c. If we choose a specific c (e.g., $c = 6.45$ or 0 or -2.01) we obtain what is called a **particular solution** of the ODE. A particular solution does not contain any arbitrary constants.

In most cases, general solutions exist, and every solution not containing an arbitrary constant is obtained as a particular solution by assigning a suitable value to c. Exceptions to these rules occur but are of minor interest in applications; see Prob. 16 in Problem Set 1.1.

Initial Value Problem

In most cases the unique solution of a given problem, hence a particular solution, is obtained from a general solution by an **initial condition** $y(x_0) = y_0$, with given values x_0 and y_0, that is used to determine a value of the arbitrary constant c. Geometrically this condition means that the solution curve should pass through the point (x_0, y_0) in the xy-plane. An ODE together with an initial condition is called an **initial value problem.** Thus, if the ODE is explicit, $y' = f(x, y)$, the initial value problem is of the form

$$y' = f(x, y), \qquad y(x_0) = y_0. \tag{5}$$

EXAMPLE 4 **Initial Value Problem**

Solve the initial value problem

$$y' = \frac{dy}{dx} = 3y, \qquad y(0) = 5.7.$$

Solution. The general solution is $y(x) = ce^{3x}$; see Example 3. From this solution and the initial condition we obtain $y(0) = ce^0 = c = 5.7$. Hence the initial value problem has the solution $y(x) = 5.7e^{3x}$. This is a particular solution. ■

Modeling

The general importance of modeling to the engineer and physicist was emphasized at the beginning of this section. We shall now consider a basic physical problem that will show the typical steps of modeling in detail: Step 1 the transition from the physical situation (the physical system) to its mathematical formulation (its mathematical model); Step 2 the solution by a mathematical method; and Step 3 the physical interpretation of the result. This may be the easiest way to obtain a first idea of the nature and purpose of differential equations and their applications. Realize at the outset that your ***computer*** (your ***CAS***) may perhaps give you a hand in Step 2, but Steps 1 and 3 are basically your work. And Step 2

requires a solid knowledge and good understanding of solution methods available to you—*you* have to choose the method for your work by hand or by the computer. Keep this in mind, and always check computer results for errors (which may result, for instance, from false inputs).

EXAMPLE 5 Radioactivity. Exponential Decay

Given an amount of a radioactive substance, say, 0.5 g (gram), find the amount present at any later time.

Physical Information. Experiments show that at each instant a radioactive substance decomposes at a rate proportional to the the amount present.

Step 1. Setting up a mathematical model (a differential equation) of the physical process. Denote by $y(t)$ the amount of substance still present at any time t. By the physical law, the time rate of change $y'(t) = dy/dt$ is proportional to $y(t)$. Denote the constant of proportionality by k. Then

$$\frac{dy}{dt} = ky. \tag{6}$$

The value of k is known from experiments for various radioactive substances (e.g., $k = -1.4 \cdot 10^{-11}\text{sec}^{-1}$, approximately, for radium ${}_{88}\text{Ra}^{226}$). *k is negative* because $y(t)$ decreases with time. The given initial amount is 0.5 g. Denote the corresponding time by $t = 0$. Then the initial condition is $y(0) = 0.5$. This is the instant at which the process begins; this motivates the term *initial condition* (which, however, is also used more generally when the independent variable is not time or when you choose a t other than $t = 0$). Hence the model of the process is the **initial value problem**

$$\frac{dy}{dt} = ky, \qquad y(0) = 0.5. \tag{7}$$

Step 2. Mathematical solution. As in Example 3 we conclude that the ODE (6) models exponential decay and has the general solution (with arbitrary constant c but definite given k)

$$y(t) = ce^{kt}. \tag{8}$$

We now use the initial condition to determine c. Since $y(0) = c$ from (8), this gives $y(0) = c = 0.5$. Hence the particular solution governing this process is

$$y(t) = 0.5e^{kt} \tag{9}$$ (Fig. 4).

Always check your result—it may involve human or computer errors! Verify by differentiation (chain rule!) that your solution (9) satisfies (7) as well as $y(0) = 0.5$:

$$\frac{dy}{dt} = 0.5ke^{kt} = k \cdot 0.5e^{kt} = ky, \qquad y(0) = 0.5e^{0} = 0.5.$$

Step 3. Interpretation of result. Formula (9) gives the amount of radioactive substance at time t. It starts from the correct given initial amount and decreases with time because k (the constant of proportionality, depending on the kind of substance) is negative. The limit of y as $t \to \infty$ is zero. ■

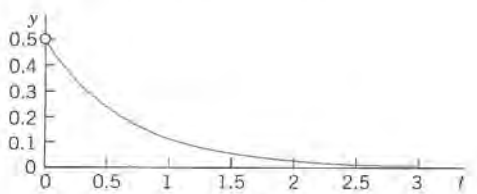

Fig. 4. Radioactivity (Exponential decay, $y = 0.5\ e^{kt}$, with $k = -1.5$ as an example)

EXAMPLE 6 A Geometric Application

Geometric problems may also lead to initial value problems. For instance, find the curve through the point (1, 1) in the xy-plane having at each of its points the slope $-y/x$.

Solution. The slope y' should equal $-y/x$. This gives the ODE $y' = -y/x$. Its general solution is $y = c/x$ (see Example 1). This is a family of hyperbolas with the coordinate axes as asymptotes.

Now, for the curve to pass through (1, 1), we must have $y = 1$ when $x = 1$. Hence the initial condition is $y(1) = 1$. From this condition and $y = c/x$ we get $y(1) = c/1 = 1$; that is, $c = 1$. This gives the particular solution $y = 1/x$ (drawn somewhat thicker in Fig. 5). ■

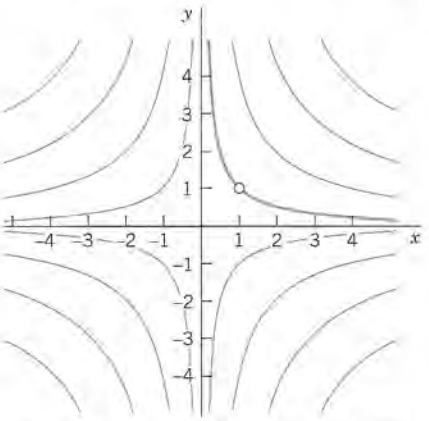

Fig. 5. Solutions of $y' = -y/x$ (hyperbolas)

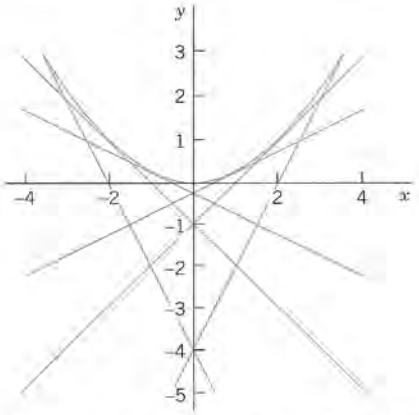

Fig. 6. Particular solutions and singular solution in Problem 16

PROBLEM SET 1.1

1–4 CALCULUS

Solve the ODE by integration.

1. $y' = -\sin \pi x$

2. $y' = e^{-3x}$

3. $y' = xe^{x^2/2}$

4. $y' = \cosh 4x$

5–9 VERIFICATION OF SOLUTION

State the order of the ODE. Verify that the given function is a solution. (a, b, c are arbitrary constants.)

5. $y' = 1 + y^2, \quad y = \tan (x + c)$

6. $y'' + \pi^2 y = 0, \quad y = a \cos \pi x + b \sin \pi x$

7. $y'' + 2y' + 10y = 0, \quad y = 4e^{-x} \sin 3x$

8. $y' + 2y = 4(x + 1)^2, \quad y = 5e^{-2x} + 2x^2 + 2x + 1$

9. $y''' = \cos x, \quad y = -\sin x + ax^2 + bx + c$

10–14 INITIAL VALUE PROBLEMS

Verify that y is a solution of the ODE. Determine from y the particular solution satisfying the given initial condition. Sketch or graph this solution.

10. $y' = 0.5y, \quad y = ce^{0.5x}, \quad y(2) = 2$

11. $y' = 1 + 4y^2, \quad y = \frac{1}{2} \tan (2x + c), \quad y(0) = 0$

12. $y' = y - x, \quad y = ce^x + x + 1, \quad y(0) = 3$

13. $y' + 2xy = 0, \quad y = ce^{-x^2}, \quad y(1) = 1/e$

14. $y' = y \tan x, \quad y = c \sec x, \quad y(0) = \frac{1}{2}\pi$

15. (Existence) **(A)** Does the ODE $y'^2 = -1$ have a (real) solution?

(B) Does the ODE $|y'| + |y| = 0$ have a general solution?

16. (Singular solution) An ODE may sometimes have an additional solution that cannot be obtained from the general solution and is then called a *singular solution*. The ODE $y'^2 - xy' + y = 0$ is of the kind. Show by differentiation and substitution that it has the general solution $y = cx - c^2$ and the singular solution $y = x^2/4$. Explain Fig. 6.

17–22 MODELING, APPLICATIONS

The following problems will give you a first impression of modeling. Many more problems on modeling follow throughout this chapter.

17. (Falling body) If we drop a stone, we can assume air resistance ("drag") to be negligible. Experiments show that under that assumption the acceleration $y'' = d^2y/dt^2$ of this motion is constant (equal to the so-called acceleration of gravity $g = 9.80$ m/sec^2 $= 32$ ft/sec^2). State this as an ODE for $y(t)$, the distance fallen as a function of time t. Solve the ODE to get the familiar law of free fall, $y = gt^2/2$.

18. (Falling body) If in Prob. 17 the stone starts at $t = 0$ from initial position y_0 with initial velocity $v = v_0$, show that the solution is $y = gt^2/2 + v_0 t + y_0$. How long does a fall of 100 m take if the body falls from rest? A fall of 200 m? (Guess first.)

19. (Airplane takeoff) If an airplane has a run of 3 km, starts with a speed 6 m/sec, moves with constant acceleration, and makes the run in 1 min, with what speed does it take off?

20. (Subsonic flight) The efficiency of the engines of subsonic airplanes depends on air pressure and usually is maximum near about 36 000 ft. Find the air pressure $y(x)$ at this height without calculation. *Physical information.* The rate of change $y'(x)$ is proportional to the pressure, and at 18 000 ft the pressure has decreased to half its value y_0 at sea level.

21. (Half-life) The half-life of a radioactive substance is the time in which half of the given amount disappears. Hence it measures the rapidity of the decay. What is the half-life of radium ${}_{88}\mathrm{Ra}^{226}$ (in years) in Example 5?

22. (Interest rates) Show by algebra that the investment $y(t)$ from a deposit y_0 after t years at an interest rate r is

$$y_a(t) = y_0[1 + r]^t \quad \text{(Interest compounded annually)}$$

$$y_d(t) = y_0[1 + (r/365)]^{365t} \quad \text{(Interest compounded daily).}$$

Recall from calculus that

$$[1 + (1/n)]^n \to e \text{ as } n \to \infty;$$

hence $[1 + (r/n)]^{nt} \to e^{rt}$; thus

$$y_c(t) = y_0 e^{rt} \quad \text{(Interest compounded continuously).}$$

What ODE does the last function satisfy? Let the initial investment be \$1000 and $r = 6\%$. Compute the value of the investment after 1 year and after 5 years using each of the three formulas. Is there much difference?

1.2 Geometric Meaning of $y' = f(x, y)$. Direction Fields

A first-order ODE

$$y' = f(x, y) \tag{1}$$

has a simple geometric interpretation. From calculus you know that the derivative $y'(x)$ of $y(x)$ is the slope of $y(x)$. Hence a solution curve of (1) that passes through a point (x_0, y_0) must have at that point the slope $y'(x_0)$ equal to the value of f at that point; that is,

$$y'(x_0) = f(x_0, y_0).$$

Read this paragraph again before you go on, and think about it.

It follows that you can indicate directions of solution curves of (1) by drawing short straight-line segments (*lineal elements*) in the xy-plane (as in Fig. 7a) and then fitting (approximate) solution curves through the direction field (or *slope field*) thus obtained. This method is important for two reasons.

1. You need not solve (1). This is essential because many ODEs have complicated solution formulas or none at all.
2. The method shows, in graphical form, the whole family of solutions and their typical properties. The accuracy is somewhat limited, but in most cases this does not matter.

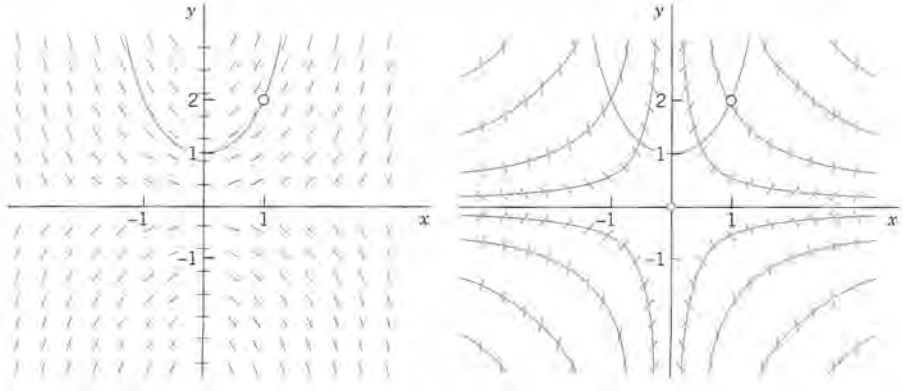
Let us illustrate this method for the ODE

$$y' = xy. \tag{2}$$

Direction Fields by a CAS (Computer Algebra System). A CAS plots lineal elements at the points of a square grid, as in Fig. 7a for (2), into which you can fit solution curves. Decrease the mesh size of the grid in regions where $f(x, y)$ varies rapidly.

Direction Fields by Using Isoclines (the Older Method). Graph the curves $f(x, y) = k = const$, called *isoclines* (meaning *curves of equal inclination*). For (2) these are the hyperbolas $f(x, y) = xy = k = const$ (and the coordinate axes) in Fig. 7b. By (1), these are the curves along which the derivative y' is constant. These are not yet solution curves—don't get confused. Along each isocline draw many parallel line elements of the corresponding slope k. This gives the direction field, into which you can now graph approximate solution curves.

We mention that for the ODE (2) in Fig. 7 we would not need the method, because we shall see in the next section that ODEs such as (2) can easily be solved exactly. For the time being, let us verify by substitution that (2) has the general solution



$$y(x) = ce^{x^2/2} \qquad (c \text{ arbitrary}).$$

Indeed, by differentiation (chain rule!) we get $y' = x(ce^{x^2/2}) = xy$. Of course, knowing the solution, we now have the advantage of obtaining a feel for the accuracy of the method by comparing with the exact solution. The particular solution in Fig. 7 through $(x, y) = (1, 2)$ must satisfy $y(1) = 2$. Thus, $2 = ce^{1/2}$, $c = 2/\sqrt{e} = 1.213$, and the particular solution is $y(x) = 1.213e^{x^2/2}$.

A famous ODE for which we *do* need direction fields is

$$y' = 0.1(1 - x^2) - \frac{x}{y}. \tag{3}$$

(It is related to the van der Pol equation of electronics, which we shall discuss in Sec. 4.5.) The direction field in Fig. 8 shows lineal elements generated by the computer. We have also added the isoclines for $k = -5, -3, \frac{1}{4}, 1$ as well as three typical solution curves, one that is (almost) a circle and two spirals approaching it from inside and outside.

(a) By a CAS (b) By isoclines

Fig. 7. Direction field of $y' = xy$

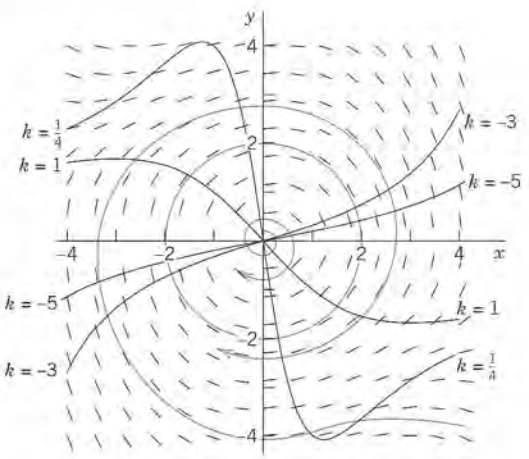


Fig. 8. Direction field of $y' = 0.1(1 - x^2) - \dfrac{x}{y}$

On Numerics

Direction fields give "all" solutions, but with limited accuracy. If we need accurate numeric values of a solution (or of several solutions) for which we have no formula, we can use a **numeric method.** If you want to get an idea of how these methods work, go to Sec. 21.1 and study the first two pages on the **Euler–Cauchy method,** which is typical of more accurate methods later in that section, notably of the classical **Runge–Kutta method.** It would make little sense to interrupt the present flow of ideas by including such methods here; indeed, it would be a duplication of the material in Sec. 21.1. For an excursion to that section you need no extra prerequisites; Sec. 1.1 just discussed is sufficient.

PROBLEM SET 1.2

1–10 DIRECTION FIELDS, SOLUTION CURVES

Graph a direction field (by a CAS or by hand). In the field graph approximate solution curves through the given point or points (x, y) by hand.

1. $y' = e^x - y$, $(0, 0)$, $(0, 1)$
2. $4yy' = -9x$, $(2, 2)$
3. $y' = 1 + y^2$, $(\frac{1}{4}\pi, 1)$
4. $y' = y - 2y^2$, $(0, 0)$, $(0, 0.25)$, $(0, 0.5)$, $(0, 1)$
5. $y' = x^2 - 1/y$, $(1, -2)$
6. $y' = 1 + \sin y$, $(-1, 0)$, $(1, -4)$
7. $y' = y^3 + x^3$, $(0, 1)$
8. $y' = 2xy + 1$, $(-1, 2)$, $(0, 0)$, $(1, -2)$
9. $y' = y \tanh x - 2$, $(-1, -2)$, $(1, 0)$, $(1, 2)$
10. $y' = e^{y/x}$, $(1, 1)$, $(2, 2)$, $(3, 3)$

11–15 ACCURACY

Direction fields are very useful because you can see solutions (as many as you want) without solving the ODE, which may be difficult or impossible in terms of a formula. To get a feel for the accuracy of the method, graph a field, sketch solution curves in it, and compare them with the exact solutions.

11. $y' = \sin \frac{1}{2}\pi x$
12. $y' = 1/x^2$
13. $y' = -2y$ (Sol. $y = ce^{-2x}$)
14. $y' = 3y/x$ (Sol. $y = cx^3$)
15. $y' = -\ln x$

16–18 MOTIONS

A body moves on a straight line, with velocity as given, and $y(t)$ is its distance from a fixed point 0 and t time. Find a model of the motion (an ODE). Graph a direction field.

In it sketch a solution curve corresponding to the given initial condition.

16. Velocity equal to the reciprocal of the distance, $y(1) = 1$

17. Product of velocity and distance equal to $-t$, $y(3) = -3$

18. Velocity plus distance equal to the square of time, $y(0) = 6$

19. (Skydiver) Two forces act on a parachutist, the attraction by the earth mg (m = mass of person plus equipment, $g = 9.8$ m/sec^2 the acceleration of gravity) and the air resistance, assumed to be proportional to the square of the velocity $v(t)$. Using **Newton's second law** of motion (mass × acceleration = resultant of the forces), set up a model (an ODE for $v(t)$). Graph a direction field (choosing m and the constant of proportionality equal to 1). Assume that the parachute opens when $v = 10$ m/sec. Graph the corresponding solution in the field. What is the limiting velocity?

20. CAS PROJECT. Direction Fields. Discuss direction fields as follows.

(a) Graph a direction field for the ODE $y' = 1 - y$ and in it the solution satisfying $y(0) = 5$ showing **exponential approach.** Can you see the limit of any solution directly from the ODE? For what initial condition will the solution be increasing? Constant? Decreasing?

(b) What do the solution curves of $y' = -x^3/y^3$ look like, as concluded from a direction field. How do they seem to differ from circles? What are the isoclines? What happens to those curves when you drop the minus on the right? Do they look similar to familiar curves? First, guess.

(c) Compare, as best as you can, the old and the computer methods, their advantages and disadvantages. Write a short report.

1.3 Separable ODEs. Modeling

Many practically useful ODEs can be reduced to the form

$$g(y)y' = f(x) \tag{1}$$

by purely algebraic manipulations. Then we can integrate on both sides with respect to x, obtaining

$$\int g(y)\, y'\, dx = \int f(x)\, dx + c. \tag{2}$$

On the left we can switch to y as the variable of integration. By calculus, $y'\, dx = dy$, so that

$$\int g(y)\, dy = \int f(x)\, dx + c. \tag{3}$$

If f and g are continuous functions, the integrals in (3) exist, and by evaluating them we obtain a general solution of (1). This method of solving ODEs is called the **method of separating variables,** and (1) is called a **separable equation,** because in (3) the variables are now separated: x appears only on the right and y only on the left.

EXAMPLE 1 **A Separable ODE**

The ODE $y' = 1 + y^2$ is separable because it can be written

$$\frac{dy}{1 + y^2} = dx. \qquad \text{By integration,} \qquad \arctan y = x + c \qquad \text{or} \qquad y = \tan(x + c).$$

It is very important to introduce the constant of integration immediately when the integration is performed. If we wrote $\arctan y = x$, then $y = \tan x$, and *then* introduced c, we would have obtained $y = \tan x + c$, which is not a solution (when $c \neq 0$). Verify this. ■

Modeling

The importance of modeling was emphasized in Sec. 1.1, and separable equations yield various useful models. Let us discuss this in terms of some typical examples.

EXAMPLE 2 **Radiocarbon Dating**[2]

In September 1991 the famous Iceman (Oetzi), a mummy from the Neolithic period of the Stone Age found in the ice of the Oetztal Alps (hence the name "Oetzi") in Southern Tyrolia near the Austrian–Italian border, caused a scientific sensation. When did Oetzi approximately live and die if the ratio of carbon ${}_6C^{14}$ to carbon ${}_6C^{12}$ in this mummy is 52.5% of that of a living organism?

Physical Information. In the atmosphere and in living organisms, the ratio of radioactive carbon ${}_6C^{14}$ (made radioactive by cosmic rays) to ordinary carbon ${}_6C^{12}$ is constant. When an organism dies, its absorption of ${}_6C^{14}$ by breathing and eating terminates. Hence one can estimate the age of a fossil by comparing the radioactive carbon ratio in the fossil with that in the atmosphere. To do this, one needs to know the half-life of ${}_6C^{14}$, which is 5715 years (*CRC Handbook of Chemistry and Physics*, 83rd ed., Boca Raton: CRC Press, 2002, page 11–52, line 9).

Solution. ***Modeling.*** Radioactive decay is governed by the ODE $y' = ky$ (see Sec. 1.1, Example 5). By separation and integration (where t is time and y_0 is the initial ratio of ${}_6C^{14}$ to ${}_6C^{12}$)

$$\frac{dy}{y} = k\,dt, \qquad \ln|y| = kt + c, \qquad y = y_0 e^{kt}.$$

Next we use the half-life $H = 5715$ to determine k. When $t = H$, half of the original substance is still present. Thus,

$$y_0 e^{kH} = 0.5y_0, \qquad e^{kH} = 0.5, \qquad k = \frac{\ln 0.5}{H} = -\frac{0.693}{5715} = -0.0001213.$$

Finally, we use the ratio 52.5% for determining the time t when Oetzi died (actually, was killed),

$$e^{kt} = e^{-0.0001213t} = 0.525, \qquad t = \frac{\ln 0.525}{-0.0001213} = 5312. \qquad \textit{Answer:} \quad \text{About 5300 years ago.}$$

Other methods show that radiocarbon dating values are usually too small. According to recent research, this is due to a variation in that carbon ratio because of industrial pollution and other factors, such as nuclear testing. ■

EXAMPLE 3 **Mixing Problem**

Mixing problems occur quite frequently in chemical industry. We explain here how to solve the basic model involving a single tank. The tank in Fig. 9 contains 1000 gal of water in which initially 100 lb of salt is dissolved. Brine runs in at a rate of 10 gal/min, and each gallon contains 5 lb of dissoved salt. The mixture in the tank is kept uniform by stirring. Brine runs out at 10 gal/min. Find the amount of salt in the tank at any time t.

Solution. ***Step 1. Setting up a model.*** Let $y(t)$ denote the amount of salt in the tank at time t. Its time rate of change is

$$y' = \text{Salt inflow rate} - \text{Salt outflow rate} \qquad \textbf{"Balance law".}$$

5 lb times 10 gal gives an inflow of 50 lb of salt. Now, the outflow is 10 gal of brine. This is 10/1000 = 0.01 (= 1%) of the total brine content in the tank, hence 0.01 of the salt content $y(t)$, that is, $0.01y(t)$. Thus the model is the ODE

$$y' = 50 - 0.01y = -0.01(y - 5000). \tag{4}$$

[2]Method by WILLARD FRANK LIBBY (1908–1980), American chemist, who was awarded for this work the 1960 Nobel Prize in chemistry.

Step 2. Solution of the model. The ODE (4) is separable. Separation, integration, and taking exponents on both sides gives

$$\frac{dy}{y - 5000} = -0.01\,dt, \qquad \ln|y - 5000| = -0.01t + c^*, \qquad y - 5000 = ce^{-0.01t}.$$

Initially the tank contains 100 lb of salt. Hence $y(0) = 100$ is the initial condition that will give the unique solution. Substituting $y = 100$ and $t = 0$ in the last equation gives $100 - 5000 = ce^0 = c$. Hence $c = -4900$. Hence the amount of salt in the tank at time t is

$$y(t) = 5000 - 4900e^{-0.01t}. \tag{5}$$

This function shows an exponential approach to the limit 5000 lb; see Fig. 9. Can you explain physically that $y(t)$ should increase with time? That its limit is 5000 lb? Can you see the limit directly from the ODE?

The model discussed becomes more realistic in problems on pollutants in lakes (see Problem Set 1.5, Prob. 27) or drugs in organs. These types of problems are more difficult because the mixing may be imperfect and the flow rates (in and out) may be different and known only very roughly. ■

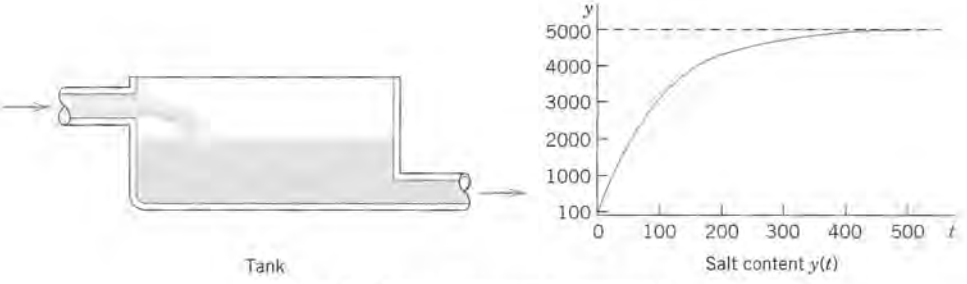

Fig. 9. Mixing problem in Example 3

EXAMPLE 4 Heating an Office Building (Newton's Law of Cooling[3])

Suppose that in Winter the daytime temperature in a certain office building is maintained at 70°F. The heating is shut off at 10 P.M. and turned on again at 6 A.M. On a certain day the temperature inside the building at 2 A.M. was found to be 65°F. The outside temperature was 50°F at 10 P.M. and had dropped to 40°F by 6 A.M. What was the temperature inside the building when the heat was turned on at 6 A.M.?

Physical information. Experiments show that the time rate of change of the temperature T of a body B (which conducts heat well, as, for example, a copper ball does) is proportional to the difference between T and the temperature of the surrounding medium **(Newton's law of cooling).**

Solution. ***Step 1. Setting up a model.*** Let $T(t)$ be the temperature inside the building and T_A the outside temperature (assumed to be constant in Newton's law). Then by Newton's law,

$$\frac{dT}{dt} = k(T - T_A). \tag{6}$$

Such experimental laws are derived under idealized assumptions that rarely hold exactly. However, even if a model seems to fit the reality only poorly (as in the present case), it may still give valuable qualitative information. To see how good a model is, the engineer will collect experimental data and compare them with calculations from the model.

---

[3]Sir ISAAC NEWTON (1642–1727), great English physicist and mathematician, became a professor at Cambridge in 1669 and Master of the Mint in 1699. He and the German mathematician and philosopher GOTTFRIED WILHELM LEIBNIZ (1646–1716) invented (independently) the differential and integral calculus. Newton discovered many basic physical laws and created the method of investigating physical problems by means of calculus. His *Philosophiae naturalis principia mathematica* (*Mathematical Principles of Natural Philosophy*, 1687) contains the development of classical mechanics. His work is of greatest importance to both mathematics and physics.

Step 2. General solution. We cannot solve (6) because we do not know T_A, just that it varied between 50°F and 40°F, so we follow the ***Golden Rule:*** *If you cannot solve your problem, try to solve a simpler one.* We solve (6) with the unknown function T_A replaced with the average of the two known values, or 45°F. For physical reasons we may expect that this will give us a reasonable approximate value of T in the building at 6 A.M.

For constant $T_A = 45$ (or any other *constant* value) the ODE (6) is separable. Separation, integration, and taking exponents gives the general solution

$$\frac{dT}{T-45} = k\,dt, \qquad \ln|T-45| = kt + c^*, \qquad T(t) = 45 + ce^{kt} \qquad (c = e^{c^*}).$$

Step 3. Particular solution. We choose 10 P.M. to be $t = 0$. Then the given initial condition is $T(0) = 70$ and yields a particular solution, call it T_p. By substitution,

$$T(0) = 45 + ce^0 = 70, \qquad c = 70 - 45 = 25, \qquad T_p(t) = 45 + 25e^{kt}.$$

Step 4. Determination of k. We use $T(4) = 65$, where $t = 4$ is 2 A.M. Solving algebraically for k and inserting k into $T_p(t)$ gives (Fig. 10)

$$T_p(4) = 45 + 25e^{4k} = 65, \qquad e^{4k} = 0.8, \qquad k = \tfrac{1}{4}\ln 0.8 = -0.056, \qquad T_p(t) = 45 + 25e^{-0.056t}.$$

Step 5. Answer and interpretation. 6 A.M. is $t = 8$ (namely, 8 hours after 10 P.M.), and

$$T_p(8) = 45 + 25e^{-0.056 \cdot 8} = 61[°\text{F}].$$

Hence the temperature in the building dropped 9°F, a result that looks reasonable. ■

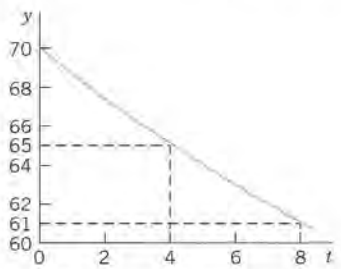

Fig. 10. Particular solution (temperature) in Example 4

EXAMPLE 5 **Leaking Tank. Outflow of Water Through a Hole (Torricelli's Law)**

This is another prototype engineering problem that leads to an ODE. It concerns the outflow of water from a cylindrical tank with a hole at the bottom (Fig. 11). You are asked to find the height of the water in the tank at any time if the tank has diameter 2 m, the hole has diameter 1 cm, and the initial height of the water when the hole is opened is 2.25 m. When will the tank be empty?

Physical information. Under the influence of gravity the outflowing water has velocity

(7) $$v(t) = 0.600\sqrt{2gh(t)} \qquad \textbf{(Torricelli's law}^4\textbf{)},$$

where $h(t)$ is the height of the water above the hole at time t, and $g = 980$ cm/sec^2 = 32.17 ft/sec^2 is the acceleration of gravity at the surface of the earth.

Solution. ***Step 1. Setting up the model.*** To get an equation, we relate the decrease in water level $h(t)$ to the outflow. The volume ΔV of the outflow during a short time Δt is

$$\Delta V = Av\,\Delta t \qquad (A = \text{Area of hole}).$$

---

[4]EVANGELISTA TORRICELLI (1608–1647), Italian physicist, pupil and successor of GALILEO GALILEI (1564–1642) at Florence. The "contraction factor" 0.600 was introduced by J. C. BORDA in 1766 because the stream has a smaller cross section than the area of the hole.

ΔV must equal the change ΔV^* of the volume of the water in the tank. Now

$$\Delta V^* = -B\,\Delta h \qquad (B = \text{Cross-sectional area of tank})$$

where Δh (> 0) is the decrease of the height $h(t)$ of the water. The minus sign appears because the volume of the water in the tank decreases. Equating ΔV and ΔV^* gives

$$-B\,\Delta h = Av\,\Delta t.$$

We now express v according to Torricelli's law and then let Δt (the length of the time interval considered) approach 0—this is a ***standard way*** of obtaining an ODE as a model. That is, we have

$$\frac{\Delta h}{\Delta t} = -\frac{A}{B}\,v = -\frac{A}{B}\,0.600\sqrt{2gh(t)},$$

and by letting $\Delta t \to 0$ we obtain the ODE

$$\frac{dh}{dt} = -26.56\,\frac{A}{B}\,\sqrt{h},$$

where $26.56 = 0.600\,\sqrt{2 \cdot 980}$. This is our model, a first-order ODE.

Step 2. General solution. Our ODE is separable. A/B is constant. Separation and integration gives

$$\frac{dh}{\sqrt{h}} = -26.56\,\frac{A}{B}\,dt \qquad \text{and} \qquad 2\sqrt{h} = c^* - 26.56\,\frac{A}{B}\,t.$$

Dividing by 2 and squaring gives $h = (c - 13.28At/B)^2$. Inserting $13.28A/B = 13.28 \cdot 0.5^2\pi/100^2\pi = 0.000332$ yields the general solution

$$h(t) = (c - 0.000332t)^2.$$

Step 3. Particular solution. The initial height (the initial condition) is $h(0) = 225$ cm. Substitution of $t = 0$ and $h = 225$ gives from the general solution $c^2 = 225$, $c = 15.00$ and thus the particular solution (Fig. 11)

$$h_p(t) = (15.00 - 0.000332t)^2.$$

Step 4. Tank empty. $h_p(t) = 0$ if $t = 15.00/0.000332 = 45\,181$ [sec] $= 12.6$ [hours].

Here you see distinctly the ***importance of the choice of units***—we have been working with the Cgs system, in which time is measured in seconds! We used $g = 980$ cm/sec^2.

Step 5. Checking. Check the result. ■

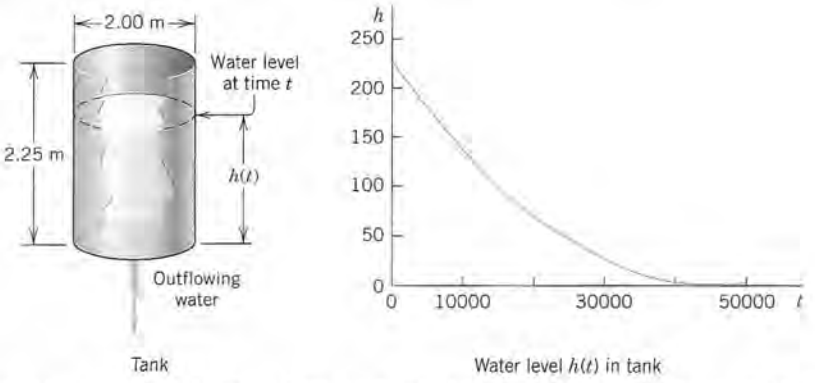

Fig. 11. Example 5. Outflow from a cylindrical tank ("leaking tank"). Torricelli's law

Extended Method: Reduction to Separable Form

Certain nonseparable ODEs can be made separable by transformations that introduce for y a new unknown function. We discuss this technique for a class of ODEs of practical

importance, namely, for equations

$$\textbf{(8)} \qquad y' = f\left(\frac{y}{x}\right).$$

Here, f is any (differentiable) function of y/x, such as $\sin(y/x)$, $(y/x)^4$, and so on. (Such an ODE is sometimes called a *homogeneous ODE*, a term we shall not use but reserve for a more important purpose in Sec. 1.5.)

The form of such an ODE suggests that we set $y/x = u$; thus,

$$(9) \qquad y = ux \qquad \text{and by product differentiation} \qquad y' = u'x + u.$$

Substitution into $y' = f(y/x)$ then gives $u'x + u = f(u)$ or $u'x = f(u) - u$. We see that this can be separated:

$$(10) \qquad \frac{du}{f(u) - u} = \frac{dx}{x}.$$

EXAMPLE 6 **Reduction to Separable Form**

Solve

$$2xyy' = y^2 - x^2.$$

Solution. To get the usual explicit form, divide the given equation by $2xy$,

$$y' = \frac{y^2 - x^2}{2xy} = \frac{y}{2x} - \frac{x}{2y}.$$

Now substitute y and y' from (9) and then simplify by subtracting u on both sides,

$$u'x + u = \frac{u}{2} - \frac{1}{2u}, \qquad u'x = -\frac{u}{2} - \frac{1}{2u} = \frac{-u^2 - 1}{2u}.$$

You see that in the last equation you can now separate the variables,

$$\frac{2u\,du}{1 + u^2} = -\frac{dx}{x}. \qquad \text{By integration,} \qquad \ln(1 + u^2) = -\ln|x| + c^* = \ln\left|\frac{1}{x}\right| + c^*.$$

Take exponents on both sides to get $1 + u^2 = c/x$ or $1 + (y/x)^2 = c/x$. Multiply the last equation by x^2 to obtain (Fig. 12)

$$x^2 + y^2 = cx. \qquad \text{Thus} \qquad \left(x - \frac{c}{2}\right)^2 + y^2 = \frac{c^2}{4}.$$

This general solution represents a family of circles passing through the origin with centers on the x-axis. ■

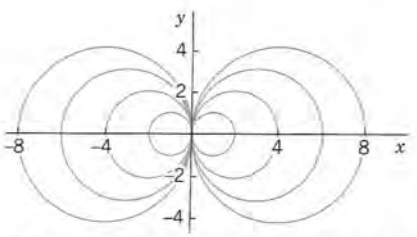

Fig. 12. General solution (family of circles) in Example 6

PROBLEM SET 1.3

1. **(Constant of integration)** An arbitrary constant of integration must be introduced immediately when the integration is performed. Why is this important? Give an example of your own.

2–9 GENERAL SOLUTION

Find a general solution. Show the steps of derivation. Check your answer by substitution.

2. $y' + (x + 2)y^2 = 0$
3. $y' = 2 \sec 2y$
4. $y' = (y + 9x)^2 \quad (y + 9x = v)$
5. $yy' + 36x = 0$
6. $y' = (4x^2 + y^2)/(xy)$
7. $y' \sin \pi x = y \cos \pi x$
8. $xy' = \frac{1}{2}y^2 + y$
9. $y'e^{\pi x} = y^2 + 1$

10–19 INITIAL VALUE PROBLEMS

Find the particular solution. Show the steps of derivation, beginning with the general solution. (L, R, b are constants.)

10. $yy' + 4x = 0,\ y(0) = 3$
11. $dr/dt = -2tr,\ r(0) = r_0$
12. $2xyy' = 3y^2 + x^2,\ y(1) = 2$
13. $L\, dI/dt + RI = 0,\ I(0) = I_0$
14. $y' = y/x + (2x^3/y)\cos(x^2),\ y(\sqrt{\pi/2}) = \sqrt{\pi}$
15. $e^{2x}y' = 2(x + 2)y^3,\ y(0) = 1/\sqrt{5} \approx 0.45$
16. $xy' = y + 4x^5 \cos^2(y/x),\ y(2) = 0$
17. $y'x \ln x = y,\ y(3) = \ln 81$
18. $dr/d\theta = b[(dr/d\theta)\cos\theta + r \sin\theta],\ r(\frac{1}{2}\pi) = \pi,\ 0 < b < 1$
19. $yy' = (x - 1)e^{-y^2},\ y(0) = 1$

20. **(Particular solution)** Introduce limits of integration in (3) such that y obtained from (3) satisfies the initial condition $y(x_0) = y_0$. Try the formula out on Prob. 19.

21–36 APPLICATIONS, MODELING

21. **(Curves)** Find all curves in the xy-plane whose tangents all pass through a given point (a, b).
22. **(Curves)** Show that any (nonvertical) straight line through the origin of the xy-plane intersects all solution curves of $y' = g(y/x)$ at the same angle.
23. **(Exponential growth)** If the growth rate of the amount of yeast at any time t is proportional to the amount present at that time and doubles in 1 week, how much yeast can be expected after 2 weeks? After 4 weeks?
24. **(Population model)** If in a population of bacteria the birth rate and death rate are proportional to the number of individuals present, what is the population as a function of time? Figure out the limiting situation for increasing time and interpret it.
25. **(Radiocarbon dating)** If a fossilized tree is claimed to be 4000 years old, what should be its ${}_6C^{14}$ content expressed as a percent of the ratio of ${}_6C^{14}$ to ${}_6C^{12}$ in a living organism?
26. **(Gompertz growth in tumors)** The Gompertz model is $y' = -Ay \ln y$ $(A > 0)$, where $y(t)$ is the mass of tumor cells at time t. The model agrees well with clinical observations. The declining growth rate with increasing $y > 1$ corresponds to the fact that cells in the interior of a tumor may die because of insufficient oxygen and nutrients. Use the ODE to discuss the growth and decline of solutions (tumors) and to find constant solutions. Then solve the ODE.
27. **(Dryer)** If wet laundry loses half of its moisture during the first 5 minutes of drying in a dryer and if the rate of loss of moisture is proportional to the moisture content, when will the laundry be practically dry, say, when will it have lost 95% of its moisture? First guess.
28. **(Alibi?)** Jack, arrested when leaving a bar, claims that he has been inside for at least half an hour (which would provide him with an alibi). The police check the water temperature of his car (parked near the entrance of the bar) at the instant of arrest and again 30 minutes later, obtaining the values 190°F and 110°F, respectively. Do these results give Jack an alibi? (Solve by inspection.)
29. **(Law of cooling)** A thermometer, reading 10°C, is brought into a room whose temperature is 23°C. Two minutes later the thermometer reading is 18°C. How long will it take until the reading is practically 23°C, say, 22.8°C? First guess.
30. **(Torricelli's law)** How does the answer in Example 5 (the time when the tank is empty) change if the diameter of the hole is doubled? First guess.
31. **(Torricelli's law)** Show that (7) looks reasonable inasmuch as $\sqrt{2gh(t)}$ is the speed a body gains if it falls a distance h (and air resistance is neglected).
32. **(Rope)** To tie a boat in a harbor, how many times must a rope be wound around a bollard (a vertical rough cylindrical post fixed on the ground) so that a man holding one end of the rope can resist a force exerted by the boat one thousand times greater than the man can exert? First guess. Experiments show that the change ΔS of the force S in a small portion of the rope is proportional to S and to the small angle $\Delta\phi$ in Fig. 13. Take the proportionality constant 0.15.

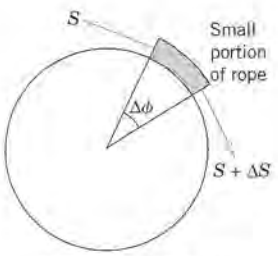

Fig. 13. Problem 32

33. (Mixing) A tank contains 800 gal of water in which 200 lb of salt is dissolved. Two gallons of fresh water runs in per minute, and 2 gal of the mixture in the tank, kept uniform by stirring, runs out per minute. How much salt is left in the tank after 5 hours?

34. WRITING PROJECT. Exponential Increase, Decay, Approach. Collect, order, and present all the information on the ODE $y' = ky$ and its applications from the text and the problems. Add examples of your own.

35. CAS EXPERIMENT. Graphing Solutions. A CAS can usually graph solutions even if they are given by integrals that cannot be evaluated by the usual methods of calculus. Show this as follows.

(A) Graph the curves for the seven initial value problems $y' = e^{-x^2/2}$, $y(0) = 0, \pm 1, \pm 2, \pm 3$, common axes. Are these curves congruent? Why?

(B) Experiment with approximate curves of nth partial sums of the Maclaurin series obtained by termwise integration of that of y in (A); graph them and describe qualitatively the accuracy for a fixed interval $0 \leqq x \leqq b$ and increasing n, and then for fixed n and increasing b.

(C) Experiment with $y' = \cos(x^2)$ as in (B).

(D) Find an initial value problem with solution $y = e^{x^2} \int_0^x e^{-t^2}\, dt$ and experiment with it as in (B).

36. TEAM PROJECT. Torricelli's Law. Suppose that the tank in Example 5 is hemispherical, of radius R, initially full of water, and has an outlet of 5 cm^2 cross-sectional area at the bottom. (Make a sketch.) Set up the model for outflow. Indicate what portion of your work in Example 5 you can use (so that it can become part of the general method independent of the shape of the tank). Find the time t to empty the tank (a) for any R, (b) for $R = 1$ m. Plot t as function of R. Find the time when $h = R/2$ (a) for any R, (b) for $R = 1$ m.

1.4 Exact ODEs. Integrating Factors

We remember from calculus that if a function $u(x, y)$ has continuous partial derivatives, its **differential** (also called its *total differential*) is

$$du = \frac{\partial u}{\partial x}\, dx + \frac{\partial u}{\partial y}\, dy.$$

From this it follows that if $u(x, y) = c = const$, then $du = 0$.

For example, if $u = x + x^2y^3 = c$, then

$$du = (1 + 2xy^3)\, dx + 3x^2y^2\, dy = 0$$

or

$$y' = \frac{dy}{dx} = -\frac{1 + 2xy^3}{3x^2y^2},$$

an ODE that we can solve by going backward. This idea leads to a powerful solution method as follows.

A first-order ODE $M(x, y) + N(x, y)y' = 0$, written as (use $dy = y'\, dx$ as in Sec. 1.3)

$$M(x, y)\, dx + N(x, y)\, dy = 0 \tag{1}$$

is called an **exact differential equation** if the **differential form** $M(x, y)\,dx + N(x, y)\,dy$ is **exact,** that is, this form is the differential

$$du = \frac{\partial u}{\partial x}\,dx + \frac{\partial u}{\partial y}\,dy \tag{2}$$

of some function $u(x, y)$. Then (1) can be written

$$du = 0.$$

By integration we immediately obtain the general solution of (1) in the form

$$u(x, y) = c. \tag{3}$$

This is called an **implicit solution,** in contrast with a solution $y = h(x)$ as defined in Sec. 1.1, which is also called an *explicit solution,* for distinction. Sometimes an implicit solution can be converted to explicit form. (Do this for $x^2 + y^2 = 1$.) If this is not possible, your CAS may graph a figure of the **contour lines** (3) of the function $u(x, y)$ and help you in understanding the solution.

Comparing (1) and (2), we see that (1) is an exact differential equation if there is some function $u(x, y)$ such that

$$\text{(a)}\quad \frac{\partial u}{\partial x} = M, \qquad \text{(b)}\quad \frac{\partial u}{\partial y} = N. \tag{4}$$

From this we can derive a formula for checking whether (1) is exact or not, as follows.

Let M and N be continuous and have continuous first partial derivatives in a region in the xy-plane whose boundary is a closed curve without self-intersections. Then by partial differentiation of (4) (see App. 3.2 for notation),

$$\frac{\partial M}{\partial y} = \frac{\partial^2 u}{\partial y\,\partial x},$$

$$\frac{\partial N}{\partial x} = \frac{\partial^2 u}{\partial x\,\partial y}.$$

By the assumption of continuity the two second partial derivatives are equal. Thus

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}. \tag{5}$$

This condition is not only necessary but also sufficient for (1) to be an exact differential equation. (We shall prove this in Sec. 10.2 in another context. Some calculus books (e.g., Ref. [GR11] also contain a proof.)

If (1) is exact, the function $u(x, y)$ can be found by inspection or in the following systematic way. From (4a) we have by integration with respect to x

(6) $$u = \int M\,dx + k(y);$$

in this integration, y is to be regarded as a constant, and $k(y)$ plays the role of a "constant" of integration. To determine $k(y)$, we derive $\partial u/\partial y$ from (6), use (4b) to get dk/dy, and integrate dk/dy to get k.

Formula (6) was obtained from (4a). Instead of (4a) we may equally well use (4b). Then instead of (6) we first have by integration with respect to y

(6*) $$u = \int N\,dy + l(x).$$

To determine $l(x)$, we derive $\partial u/\partial x$ from (6*), use (4a) to get dl/dx, and integrate. We illustrate all this by the following typical examples.

EXAMPLE 1 **An Exact ODE**

Solve

(7) $$\cos(x + y)\,dx + (3y^2 + 2y + \cos(x + y))\,dy = 0.$$

Solution. ***Step 1. Test for exactness.*** Our equation is of the form (1) with

$$M = \cos(x + y),$$

$$N = 3y^2 + 2y + \cos(x + y).$$

Thus

$$\frac{\partial M}{\partial y} = -\sin(x + y),$$

$$\frac{\partial N}{\partial x} = -\sin(x + y).$$

From this and (5) we see that (7) is exact.

Step 2. Implicit general solution. From (6) we obtain by integration

(8) $$u = \int M\,dx + k(y) = \int \cos(x + y)\,dx + k(y) = \sin(x + y) + k(y).$$

To find $k(y)$, we differentiate this formula with respect to y and use formula (4b), obtaining

$$\frac{\partial u}{\partial y} = \cos(x + y) + \frac{dk}{dy} = N = 3y^2 + 2y + \cos(x + y).$$

Hence $dk/dy = 3y^2 + 2y$. By integration, $k = y^3 + y^2 + c^*$. Inserting this result into (8) and observing (3), we obtain the *answer*

$$u(x, y) = \sin(x + y) + y^3 + y^2 = c.$$

Step 3. Checking an implicit solution. We can check by differentiating the implicit solution $u(x, y) = c$ implicitly and see whether this leads to the given ODE (7):

(9) $$du = \frac{\partial u}{\partial x}\,dx + \frac{\partial u}{\partial y}\,dy = \cos(x + y)\,dx + (\cos(x + y) + 3y^2 + 2y)\,dy = 0.$$

This completes the check. ■

EXAMPLE 2 An Initial Value Problem

Solve the initial value problem

$$(\cos y \sinh x + 1)\,dx - \sin y \cosh x\,dy = 0, \qquad y(1) = 2. \tag{10}$$

Solution. You may verify that the given ODE is exact. We find u. For a change, let us use (6*),

$$u = -\int \sin y \cosh x\,dy + l(x) = \cos y \cosh x + l(x).$$

From this, $\partial u/\partial x = \cos y \sinh x + dl/dx = M = \cos y \sinh x + 1$. Hence $dl/dx = 1$. By integration, $l(x) = x + c^*$. This gives the general solution $u(x, y) = \cos y \cosh x + x = c$. From the initial condition, $\cos 2 \cosh 1 + 1 = 0.358 = c$. Hence the answer is $\cos y \cosh x + x = 0.358$. Figure 14 shows the particular solutions for $c = 0$, 0.358 (thicker curve), 1, 2, 3. Check that the answer satisfies the ODE. (Proceed as in Example 1.) Also check that the initial condition is satisfied. ■

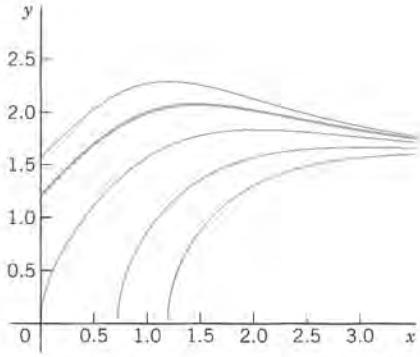

Fig. 14. Particular solu.ions in Example 2

EXAMPLE 3 WARNING! Breakdown in the Case of Nonexactness

The equation $-y\,dx + x\,dy = 0$ is not exact because $M = -y$ and $N = x$, so that in (5), $\partial M/\partial y = -1$ but $\partial N/\partial x = 1$. Let us show that in such a case the present method does not work. From (6),

$$u = \int M\,dx + k(y) = -xy + k(y), \qquad \text{hence} \qquad \frac{\partial u}{\partial y} = -x + \frac{dk}{dy}.$$

Now, $\partial u/\partial y$ should equal $N = x$, by (4b). However, this is impossible because $k(y)$ can depend only on y. Try (6*); it will also fail. Solve the equation by another method that we have discussed. ■

Reduction to Exact Form. Integrating Factors

The ODE in Example 3 is $-y\,dx + x\,dy = 0$. It is not exact. However, if we multiply it by $1/x^2$, we get an exact equation [check exactness by (5)!],

$$\frac{-y\,dx + x\,dy}{x^2} = -\frac{y}{x^2}\,dx + \frac{1}{x}\,dy = d\left(\frac{y}{x}\right) = 0. \tag{11}$$

Integration of (11) then gives the general solution $y/x = c = const.$

This example gives the idea. All we did was multiply a given nonexact equation, say,

$$P(x, y)\,dx + Q(x, y)\,dy = 0, \tag{12}$$

by a function F that, in general, will be a function of both x and y. The result was an equation

$$FP\,dx + FQ\,dy = 0 \tag{13}$$

that is exact, so we can solve it as just discussed. Such a function $F(x, y)$ is then called an **integrating factor** of (12).

EXAMPLE 4 **Integrating Factor**

The integrating factor in (11) is $F = 1/x^2$. Hence in this case the exact equation (13) is

$$FP\,dx + FQ\,dy = \frac{-y\,dx + x\,dy}{x^2} = d\left(\frac{y}{x}\right) = 0. \qquad \text{Solution} \qquad \frac{y}{x} = c.$$

These are straight lines $y = cx$ through the origin.

It is remarkable that we can readily find other integrating factors for the equation $-y\,dx + x\,dy = 0$, namely, $1/y^2$, $1/(xy)$, and $1/(x^2 + y^2)$, because

$$\frac{-y\,dx + x\,dy}{y^2} = d\left(\frac{x}{y}\right), \quad \frac{-y\,dx + x\,dy}{xy} = -d\left(\ln\frac{x}{y}\right), \quad \frac{-y\,dx + x\,dy}{x^2 + y^2} = d\left(\arctan\frac{y}{x}\right). \tag{14}$$

■

How to Find Integrating Factors

In simpler cases we may find integrating factors by inspection or perhaps after some trials, keeping (14) in mind. In the general case, the idea is the following.

For $M\,dx + N\,dy = 0$ the exactness condition (4) is $\partial M/\partial y = \partial N/\partial x$. Hence for (13), $FP\,dx + FQ\,dy = 0$, the exactness condition is

$$\frac{\partial}{\partial y}(FP) = \frac{\partial}{\partial x}(FQ). \tag{15}$$

By the product rule, with subscripts denoting partial derivatives, this gives

$$F_y P + FP_y = F_x Q + FQ_x.$$

In the general case, this would be complicated and useless. So we follow the ***Golden Rule:*** *If you cannot solve your problem, try to solve a simpler one*—the result may be useful (and may also help you later on). Hence we look for an integrating factor depending only on ***one*** variable; fortunately, in many practical cases, there are such factors, as we shall see. Thus, let $F = F(x)$. Then $F_y = 0$, and $F_x = F' = dF/dx$, so that (15) becomes

$$FP_y = F'Q + FQ_x.$$

Dividing by FQ and reshuffling terms, we have

$$\frac{1}{F}\frac{dF}{dx} = R, \qquad \text{where} \qquad R = \frac{1}{Q}\left(\frac{\partial P}{\partial y} - \frac{\partial Q}{\partial x}\right). \tag{16}$$

This proves the following theorem.

THEOREM 1

Integrating Factor $F(x)$

If (12) *is such that the right side* R *of* (16), *depends only on* x, *then* (12) *has an integrating factor* $F = F(x)$, *which is obtained by integrating* (16) *and taking exponents on both sides,*

(17) $$F(x) = \exp \int R(x)\, dx.$$

Similarly, if $F^* = F^*(y)$, then instead of (16) we get

(18) $$\frac{1}{F^*}\frac{dF^*}{dy} = R^*, \qquad \text{where} \qquad R^* = \frac{1}{P}\left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)$$

and we have the companion

THEOREM 2

Integrating Factor $F^*(y)$

If (12) *is such that the right side* R^* *of* (18) *depends only on* y, *then* (12) *has an integrating factor* $F^* = F^*(y)$, *which is obtained from* (18) *in the form*

(19) $$F^*(y) = \exp \int R^*(y)\, dy.$$

EXAMPLE 5 **Application of Theorems 1 and 2. Initial Value Problem**

Using Theorem 1 or 2, find an integrating factor and solve the initial value problem

(20) $$(e^{x+y} + ye^y)\, dx + (xe^y - 1)\, dy = 0, \quad y(0) = -1$$

Solution. ***Step 1. Nonexactness.*** The exactness check fails:

$$\frac{\partial P}{\partial y} = \frac{\partial}{\partial y}(e^{x+y} + ye^y) = e^{x+y} + e^y + ye^y \qquad \text{but} \qquad \frac{\partial Q}{\partial x} = \frac{\partial}{\partial x}(xe^y - 1) = e^y.$$

Step 2. Integrating factor. General solution. Theorem 1 fails because R [the right side of (16)] depends on both x and y,

$$R = \frac{1}{Q}\left(\frac{\partial P}{\partial y} - \frac{\partial Q}{\partial x}\right) = \frac{1}{xe^y - 1}(e^{x+y} + e^y + ye^y - e^y).$$

Try Theorem 2. The right side of (18) is

$$R^* = \frac{1}{P}\left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) = \frac{1}{e^{x+y} + ye^y}(e^y - e^{x+y} - e^y - ye^y) = -1.$$

Hence (19) gives the integrating factor $F^*(y) = e^{-y}$. From this result and (20) you get the exact equation

$$(e^x + y)\, dx + (x - e^{-y})\, dy = 0.$$

Test for exactness; you will get 1 on both sides of the exactness condition. By integration, using (4a),

$$u = \int (e^x + y)\, dx = e^x + xy + k(y).$$

Differentiate this with respect to y and use (4b) to get

$$\frac{\partial u}{\partial y} = x + \frac{dk}{dy} = N = x - e^{-y}, \qquad \frac{dk}{dy} = -e^{-y}, \qquad k = e^{-y} + c^*.$$

Hence the general solution is

$$u(x, y) = e^x + xy + e^{-y} = c.$$

Step 3. Particular solution. The initial condition $y(0) = 1$ gives $u(0, -1) = 1 + 0 + e = 3.72$. Hence the answer is $e^x + xy + e^{-y} = 1 + e = 3.72$. Figure 15 shows several particular solutions obtained as level curves of $u(x, y) = c$, obtained by a CAS, a convenient way in cases in which it is impossible or difficult to cast a solution into explicit form. Note the curve that (nearly) satisfies the initial condition.

Step 4. Checking. Check by substitution that the answer satisfies the given equation as well as the initial condition. ■

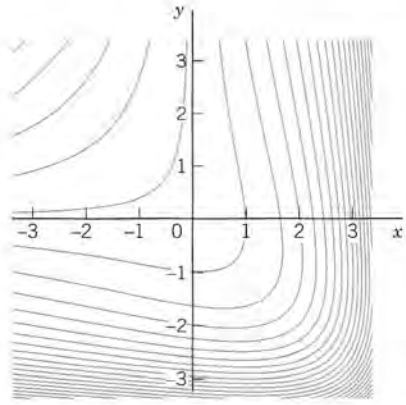

Fig. 15. Particular solutions in Example 5

PROBLEM SET 1.4

1–20 EXACT ODEs, INTEGRATING FACTORS

Test for exactness. If exact, solve. If not, use an integrating factor as given or find it by inspection or from the theorems in the text. Also, if an initial condition is given, determine the corresponding particular solution.

1. $x^3\,dx + y^3\,dy = 0$

2. $(x - y)(dx - dy) = 0$

3. $-\pi \sin \pi x \sinh y\,dx + \cos \pi x \cosh y\,dy = 0$

4. $(e^y - ye^x)\,dx + (xe^y - e^x)\,dy = 0$

5. $9x\,dx + 4y\,dy = 0$

6. $e^x(\cos y\,dx - \sin y\,dy) = 0$

7. $e^{-2\theta}\,dr - 2re^{-2\theta}\,d\theta = 0$

8. $(2x + 1/y - y/x^2)\,dx + (2y + 1/x - x/y^2)\,dy = 0$

9. $(-y/x^2 + 2\cos 2x)\,dx + (1/x - 2\sin 2y)\,dy = 0$

10. $-2xy \sin(x^2)\,dx + \cos(x^2)\,dy = 0$

11. $-y\,dx + x\,dy = 0$

12. $(e^{x+y} - y)\,dx + (xe^{x+y} + 1)\,dy = 0$

13. $-3y\,dx + 2x\,dy = 0, \quad F(x, y) = y/x^4$

14. $(x^4 + y^2)\,dx - xy\,dy = 0, \quad y(2) = 1$

15. $e^{2x}(2\cos y\,dx - \sin y\,dy) = 0, \quad y(0) = 0$

16. $-\sin xy\,(y\,dx + x\,dy) = 0, \quad y(1) = \pi$

17. $(\cos \omega x + \omega \sin \omega x)\,dx + e^x\,dy = 0, \; y(0) = 1$

18. $(\cos xy + x/y)\,dx + (1 + (x/y)\cos xy)\,dy = 0$

19. $e^{-y}\,dx + e^{-x}(-e^{-y} + 1)\,dy = 0, \quad F = e^{x+y}$

20. $(\sin y \cos y + x\cos^2 y)\,dx + x\,dy = 0$

21. Under what conditions for the constants A, B, C, D is $(Ax + By)\,dx + (Cx + Dy)\,dy = 0$ exact? Solve the exact equation.

22. CAS PROJECT. Graphing Particular Solutions Graph particular solutions of the following ODE, proceeding as explained.

$$(21) \qquad y \cos x \, dx + \frac{1}{y} \, dy = 0$$

(a) Test for exactness. If necessary, find an integrating factor. Find the general solution $u(x, y) = c$.

(b) Solve (21) by separating variables. Is this simpler than **(a)**?

(c) Graph contours $u(x, y) = c$ by your CAS. (Cf. Fig. 16.)

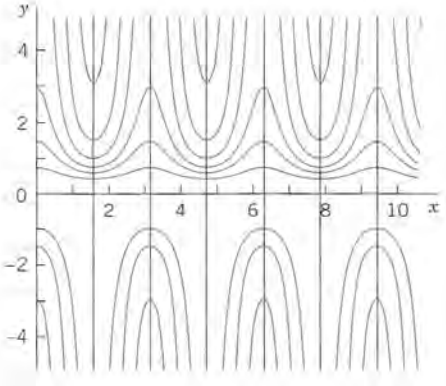

Fig. 16. Particular solutions in CAS Project 22

(d) In another graph show the solution curves satisfying $y(0) = \pm 1, \pm 2, \pm 3, \pm 4$. Compare the quality of **(c)** and **(d)** and comment.

(e) Do the same steps for another nonexact ODE of your choice.

23. WRITING PROJECT. Working Backward. Start from solutions $u(x, y) = c$ of your choice, find a corresponding exact ODE, destroy exactness by a multiplication or division. This should give you a feel for the form of ODEs you can reach by the method of integrating factors. (Working backward is useful in other areas, too; Euler and other great masters frequently did it.)

24. TEAM PROJECT. Solution by Several Methods. Show this as indicated. Compare the amount of work.

(A) $e^y(\sinh x \, dx + \cosh x \, dy) = 0$ as an exact ODE and by separation.

(B) $(1 + 2x) \cos y \, dx + dy/\cos y = 0$ by Theorem 2 and by separation.

(C) $(x^2 + y^2) \, dx - 2xy \, dy = 0$ by Theorem 1 or 2 and by separation with $v = y/x$.

(D) $3x^2 y \, dx + 4x^3 \, dy = 0$ by Theorems 1 and 2 and by separation.

(E) Search the text and the problems for further ODEs that can be solved by more than one of the methods discussed so far. Make a list of these ODEs. Find further cases of your own.

1.5 Linear ODEs. Bernoulli Equation. Population Dynamics

Linear ODEs or ODEs that can be transformed to linear form are models of various phenomena, for instance, in physics, biology, population dynamics, and ecology, as we shall see. A first-order ODE is said to be ***linear*** if it can be written

$$(1) \qquad y' + p(x)y = r(x).$$

The defining feature of this equation is that it is linear in both the unknown function y and its derivative $y' = dy/dx$, whereas p and r may be ***any*** given functions of x. If in an application the independent variable is time, we write t instead of x.

If the first term is $f(x)y'$ (instead of y'), divide the equation by $f(x)$ to get the **"standard form"** (1), with y' as the first term, which is practical.

For instance, $y' \cos x + y \sin x = x$ is a linear ODE, and its standard form is $y' + y \tan x = x \sec x$.

The function $r(x)$ on the right may be a force, and the solution $y(x)$ a displacement in a motion or an electrical current or some other physical quantity. In engineering, $r(x)$ is frequently called the **input,** and $y(x)$ is called the **output** or the *response* to the input (and, if given, to the initial condition).

Homogeneous Linear ODE. We want to solve (1) in some interval $a < x < b$, call it J, and we begin with the simpler special case that $r(x)$ is zero for all x in J. (This is sometimes written $r(x) \equiv 0$.) Then the ODE (1) becomes

$$y' + p(x)y = 0 \tag{2}$$

and is called **homogeneous.** By separating variables and integrating we then obtain

$$\frac{dy}{y} = -p(x)\,dx, \qquad \text{thus} \qquad \ln|y| = -\int p(x)\,dx + c^*.$$

Taking exponents on both sides, we obtain the general solution of the homogeneous ODE (2),

$$y(x) = ce^{-\int p(x)\,dx} \qquad (c = \pm e^{c^*} \quad \text{when} \quad y \gtrless 0); \tag{3}$$

here we may also choose $c = 0$ and obtain the **trivial solution** $y(x) = 0$ for all x in that interval.

Nonhomogeneous Linear ODE. We now solve (1) in the case that $r(x)$ in (1) is not everywhere zero in the interval J considered. Then the ODE (1) is called **nonhomogeneous.** It turns out that in this case, (1) has a pleasant property; namely, it has an integrating factor depending only on x. We can find this factor $F(x)$ by Theorem 1 in the last section. For this purpose we write (1) as

$$(py - r)\,dx + dy = 0.$$

This is $P\,dx + Q\,dy = 0$, where $P = py - r$ and $Q = 1$. Hence the right side of (16) in Sec. 1.4 is simply $1(p - 0) = p$, so that (16) becomes

$$\frac{1}{F}\,\frac{dF}{dx} = p(x).$$

Separation and integration gives

$$\frac{dF}{F} = p\,dx \qquad \text{and} \qquad \ln|F| = \int p\,dx.$$

Taking exponents on both sides, we obtain the desired integrating factor $F(x)$,

$$F(x) = e^{\int p\,dx}.$$

We now multiply (1) on both sides by this F. Then by the product rule,

$$e^{\int p\,dx}(y' + py) = (e^{\int p\,dx}y)' = e^{\int p\,dx}r.$$

By integrating the second and third of these three expressions with respect to x we get

$$e^{\int p\,dx}y = \int e^{\int p\,dx}r\,dx + c.$$

Dividing this equation by $e^{\int p\,dx}$ and denoting the exponent $\int p\,dx$ by h, we obtain

$$y(x) = e^{-h}\left(\int e^{h}r\,dx + c\right), \qquad h = \int p(x)\,dx. \tag{4}$$

(The constant of integration in h does not matter; see Prob. 2.) Formula (4) is the general solution of (1) in the form of an integral. Solving (1) is now reduced to the evaluation of an integral. In cases in which this cannot be done by the usual methods of calculus, one may have to use a numeric method for integrals (Sec. 19.5) or for the ODE itself (Sec. 21.1).

The structure of (4) is interesting. The only quantity depending on a given initial condition is c. Accordingly, writing (4) as a sum of two terms,

$$(4^*) \qquad y(x) = e^{-h}\int e^{h} r\,dx + ce^{-h},$$

we see the following:

(5) Total Output = Response to the Input r + Response to the Initial Data.

EXAMPLE 1 **First-Order ODE, General Solution**

Solve the linear ODE

$$y' - y = e^{2x}.$$

Solution. Here,

$$p = -1, \qquad r = e^{2x}, \qquad h = \int p\,dx = -x$$

and from (4) we obtain the general solution

$$y(x) = e^{x}\left(\int e^{-x}e^{2x}\,dx + c\right) = e^{x}(e^{x} + c) = ce^{x} + e^{2x}.$$

From (4*) and (5) we see that the response to the input is e^{2x}.

In simpler cases, such as the present, we may not need the general formula (4), but may wish to proceed directly, multiplying the given equation by $e^{h} = e^{-x}$. This gives

$$(y' - y)e^{-x} = (ye^{-x})' = e^{2x}e^{-x} = e^{x}.$$

Integrating on both sides, we obtain the same result as before:

$$ye^{-x} = e^{x} + c, \qquad \text{hence} \qquad y = e^{2x} + ce^{x}.$$

EXAMPLE 2 **First-Order ODE, Initial Value Problem**

Solve the initial value problem

$$y' + y\tan x = \sin 2x, \qquad y(0) = 1.$$

Solution. Here $p = \tan x$, $r = \sin 2x = 2\sin x\cos x$, and

$$\int p\,dx = \int \tan x\,dx = \ln|\sec x|.$$

From this we see that in (4),

$$e^{h} = \sec x, \qquad e^{-h} = \cos x, \qquad e^{h}r = (\sec x)(2\sin x\cos x) = 2\sin x,$$

and the general solution of our equation is

$$y(x) = \cos x\left(2\int \sin x\,dx + c\right) = c\cos x - 2\cos^2 x.$$

From this and the initial condition, $1 = c\cdot 1 - 2\cdot 1^2$; thus $c = 3$ and the solution of our initial value problem is $y = 3\cos x - 2\cos^2 x$. Here $3\cos x$ is the response to the initial data, and $-2\cos^2 x$ is the response to the input $\sin 2x$.

EXAMPLE 3 **Hormone Level**

Assume that the level of a certain hormone in the blood of a patient varies with time. Suppose that the time rate of change is the difference between a sinusoidal input of a 24-hour period from the thyroid gland and a continuous removal rate proportional to the level present. Set up a model for the hormone level in the blood and find its general solution. Find the particular solution satisfying a suitable initial condition.

Solution. ***Step 1. Setting up a model.*** Let $y(t)$ be the hormone level at time t. Then the removal rate is $Ky(t)$. The input rate is $A + B\cos(2\pi t/24)$, where A is the average input rate, and $A \geqq B$ to make the input nonnegative. (The constants A, B, and K can be determined by measurements.) Hence the model is

$$y'(t) = \text{In} - \text{Out} = A + B\cos\left(\tfrac{1}{12}\pi t\right) - Ky(t) \qquad \text{or} \qquad y' + Ky = A + B\cos\left(\tfrac{1}{12}\pi t\right).$$

The initial condition for a particular solution y_{part} is $y_{part}(0) = y_0$ with $t = 0$ suitably chosen, e.g., 6:00 A.M.

Step 2. General solution. In (4) we have $p = K = const$, $h = Kt$, and $r = A + B\cos\left(\frac{1}{12}\pi t\right)$. Hence (4) gives the general solution

$$y(t) = e^{-Kt}\int e^{Kt}\left(A + B\cos\frac{\pi t}{12}\right)dt + ce^{-Kt}$$

$$= e^{-Kt}e^{Kt}\left[\frac{A}{K} + \frac{B}{144K^2 + \pi^2}\left(144K\cos\frac{\pi t}{12} + 12\pi\sin\frac{\pi t}{12}\right)\right] + ce^{-Kt}$$

$$= \frac{A}{K} + \frac{B}{144K^2 + \pi^2}\left(144K\cos\frac{\pi t}{12} + 12\pi\sin\frac{\pi t}{12}\right) + ce^{-Kt}.$$

The last term decreases to 0 as t increases, practically after a short time and regardless of c (that is, of the initial condition). The other part of $y(t)$ is called the **steady-state solution** because it consists of constant and periodic terms. The entire solution is called the **transient-state solution** because it models the transition from rest to the steady state. These terms are used quite generally for physical and other systems whose behavior depends on time.

Step 3. Particular solution. Setting $t = 0$ in $y(t)$ and choosing $y_0 = 0$, we have

$$y(0) = \frac{A}{K} + \frac{B}{144K^2 + \pi^2}\cdot 144K + c = 0, \qquad \text{thus} \qquad c = -\frac{A}{K} - \frac{B}{144K^2 + \pi^2}\cdot 144K.$$

Inserting this result into $y(t)$, we obtain the particular solution

$$y_{part}(t) = \frac{A}{K} + \frac{B}{144K^2 + \pi^2}\left(144K\cos\frac{\pi t}{12} + 12\pi\sin\frac{\pi t}{12}\right) - \left(\frac{A}{K} + \frac{144KB}{144K^2 + \pi^2}\right)e^{-Kt}$$

with the steady-state part as before. To plot y_{part} we must specify values for the constants, say, $A = B = 1$ and $K = 0.05$. Figure 17 shows this solution. Notice that the transition period is relatively short (although K is small), and the curve soon looks sinusoidal: this is the response to the input $A + B\cos\left(\frac{1}{12}\pi t\right) = 1 + \cos\left(\frac{1}{12}\pi t\right)$. ■

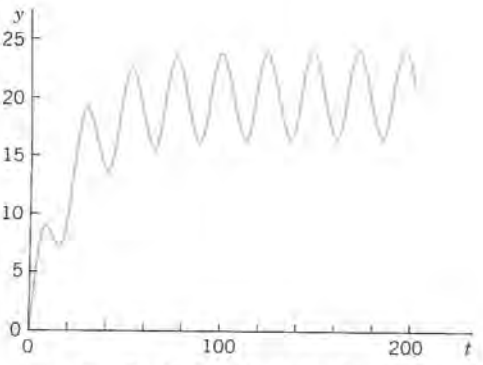

Fig. 17. Particular solution in Example 3

Reduction to Linear Form. Bernoulli Equation

Numerous applications can be modeled by ODEs that are nonlinear but can be transformed to linear ODEs. One of the most useful ones of these is the **Bernoulli equation**[5]

$$y' + p(x)y = g(x)y^a \qquad (a \text{ any real number}). \tag{6}$$

If $a = 0$ or $a = 1$, Equation (6) is linear. Otherwise it is nonlinear. Then we set

$$u(x) = [y(x)]^{1-a}.$$

We differentiate this and substitute y' from (6), obtaining

$$u' = (1 - a)y^{-a}y' = (1 - a)y^{-a}(gy^a - py).$$

Simplification gives

$$u' = (1 - a)(g - py^{1-a}),$$

where $y^{1-a} = u$ on the right, so that we get the linear ODE

$$u' + (1 - a)pu = (1 - a)g. \tag{7}$$

For further ODEs reducible to linear from, see Ince's classic [A11] listed in App. 1. See also Team Project 44 in Problem Set 1.5.

EXAMPLE 4 **Logistic Equation**

Solve the following Bernoulli equation, known as the **logistic equation** (or **Verhulst equation**[6]):

$$y' = Ay - By^2 \tag{8}$$

Solution. Write (8) in the form (6), that is,

$$y' - Ay = -By^2$$

to see that $a = 2$, so that $u = y^{1-a} = y^{-1}$. Differentiate this u and substitute y' from (8),

$$u' = -y^{-2}y' = -y^{-2}(Ay - By^2) = B - Ay^{-1}.$$

The last term is $-Ay^{-1} = -Au$. Hence we have obtained the linear ODE

---

[5]JAKOB BERNOULLI (1654–1705), Swiss mathematician, professor at Basel, also known for his contribution to elasticity theory and mathematical probability. The method for solving Bernoulli's equation was discovered by the Leibniz in 1696. Jakob Bernoulli's students included his nephew NIKLAUS BERNOULLI (1687–1759), who contributed to probability theory and infinite series, and his youngest brother JOHANN BERNOULLI (1667–1748), who had profound influence on the development of calculus, became Jakob's successor at Basel, and had among his students GABRIEL CRAMER (see Sec. 7.7) and LEONHARD EULER (see Sec. 2.5). His son DANIEL BERNOULLI (1700–1782) is known for his basic work in fluid flow and the kinetic theory of gases.

[6]PIERRE-FRANÇOIS VERHULST, Belgian statistician, who introduced Eq. (8) as a model for human population growth in 1838.

$$u' + Au = B.$$

The general solution is [by (4)]

$$u = ce^{-At} + B/A.$$

Since $u = 1/y$, this gives the general solution of (8),

$$y = \frac{1}{u} = \frac{1}{ce^{-At} + B/A} \tag{9}$$

(Fig. 18).

Directly from (8) we see that $y \equiv 0$ ($y(t) = 0$ for all t) is also a solution.

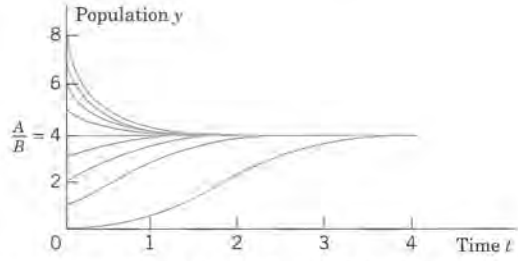

Fig. 18. Logistic population model. Curves (9) in Example 4 with $A/B = 4$

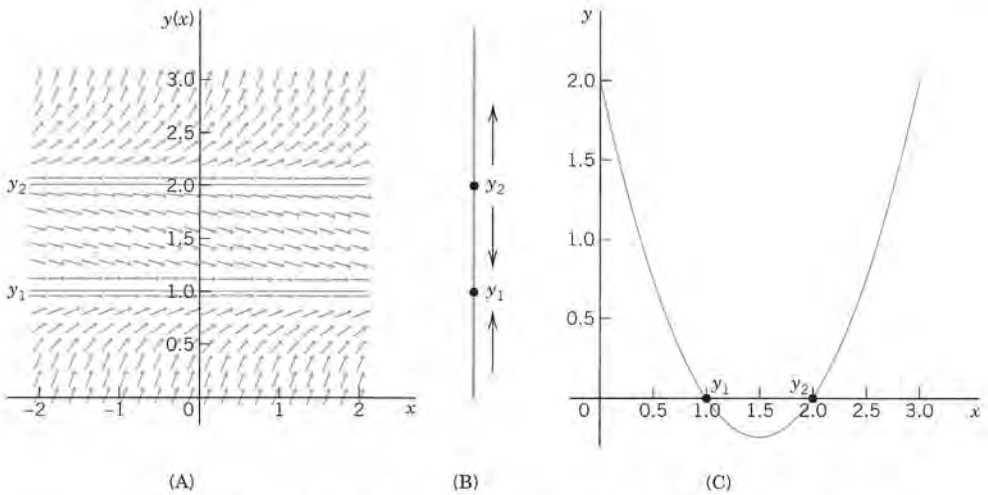
Population Dynamics

The logistic equation (8) plays an important role in **population dynamics,** a field that models the evolution of populations of plants, animals, or humans over time t. If $B = 0$, then (8) is $y' = dy/dt = Ay$. In this case its solution (9) is $y = (1/c)e^{At}$ and gives exponential growth, as for a small population in a large country (the United States in early times!). This is called ***Malthus's law.*** (See also Example 3 in Sec. 1.1.)

The term $-By^2$ in (8) is a "braking term" that prevents the population from growing without bound. Indeed, if we write $y' = Ay[1 - (B/A)y]$, we see that if $y < A/B$, then $y' > 0$, so that an initially small population keeps growing as long as $y < A/B$. But if $y > A/B$, then $y' < 0$ and the population is decreasing as long as $y > A/B$. The limit is the same in both cases, namely, A/B. See Fig. 18.

We see that in the logistic equation (8) the independent variable t does not occur explicitly. An ODE $y' = f(t, y)$ in which t does not occur explicitly is of the form



$$y' = f(y) \tag{10}$$

and is called an **autonomous ODE.** Thus the logistic equation (8) is autonomous.

Equation (10) has constant solutions, called **equilibrium solutions** or **equilibrium points.** These are determined by the zeros of $f(y)$, because $f(y) = 0$ gives $y' = 0$ by (10); hence $y = const$. These zeros are known as **critical points** of (10). An equilibrium solution is called **stable** if solutions close to it for some t remain close to it for all further t. It is called **unstable** if solutions initially close to it do not remain close to it as t increases. For instance, $y = 0$ in Fig. 18 is an unstable equilibrium solution, and $y = 4$ is a stable one.

EXAMPLE 5 Stable and Unstable Equilibrium Solutions. "Phase Line Plot"

The ODE $y' = (y - 1)(y - 2)$ has the stable equilibrium solution $y_1 = 1$ and the unstable $y_2 = 2$, as the direction field in Fig. 19 suggests. The values y_1 and y_2 are the zeros of the parabola $f(y) = (y - 1)(y - 2)$ in the figure. Now, since the ODE is autonomous, we can "condense" the direction field to a "phase line plot" giving y_1 and y_2, and the direction (upward or downward) of the arrows in the field, and thus giving information about the stability or instability of the equilibrium solutions. ■

(A) (B) (C)

Fig. 19. Example 5. (A) Direction field. (B) "Phase line". (C) Parabola $f(y)$

A few further population models will be discussed in the problem set. For some more details of population dynamics, see C. W. Clark, *Mathematical Bioeconomics,* New York, Wiley, 1976.

Further important applications of linear ODEs follow in the next section.

PROBLEM SET 1.5

1. (CAUTION!) Show that $e^{-\ln x} = 1/x$ (not $-x$) and $e^{-\ln(\sec x)} = \cos x$.
2. **(Integration constant)** Give a reason why in (4) you may choose the constant of integration in $\int p\,dx$ to be zero.

3–17 GENERAL SOLUTION. INITIAL VALUE PROBLEMS

Find the general solution. If an initial condition is given, find also the corresponding particular solution and graph or sketch it. (Show the details of your work.)

3. $y' + 3.5y = 2.8$
4. $y' = 4y + x$
5. $y' + 1.25y = 5, \quad y(0) = 6.6$
6. $x^2y' + 3xy = 1/x, \quad y(1) = -1$
7. $y' + ky = e^{2kx}$
8. $y' + 2y = 4 \cos 2x, \quad y(\frac{1}{4}\pi) = 2$
9. $y' = 6(y - 2.5) \tanh 1.5x$
10. $y' + 4x^2y = (4x^2 - x)e^{-x^2/2}$
11. $y' + 2y \sin 2x = 2e^{\cos 2x}, \quad y(0) = 0$
12. $y' \tan x = 2y - 8, \quad y(\frac{1}{2}\pi) = 0$
13. $y' + 4y \cot 2x = 6 \cos 2x, \quad y(\frac{1}{4}\pi) = 2$
14. $y' + y \tan x = e^{-0.01x} \cos x, \quad y(0) = 0$
15. $y' + y/x^2 = 2xe^{1/x}, \quad y(1) = 13.86$
16. $y' \cos^2 x + 3y = 1, \quad y(\frac{1}{4}\pi) = \frac{4}{3}$
17. $x^3y' + 3x^2y = 5 \sinh 10x$

18–24 NONLINEAR ODEs

Using a method of this section or separating variables, find the general solution. If an initial condition is given, find also the particular solution and sketch or graph it.

18. $y' + y = y^2, \quad y(0) = -1$

19. $y' = 5.7y - 6.5y^2$

20. $(x^2 + 1)y' = -\tan y, \quad y(0) = \frac{1}{2}\pi$

21. $y' + (x + 1)y = e^{x^2}y^3, \quad y(0) = 0.5$

22. $y' \sin 2y + x \cos 2y = 2x$

23. $2yy' + y^2 \sin x = \sin x, \quad y(0) = \sqrt{2}$

24. $y' + x^2y = (e^{-x^3} \sinh x)/(3y^2)$

25–36 FURTHER APPLICATIONS

25. (Investment programs) Bill opens a retirement savings account with an initial amount y_0 and then adds \$$k$ to the account at the beginning of every year until retirement at age 65. Assume that the interest is compounded continuously at the same rate R over the years. Set up a model for the balance in the account and find the general solution as well as the particular solution, letting $t = 0$ be the instant when the account is opened. How much money will Bill have in the account at age 65 if he starts at 25 and invests \$1000 initially as well as annually, and the interest rate R is 6%? How much should he invest initially and annually (same amounts) to obtain the same final balance as before if he starts at age 45? First, guess.

26. (Mixing problem) A tank (as in Fig. 9 in Sec. 1.3) contains 1000 gal of water in which 200 lb of salt is dissolved. 50 gal of brine, each gallon containing $(1 + \cos t)$ lb of dissolved salt, runs into the tank per minute. The mixture, kept uniform by stirring, runs out at the same rate. Find the amount of salt in the tank at any time t (Fig. 20).

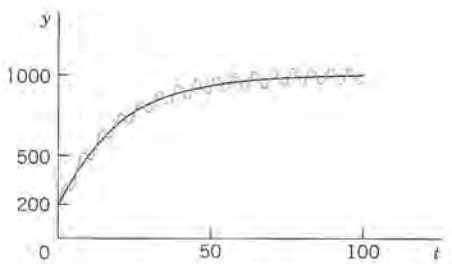


Fig. 20. Amount of salt $y(t)$ in the tank in Problem 26

27. (Lake Erie) Lake Erie has a water volume of about 450 km^3 and a flow rate (in and out) of about 175 km^3 per year. If at some instant the lake has pollution concentration $p = 0.04\%$, how long, approximately, will it take to decrease it to $p/2$, assuming that the inflow is much cleaner, say, it has pollution concentration $p/4$, and the mixture is uniform (an assumption that is only very imperfectly true)? First, guess.

28. (Heating and cooling of a building) Heating and cooling of a building can be modeled by the ODE

$$T' = k_1(T - T_a) + k_2(T - T_w) + P,$$

where $T = T(t)$ is the temperature in the building at time t, T_a the outside temperature, T_w the temperature wanted in the building, and P the rate of increase of T due to machines and people in the building, and k_1 and k_2 are (negative) constants. Solve this ODE, assuming $P = const$, $T_w = const$, and T_a varying sinusoidally over 24 hours, say, $T_a = A - C \cos(2\pi/24)t$. Discuss the effect of each term of the equation on the solution.

29. (Drug injection) Find and solve the model for drug injection into the bloodstream if, beginning at $t = 0$, a constant amount A g/min is injected and the drug is simultaneously removed at a rate proportional to the amount of the drug present at time t.

30. (Epidemics) A model for the spread of contagious diseases is obtained by assuming that the rate of spread is proportional to the number of contacts between infected and noninfected persons, who are assumed to move freely among each other. Set up the model. Find the equilibrium solutions and indicate their stability or instability. Solve the ODE. Find the limit of the proportion of infected persons as $t \to \infty$ and explain what it means.

31. (Extinction vs. unlimited growth) If in a population $y(t)$ the death rate is proportional to the population, and the birth rate is proportional to the chance encounters of meeting mates for reproduction, what will the model be? Without solving, find out what will eventually happen to a small initial population. To a large one. Then solve the model.

32. (Harvesting renewable resources. Fishing) Suppose that the population $y(t)$ of a certain kind of fish is given by the logistic equation (8), and fish are caught at a rate Hy proportional to y. Solve this so-called *Schaefer model*. Find the equilibrium solutions y_1 and y_2 (> 0) when $H < A$. The expression $Y = Hy_2$ is called the **equilibrium harvest** or **sustainable yield** *corresponding to H*. Why?

33. (Harvesting) In Prob. 32 find and graph the solution satisfying $y(0) = 2$ when (for simplicity) $A = B = 1$ and $H = 0.2$. What is the limit? What does it mean? What if there were no fishing?

34. (Intermittent harvesting) In Prob. 32 assume that you fish for 3 years, then fishing is banned for the next 3 years. Thereafter you start again. And so on. This is called *intermittent harvesting*. Describe qualitatively how the population will develop if intermitting is

continued periodically. Find and graph the solution for the first 9 years, assuming that $A = B = 1$, $H = 0.2$, and $y(0) = 2$.

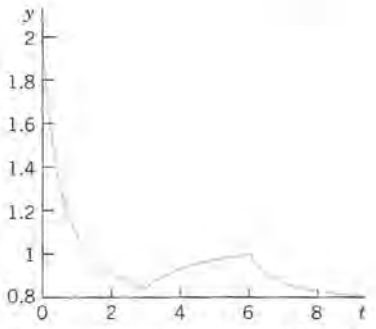

Fig. 21 Fish population in Problem 34

35. (Harvesting) If a population of mice (in multiples of 1000) follows the logistic law with $A = 1$ and $B = 0.25$, and if owls catch at a time rate of 10% of the population present, what is the model, its equilibrium harvest for that catch, and its solution?

36. (Harvesting) Do you save work in Prob. 34 if you first transform the ODE to a linear ODE? Do this transformation. Solve the resulting ODE. Does the resulting $y(t)$ agree with that in Prob. 34?

37–40 GENERAL PROPERTIES OF LINEAR ODEs

These properties are of practical and theoretical importance because they enable us to obtain new solutions from given ones. Thus in modeling, whenever possible, we prefer linear ODEs over nonlinear ones, which have no similar properties.

Show that nonhomogeneous linear ODEs (1) and homogeneous linear ODEs (2) have the following properties. Illustrate each property by a calculation for two or three equations of your choice. Give proofs.

37. The sum $y_1 + y_2$ of two solutions y_1 and y_2 of the homogeneous equation (2) is a solution of (2), and so is a scalar multiple ay_1 for any constant a. These properties are not true for (1)!

38. $y = 0$ (that is, $y(x) = 0$ for all x, also written $y(x) \equiv 0$) is a solution of (2) [not of (1) if $r(x) \neq 0$!], called the **trivial solution.**

39. The sum of a solution of (1) and a solution of (2) is a solution of (1).

40. The difference of two solutions of (1) is a solution of (2).

41. If y_1 is a solution of (1), what can you say about cy_1?

42. If y_1 and y_2 are solutions of $y_1' + py_1 = r_1$ and $y_2' + py_2 = r_2$, respectively (with the same p!), what can you say about the sum $y_1 + y_2$?

43. CAS EXPERIMENT. (a) Solve the ODE $y' - y/x = -x^{-1}\cos(1/x)$. Find an initial condition for which the arbitrary constant is zero. Graph the resulting particular solution, experimenting to obtain a good figure near $x = 0$.

(b) Generalizing (a) from $n = 1$ to arbitrary n, solve the ODE $y' - ny/x = -x^{n-2}\cos(1/x)$. Find an initial condition as in (a), and experiment with the graph.

44. TEAM PROJECT. Riccati Equation, Clairaut Equation. A **Riccati equation** is of the form

$$y' + p(x)y = g(x)y^2 + h(x). \tag{11}$$

A **Clairaut equation** is of the form

$$y = xy' + g(y'). \tag{12}$$

(a) Apply the transformation $y = Y + 1/u$ to the Riccati equation (11), where Y is a solution of (11), and obtain for u the linear ODE $u' + (2Yg - p)u = -g$. Explain the effect of the transformation by writing it as $y = Y + v$, $v = 1/u$.

(b) Show that $y = Y = x$ is a solution of $y' - (2x^3 + 1)y = -x^2y^2 - x^4 - x + 1$ and solve this Riccati equation, showing the details.

(c) Solve $y' + (3 - 2x^2\sin x)y = -y^2\sin x + 2x + 3x^2 - x^4\sin x$, using (and verifying) that $y = x^2$ is a solution.

(d) By working "backward" from the u-equation find further Riccati equations that have relatively simple solutions.

(e) Solve the Clairaut equation $y = xy' + 1/y'$. *Hint.* Differentiate this ODE with respect to x.

(f) Solve the Clairaut equation $y'^2 - xy' + y = 0$ in Prob. 16 of Problem Set 1.1.

(g) Show that the Clairaut equation (12) has as solutions a family of straight lines $y = cx + g(c)$ and a singular solution determined by $g'(s) = -x$, where $s = y'$, that forms the envelope of that family.

45. (Variation of parameter) Another method of obtaining (4) results from the following idea. Write (3) as cy^*, where y^* is the exponential function, which is a solution of the homogeneous linear ODE $y^{*\prime} + py^* = 0$. Replace the arbitrary constant c in (3) with a function u to be determined so that the resulting function $y = uy^*$ is a solution of the nonhomogeneous linear ODE $y' + py = r$.

46. TEAM PROJECT. Transformations of ODEs. We have transformed ODEs to separable form, to exact form, and to linear form. The purpose of such transformations is an extension of solution methods to larger classes of ODEs. Describe the key idea of each of these transformations and give three typical examples of your choice for each transformation, showing each step (not just the transformed ODE).

1.6 Orthogonal Trajectories. Optional

An important type of problem in physics or geometry is to find a family of curves that intersect a given family of curves at right angles. The new curves are called **orthogonal trajectories** of the given curves (and conversely). Examples are curves of equal temperature (*isotherms*) and curves of heat flow, curves of equal altitude (*contour lines*) on a map and curves of steepest descent on that map, curves of equal potential (*equipotential curves*, curves of equal voltage—the concentric circles in Fig. 22), and curves of electric force (the straight radial segments in Fig. 22).

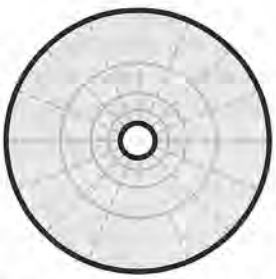

Fig. 22. Equipotential lines and curves of electric force (dashed) between two concentric (black) circles (cylinders in space)

Here the **angle of intersection** between two curves is defined to be the angle between the tangents of the curves at the intersection point. *Orthogonal* is another word for *perpendicular*.

In many cases orthogonal trajectories can be found by using ODEs, as follows. Let

$$G(x, y, c) = 0 \tag{1}$$

be a given family of curves in the xy-plane, where each curve is specified by some value of c. This is called a **one-parameter family of curves,** and c is called the *parameter* of the family. For instance, a one-parameter family of quadratic parabolas is given by (Fig. 23)

$$y = cx^2 \qquad \text{or, written as in (1),} \qquad G(x, y, c) = y - cx^2 = 0.$$

Step 1. Find an ODE for which the given family is a general solution. Of course, this ODE must no longer contain the parameter c. In our example we solve algebraically for c and then differentiate and simplify; thus,

$$\frac{y}{x^2} = c, \qquad \frac{y'x^2 - 2xy}{x^4} = 0,$$

hence

$$y' = \frac{2y}{x}.$$

The last of these equations is the ODE of the given family of curves. It is of the form

$$y' = f(x, y). \tag{2}$$

Step 2. Write down the ODE of the orthogonal trajectories, that is, the ODE whose general solution gives the orthogonal trajectories of the given curves. This ODE is

$$\tilde{y}' = -\frac{1}{f(x, \tilde{y})} \tag{3}$$

with the same f as in (2). Why? Well, a given curve passing through a point (x_0, y_0) has slope $f(x_0, y_0)$ at that point, by (2). The trajectory through (x_0, y_0) has slope $-1/f(x_0, y_0)$ by (3). The product of these slopes is -1, as we see. From calculus it is known that this is the condition for orthogonality (perpendicularity) of two straight lines (the tangents at (x_0, y_0)), hence of the curve and its orthogonal trajectory at (x_0, y_0).

Step 3. Solve (3).

For our parabolas $y = cx^2$ we have $y' = 2y/x$. Hence their orthogonal trajectories are obtained from $\tilde{y}' = -x/2\tilde{y}$ or $2\tilde{y}\tilde{y}' + x = 0$. By integration, $\tilde{y}^2 + \frac{1}{2}x^2 = c^*$. These are the ellipses in Fig. 23 with semi-axes $\sqrt{2c^*}$ and $\sqrt{c^*}$. Here, $c^* > 0$ because $c^* = 0$ gives just the origin, and $c^* < 0$ gives no real solution at all.

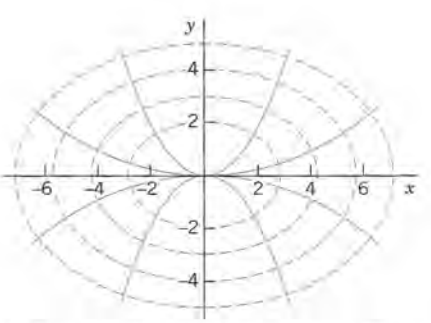

Fig. 23. Parabolas and orthogonal trajectories (ellipses) in the text

PROBLEM SET 1.6

1–12 ORTHOGONAL TRAJECTORIES

Sketch or graph some of the given curves. Guess what their orthogonal trajectories may look like. Find these trajectories.

(Show the details of your work.)

1. $y = 4x + c$
2. $y = c/x$
3. $y = cx$
4. $y^2 = 2x^2 + c$
5. $x^2y = c$
6. $y = ce^{-3x}$
7. $y = ce^{x^2/2}$
8. $x^2 - y^2 = c$
9. $4x^2 + y^2 = c$
10. $x = c\sqrt{y}$
11. $x = ce^{y/4}$
12. $x^2 + (y - c)^2 = c^2$

13–15 OTHER FORMS OF THE ODEs (2) AND (3)

13. **(y as independent variable)** Show that (3) may be written $dx/d\tilde{y} = -f(x, \tilde{y})$. Use this form to find the orthogonal trajectories of $y = 2x + ce^{-x}$.

14. (Family $g(x, y) = c$) Show that if a family is given as $g(x, y) = c$, then the orthogonal trajectories can be obtained from the following ODE, and use the latter to solve Prob. 6 written in the form $g(x, y) = c$.

$$\frac{d\tilde{y}}{dx} = \frac{\partial g/\partial \tilde{y}}{\partial g/\partial x}$$

15. (Cauchy–Riemann equations) Show that for a family $u(x, y) = c = const$ the orthogonal trajectories $v(x, y) = c^* = const$ can be obtained from the following *Cauchy–Riemann equations* (which are basic in complex analysis in Chap. 13) and use them to find the orthogonal trajectories of $e^x \sin y = const$. (Here, subscripts denote partial derivatives.)

$$u_x = v_y, \qquad u_y = -v_x$$

16–20 APPLICATIONS

16. (Fluid flow) Suppose that the *streamlines* of the flow (paths of the particles of the fluid) in Fig. 24 are $\Psi(x, y) = xy = const$. Find their orthogonal trajectories (called **equipotential lines,** for reasons given in Sec. 18.4).

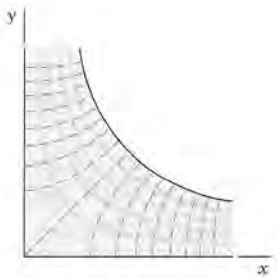

Fig. 24. Flow in a channel in Problem 16

17. (Electric field) Let the electric equipotential lines (curves of constant potential) between two concentric cylinders (Fig. 22) be given by $u(x, y) = x^2 + y^2 = c$. Use the method in the text to find their orthogonal trajectories (the curves of electric force).

18. (Electric field) The lines of electric force of two opposite charges of the same strength at $(-1, 0)$ and $(1, 0)$ are the circles through $(-1, 0)$ and $(1, 0)$. Show that these circles are given by $x^2 + (y - c)^2 = 1 + c^2$. Show that the **equipotential lines** (orthogonal trajectories of those circles) are the circles given by $(x + c^*)^2 + \tilde{y}^2 = c^{*2} - 1$ (dashed in Fig. 25).

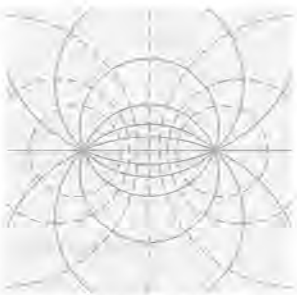

Fig. 25. Electric field in Problem 18

19. (Temperature field) Let the **isotherms** (curves of constant temperature) in a body in the upper half-plane $y > 0$ be given by $4x^2 + 9y^2 = c$. Find the orthogonal trajectories (the curves along which heat will flow in regions filled with heat-conducting material and free of heat sources or heat sinks).

20. TEAM PROJECT. Conic Sections. (A) State the main steps of the present method of obtaining orthogonal trajectories.

(B) Find conditions under which the orthogonal trajectories of families of ellipses $x^2/a^2 + y^2/b^2 = c$ are again conic sections. Illustrate your result graphically by sketches or by using your CAS. What happens if $a \to 0$? If $b \to 0$?

(C) Investigate families of hyperbolas $x^2/a^2 - y^2/b^2 = c$ in a similar fashion.

(D) Can you find more complicated curves for which you get ODEs that you can solve? Give it a try.

1.7 Existence and Uniqueness of Solutions

The initial value problem

$$|y'| + |y| = 0, \qquad y(0) = 1$$

has no solution because $y = 0$ (that is, $y(x) = 0$ for all x) is the only solution of the ODE. The initial value problem

$$y' = 2x, \qquad y(0) = 1$$

has precisely one solution, namely, $y = x^2 + 1$. The initial value problem

$$xy' = y - 1, \qquad y(0) = 1$$

has infinitely many solutions, namely, $y = 1 + cx$, where c is an arbitrary constant because $y(0) = 1$ for all c.

From these examples we see that an **initial value problem**

$$\textbf{(1)} \qquad y' = f(x, y), \qquad y(x_0) = y_0$$

may have no solution, precisely one solution, or more than one solution. This fact leads to the following two fundamental questions.

Problem of Existence

Under what conditions does an initial value problem of the form (1) *have at least one solution (hence one or several solutions)?*

Problem of Uniqueness

Under what conditions does that problem have at most one solution (hence excluding the case that is has more than one solution)?

Theorems that state such conditions are called **existence theorems** and **uniqueness theorems,** respectively.

Of course, for our simple examples we need no theorems because we can solve these examples by inspection; however, for complicated ODEs such theorems may be of considerable practical importance. Even when you are sure that your physical or other system behaves uniquely, occasionally your model may be oversimplified and may not give a faithful picture of the reality.

THEOREM 1

Existence Theorem

Let the right side $f(x, y)$ of the ODE in the initial value problem

$$\textbf{(1)} \qquad y' = f(x, y), \qquad y(x_0) = y_0$$

be continuous at all points (x, y) in some rectangle

$$R\text{: } |x - x_0| < a, \qquad |y - y_0| < b \qquad \text{(Fig. 26)}$$

and **bounded** *in R; that is, there is a number K such that*

$$\textbf{(2)} \qquad |f(x, y)| \leqq K \qquad \textit{for all } (x, y) \textit{ in } R.$$

Then the initial value problem (1) *has at least one solution $y(x)$. This solution exists at least for all x in the subinterval $|x - x_0| < \alpha$ of the interval $|x - x_0| < a$; here, α is the smaller of the two numbers a and b/K.*

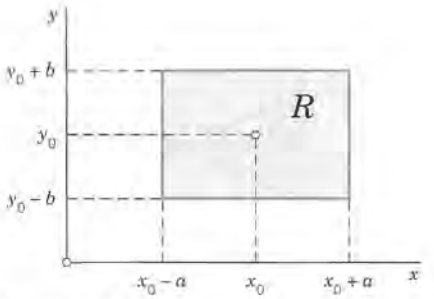

Fig. 26. Rectangle R in the existence and uniqueness theorems

(*Example of Boundedness.* The function $f(x, y) = x^2 + y^2$ is bounded (with $K = 2$) in the square $|x| < 1$, $|y| < 1$. The function $f(x, y) = \tan(x + y)$ is not bounded for $|x + y| < \pi/2$. Explain!)

THEOREM 2

Uniqueness Theorem

Let f and its partial derivative $f_y = \partial f/\partial y$ be continuous for all (x, y) in the rectangle R (Fig. 26) *and bounded, say,*

(3) (a) $|f(x, y)| \leqq K$, (b) $|f_y(x, y)| \leqq M$ *for all (x, y) in R.*

Then the initial value problem (1) *has at most one solution $y(x)$. Thus, by Theorem* 1, *the problem has precisely one solution. This solution exists at least for all x in that subinterval $|x - x_0| < \alpha$.*

Understanding These Theorems

These two theorems take care of almost all practical cases. Theorem 1 says that if $f(x, y)$ is continuous in some region in the xy-plane containing the point (x_0, y_0), then the initial value problem (1) has at least one solution.

Theorem 2 says that if, moreover, the partial derivative $\partial f/\partial y$ of f with respect to y exists and is continuous in that region, then (1) can have at most one solution; hence, by Theorem 1, it has precisely one solution.

Read again what you have just read—these are entirely new ideas in our discussion.

Proofs of these theorems are beyond the level of this book (see Ref. [A11] in App. 1); however, the following remarks and examples may help you to a good understanding of the theorems.

Since $y' = f(x, y)$, the condition (2) implies that $|y'| \leqq K$; that is, the slope of any solution curve $y(x)$ in R is at least $-K$ and at most K. Hence a solution curve that passes through the point (x_0, y_0) must lie in the colored region in Fig. 27 on the next page bounded by the lines l_1 and l_2 whose slopes are $-K$ and K, respectively. Depending on the form of R, two different cases may arise. In the first case, shown in Fig. 27a, we have $b/K \geqq a$ and therefore $\alpha = a$ in the existence theorem, which then asserts that the solution exists for all x between $x_0 - a$ and $x_0 + a$. In the second case, shown in Fig. 27b, we have $b/K < a$. Therefore, $\alpha = b/K < a$, and all we can conclude from the theorems is that the solution exists for all x between $x_0 - b/K$ and $x_0 + b/K$. For larger or smaller x's the solution curve may leave the rectangle R, and since nothing is assumed about f outside R, nothing can be concluded about the solution for those larger or smaller x's; that is, for such x's the solution may or may not exist—we don't know.

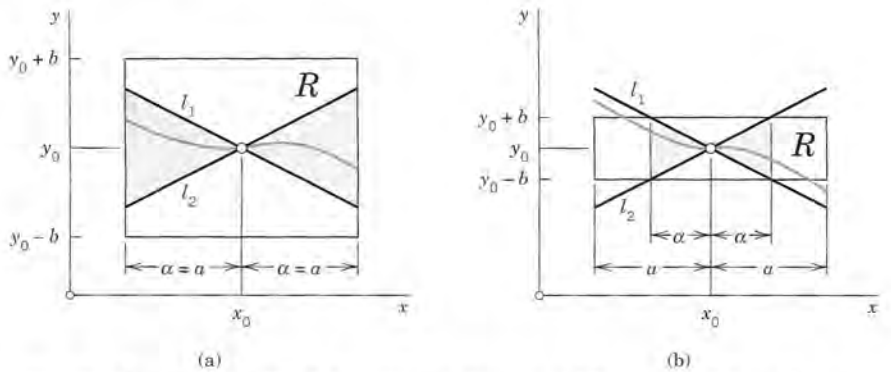

Fig. 27. The condition (2) of the existence theorem. (a) First case. (b) Second case

Let us illustrate our discussion with a simple example. We shall see that our choice of a rectangle R with a large base (a long x-interval) will lead to the case in Fig. 27b.

EXAMPLE 1 **Choice of a Rectangle**

Consider the initial value problem

$$y' = 1 + y^2, \qquad y(0) = 0$$

and take the rectangle R: $|x| < 5$, $|y| < 3$. Then $a = 5$, $b = 3$, and

$$|f(x, y)| = |1 + y^2| \leqq K = 10,$$

$$\left|\frac{\partial f}{\partial y}\right| = 2|y| \leqq M = 6,$$

$$\alpha = \frac{b}{K} = 0.3 < a.$$

Indeed, the solution of the problem is $y = \tan x$ (see Sec. 1.3, Example 1). This solution is discontinuous at $\pm\pi/2$, and there is no *continuous* solution valid in the entire interval $|x| < 5$ from which we started. ■

The conditions in the two theorems are sufficient conditions rather than necessary ones, and can be lessened. In particular, by the mean value theorem of differential calculus we have

$$f(x, y_2) - f(x, y_1) = (y_2 - y_1)\left.\frac{\partial f}{\partial y}\right|_{y=\tilde{y}}$$

where (x, y_1) and (x, y_2) are assumed to be in R, and $\tilde{y}$ is a suitable value between y_1 and y_2. From this and (3b) it follows that

$$|f(x, y_2) - f(x, y_1)| \leqq M|y_2 - y_1|. \tag{4}$$

It can be shown that (3b) may be replaced by the weaker condition (4), which is known as a **Lipschitz condition.**[7] However, continuity of $f(x, y)$ is not enough to guarantee the *uniqueness* of the solution. This may be illustrated by the following example.

EXAMPLE 2 Nonuniqueness

The initial value problem

$$y' = \sqrt{|y|}, \qquad y(0) = 0$$

has the two solutions

$$y = 0 \qquad \text{and} \qquad y^* = \begin{cases} x^2/4 & \text{if } x \geqq 0 \\ -x^2/4 & \text{if } x < 0 \end{cases}$$

although $f(x, y) = \sqrt{|y|}$ is continuous for all y. The Lipschitz condition (4) is violated in any region that includes the line $y = 0$, because for $y_1 = 0$ and positive y_2 we have

$$\frac{|f(x, y_2) - f(x, y_1)|}{|y_2 - y_1|} = \frac{\sqrt{y_2}}{y_2} = \frac{1}{\sqrt{y_2}}, \qquad (\sqrt{y_2} > 0) \tag{5}$$

and this can be made as large as we please by choosing y_2 sufficiently small, whereas (4) requires that the quotient on the left side of (5) should not exceed a fixed constant M. ■

PROBLEM SET 1.7

1. **(Vertical strip)** If the assumptions of Theorems 1 and 2 are satisfied not merely in a rectangle but in a vertical infinite strip $|x - x_0| < a$, in what interval will the solution of (1) exist?
2. **(Existence?)** Does the initial value problem $(x - 1)y' = 2y$, $y(1) = 1$ have a solution? Does your result contradict our present theorems?
3. **(Common points)** Can two solution curves of the same ODE have a common point in a rectangle in which the assumptions of the present theorems are satisfied?
4. **(Change of initial condition)** What happens in Prob. 2 if you replace $y(1) = 1$ with $y(1) = k$?
5. **(Linear ODE)** If p and r in $y' + p(x)y = r(x)$ are continuous for all x in an interval $|x - x_0| \leqq a$, show that $f(x, y)$ in this ODE satisfies the conditions of our present theorems, so that a corresponding initial value problem has a unique solution. Do you actually need these theorems for this ODE?
6. **(Three possible cases)** Find all initial conditions such that $(x^2 - 4x)y' = (2x - 4)y$ has no solution, precisely one solution, and more than one solution.
7. **(Length of x-interval)** In most cases the solution of an initial value problem (1) exists in an x-interval larger than that guaranteed by the present theorems. Show this fact for $y' = 2y^2$, $y(1) = 1$ by finding the best possible α (choosing b optimally) and comparing the result with the actual solution.
8. **PROJECT. Lipschitz Condition. (A)** State the definition of a Lipschitz condition. Explain its relation to the existence of a partial derivative. Explain its significance in our present context. Illustrate your statements by examples of your own.

   (B) Show that for a ***linear*** ODE $y' + p(x)y = r(x)$ with continuous p and r in $|x - x_0| \leqq a$ a Lipschitz condition holds. This is remarkable because it means that for a *linear* ODE the continuity of $f(x, y)$ guarantees not only the existence but also the uniqueness of the solution of an initial value problem. (Of course, this also follows directly from (4) in Sec. 1.5.)

   (C) Discuss the uniqueness of solution for a few simple ODEs that you can solve by one of the methods considered, and find whether a Lipschitz condition is satisfied.
9. **(Maximum α)** What is the largest possible α in Example 1 in the text?
10. **CAS PROJECT. Picard Iteration. (A)** Show that by integrating the ODE in (1) and observing the initial condition you obtain

$$y(x) = y_0 + \int_{x_0}^{x} f(t, y(t))\, dt. \tag{6}$$

[7]RUDOLF LIPSCHITZ (1832–1903), German mathematician. Lipschitz and similar conditions are important in modern theories, for instance, in partial differential equations.

This form (6) of (1) suggests **Picard's iteration method**[8], which is defined by

$$(7)\quad y_n(x) = y_0 + \int_{x_0}^{x} f(t, y_{n-1}(t))\, dt, \quad n = 1, 2, \cdots.$$

It gives approximations $y_1, y_2, y_3, \cdots$ of the unknown solution y of (1). Indeed, you obtain y_1 by substituting $y = y_0$ on the right and integrating—this is the first step—, then y_2 by substituting $y = y_1$ on the right and integrating—this is the second step—, and so on. Write a program of the iteration that gives a printout of the first approximations $y_0, y_1, \cdots, y_N$ as well as their graphs on common axes. Try your program on two initial value problems of your own choice.

(B) Apply the iteration to $y' = x + y$, $y(0) = 0$. Also solve the problem exactly.

(C) Apply the iteration to $y' = 2y^2$, $y(0) = 1$. Also solve the problem exactly.

(D) Find all solutions of $y' = 2\sqrt{y}$, $y(1) = 0$. Which of them does Picard's iteration approximate?

(E) Experiment with the conjecture that Picard's iteration converges to the solution of the problem for any initial choice of y in the integrand in (7) (leaving y_0 outside the integral as it is). Begin with a simple ODE and see what happens. When you are reasonably sure, take a slightly more complicated ODE and give it a try.

CHAPTER 1 REVIEW QUESTIONS AND PROBLEMS

1. Explain the terms *ordinary differential equation (ODE)*, *partial differential equation (PDE)*, *order*, *general solution*, and *particular solution*. Give examples. Why are these concepts of importance?
2. What is an initial condition? How is this condition used in an initial value problem?
3. What is a homogeneous linear ODE? A nonhomogeneous linear ODE? Why are these equations simpler than nonlinear ODEs?
4. What do you know about direction fields and their practical importance?
5. Give examples of mechanical problems that lead to ODEs.
6. Why do electric circuits lead to ODEs?
7. Make a list of the solution methods considered. Explain each method with a few short sentences and illustrate it by a typical example.
8. Can certain ODEs be solved by more than one method? Give three examples.
9. What are integrating factors? Explain the idea. Give examples.
10. Does every first-order ODE have a solution? A general solution? What do you know about uniqueness of solutions?

11–14 DIRECTION FIELDS

Graph a direction field (by a CAS or by hand) and sketch some of the solution curves. Solve the ODE exactly and compare.

11. $y' = 1 + 4y^2$ **12.** $y' = 3y - 2x$

13. $y' = 4y - y^2$ **14.** $y' = 16x/y$

15–26 GENERAL SOLUTION

Find the general solution. Indicate which method in this chapter you are using. Show the details of your work.

15. $y' = x^2(1 + y^2)$

16. $y' = x(y - x^2 + 1)$

17. $yy' + xy^2 = x$

18. $-\pi \sin \pi x \cosh 3y\, dx + 3 \cos \pi x \sinh 3y\, dy = 0$

19. $y' + y \sin x = \sin x$ **20.** $y' - y = 1/y$

21. $3 \sin 2y\, dx + 2x \cos 2y\, dy = 0$

22. $xy' = x \tan (y/x) + y$

23. $(y \cos xy - 2x)\, dx + (x \cos xy + 2y)\, dy = 0$

24. $xy' = (y - 2x)^2 + y$ (Set $y - 2x = z$.)

25. $\sin (y - x)\, dx + [\cos (y - x) - \sin (y - x)]\, dy = 0$

26. $xy' = (y/x)^3 + y$

27–32 INITIAL VALUE PROBLEMS

Solve the following initial value problems. Indicate the method used. Show the details of your work.

27. $yy' + x = 0$, $y(3) = 4$

28. $y' - 3y = -12y^2$, $y(0) = 2$

29. $y' = 1 + y^2$, $y(\frac{1}{4}\pi) = 0$

30. $y' + \pi y = 2b \cos \pi x$, $y(0) = 0$

31. $(2xy^2 - \sin x)\, dx + (2 + 2x^2 y)\, dy = 0$, $y(0) = 1$

32. $[2y + y^2/x + e^x(1 + 1/x)]\, dx + (x + 2y)\, dy = 0$, $y(1) = 1$

[8] EMILE PICARD (1856–1941), French mathematician, also known for his important contributions to complex analysis (see Sec. 16.2 for his famous theorem). Picard used his method to prove Theorems 1 and 2 as well as the convergence of the sequence (7) to the solution of (1). In precomputer times the iteration was of little *practical* value because of the integrations.

33–43 APPLICATIONS, MODELING

33. (Heat flow) If the isotherms in a region are $x^2 - y^2 = c$, what are the curves of heat flow (assuming orthogonality)?

34. (Law of cooling) A thermometer showing 10°C is brought into a room whose temperature is 25°C. After 5 minutes it shows 20°C. When will the thermometer practically reach the room temperature, say, 24.9°C?

35. (Half-life) If 10% of a radioactive substance disintegrates in 4 days, what is its half-life?

36. (Half-life) What is the half-life of a substance if after 5 days, 0.020 g is present and after 10 days, 0.015 g?

37. (Half-life) When will 99% of the substance in Prob. 35 have disintegrated?

38. (Air circulation) In a room containing 20 000 ft^3 of air, 600 ft^3 of fresh air flows in per minute, and the mixture (made practically uniform by circulating fans) is exhausted at a rate of 600 cubic feet per minute (cfm). What is the amount of fresh air $y(t)$ at any time if $y(0) = 0$? After what time will 90% of the air be fresh?

39. (Electric field) If the equipotential lines in a region of the xy-plane are $4x^2 + y^2 = c$, what are the curves of the electrical force? Sketch both families of curves.

40. (Chemistry) In a bimolecular reaction $A + B \rightarrow M$, a moles per liter of a substance A and b moles per liter of a substance B are combined. Under constant temperature the rate of reaction is

$$y' = k(a - y)(b - y) \qquad \textbf{(Law of mass action);}$$

that is, y' is proportional to the product of the concentrations of the substances that are reacting, where $y(t)$ is the number of moles per liter which have reacted after time t. Solve this ODE, assuming that $a \neq b$.

41. (Population) Find the population $y(t)$ if the birth rate is proportional to $y(t)$ and the death rate is proportional to the square of $y(t)$.

42. (Curves) Find all curves in the first quadrant of the xy-plane such that for every tangent, the segment between the coordinate axes is bisected by the point of tangency. (Make a sketch.)

43. (Optics) Lambert's law of absorption[9] states that the absorption of light in a thin transparent layer is proportional to the thickness of the layer and to the amount of light incident on that layer. Formulate this law as an ODE and solve it.

SUMMARY OF CHAPTER 1
First-Order ODEs

This chapter concerns **ordinary differential equations (ODEs) of first order** and their applications. These are equations of the form

(1) $\qquad F(x, y, y') = 0 \qquad$ or in explicit form $\qquad y' = f(x, y)$

involving the derivative $y' = dy/dx$ of an unknown function y, given functions of x, and, perhaps, y itself. If the independent variable x is time, we denote it by t.

In Sec. 1.1 we explained the basic concepts and the process of **modeling,** that is, of expressing a physical or other problem in some mathematical form and solving it. Then we discussed the method of direction fields (Sec. 1.2), solution methods and models (Secs. 1.3–1.6), and, finally, ideas on existence and uniqueness of solutions (Sec. 1.7).

[9]JOHANN HEINRICH LAMBERT (1728–1777). German physicist and mathematician.

A first-order ODE usually has a **general solution,** that is, a solution involving an arbitrary constant, which we denote by c. In applications we usually have to find a unique solution by determining a value of c from an **initial condition** $y(x_0) = y_0$. Together with the ODE this is called an **initial value problem**

$$y' = f(x, y), \qquad y(x_0,) = y_0 \quad (x_0, y_0 \text{ given numbers}) \tag{2}$$

and its solution is a **particular solution** of the ODE. Geometrically, a general solution represents a family of curves, which can be graphed by using **direction fields** (Sec. 1.2). And each particular solution corresponds to one of these curves.

A **separable ODE** is one that we can put into the form

$$g(y)\,dy = f(x)\,dx \tag{3}$$ (Sec. 1.3)

by algebraic manipulations (possibly combined with transformations, such as $y/x = u$) and solve by integrating on both sides.

An **exact ODE** is of the form

$$M(x, y)\,dx + N(x, y)\,dy = 0 \tag{4}$$ (Sec. 1.4)

where $M\,dx + N\,dy$ is the **differential**

$$du = u_x\,dx + u_y\,dy$$

of a function $u(x, y)$, so that from $du = 0$ we immediately get the implicit general solution $u(x, y) = c$. This method extends to nonexact ODEs that can be made exact by multiplying them by some function $F(x, y)$, called an **integrating factor** (Sec. 1.4).

Linear ODEs

$$y' + p(x)y = r(x) \tag{5}$$

are very important. Their solutions are given by the integral formula (4), Sec. 1.5. Certain nonlinear ODEs can be transformed to linear form in terms of new variables. This holds for the **Bernoulli equation**

$$y' + p(x)y = g(x)y^a$$ (Sec. 1.5).

Applications and **modeling** are discussed throughout the chapter, in particular in Secs. 1.1, 1.3, 1.5 (**population dynamics,** etc.), and 1.6 (**trajectories**).

Picard's **existence** and **uniqueness theorems** are explained in Sec. 1.7 (and *Picard's iteration* in Problem Set 1.7).

Numeric methods for first-order ODEs can be studied in Secs. 21.1 and 21.2 immediately after this chapter, as indicated in the chapter opening.

CHAPTER 2

Second-Order Linear ODEs

Ordinary differential equations (ODEs) may be divided into two large classes, **linear ODEs** and **nonlinear ODEs.** Whereas nonlinear ODEs of second (and higher) order generally are difficult to solve, linear ODEs are much simpler because various properties of their solutions can be characterized in a general way, and there are standard methods for solving many of these equations.

Linear ODEs ***of the second order*** are the most important ones because of their applications in mechanical and electrical engineering (Secs. 2.4, 2.8, 2.9). And their theory is typical of that of all linear ODEs, but the formulas are simpler than for higher order equations. Also the transition to higher order (in Chap. 3) will be almost immediate.

This chapter includes the derivation of general and particular solutions, the latter in connection with initial value problems.

(Boundary value problems follow in Chap. 5, which also contains solution methods for Legendre's, Bessel's, and the hypergeometric equations.)

COMMENT. ***Numerics for second-order ODEs can be studied immediately after this chapter.*** See Sec. 21.3, which is independent of other sections in Chaps. 19–21.

Prerequisite: Chap. 1, in particular, Sec. 1.5.
Sections that may be omitted in a shorter course: 2.3, 2.9, 2.10.
References and Answers to Problems: App. 1 Part A, and App. 2.

2.1 Homogeneous Linear ODEs of Second Order

We have already considered first-order linear ODEs (Sec. 1.5) and shall now define and discuss linear ODEs of second order. These equations have important engineering applications, especially in connection with mechanical and electrical vibrations (Secs. 2.4, 2.8, 2.9) as well as in wave motion, heat conduction, and other parts of physics, as we shall see in Chap. 12.

A second-order ODE is called **linear** if it can be written

$$y'' + p(x)y' + q(x)y = r(x) \tag{1}$$

and **nonlinear** if it cannot be written in this form.

The distinctive feature of this equation is that it is *linear in y and its derivatives,* whereas the functions p, q, and r on the right may be any given functions of x. If the equation begins with, say, $f(x)y''$, then divide by $f(x)$ to have the **standard form** (1) with y'' as the first term, which is practical.

If $r(x) \equiv 0$ (that is, $r(x) = 0$ for all x considered; read "$r(x)$ is identically zero"), then (1) reduces to

$$y'' + p(x)y' + q(x)y = 0 \tag{2}$$

and is called **homogeneous.** If $r(x) \not\equiv 0$, then (1) is called **nonhomogeneous.** This is similar to Sec. 1.5.

For instance, a nonhomogeneous linear ODE is

$$y'' + 25y = e^{-x} \cos x,$$

and a homogeneous linear ODE is

$$xy'' + y' + xy = 0, \qquad \text{in standard form} \qquad y'' + \frac{1}{x}\, y' + y = 0.$$

An example of a nonlinear ODE is

$$y''y + y'^2 = 0.$$

The functions p and q in (1) and (2) are called the **coefficients** of the ODEs.

Solutions are defined similarly as for first-order ODEs in Chap. 1. A function

$$y = h(x)$$

is called a *solution* of a (linear or nonlinear) second-order ODE on some open interval I if h is defined and twice differentiable throughout that interval and is such that the ODE becomes an identity if we replace the unknown y by h, the derivative y' by h', and the second derivative y'' by h''. Examples are given below.

Homogeneous Linear ODEs: Superposition Principle

Sections 2.1–2.6 will be devoted to **homogeneous** linear ODEs (2) and the remaining sections of the chapter to nonhomogeneous linear ODEs.

Linear ODEs have a rich solution structure. For the homogeneous equation the backbone of this structure is the *superposition principle* or *linearity principle,* which says that we can obtain further solutions from given ones by adding them or by multiplying them with any constants. Of course, this is a great advantage of homogeneous linear ODEs. Let us first discuss an example.

EXAMPLE 1 Homogeneous Linear ODEs: Superposition of Solutions

The functions $y = \cos x$ and $y = \sin x$ are solutions of the homogeneous linear ODE

$$y'' + y = 0$$

for all x. We verify this by differentiation and substitution. We obtain $(\cos x)'' = -\cos x$; hence

$$y'' + y = (\cos x)'' + \cos x = -\cos x + \cos x = 0.$$

Similarly for $y = \sin x$ (verify!). We can go an important step further. We multiply $\cos x$ by any constant, for instance, 4.7, and $\sin x$ by, say, -2, and take the sum of the results, claiming that it is a solution. Indeed, differentiation and substitution gives

$$(4.7 \cos x - 2 \sin x)'' + (4.7 \cos x - 2 \sin x) = -4.7 \cos x + 2 \sin x + 4.7 \cos x - 2 \sin x = 0. \quad \blacksquare$$

In this example we have obtained from y_1 (= cos x) and y_2 (= sin x) a function of the form

$$y = c_1y_1 + c_2y_2 \qquad (c_1, c_2 \text{ arbitrary constants}). \tag{3}$$

This is called a **linear combination** of y_1 and y_2. In terms of this concept we can now formulate the result suggested by our example, often called the **superposition principle** or **linearity principle.**

THEOREM 1

Fundamental Theorem for the Homogeneous Linear ODE (2)

For a homogeneous linear ODE (2), *any linear combination of two solutions on an open interval I is again a solution of* (2) *on I. In particular, for such an equation, sums and constant multiples of solutions are again solutions.*

PROOF Let y_1 and y_2 be solutions of (2) on I. Then by substituting $y = c_1y_1 + c_2y_2$ and its derivatives into (2), and using the familiar rule $(c_1y_1 + c_2y_2)' = c_1y_1' + c_2y_2'$, etc., we get

$$\begin{aligned} y'' + py' + qy &= (c_1y_1 + c_2y_2)'' + p(c_1y_1 + c_2y_2)' + q(c_1y_1 + c_2y_2) \\ &= c_1y_1'' + c_2y_2'' + p(c_1y_1' + c_2y_2') + q(c_1y_1 + c_2y_2) \\ &= c_1(y_1'' + py_1' + qy_1) + c_2(y_2'' + py_2' + qy_2) = 0, \end{aligned}$$

since in the last line, $(\cdots) = 0$ because y_1 and y_2 are solutions, by assumption. This shows that y is a solution of (2) on I. ■

CAUTION! Don't forget that this highly important theorem holds for *homogeneous linear* ODEs only but ***does not hold*** for nonhomogeneous linear or nonlinear ODEs, as the following two examples illustrate.

EXAMPLE 2 **A Nonhomogeneous Linear ODE**

Verify by substitution that the functions $y = 1 + \cos x$ and $y = 1 + \sin x$ are solutions of the nonhomogeneous linear ODE

$$y'' + y = 1,$$

but their sum is not a solution. Neither is, for instance, $2(1 + \cos x)$ or $5(1 + \sin x)$. ■

EXAMPLE 3 **A Nonlinear ODE**

Verify by substitution that the functions $y = x^2$ and $y = 1$ are solutions of the nonlinear ODE

$$y''y - xy' = 0,$$

but their sum is not a solution. Neither is $-x^2$, so you cannot even multiply by -1! ■

Initial Value Problem. Basis. General Solution

Recall from Chap. 1 that for a first-order ODE, an *initial value problem* consists of the ODE and one *initial condition* $y(x_0) = y_0$. The initial condition is used to determine the *arbitrary constant* c in the *general solution* of the ODE. This results in a unique solution, as we need it in most applications. That solution is called a *particular solution* of the ODE. These ideas extend to second-order equations as follows.

For a second-order homogeneous linear ODE (2) an **initial value problem** consists of (2) and two **initial conditions**

$$\textbf{(4)} \qquad y(x_0) = K_0, \qquad y'(x_0) = K_1.$$

These conditions prescribe given values K_0 and K_1 of the solution and its first derivative (the slope of its curve) at the same given $x = x_0$ in the open interval considered.

The conditions (4) are used to determine the two arbitrary constants c_1 and c_2 in a **general solution**

$$\textbf{(5)} \qquad y = c_1 y_1 + c_2 y_2$$

of the ODE; here, y_1 and y_2 are suitable solutions of the ODE, with "suitable" to be explained after the next example. This results in a unique solution, passing through the point (x_0, K_0) with K_1 as the tangent direction (the slope) at that point. That solution is called a **particular solution** of the ODE (2).

EXAMPLE 4 **Initial Value Problem**

Solve the initial value problem

$$y'' + y = 0, \qquad y(0) = 3.0, \qquad y'(0) = -0.5.$$

Solution. ***Step 1. General solution.*** The functions $\cos x$ and $\sin x$ are solutions of the ODE (by Example 1), and we take

$$y = c_1 \cos x + c_2 \sin x.$$

This will turn out to be a general solution as defined below.

Step 2. Particular solution. We need the derivative $y' = -c_1 \sin x + c_2 \cos x$. From this and the initial values we obtain, since $\cos 0 = 1$ and $\sin 0 = 0$,

$$y(0) = c_1 = 3.0 \qquad \text{and} \qquad y'(0) = c_2 = -0.5.$$

This gives as the solution of our initial value problem the particular solution

$$y = 3.0 \cos x - 0.5 \sin x.$$

Figure 28 shows that at $x = 0$ it has the value 3.0 and the slope -0.5, so that its tangent intersects the x-axis at $x = 3.0/0.5 = 6.0$. (The scales on the axes differ!) ■

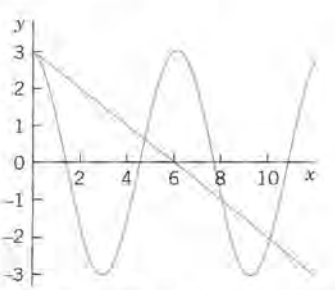

Fig. 28. Particular solution and initial tangent in Example 4

Observation. Our choice of y_1 and y_2 was general enough to satisfy both initial conditions. Now let us take instead two proportional solutions $y_1 = \cos x$ and

$y_2 = k \cos x$, so that $y_1/y_2 = 1/k = const$. Then we can write $y = c_1y_1 + c_2y_2$ in the form

$$y = c_1 \cos x + c_2(k \cos x) = C \cos x \qquad \text{where} \qquad C = c_1 + c_2k.$$

Hence we are no longer able to satisfy two initial conditions with only one arbitrary constant C. Consequently, in defining the concept of a general solution, we must exclude proportionality. And we see at the same time why the concept of a general solution is of importance in connection with initial value problems.

DEFINITION

General Solution, Basis, Particular Solution

A **general solution** of an ODE (2) on an open interval I is a solution (5) in which y_1 and y_2 are solutions of (2) on I that are not proportional, and c_1 and c_2 are arbitrary constants. These y_1, y_2 are called a **basis** (or a **fundamental system**) of solutions of (2) on I.

A **particular solution** of (2) on I is obtained if we assign specific values to c_1 and c_2 in (5).

For the definition of an *interval* see Sec. 1.1. Also, c_1 and c_2 must sometimes be restricted to some interval in order to avoid complex expressions in the solution. Furthermore, as usual, y_1 and y_2 are called *proportional* on I if for all x on I,

$$(6) \qquad (a) \quad y_1 = ky_2 \qquad \text{or} \qquad (b) \quad y_2 = ly_1$$

where k and l are numbers, zero or not. (Note that (a) implies (b) if and only if $k \neq 0$).

Actually, we can reformulate our definition of a basis by using a concept of general importance. Namely, two functions y_1 and y_2 are called **linearly independent** on an interval I where they are defined if

$$(7) \qquad k_1y_1(x) + k_2y_2(x) = 0 \qquad \text{everywhere on } I \text{ implies} \qquad k_1 = 0 \text{ and } k_2 = 0.$$

And y_1 and y_2 are called **linearly dependent** on I if (7) also holds for some constants k_1, k_2 not both zero. Then if $k_1 \neq 0$ or $k_2 \neq 0$, we can divide and see that y_1 and y_2 are proportional,

$$y_1 = -\frac{k_2}{k_1} y_2 \qquad \text{or} \qquad y_2 = -\frac{k_1}{k_2} y_1.$$

In contrast, in the case of linear *independence* these functions are not proportional because then we cannot divide in (7). This gives the following

DEFINITION

Basis (Reformulated)

A **basis** of solutions of (2) on an open interval I is a pair of linearly independent solutions of (2) on I.

If the coefficients p and q of (2) are continuous on some open interval I, then (2) has a general solution. It yields the unique solution of any initial value problem (2), (4). It

includes all solutions of (2) on I; hence (2) has no *singular solutions* (solutions not obtainable from of a general solution; see also Problem Set 1.1). All this will be shown in Sec. 2.6.

EXAMPLE 5 **Basis, General Solution, Particular Solution**

$\cos x$ and $\sin x$ in Example 4 form a basis of solutions of the ODE $y'' + y = 0$ for all x because their quotient is $\cot x \neq const$ (or $\tan x \neq const$). Hence $y = c_1 \cos x + c_2 \sin x$ is a general solution. The solution $y = 3.0 \cos x - 0.5 \sin x$ of the initial value problem is a particular solution. ■

EXAMPLE 6 **Basis, General Solution, Particular Solution**

Verify by substitution that $y_1 = e^x$ and $y_2 = e^{-x}$ are solutions of the ODE $y'' - y = 0$. Then solve the initial value problem

$$y'' - y = 0, \qquad y(0) = 6, \qquad y'(0) = -2.$$

Solution. $(e^x)'' - e^x = 0$ and $(e^{-x})'' - e^{-x} = 0$ shows that e^x and e^{-x} are solutions. They are not proportional, $e^x/e^{-x} = e^{2x} \neq const$. Hence e^x, e^{-x} form a basis for all x. We now write down the corresponding general solution and its derivative and equate their values at 0 to the given initial conditions.

$$y = c_1e^x + c_2e^{-x}, \qquad y' = c_1e^x - c_2e^{-x}, \qquad y(0) = c_1 + c_2 = 6, \qquad y'(0) = c_1 - c_2 = -2.$$

By addition and subtraction, $c_1 = 2$, $c_2 = 4$, so that the *answer* is $y = 2e^x + 4e^{-x}$. This is the particular solution satisfying the two initial conditions. ■

Find a Basis if One Solution Is Known. Reduction of Order

It happens quite often that one solution can be found by inspection or in some other way. Then a second linearly independent solution can be obtained by solving a first-order ODE. This is called the method of **reduction of order.**[1] We first show this method for an example and then in general.

EXAMPLE 7 **Reduction of Order if a Solution Is Known. Basis**

Find a basis of solutions of the ODE

$$(x^2 - x)y'' - xy' + y = 0.$$

Solution. Inspection shows that $y_1 = x$ is a solution because $y_1' = 1$ and $y_1'' = 0$, so that the first term vanishes identically and the second and third terms cancel. The idea of the method is to substitute

$$y = uy_1 = ux, \qquad y' = u'x + u, \qquad y'' = u''x + 2u'$$

into the ODE. This gives

$$(x^2 - x)(u''x + 2u') - x(u'x + u) + ux = 0.$$

ux and $-xu$ cancel and we are left with the following ODE, which we divide by x, order, and simplify,

$$(x^2 - x)(u''x + 2u') - x^2u' = 0, \qquad (x^2 - x)u'' + (x - 2)u' = 0.$$

---

[1]Credited to the great mathematician JOSEPH LOUIS LAGRANGE (1736–1813), who was born in Turin, of French extraction, got his first professorship when he was 19 (at the Military Academy of Turin), became director of the mathematical section of the Berlin Academy in 1766, and moved to Paris in 1787. His important major work was in the calculus of variations, celestial mechanics, general mechanics (*Mécanique analytique*, Paris, 1788), differential equations, approximation theory, algebra, and number theory.

This ODE is of first order in $v = u'$, namely, $(x^2 - x)v' + (x - 2)v = 0$. Separation of variables and integration gives

$$\frac{dv}{v} = -\frac{x-2}{x^2-x}\,dx = \left(\frac{1}{x-1} - \frac{2}{x}\right)dx, \qquad \ln|v| = \ln|x-1| - 2\ln|x| = \ln\frac{|x-1|}{x^2}.$$

We need no constant of integration because we want to obtain a particular solution; similarly in the next integration. Taking exponents and integrating again, we obtain

$$v = \frac{x-1}{x^2} = \frac{1}{x} - \frac{1}{x^2}, \qquad u = \int v\,dx = \ln|x| + \frac{1}{x}, \qquad \text{hence} \qquad y_2 = ux = x\ln|x| + 1.$$

Since $y_1 = x$ and $y_2 = x\ln|x| + 1$ are linearly independent (their quotient is not constant), we have obtained a basis of solutions, valid for all positive x. ■

In this example we applied **reduction of order** to a homogeneous linear ODE [see (2)]

$$y'' + p(x)y' + q(x)y = 0.$$

Note that we now take the ODE in standard form, with y'', not $f(x)y''$—this is essential in applying our subsequent formulas. We assume a solution y_1 of (2) on an open interval I to be known and want to find a basis. For this we need a second linearly independent solution y_2 of (2) on I. To get y_2, we substitute

$$y = y_2 = uy_1, \qquad y' = y_2' = u'y_1 + uy_1', \qquad y'' = y_2'' = u''y_1 + 2u'y_1' + uy_1''$$

into (2). This gives

$$u''y_1 + 2u'y_1' + uy_1'' + p(u'y_1 + uy_1') + quy_1 = 0. \tag{8}$$

Collecting terms in u'', u', and u, we have

$$u''y_1 + u'(2y_1' + py_1) + u(y_1'' + py_1' + qy_1) = 0.$$

Now comes the main point. Since y_1 is a solution of (2), the expression in the last parentheses is zero. Hence u is gone, and we are left with an ODE in u' and u''. We divide this remaining ODE by y_1 and set $u' = U$, $u'' = U'$,

$$u'' + u'\,\frac{2y_1' + py_1}{y_1} = 0, \qquad \text{thus} \qquad U' + \left(\frac{2y_1'}{y_1} + p\right)U = 0.$$

This is the desired first-order ODE, the reduced ODE. Separation of variables and integration gives

$$\frac{dU}{U} = -\left(\frac{2y_1'}{y_1} + p\right)dx \qquad \text{and} \qquad \ln|U| = -2\ln|y_1| - \int p\,dx.$$

By taking exponents we finally obtain

$$U = \frac{1}{y_1^2}\,e^{-\int p\,dx}. \tag{9}$$

Here $U = u'$, so that $u = \int U\,dx$. Hence the desired second solution is

$$y_2 = y_1 u = y_1 \int U\,dx.$$

The quotient $y_2/y_1 = u = \int U\,dx$ cannot be constant (since $U > 0$), so that y_1 and y_2 form a basis of solutions.

PROBLEM SET 2.1

1–6 GENERAL SOLUTION. INITIAL VALUE PROBLEM

(More in the next problem set.) Verify by substitution that the given functions form a basis. Solve the given initial value problem. (Show the details of your work.)

1. $y'' - 16y = 0$, e^{4x}, e^{-4x}, $y(0) = 3$, $y'(0) = 8$
2. $y'' + 25y = 0$, $\cos 5x, \sin 5x$, $y(0) = 0.8$, $y'(0) = -6.5$
3. $y'' + 2y' + 2y = 0$, $e^{-x}\cos x, e^{-x}\sin x$, $y(0) = 1$, $y'(0) = -1$
4. $y'' - 6y' + 9y = 0$, e^{3x}, xe^{3x}, $y(0) = -1.4$, $y'(0) = 4.6$
5. $x^2y'' + xy' - 4y = 0$, x^2, x^{-2}, $y(1) = 11$, $y'(1) = -6$
6. $x^2y'' - 7xy' + 15y = 0$, x^3, x^5, $y(1) = 0.4$, $y'(1) = 1.0$

7–14 LINEAR INDEPENDENCE AND DEPENDENCE

Are the following functions linearly independent on the given interval?

7. x, $x \ln x$ $(0 < x < 10)$
8. $3x^2$, $2x^n$ $(0 < x < 1)$
9. e^{ax}, e^{-ax} (any interval)
10. $\cos^2 x$, $\sin^2 x$ (any interval)
11. $\ln x$, $\ln x^2$ $(x > 0)$
12. $x - 2$, $x + 2$ $(-2 < x < 2)$
13. $5 \sin x \cos x$, $3 \sin 2x$ $(x > 0)$
14. 0, $\sinh \pi x$ $(x > 0)$

REDUCTION OF ORDER is important because it gives a simpler ODE. A second-order ODE $F(x, y, y', y'') = 0$, linear or not, can be reduced to first order if y does not occur explicitly (Prob. 15) or if x does not occur explicitly (Prob. 16) or if the ODE is homogeneous linear and we know a solution (see the text).

15. **(Reduction)** Show that $F(x, y', y'') = 0$ can be reduced to first order in $z = y'$ (from which y follows by integration). Give two examples of your own.
16. **(Reduction)** Show that $F(y, y', y'') = 0$ can be reduced to a first-order ODE with y as the independent variable and $y'' = (dz/dy)z$, where $z = y'$; derive this by the chain rule. Give two examples.

17–22

Reduce to first order and solve (showing each step in detail).

17. $y'' = ky'$
18. $y'' = 1 + y'^2$
19. $yy'' = 4y'^2$
20. $xy'' + 2y' + xy = 0$, $y_1 = x^{-1}\cos x$
21. $y'' + y'^3 \sin y = 0$
22. $(1 - x^2)y'' - 2xy' + 2y = 0$, $y_1 = x$

23. **(Motion)** A small body moves on a straight line. Its velocity equals twice the reciprocal of its acceleration. If at $t = 0$ the body has distance 1 m from the origin and velocity 2 m/sec, what are its distance and velocity after 3 sec?
24. **(Hanging cable)** It can be shown that the curve $y(x)$ of an inextensible flexible homogeneous cable hanging between two fixed points is obtained by solving $y'' = k\sqrt{1 + y'^2}$, where the constant k depends on the weight. This curve is called a *catenary* (from Latin *catena* = the chain). Find and graph $y(x)$, assuming $k = 1$ and those fixed points are $(-1, 0)$ and $(1, 0)$ in a vertical xy-plane.
25. **(Curves)** Find and sketch or graph the curves passing through the origin with slope 1 for which the second derivative is proportional to the first.
26. **WRITING PROJECT. General Properties of Solutions of Linear ODEs.** Write a short essay (with proofs and simple examples of your own) that includes the following.

    (a) The superposition principle.

    (b) $y \equiv 0$ is a solution of the homogeneous equation (2) (called the **trivial solution**).

    (c) The sum $y = y_1 + y_2$ of a solution y_1 of (1) and y_2 of (2) is a solution of (1).

    (d) Explore possibilities of making further general statements on solutions of (1) and (2) (sums, differences, multiples).
27. **CAS PROJECT. Linear Independence.** Write a program for testing linear independence and dependence. Try it out on some of the problems in this problem set and on examples of your own.

2.2 Homogeneous Linear ODEs with Constant Coefficients

We shall now consider second-order homogeneous linear ODEs whose coefficients a and b are constant,

$$y'' + ay' + by = 0. \tag{1}$$

These equations have important applications, especially in connection with mechanical and electrical vibrations, as we shall see in Secs. 2.4, 2.8, and 2.9.

How to solve (1)? We remember from Sec. 1.5 that the solution of the *first-order* linear ODE with a constant coefficient k

$$y' + ky = 0$$

is an exponential function $y = ce^{-kx}$. This gives us the idea to try as a solution of (1) the function

$$y = e^{\lambda x}. \tag{2}$$

Substituting (2) and its derivatives

$$y' = \lambda e^{\lambda x} \qquad \text{and} \qquad y'' = \lambda^2 e^{\lambda x}$$

into our equation (1), we obtain

$$(\lambda^2 + a\lambda + b)e^{\lambda x} = 0.$$

Hence if λ is a solution of the important **characteristic equation** (or *auxiliary equation*)

$$\lambda^2 + a\lambda + b = 0 \tag{3}$$

then the exponential function (2) is a solution of the ODE (1). Now from elementary algebra we recall that the roots of this quadratic equation (3) are

$$\lambda_1 = \tfrac{1}{2}(-a + \sqrt{a^2 - 4b}), \qquad \lambda_2 = \tfrac{1}{2}(-a - \sqrt{a^2 - 4b}). \tag{4}$$

(3) and (4) will be basic because our derivation shows that the functions

$$y_1 = e^{\lambda_1 x} \qquad \text{and} \qquad y_2 = e^{\lambda_2 x} \tag{5}$$

are solutions of (1). Verify this by substituting (5) into (1).

From algebra we further know that the quadratic equation (3) may have three kinds of roots, depending on the sign of the discriminant $a^2 - 4b$, namely,

(Case I) *Two real roots if* $a^2 - 4b > 0$,
(Case II) *A real double root if* $a^2 - 4b = 0$,
(Case III) *Complex conjugate roots if* $a^2 - 4b < 0$.

Case I. Two Distinct Real Roots λ_1 and λ_2

In this case, a basis of solutions of (1) on any interval is

$$y_1 = e^{\lambda_1 x} \qquad \text{and} \qquad y_2 = e^{\lambda_2 x}$$

because y_1 and y_2 are defined (and real) for all x and their quotient is not constant. The corresponding general solution is

$$\textbf{(6)} \qquad y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}.$$

EXAMPLE 1 **General Solution in the Case of Distinct Real Roots**

We can now solve $y'' - y = 0$ in Example 6 of Sec. 2.1 systematically. The characteristic equation is $\lambda^2 - 1 = 0$. Its roots are $\lambda_1 = 1$ and $\lambda_2 = -1$. Hence a basis of solutions is e^x and e^{-x} and gives the same general solution as before,

$$y = c_1 e^x + c_2 e^{-x}.$$

■

EXAMPLE 2 **Initial Value Problem in the Case of Distinct Real Roots**

Solve the initial value problem

$$y'' + y' - 2y = 0, \qquad y(0) = 4, \qquad y'(0) = -5.$$

Solution. ***Step 1. General solution.*** The characteristic equation is

$$\lambda^2 + \lambda - 2 = 0.$$

Its roots are

$$\lambda_1 = \tfrac{1}{2}(-1 + \sqrt{9}) = 1 \qquad \text{and} \qquad \lambda_2 = \tfrac{1}{2}(-1 - \sqrt{9}) = -2$$

so that we obtain the general solution

$$y = c_1 e^x + c_2 e^{-2x}.$$

Step 2. Particular solution. Since $y'(x) = c_1 e^x - 2c_2 e^{-2x}$, we obtain from the general solution and the initial conditions

$$y(0) = c_1 + c_2 = 4,$$
$$y'(0) = c_1 - 2c_2 = -5.$$

Hence $c_1 = 1$ and $c_2 = 3$. This gives the *answer* $y = e^x + 3e^{-2x}$. Figure 29 shows that the curve begins at $y = 4$ with a negative slope (-5, but note that the axes have different scales!), in agreement with the initial conditions. ■

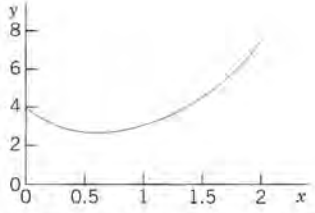

Fig. 29. Solution in Example 2

Case II. Real Double Root $\lambda = -a/2$

If the discriminant $a^2 - 4b$ is zero, we see directly from (4) that we get only one root, $\lambda = \lambda_1 = \lambda_2 = -a/2$, hence only one solution,

$$y_1 = e^{-(a/2)x}.$$

To obtain a second independent solution y_2 (needed for a basis), we use the method of reduction of order discussed in the last section, setting $y_2 = uy_1$. Substituting this and its derivatives $y_2' = u'y_1 + uy_1'$ and y_2'' into (1), we first have

$$(u''y_1 + 2u'y_1' + uy_1'') + a(u'y_1 + uy_1') + buy_1 = 0.$$

Collecting terms in u'', u', and u, as in the last section, we obtain

$$u''y_1 + u'(2y_1' + ay_1) + u(y_1'' + ay_1' + by_1) = 0.$$

The expression in the last parentheses is zero, since y_1 is a solution of (1). The expression in the first parentheses is zero, too, since

$$2y_1' = -ae^{-ax/2} = -ay_1.$$

We are thus left with $u''y_1 = 0$. Hence $u'' = 0$. By two integrations, $u = c_1x + c_2$. To get a second independent solution $y_2 = uy_1$, we can simply choose $c_1 = 1$, $c_2 = 0$ and take $u = x$. Then $y_2 = xy_1$. Since these solutions are not proportional, they form a basis. Hence in the case of a double root of (3) a basis of solutions of (1) on any interval is

$$e^{-ax/2}, \qquad xe^{-ax/2}.$$

The corresponding general solution is

$$y = (c_1 + c_2x)e^{-ax/2}. \tag{7}$$

Warning. If λ is a *simple* root of (4), then $(c_1 + c_2x)e^{\lambda x}$ with $c_2 \neq 0$ is ***not*** a solution of (1).

EXAMPLE 3 General Solution in the Case of a Double Root

The characteristic equation of the ODE $y'' + 6y' + 9y = 0$ is $\lambda^2 + 6\lambda + 9 = (\lambda + 3)^2 = 0$. It has the double root $\lambda = -3$. Hence a basis is e^{-3x} and xe^{-3x}. The corresponding general solution is $y = (c_1 + c_2x)e^{-3x}$. ■

EXAMPLE 4 Initial Value Problem in the Case of a Double Root

Solve the initial value problem

$$y'' + y' + 0.25y = 0, \qquad y(0) = 3.0, \quad y'(0) = -3.5.$$

Solution. The characteristic equation is $\lambda^2 + \lambda + 0.25 = (\lambda + 0.5)^2 = 0$. It has the double root $\lambda = -0.5$. This gives the general solution

$$y = (c_1 + c_2x)e^{-0.5x}.$$

We need its derivative

$$y' = c_2e^{-0.5x} - 0.5(c_1 + c_2x)e^{-0.5x}.$$

From this and the initial conditions we obtain

$$y(0) = c_1 = 3.0, \qquad y'(0) = c_2 - 0.5c_1 = -3.5; \qquad \text{hence} \qquad c_2 = -2.$$

The particular solution of the initial value problem is $y = (3 - 2x)e^{-0.5x}$. See Fig. 30.

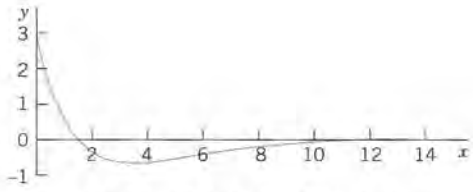

Fig. 30. Solution in Example 4

Case III. Complex Roots $-\frac{1}{2}a + i\omega$ and $-\frac{1}{2}a - i\omega$

This case occurs if the discriminant $a^2 - 4b$ of the characteristic equation (3) is negative. In this case, the roots of (3) and thus the solutions of the ODE (1) come at first out complex. However, we show that from them we can obtain a basis of *real* solutions

$$(8) \qquad y_1 = e^{-ax/2}\cos \omega x, \qquad y_2 = e^{-ax/2}\sin \omega x \qquad (\omega > 0)$$

where $\omega^2 = b - \frac{1}{4}a^2$. It can be verified by substitution that these are solutions in the present case. We shall derive them systematically after the two examples by using the complex exponential function. They form a basis on any interval since their quotient $\cot \omega x$ is not constant. Hence a real general solution in Case III is

$$(9) \qquad y = e^{-ax/2}(A \cos \omega x + B \sin \omega x) \qquad (A, B \text{ arbitrary}).$$

EXAMPLE 5 **Complex Roots. Initial Value Problem**

Solve the initial value problem

$$y'' + 0.4y' + 9.04y = 0, \qquad y(0) = 0, \qquad y'(0) = 3.$$

Solution. ***Step 1. General solution.*** The characteristic equation is $\lambda^2 + 0.4\lambda + 9.04 = 0$. It has the roots $-0.2 \pm 3i$. Hence $\omega = 3$, and a general solution (9) is

$$y = e^{-0.2x}(A \cos 3x + B \sin 3x).$$

Step 2. Particular solution. The first initial condition gives $y(0) = A = 0$. The remaining expression is $y = Be^{-0.2x} \sin 3x$. We need the derivative (chain rule!)

$$y' = B(-0.2e^{-0.2x} \sin 3x + 3e^{-0.2x} \cos 3x).$$

From this and the second initial condition we obtain $y'(0) = 3B = 3$. Hence $B = 1$. Our solution is

$$y = e^{-0.2x} \sin 3x.$$

Figure 31 shows y and the curves of $e^{-0.2x}$ and $-e^{-0.2x}$ (dashed), between which the curve of y oscillates. Such "damped vibrations" (with $x = t$ being time) have important mechanical and electrical applications, as we shall soon see (in Sec. 2.4).

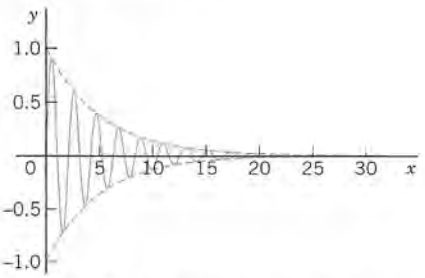

Fig. 31. Solution in Example 5

EXAMPLE 6 **Complex Roots**

A general solution of the ODE

$$y'' + \omega^2 y = 0 \qquad (\omega \text{ constant, not zero})$$

is

$$y = A \cos \omega x + B \sin \omega x.$$

With $\omega = 1$ this confirms Example 4 in Sec. 2.1. ■

Summary of Cases I–III

Case	Roots of (2)	Basis of (1)	General Solution of (1)
I	Distinct real λ_1, λ_2	$e^{\lambda_1 x}, e^{\lambda_2 x}$	$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$
II	Real double root $\lambda = -\frac{1}{2}a$	$e^{-ax/2}, xe^{-ax/2}$	$y = (c_1 + c_2 x)e^{-ax/2}$
III	Complex conjugate $\lambda_1 = -\frac{1}{2}a + i\omega$, $\lambda_2 = -\frac{1}{2}a - i\omega$	$e^{-ax/2} \cos \omega x$, $e^{-ax/2} \sin \omega x$	$y = e^{-ax/2}(A \cos \omega x + B \sin \omega x)$

It is very interesting that in applications to mechanical systems or electrical circuits, these three cases correspond to three different forms of motion or flows of current, respectively. We shall discuss this basic relation between theory and practice in detail in Sec. 2.4 (and again in Sec. 2.8).

Derivation in Case III. Complex Exponential Function

If verification of the solutions in (8) satisfies you, skip the systematic derivation of these real solutions from the complex solutions by means of the complex exponential function e^z of a complex variable $z = r + it$. We write $r + it$, not $x + iy$ because x and y occur in the ODE. The definition of e^z in terms of the real functions e^r, $\cos t$, and $\sin t$ is

(10) $$e^z = e^{r+it} = e^r e^{it} = e^r(\cos t + i \sin t).$$

This is motivated as follows. For real $z = r$, hence $t = 0$, $\cos 0 = 1$, $\sin 0 = 0$, we get the real exponential function e^r. It can be shown that $e^{z_1+z_2} = e^{z_1}e^{z_2}$, just as in real. (Proof in Sec. 13.5.) Finally, if we use the Maclaurin series of e^z with $z = it$ as well as $i^2 = -1$, $i^3 = -i$, $i^4 = 1$, etc., and reorder the terms as shown (this is permissible, as can be proved), we obtain the series

$$\begin{aligned} e^{it} &= 1 + it + \frac{(it)^2}{2!} + \frac{(it)^3}{3!} + \frac{(it)^4}{4!} + \frac{(it)^5}{5!} + \cdots \\ &= 1 - \frac{t^2}{2!} + \frac{t^4}{4!} - + \cdots + i\left(t - \frac{t^3}{3!} + \frac{t^5}{5!} - + \cdots\right) \\ &= \cos t + i \sin t. \end{aligned}$$

(Look up these real series in your calculus book if necessary.) We see that we have obtained the formula

$$e^{it} = \cos t + i \sin t, \tag{11}$$

called the **Euler formula.** Multiplication by e^r gives (10).

For later use we note that $e^{-it} = \cos(-t) + i \sin(-t) = \cos t - i \sin t$, so that by addition and subtraction of this and (11),

$$\cos t = \frac{1}{2}(e^{it} + e^{-it}), \qquad \sin t = \frac{1}{2i}(e^{it} - e^{-it}). \tag{12}$$

After these comments on the definition (10), let us now turn to Case III.

In Case III the radicand $a^2 - 4b$ in (4) is negative. Hence $4b - a^2$ is positive and, using $\sqrt{-1} = i$, we obtain in (4)

$$\tfrac{1}{2}\sqrt{a^2 - 4b} = \tfrac{1}{2}\sqrt{-(4b - a^2)} = \sqrt{-(b - \tfrac{1}{4}a^2)} = i\sqrt{b - \tfrac{1}{4}a^2} = i\omega$$

with ω defined as in (8). Hence in (4),

$$\lambda_1 = \tfrac{1}{2}a + i\omega \qquad \text{and, similarly,} \qquad \lambda_2 = \tfrac{1}{2}a - i\omega.$$

Using (10) with $r = -\frac{1}{2}ax$ and $t = \omega x$, we thus obtain

$$\begin{aligned} e^{\lambda_1 x} &= e^{-(a/2)x + i\omega x} = e^{-(a/2)x}(\cos \omega x + i \sin \omega x) \\ e^{\lambda_2 x} &= e^{-(a/2)x - i\omega x} = e^{-(a/2)x}(\cos \omega x - i \sin \omega x). \end{aligned}$$

We now add these two lines and multiply the result by $\frac{1}{2}$. This gives y_1 as in (8). Then we subtract the second line from the first and multiply the result by $1/(2i)$. This gives y_2 as in (8). These results obtained by addition and multiplication by constants are again solutions, as follows from the superposition principle in Sec. 2.1. This concludes the derivation of these real solutions in Case III.

PROBLEM SET 2.2

1–14 GENERAL SOLUTION

Find a general solution. Check your answer by substitution.

1. $y'' - 6y' - 7y = 0$
2. $10y'' - 7y' + 1.2y = 0$
3. $4y'' - 20y' + 25y = 0$
4. $y'' + 4\pi y' + 4\pi^2 y = 0$
5. $100y'' + 20y' - 99y = 0$
6. $y'' + 2y' + 5y = 0$
7. $y'' - y' + 2.5y = 0$
8. $y'' + 2.6y' + 1.69y = 0$
9. $y'' - 2y' - 5.25y = 0$
10. $y'' - 2y = 0$
11. $y'' + 9\pi^2 y = 0$
12. $y'' + 2.4y' + 4.0y = 0$
13. $y'' - 144y = 0$
14. $y'' + y' - 0.96y = 0$

15–20 FIND ODE

Find an ODE $y'' + ay' + by = 0$ for the given basis.

15. e^{2x}, e^{x}
16. $e^{0.5x}, e^{-3.5x}$
17. $e^{x\sqrt{3}}, xe^{x\sqrt{3}}$
18. $1, e^{-3x}$
19. e^{4x}, e^{-4x}
20. $e^{(-1+i)x}, e^{-(1+i)x}$

21–32 INITIAL VALUE PROBLEMS

Solve the initial value problem. Check that your answer satisfies the ODE as well as the initial conditions. (Show the details of your work.)

21. $y'' - 2y' - 3y = 0,\ y(0) = 2,\ y'(0) = 14$
22. $y'' + 2y' + y = 0,\ y(0) = 4,\ y'(0) = -6$
23. $y'' + 4y' + 5y = 0,\ y(0) = 2,\ y'(0) = -5$
24. $10y'' - 50y' + 65y = 0,\ y(0) = 1.5,\ y'(0) = 1.5$
25. $y'' + \pi y' = 0,\ y(0) = 3,\ y'(0) = -\pi$
26. $10y'' + 18y' + 5.6y = 0,\ y(0) = 4,\ y'(0) = -3.8$
27. $10y'' + 5y' + 0.625y = 0,\ y(0) = 2,\ y'(0) = -4.5$
28. $y'' - 9y = 0,\ y(0) = -2,\ y'(0) = -12$
29. $20y'' + 4y' + y = 0,\ y(0) = 3.2,\ y'(0) = 0$
30. $y'' + 2ky' + (k^2 + \omega^2)y = 0,\ y(0) = 1,\ y'(0) = -k$
31. $y'' - 25y = 0,\ y(0) = 0,\ y'(0) = 40$
32. $y'' - 2y' - 24y = 0,\ y(0) = 0,\ y'(0) = 20$

33. **(Instability)** Solve $y'' - y = 0$ for the initial conditions $y(0) = 1, y'(0) = -1$. Then change the initial conditions to $y(0) = 1.001$, $y'(0) = -0.999$ and explain why this small change of 0.001 at $x = 0$ causes a large change later, e.g., 22 at $x = 10$.

34. **TEAM PROJECT. General Properties of Solutions**

(A) Coefficient formulas. Show how a and b in (1) can be expressed in terms of λ_1 and λ_2. Explain how these formulas can be used in constructing equations for given bases.

(B) Root zero. Solve $y'' + 4y' = 0$ (i) by the present method, and (ii) by reduction to first order. Can you explain why the result must be the same in both cases? Can you do the same for a general ODE $y'' + ay' = 0$?

(C) Double root. Verify directly that $xe^{\lambda x}$ with $\lambda = -a/2$ is a solution of (1) in the case of a double root. Verify and explain why $y = e^{-2x}$ is a solution of $y'' - y' - 6y = 0$ but xe^{-2x} is not.

(D) Limits. Double roots should be limiting cases of distinct roots λ_1, λ_2 as, say, $\lambda_2 \to \lambda_1$. Experiment with this idea. (Remember l'Hôpital's rule from calculus.) Can you arrive at $xe^{\lambda_1 x}$? Give it a try.

35. **(Verification)** Show by substitution that y_1 in (8) is a solution of (1).

2.3 Differential Operators. *Optional*

This short section can be omitted without interrupting the flow of ideas; it will not be used in the sequel (except for the notations Dy, D^2y, etc., for y', y'', etc.).

Operational calculus means the technique and application of operators. Here, an **operator** is a transformation that transforms a function into another function. Hence differential calculus involves an operator, the **differential operator** D, which transforms a (differentiable) function into its derivative. In operator notation we write

$$\text{(1)} \qquad Dy = y' = \frac{dy}{dx}.$$

Similarly, for the higher derivatives we write $D^2y = D(Dy) = y''$, and so on. For example, $D \sin = \cos$, $D^2 \sin = -\sin$, etc.

For a homogeneous linear ODE $y'' + ay' + by = 0$ with constant coefficients we can now introduce the **second-order differential operator**

$$L = P(D) = D^2 + aD + bI,$$

where I is the **identity operator** defined by $Iy = y$. Then we can write that ODE as

$$Ly = P(D)y = (D^2 + aD + bI)y = 0. \tag{2}$$

P suggests "polynomial." L is a **linear operator.** By definition this means that if Ly and Lw exist (this is the case if y and w are twice differentiable), then $L(cy + kw)$ exists for any constants c and k, and

$$L(cy + kw) = cLy + kLw.$$

Let us show that from (2) we reach agreement with the results in Sec. 2.2. Since $(De^{\lambda})(x) = \lambda e^{\lambda x}$ and $(D^2e^{\lambda})(x) = \lambda^2 e^{\lambda x}$, we obtain

$$\begin{aligned} Le^{\lambda}(x) &= P(D)e^{\lambda}(x) = (D^2 + aD + bI)e^{\lambda}(x) \\ &= (\lambda^2 + a\lambda + b)e^{\lambda x} = P(\lambda)e^{\lambda x} = 0. \end{aligned} \tag{3}$$

This confirms our result of Sec. 2.2 that *$e^{\lambda x}$ is a solution of the ODE* (2) *if and only if λ is a solution of the characteristic equation* $P(\lambda) = 0$.

$P(\lambda)$ is a polynomial in the usual sense of algebra. If we replace λ by the operator D, we obtain the "operator polynomial" $P(D)$. *The point of this operational calculus is that $P(D)$ can be treated just like an algebraic quantity.* In particular, we can factor it.

EXAMPLE 1 **Factorization, Solution of an ODE**

Factor $P(D) = D^2 - 3D - 40I$ and solve $P(D)y = 0$.

Solution. $D^2 - 3D - 40I = (D - 8I)(D + 5I)$ because $I^2 = I$. Now $(D - 8I)y = y' - 8y = 0$ has the solution $y_1 = e^{8x}$. Similarly, the solution of $(D + 5I)y = 0$ is $y_2 = e^{-5x}$. This is a basis of $P(D)y = 0$ on any interval. From the factorization we obtain the ODE, as expected,

$$\begin{aligned} (D - 8I)(D + 5I)y = (D - 8I)(y' + 5y) &= D(y' + 5y) - 8(y' + 5y) \\ &= y'' + 5y' - 8y' - 40y = y'' - 3y' - 40y = 0. \end{aligned}$$

Verify that this agrees with the result of our method in Sec. 2.2. This is not unexpected because we factored $P(D)$ in the same way as the characteristic polynomial $P(\lambda) = \lambda^2 - 3\lambda - 40$. ■

It was essential that L in (2) has *constant* coefficients. Extension of operator methods to variable-coefficient ODEs is more difficult and will not be considered here.

If operational methods were limited to the simple situations illustrated in this section, it would perhaps not be worth mentioning. Actually, the power of the operator approach appears in more complicated engineering problems, as we shall see in Chap. 6.

PROBLEM SET 2.3

1–5 APPLICATION OF DIFFERENTIAL OPERATORS

Apply the given operator to the given functions. (Show all steps in detail.)

1. $(D - I)^2$; e^x, xe^x, $\sin x$
2. $8D^2 + 2D - I$; $\cosh \frac{1}{2}x$, $\sinh \frac{1}{2}x$, $e^{x/2}$
3. $D - 0.4I$; $2x^3 - 1$, $e^{0.4x}$, $xe^{0.4x}$
4. $(D + 5I)(D - I)$; $e^{-5x} \sin x$, e^{5x}, x^2
5. $(D - 4I)(D + 3I)$; $x^3 - x^2$, $\sin 4x$, e^{-3x}

6–13 GENERAL SOLUTION

Factor as in the text and solve. (Show the details.)

6. $(D^2 - 5.5D + 6.66I)y = 0$
7. $(D + 2I)^2 y = 0$
8. $(D^2 - 0.49I)y = 0$
9. $(D^2 + 6D + 13I)y = 0$
10. $(10D^2 + 2D + 1.7I)y = 0$
11. $(D^2 + 4.1D + 3.1I)y = 0$
12. $(4D^2 + 4\pi D + \pi^2 I)y = 0$
13. $(D^2 + 17.64\omega^2 I)y = 0$
14. **(Double root)** If $D^2 + aD + bI$ has distinct roots μ and λ, show that a particular solution is $y = (e^{\mu x} - e^{\lambda x})/(\mu - \lambda)$. Obtain from this a solution $xe^{\lambda x}$ by letting $\mu \to \lambda$ and applying l'Hôpital's rule.
15. **(Linear operator)** Illustrate the linearity of L in (2) by taking $c = 4$, $k = -6$, $y = e^{2x}$, and $w = \cos 2x$. Prove that L is linear.
16. **(Definition of linearity)** Show that the definition of linearity in the text is equivalent to the following. If $L[y]$ and $L[w]$ exist, then $L[y + w]$ exists and $L[cy]$ and $L[kw]$ exist for all constants c and k, and $L[y + w] = L[y] + L[w]$ as well as $L[cy] = cL[y]$ and $L[kw] = kL[w]$.

2.4 Modeling: Free Oscillations (Mass–Spring System)

Linear ODEs with constant coefficients have important applications in mechanics, as we show now (and in Sec. 2.8), and in electric circuits (to be shown in Sec. 2.9). In this section we consider a basic mechanical system, a mass on an elastic spring ("mass-spring system," Fig. 32), which moves up and down. Its model will be a homogeneous linear ODE.

Setting Up the Model

We take an ordinary spring that resists compression as well extension and suspend it vertically from a fixed support, as shown in Fig. 32. At the lower end of the spring we

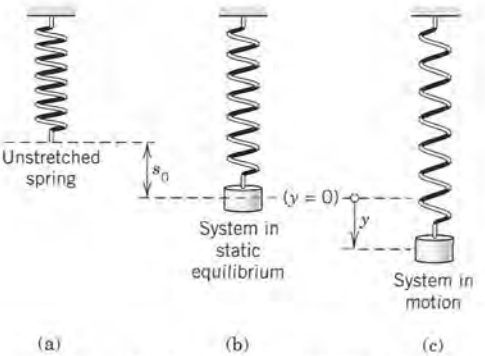

Fig. 32. Mechanical mass–spring system

attach a body of mass m. We assume m to be so large that we can neglect the mass of the spring. If we pull the body down a certain distance and then release it, it starts moving. We assume that it moves strictly vertically.

How can we obtain the motion of the body, say, the displacement $y(t)$ as function of time t? Now this motion is determined by **Newton's second law**

(1) $$\text{Mass} \times \text{Acceleration} = my'' = \text{Force}$$

where $y'' = d^2y/dt^2$ and "Force" is the resultant of all the forces acting on the body.

(For systems of units and conversion factors, see the inside of the front cover.)

We choose the ***downward direction as the positive direction,*** thus regarding downward forces as positive and upward forces as negative.

Consider Fig. 32. The spring is first unstretched. We now attach the body. This stretches the spring by an amount s_0 shown in the figure. It causes an upward force F_0 in the spring. Experiments show that F_0 is proportional to the stretch s_0, say,

(2) $$F_0 = -ks_0 \qquad \textbf{(Hooke's law}^2\textbf{).}$$

k (> 0) is called the **spring constant** (or *spring modulus*). The minus sign indicates that F_0 points upward, in our negative direction. Stiff springs have large k. (Explain!)

The extension s_0 is such that F_0 in the spring balances the weight $W = mg$ of the body (where $g = 980$ cm/sec^2 $= 32.17$ ft/sec^2 is the gravitational constant). Hence $F_0 + W = -ks_0 + mg = 0$. These forces will not affect the motion. Spring and body are again at rest. This is called the **static equilibrium** of the system (Fig. 32b). We measure the displacement $y(t)$ of the body from this 'equilibrium point' as the origin $y = 0$, downward positive and upward negative.

From the position $y = 0$ we pull the body downward. This further stretches the spring by some amount $y > 0$ (the distance we pull it down). By Hooke's law this causes an (additional) upward force F_1 in the spring,

$$F_1 = -ky.$$

F_1 is a **restoring force.** It has the tendency to *restore* the system, that is, to pull the body back to $y = 0$.

Undamped System: ODE and Solution

Every system has damping—otherwise it would keep moving forever. But practically, the effect of damping may often be negligible, for example, for the motion of an iron ball on a spring during a few minutes. Then F_1 is the only force in (1) causing the motion. Hence (1) gives the model $my'' = -ky$ or

(3) $$my'' + ky = 0.$$

---

[2]ROBERT HOOKE (1635–1703), English physicist, a forerunner of Newton with respect to the law of gravitation.

By the method in Sec. 2.2 (see Example 6) we obtain as a general solution

$$\textbf{(4)} \qquad y(t) = A \cos \omega_0 t + B \sin \omega_0 t, \qquad \omega_0 = \sqrt{\frac{k}{m}}.$$

The corresponding motion is called a **harmonic oscillation.**

Since the trigonometric functions in (4) have the period $2\pi/\omega_0$, the body executes $\omega_0/2\pi$ cycles per second. This is the **frequency** of the oscillation, which is also called the **natural frequency** of the system. It is measured in cycles per second. Another name for cycles/sec is hertz (Hz).[3]

The sum in (4) can be combined into a phase-shifted cosine with amplitude $C = \sqrt{A^2 + B^2}$ and phase angle $\delta = \arctan(B/A)$,

$$\textbf{(4*)} \qquad y(t) = C \cos(\omega_0 t - \delta).$$

To verify this, apply the addition formula for the cosine [(6) in App. 3.1] to (4*) and then compare with (4). Equation (4) is simpler in connection with initial value problems, whereas (4*) is physically more informative because it exhibits the amplitude and phase of the oscillation.

Figure 33 shows typical forms of (4) and (4*), all corresponding to some positive initial displacement $y(0)$ [which determines $A = y(0)$ in (4)] and different initial velocities $y'(0)$ [which determine $B = y'(0)/\omega_0$].

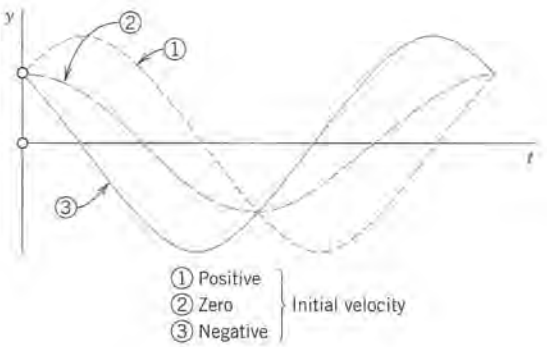

Fig. 33. Harmonic oscillations

EXAMPLE 1 Undamped Motion. Harmonic Oscillation

If an iron ball of weight $W = 98$ nt (about 22 lb) stretches a spring 1.09 m (about 43 in.), how many cycles per minute will this mass–spring system execute? What will its motion be if we pull down the weight an additional 16 cm (about 6 in.) and let it start with zero initial velocity?

Solution. Hooke's law (2) with W as the force and 1.09 meter as the stretch gives $W = 1.09k$; thus $k = W/1.09 = 98/1.09 = 90$ [kg/sec^2] $= 90$ [nt/meter]. The mass is $m = W/g = 98/9.8 = 10$ [kg]. This gives the frequency $\omega_0/(2\pi) = \sqrt{k/m}/(2\pi) = 3/(2\pi) = 0.48$ [Hz] $= 29$ [cycles/min].

[3]HEINRICH HERTZ (1857–1894), German physicist, who discovered electromagnetic waves, as the basis of wireless communication developed by GUGLIELMO MARCONI (1874–1937), Italian physicist (Nobel prize in 1909).

From (4) and the initial conditions, $y(0) = A = 0.16$ [meter] and $y'(0) = \omega_0 B = 0$. Hence the motion is

$$y(t) = 0.16 \cos 3t \text{ [meter]} \qquad \text{or} \qquad 0.52 \cos 3t \text{ [ft]} \qquad \text{(Fig. 34).}$$

If you have a chance of experimenting with a mass–spring system, don't miss it. You will be surprised about the good agreement between theory and experiment, usually within a fraction of one percent if you measure carefully. ■

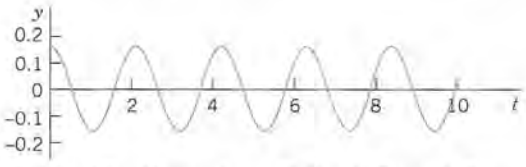

Fig. 34. Harmonic oscillation in Example 1

Damped System: ODE and Solutions

We now add a **damping force**

$$F_2 = -cy'$$

to our model $my'' = -ky$, so that we have $my'' = -ky - cy'$ or

$$\textbf{(5)} \qquad my'' + cy' + ky = 0.$$

Physically this can be done by connecting the body to a dashpot; see Fig. 35. We assume this new force to be proportional to the velocity $y' = dy/dt$, as shown. This is generally a good approximation, at least for small velocities.

c is called the **damping constant.** We show that c is positive. If at some instant, y' is positive, the body is moving downward (which is the positive direction). Hence the damping force $F_2 = -cy'$, always acting *against* the direction of motion, must be an upward force, which means that it must be negative, $F_2 = -cy' < 0$, so that $-c < 0$ and $c > 0$. For an upward motion, $y' < 0$ and we have a downward $F_2 = -cy > 0$; hence $-c < 0$ and $c > 0$, as before.

The ODE (5) is homogeneous linear and has constant coefficients. Hence we can solve it by the method in Sec. 2.2. The characteristic equation is (divide (5) by m)

$$\lambda^2 + \frac{c}{m}\lambda + \frac{k}{m} = 0.$$

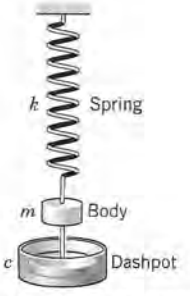

Fig. 35. Damped system

By the usual formula for the roots of a quadratic equation we obtain, as in Sec. 2.2,

(6) $\lambda_1 = -\alpha + \beta, \quad \lambda_2 = -\alpha - \beta, \quad \text{where} \quad \alpha = \dfrac{c}{2m} \quad \text{and} \quad \beta = \dfrac{1}{2m}\sqrt{c^2 - 4mk}.$

It is now most interesting that depending on the amount of damping (much, medium, or little) there will be three types of motion corresponding to the three Cases I, II, II in Sec. 2.2:

Case I.	$c^2 > 4mk$.	*Distinct real roots* λ_1, λ_2.	**(Overdamping)**
Case II.	$c^2 = 4mk$.	*A real double root.*	**(Critical damping)**
Case III.	$c^2 < 4mk$.	*Complex conjugate roots.*	**(Underdamping)**

Discussion of the Three Cases

Case I. Overdamping

If the damping constant c is so large that $c^2 > 4mk$, then λ_1 and λ_2 are distinct real roots. In this case the corresponding general solution of (5) is

(7) $$y(t) = c_1 e^{-(\alpha-\beta)t} + c_2 e^{-(\alpha+\beta)t}.$$

We see that in this case, damping takes out energy so quickly that the body does not oscillate. For $t > 0$ both exponents in (7) are negative because $\alpha > 0$, $\beta > 0$, and $\beta^2 = \alpha^2 - k/m < \alpha^2$. Hence both terms in (7) approach zero as $t \to \infty$. Practically speaking, after a sufficiently long time the mass will be at rest at the static equilibrium position ($y = 0$). Figure 36 shows (7) for some typical initial conditions.

Case II. Critical Damping

Critical damping is the border case between nonoscillatory motions (Case I) and oscillations (Case III). It occurs if the characteristic equation has a double root, that is, if $c^2 = 4mk$,

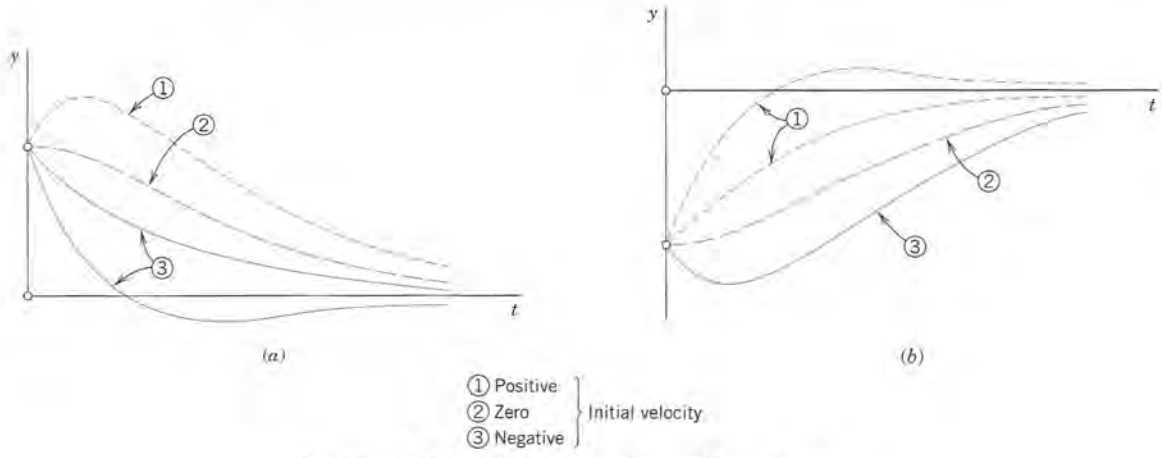

Fig. 36. Typical motions (7) in the overdamped case
(*a*) Positive initial displacement
(*b*) Negative initial displacement

so that $\beta = 0$, $\lambda_1 = \lambda_2 = -\alpha$. Then the corresponding general solution of (5) is

$$\textbf{(8)} \qquad y(t) = (c_1 + c_2 t)e^{-\alpha t}.$$

This solution can pass through the equilibrium position $y = 0$ at most once because $e^{-\alpha t}$ is never zero and $c_1 + c_2 t$ can have at most one positive zero. If both c_1 and c_2 are positive (or both negative), it has no positive zero, so that y does not pass through 0 at all. Figure 37 shows typical forms of (8). Note that they look almost like those in the previous figure.

Case III. Underdamping

This is the most interesting case. It occurs if the damping constant c is so small that $c^2 < 4mk$. Then β in (6) is no longer real but pure imaginary, say,

$$(9) \qquad \beta = i\omega^* \qquad \text{where} \qquad \omega^* = \frac{1}{2m}\sqrt{4mk - c^2} = \sqrt{\frac{k}{m} - \frac{c^2}{4m^2}} \quad (> 0).$$

(We write ω^* to reserve ω for driving and electromotive forces in Secs. 2.8 and 2.9.) The roots of the characteristic equation are now complex conjugate,

$$\lambda_1 = -\alpha + i\omega^*, \qquad \lambda_2 = -\alpha - i\omega^*$$

with $\alpha = c/(2m)$, as given in (6). Hence the corresponding general solution is

$$\textbf{(10)} \qquad y(t) = e^{-\alpha t}(A \cos \omega^* t + B \sin \omega^* t) = Ce^{-\alpha t} \cos (\omega^* t - \delta)$$

where $C^2 = A^2 + B^2$ and $\tan \delta = B/A$, as in (4*).

This represents **damped oscillations.** Their curve lies between the dashed curves $y = Ce^{-\alpha t}$ and $y = -Ce^{-\alpha t}$ in Fig. 38, touching them when $\omega^* t - \delta$ is an integer multiple of π because these are the points at which $\cos(\omega^* t - \delta)$ equals 1 or -1.

The frequency is $\omega^*/(2\pi)$ Hz (hertz, cycles/sec). From (9) we see that the smaller c (> 0) is, the larger is ω^* and the more rapid the oscillations become. If c approaches 0, then ω^* approaches $\omega_0 = \sqrt{k/m}$, giving the harmonic oscillation (4), whose frequency $\omega_0/(2\pi)$ is the natural frequency of the system.

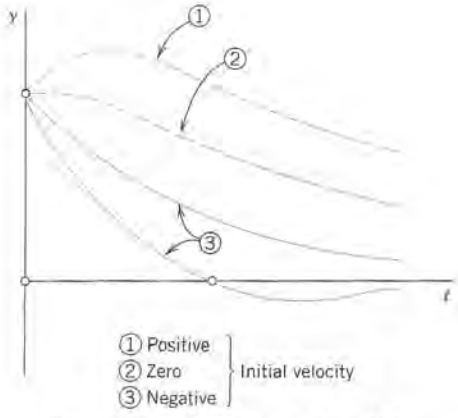

Fig. 37. Critical damping [see (8)]

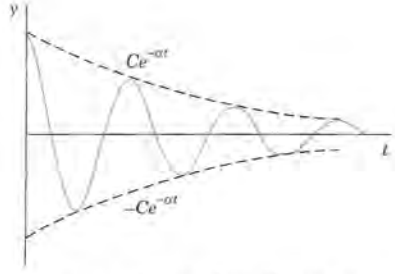

Fig. 38. Damped oscillation in Case III [see (10)]

EXAMPLE 2 The Three Cases of Damped Motion

How does the motion in Example 1 change if we change the damping constant c to one of the following three values, with $y(0) = 0.16$ and $y'(0) = 0$ as before?

$$\text{(I) } c = 100 \text{ kg/sec}, \qquad \text{(II) } c = 60 \text{ kg/sec}, \qquad \text{(III) } c = 10 \text{ kg/sec}.$$

Solution. It is interesting to see how the behavior of the system changes due to the effect of the damping, which takes energy from the system, so that the oscillations decrease in amplitude (Case III) or even disappear (Cases II and I).

(I) With $m = 10$ and $k = 90$, as in Example 1, the model is the initial value problem

$$10y'' + 100y' + 90y = 0, \qquad y(0) = 0.16 \text{ [meter]}, \qquad y'(0) = 0.$$

The characteristic equation is $10\lambda^2 + 100\lambda + 90 = 10(\lambda + 9)(\lambda + 1) = 0$. It has the roots -9 and -1. This gives the general solution

$$y = c_1e^{-9t} + c_2e^{-t}. \qquad \text{We also need} \qquad y' = -9c_1e^{-9t} - c_2e^{-t}.$$

The initial conditions give $c_1 + c_2 = 0.16$, $-9c_1 - c_2 = 0$. The solution is $c_1 = -0.02$, $c_2 = 0.18$. Hence in the overdamped case the solution is

$$y = -0.02e^{-9t} + 0.18e^{-t}.$$

It approaches 0 as $t \to \infty$. The approach is rapid; after a few seconds the solution is practically 0, that is, the iron ball is at rest.

(II) The model is as before, with $c = 60$ instead of 100. The characteristic equation now has the form $10\lambda^2 + 60\lambda + 90 = 10(\lambda + 3)^2 = 0$. It has the double root -3. Hence the corresponding general solution is

$$y = (c_1 + c_2t)e^{-3t}. \qquad \text{We also need} \qquad y' = (c_2 - 3c_1 - 3c_2t)e^{-3t}.$$

The initial conditions give $y(0) = c_1 = 0.16$, $y'(0) = c_2 - 3c_1 = 0$, $c_2 = 0.48$. Hence in the critical case the solution is

$$y = (0.16 + 0.48t)e^{-3t}.$$

It is always positive and decreases to 0 in a monotone fashion.

(III) The model now is $10y'' + 10y' + 90y = 0$. Since $c = 10$ is smaller than the critical c, we shall get oscillations. The characteristic equation is $10\lambda^2 + 10\lambda + 90 = 10\left[(\lambda + \frac{1}{2})^2 + 9 - \frac{1}{4}\right] = 0$. It has the complex roots [see (4) in Sec. 2.2 with $a = 1$ and $b = 9$]

$$\lambda = -0.5 \pm \sqrt{0.5^2 - 9} = -0.5 \pm 2.96i.$$

This gives the general solution

$$y = e^{-0.5t}(A \cos 2.96t + B \sin 2.96t).$$

Thus $y(0) = A = 0.16$. We also need the derivative

$$y' = e^{-0.5t}(-0.5A \cos 2.96t - 0.5B \sin 2.96t - 2.96A \sin 2.96t + 2.96B \cos 2.96t).$$

Hence $y'(0) = -0.5A + 2.96B = 0$, $B = 0.5A/2.96 = 0.027$. This gives the solution

$$y = e^{-0.5t}(0.16 \cos 2.96t + 0.027 \sin 2.96t) = 0.162e^{-0.5t} \cos (2.96t - 0.17).$$

We see that these damped oscillations have a smaller frequency than the harmonic oscillations in Example 1 by about 1% (since 2.96 is smaller than 3.00 by about 1%). Their amplitude goes to zero. See Fig. 39. ■

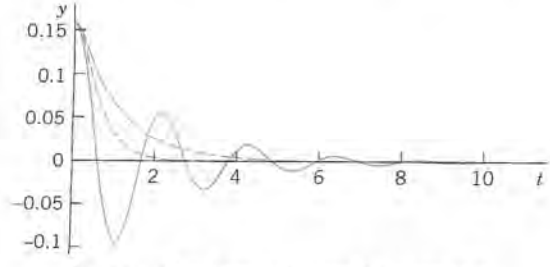

Fig. 39. The three solutions in Example 2

This section concerned ***free motions*** of mass-spring systems. Their models are *homogeneous* linear ODEs. *Nonhomogeneous* linear ODEs will arise as models of **forced motions,** that is, motions under the influence of a "driving force". We shall study them in Sec. 2.8, after we have learned how to solve those ODEs.

PROBLEM SET 2.4

1–11 MOTION WITHOUT DAMPING (HARMONIC OSCILLATIONS)

1. **(Initial value problem)** Find the harmonic motion (4) that starts from y_0 with initial velocity v_0. Graph or sketch the solutions for $\omega_0 = \pi$, $y_0 = 1$, and various v_0 of your choice on common axes. At what t-values do all these curves intersect? Why?
2. **(Spring combinations)** Find the frequency of vibration of a ball of mass $m = 3$ kg on a spring of modulus (i) $k_1 = 27$ nt/m, (ii) $k_2 = 75$ nt/m, (iii) on these springs in parallel (see Fig. 40), (iv) in series, that is, the ball hangs on one spring, which in turn hangs on the other spring.
3. **(Pendulum)** Find the frequency of oscillation of a pendulum of length L (Fig. 41), neglecting air resistance and the weight of the rod, and assuming θ to be so small that $\sin\theta$ practically equals θ.
4. **(Frequency)** What is the frequency of a harmonic oscillation if the static equilibrium position of the ball is 10 cm lower than the lower end of the spring before the ball is attached?
5. **(Initial velocity)** Could you make a harmonic oscillation move faster by giving the body a greater initial push?
6. **(Archimedian principle)** This principle states that the buoyancy force equals the weight of the water displaced by the body (partly or totally submerged). The cylindrical buoy of diameter 60 cm in Fig. 42 is floating in water with its axis vertical. When depressed downward in the water and released, it vibrates with period 2 sec. What is its weight?

Fig. 40. Parallel springs (Problem 2)

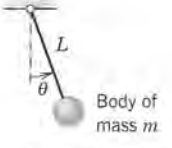

Fig. 41. Pendulum (Problem 3)

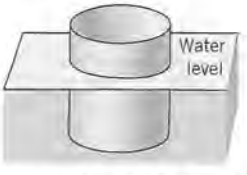

Fig. 42. Buoy (Problem 6)

7. **(Frequency)** How does the frequency of a harmonic motion change if we take (i) a spring of three times the modulus, (ii) a heavier ball?
8. **TEAM PROJECT. Harmonic Motions in Different Physical Systems.** Different physical or other systems may have the same or similar models, thus showing the ***unifying power of mathematical methods.*** Illustrate this for the systems in Figs. 43–45.

   (a) Flat spring (Fig. 43). The spring is horizontally clamped at one end, and a body of weight 25 nt (about 5.6 lb) is attached at the other end. Find the motion of the system, assuming that its static equilibrium is 2 cm below the horizontal line, we let the system start from this position with initial velocity 15 cm/sec, and damping is negligible.

   (b) Torsional vibrations (Fig. 44). Undamped torsional vibrations (rotations back and forth) of a wheel attached to an elastic thin rod are modeled by the ODE $I_0\theta'' + K\theta = 0$, where θ is the angle measured from the state of equilibrium, I_0 is the polar moment of inertia of the wheel about its center, and K is the torsional stiffness of the rod. Solve this ODE for $K/I_0 = 17.64\ \text{sec}^{-2}$, initial angle 45°, and initial angular velocity $15°\ \text{sec}^{-1}$.

   (c) Water in a tube (Fig. 45). What is the frequency of vibration of 5 liters of water (about 1.3 gal) in a U-shaped tube of diameter 4 cm, neglecting friction?

Fig. 43. Flat spring (Project 8a)

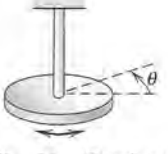

Fig. 44. Torsional vibrations (Project 8b)

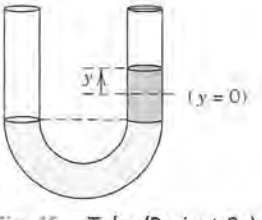

Fig. 45. Tube (Project 8c)

9–17 DAMPED MOTION

9. **(Frequency)** Find an approximation formula for ω^* in terms of ω_0 by applying the binomial theorem in (9) and retaining only the first two terms. How good is the approximation in Example 2, III?

10. **(Extrema)** Find the location of the maxima and minima of $y = e^{-2t} \cos t$ obtained approximately from a graph of y and compare it with the exact values obtained by calculation.

11. **(Maxima)** Show that the maxima of an underdamped motion occur at equidistant t-values and find the distance.

12. **(Logarithmic decrement)** Show that the ratio of two consecutive maximum amplitudes of a damped oscillation (10) is constant, and the natural logarithm of this ratio, called the *logarithmic decrement*, equals $\Delta = 2\pi\alpha/\omega^*$. Find Δ for the solutions of $y'' + 2y' + 5y = 0$.

13. **(Shock absorber)** What is the smallest value of the damping constant of a shock absorber in the suspension of a wheel of a car (consisting of a spring and an absorber) that will provide (theoretically) an oscillation-free ride if the mass of the car is 2000 kg and the spring constant equals 4500 kg/sec^2?

14. **(Damping constant)** Consider an underdamped motion of a body of mass $m = 2$ kg. If the time between two consecutive maxima is 2 sec and the maximum amplitude decreases to $\frac{1}{4}$ of its initial value after 15 cycles, what is the damping constant of the system?

15. **(Initial value problem)** Find the critical motion (8) that starts from y_0 with initial velocity v_0. Graph solution curves for $\alpha = 1$, $y_0 = 1$ and several v_0 such that (i) the curve does not intersect the t-axis, (ii) it intersects it at $t = 1, 2, \cdots, 5$, respectively.

16. **(Initial value problem)** Find the overdamped motion (7) that starts from y_0 with initial velocity v_0.

17. **(Overdamping)** Show that in the overdamped case, the body can pass through $y = 0$ at most once.

18. **CAS PROJECT. Transition Between Cases I, II, III.** Study this transition in terms of graphs of typical solutions. (Cf. Fig. 46.)

(a) ***Avoiding unnecessary generality is part of good modeling.*** Decide that the initial value problems (A) and (B),

(A) $y'' + cy' + y = 0, \quad y(0) = 1, \quad y'(0) = 0$

(B) the same with different c and $y'(0) = -2$ (instead of 0), will give practically as much information as a problem with other m, k, $y(0)$, $y'(0)$.

(b) ***Consider* (A).** Choose suitable values of c, perhaps better ones than in Fig. 46 for the transition from Case III to II and I. Guess c for the curves in the figure.

(c) ***Time to go to rest.*** Theoretically, this time is infinite (why?). Practically, the system is at rest when its motion has become very small, say, less than 0.1% of the initial displacement (this choice being up to us), that is in our case,

(11) $|y(t)| < 0.001$ for all t greater than some t_1.

In engineering constructions, damping can often be varied without too much trouble. Experimenting with your graphs, find empirically a relation between t_1 and c.

(d) ***Solve* (A) *analytically.*** Give a reason why the solution c of $y(t_2) = -0.001$, with t_2 the solution of $y'(t) = 0$, will give you the best possible c satisfying (11).

(e) Consider (B) empirically as in (a) and (b). What is the main difference between (B) and (A)?

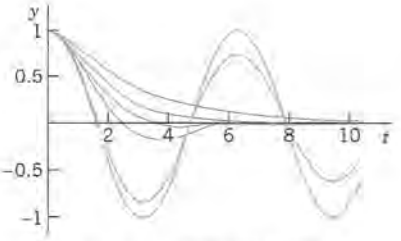

Fig. 46. CAS Project 18

2.5 Euler–Cauchy Equations

Euler–Cauchy equations[4] are ODEs of the form

(1) $$x^2y'' + axy' + by = 0$$

[4]LEONHARD EULER (1707–1783) was an enormously creative Swiss mathematician. He made fundamental contributions to almost all branches of mathematics and its application to physics. His important books on algebra and calculus contain numerous basic results of his own research. The great French mathematician AUGUSTIN LOUIS CAUCHY (1789–1857) is the father of modern analysis. He is the creator of complex analysis and had great influence on ODEs, PDEs, infinite series, elasticity theory, and optics.

with given constants a and b and unknown $y(x)$. We substitute

$$y = x^m \tag{2}$$

and its derivatives $y' = mx^{m-1}$ and $y'' = m(m-1)x^{m-2}$ into (1). This gives

$$x^2m(m-1)x^{m-2} + axmx^{m-1} + bx^m = 0.$$

We now see that (2) was a rather natural choice because we have obtained a common factor x^m. Dropping it, we have the auxiliary equation $m(m-1) + am + b = 0$ or

$$m^2 + (a-1)m + b = 0. \qquad \text{(Note: } a - 1\text{, not } a\text{.)} \tag{3}$$

Hence $y = x^m$ is a solution of (1) if and only if m is a root of (3). The roots of (3) are

$$m_1 = \tfrac{1}{2}(1-a) + \sqrt{\tfrac{1}{4}(1-a)^2 - b}, \qquad m_2 = \tfrac{1}{2}(1-a) - \sqrt{\tfrac{1}{4}(1-a)^2 - b}. \tag{4}$$

Case I. If the roots m_1 and m_2 are real and different, then solutions are

$$y_1(x) = x^{m_1} \qquad \text{and} \qquad y_2(x) = x^{m_2}$$

They are linearly independent since their quotient is not constant. Hence they constitute a basis of solutions of (1) for all x for which they are real. The corresponding general solution for all these x is

$$y = c_1x^{m_1} + c_2x^{m_2} \qquad (c_1, c_2 \text{ arbitrary}). \tag{5}$$

EXAMPLE 1 **General Solution in the Case of Different Real Roots**

The Euler–Cauchy equation

$$x^2y'' + 1.5xy' - 0.5y = 0$$

has the auxiliary equation

$$m^2 + 0.5m - 0.5 = 0. \qquad \text{(Note: 0.5, not 1.5!)}$$

The roots are 0.5 and -1. Hence a basis of solutions for all positive x is $y_1 = x^{0.5}$ and $y_2 = 1/x$ and gives the general solution

$$y = c_1\sqrt{x} + \frac{c_2}{x} \qquad (x > 0). \qquad \blacksquare$$

Case II. Equation (4) shows that the auxiliary equation (3) has a double root $m_1 = \frac{1}{2}(1-a)$ if and only if $(1-a)^2 - 4b = 0$. The Euler–Cauchy equation (1) then has the form

$$x^2y'' + axy' + \tfrac{1}{4}(1-a)^2y = 0. \tag{6}$$

A solution is $y_1 = x^{(1-a)/2}$. To obtain a second linearly independent solution, we apply the method of reduction of order from Sec. 2.1 as follows. Starting from $y_2 = uy_1$, we obtain for u the expression (9), Sec. 2.1, namely,

$$u = \int U\,dx \qquad \text{where} \qquad U = \frac{1}{y_1^2}\exp\left(-\int p\,dx\right).$$

Here it is crucial that p is taken from the ODE written in standard form, in our case,

$$(6^*) \qquad y'' + \frac{a}{x}y' + \frac{(1-a)^2}{4x^2}y = 0.$$

This shows that $p = a/x$ (not ax). Hence its integral is $a \ln x = \ln (x^a)$, the exponential function in U is $1/x^a$, and division by ${y_1}^2 = x^{1-a}$ gives $U = 1/x$, and $u = \ln x$ by integration.

Thus, in this "critical case," a basis of solutions for positive x is $y_1 = x^m$ and $y_2 = x^m \ln x$, where $m = \frac{1}{2}(1 - a)$. Linear independence follows from the fact that the quotient of these solutions is not constant. Hence, for all x for which y_1 and y_2 are defined and real, a general solution is

$$(7) \qquad y = (c_1 + c_2 \ln x)x^m, \qquad m = \tfrac{1}{2}(1 - a).$$

EXAMPLE 2 General Solution in the Case of a Double Root

The Euler–Cauchy equation $x^2y'' - 5xy' + 9y = 0$ has the auxiliary equation $m^2 - 6m + 9 = 0$. It has the double root $m = 3$, so that a general solution for all positive x is

$$y = (c_1 + c_2 \ln x)x^3.$$

■

Case III. The case of complex roots is of minor practical importance, and it suffices to present an example that explains the derivation of real solutions from complex ones.

EXAMPLE 3 Real General Solution in the Case of Complex Roots

The Euler–Cauchy equation

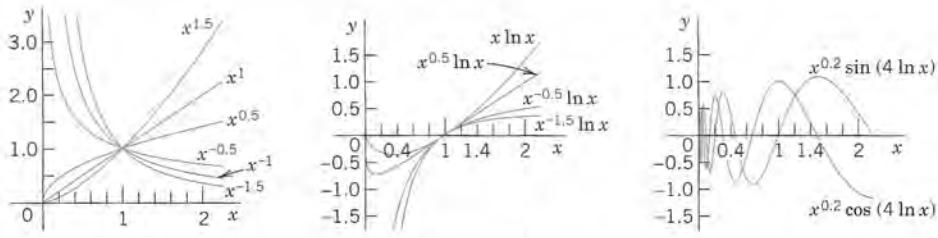
$$x^2y'' + 0.6xy' + 16.04y = 0$$

has the auxiliary equation $m^2 - 0.4m + 16.04 = 0$. The roots are complex conjugate, $m_1 = 0.2 + 4i$ and $m_2 = 0.2 - 4i$, where $i = \sqrt{-1}$. (We know from algebra that if a polynomial with real coefficients has complex roots, these are always conjugate.) Now use the trick of writing $x = e^{\ln x}$ and obtain

$$x^{m_1} = x^{0.2+4i} = x^{0.2}(e^{\ln x})^{4i} = x^{0.2}e^{(4 \ln x)i},$$
$$x^{m_2} = x^{0.2-4i} = x^{0.2}(e^{\ln x})^{-4i} = x^{0.2}e^{-(4 \ln x)i}.$$

Next apply Euler's formula (11) in Sec. 2.2 with $t = 4 \ln x$ to these two formulas. This gives

$$x^{m_1} = x^{0.2}[\cos (4 \ln x) + i \sin (4 \ln x)],$$
$$x^{m_2} = x^{0.2}[\cos (4 \ln x) - i \sin (4 \ln x)].$$



Add these two formulas, so that the sine drops out, and divide the result by 2. Then subtract the second formula from the first, so that the cosine drops out, and divide the result by $2i$. This yields

$$x^{0.2} \cos (4 \ln x) \qquad \text{and} \qquad x^{0.2} \sin (4 \ln x)$$

respectively. By the superposition principle in Sec. 2.2 these are solutions of the Euler–Cauchy equation (1). Since their quotient $\cot (4 \ln x)$ is not constant, they are linearly independent. Hence they form a basis of solutions, and the corresponding real general solution for all positive x is

$$(8) \qquad y = x^{0.2}[A \cos (4 \ln x) + B \sin (4 \ln x)].$$

Figure 47 shows typical solution curves in the three cases discussed, in particular the basis functions in Examples 1 and 3. ■

Case I: Real roots Case II: Double root Case III: Complex roots

Fig. 47. Euler–Cauchy equations

EXAMPLE 4 **Boundary Value Problem. Electric Potential Field Between Two Concentric Spheres**

Find the electrostatic potential $v = v(r)$ between two concentric spheres of radii $r_1 = 5$ cm and $r_2 = 10$ cm kept at potentials $v_1 = 110$ V and $v_2 = 0$, respectively.

Physical Information. $v(r)$ is a solution of the Euler–Cauchy equation $rv'' + 2v' = 0$, where $v' = dv/dr$.

Solution. The auxiliary equation is $m^2 + m = 0$. It has the roots 0 and -1. This gives the general solution $v(r) = c_1 + c_2/r$. From the "boundary conditions" (the potentials on the spheres) we obtain

$$v(5) = c_1 + \frac{c_2}{5} = 110, \qquad v(10) = c_1 + \frac{c_2}{10} = 0.$$

By subtraction, $c_2/10 = 110$, $c_2 = 1100$. From the second equation, $c_1 = -c_2/10 = -110$. *Answer:* $v(r) = -110 + 1100/r$ V. Figure 48 shows that the potential is not a straight line, as it would be for a potential between two parallel plates. For example, on the sphere of radius 7.5 cm it is not 110/2 = 55 V, but considerably less. (What is it?) ■

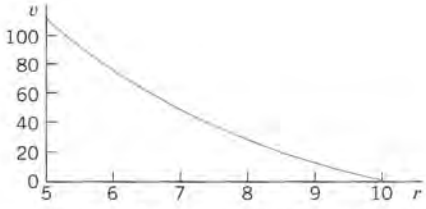


Fig. 48. Potential $v(r)$ in Example 4

PROBLEM SET 2.5

1–10 GENERAL SOLUTION

Find a real general solution, showing the details of your work.

1. $x^2y'' - 6y = 0$
2. $4x^2y'' + 4xy' - y = 0$
3. $x^2y'' - 7xy' + 16y = 0$
4. $x^2y'' + 3xy' + y = 0$
5. $x^2y'' - xy' + 2y = 0$
6. $2x^2y'' + 4xy' + 5y = 0$
7. $(10x^2D^2 - 20xD + 22.4I)y = 0$
8. $(4x^2D^2 + I)y = 0$
9. $(100x^2D^2 + 9I)y = 0$
10. $(10x^2D^2 + 6xD + 0.5I)y = 0$

11–15 INITIAL VALUE PROBLEM

Solve and graph the solution, showing the details of your work.

11. $x^2y'' - 4xy' + 6y = 0$, $y(1) = 1$, $y'(1) = 0$
12. $x^2y'' + 3xy' + y = 0$, $y(1) = 4$, $y'(1) = -2$
13. $(x^2D^2 + 2xD + 100.25I)y = 0$, $y(1) = 2$, $y'(1) = -11$
14. $(x^2D^2 - 2xD + 2.25I)y = 0$, $y(1) = 2.2$, $y'(1) = 2.5$
15. $(xD^2 + 4D)y = 0$, $y(1) = 12$, $y'(1) = -6$

16. TEAM PROJECT. Double Root

(A) Derive a second linearly independent solution of (1) by reduction of order; but instead of using (9), Sec. 2.1, perform all steps directly for the present ODE (1).

(B) Obtain $x^m \ln x$ by considering the solutions x^m and x^{m+s} of a suitable Euler–Cauchy equation and letting $s \to 0$.

(C) Verify by substitution that $x^m \ln x$, $m = (1 - a)/2$, is a solution in the critical case.

(D) Transform the Euler–Cauchy equation (1) into an ODE with constant coefficients by setting $x = e^t$ $(x > 0)$.

(E) Obtain a second linearly independent solution of the Euler–Cauchy equation in the "critical case" from that of a constant-coefficient ODE.

2.6 Existence and Uniqueness of Solutions. Wronskian

In this section we shall discuss the general theory of homogeneous linear ODEs

$$y'' + p(x)y' + q(x)y = 0 \tag{1}$$

with continuous, but otherwise arbitrary ***variable coefficients*** p and q. This will concern the existence and form of a general solution of (1) as well as the uniqueness of the solution of initial value problems consisting of such an ODE and two initial conditions

$$y(x_0) = K_0, \qquad y'(x_0) = K_1 \tag{2}$$

with given x_0, K_0, and K_1.

The two main results will be Theorem 1, stating that such an initial value problem always has a solution which is unique, and Theorem 4, stating that a general solution

$$y = c_1 y_1 + c_2 y_2 \qquad (c_1, c_2 \text{ arbitrary}) \tag{3}$$

includes all solutions. Hence *linear* ODEs with continuous coefficients have no *"singular solutions"* (solutions not obtainable from a general solution).

Clearly, no such theory was needed for constant-coefficient or Euler–Cauchy equations because everything resulted explicitly from our calculations.

Central to our present discussion is the following theorem.

THEOREM 1

Existence and Uniqueness Theorem for Initial Value Problems

If $p(x)$ and $q(x)$ are continuous functions on some open interval I (see Sec. 1.1) *and x_0 is in I, then the initial value problem consisting of* (1) *and* (2) *has a unique solution $y(x)$ on the interval I.*

The proof of existence uses the same prerequisites as the existence proof in Sec. 1.7 and will not be presented here; it can be found in Ref. [A11] listed in App. 1. Uniqueness proofs are usually simpler than existence proofs. But for Theorem 1, even the uniqueness proof is long, and we give it as an additional proof in App. 4.

Linear Independence of Solutions

Remember from Sec. 2.1 that a general solution on an open interval I is made up from a **basis** y_1, y_2 on I, that is, from a pair of linearly independent solutions on I. Here we call y_1, y_2 **linearly independent** on I if the equation

$$(4) \qquad k_1y_1(x) + k_2y_2(x) = 0 \quad \text{on } I \qquad \text{implies} \qquad k_1 = 0, \quad k_2 = 0.$$

We call y_1, y_2 **linearly dependent** on I if this equation also holds for constants k_1, k_2 not both 0. In this case, and only in this case, y_1 and y_2 are proportional on I, that is (see Sec. 2.1),

$$(5) \qquad \text{(a)} \quad y_1 = ky_2 \qquad \text{or} \qquad \text{(b)} \quad y_2 = ly_1 \qquad \text{for all } x \text{ on } I.$$

For our discussion the following criterion of linear independence and dependence of solutions will be helpful.

THEOREM 2

Linear Dependence and Independence of Solutions

Let the ODE (1) *have continuous coefficients* $p(x)$ *and* $q(x)$ *on an open interval* I. *Then two solutions* y_1 *and* y_2 *of* (1) *on* I *are linearly dependent on* I *if and only if their* **"Wronskian"**

$$(6) \qquad W(y_1, y_2) = y_1y_2' - y_2y_1'$$

is 0 *at some* x_0 *in* I. *Furthermore, if* $W = 0$ *at an* $x = x_0$ *in* I, *then* $W \equiv 0$ *on* I; *hence if there is an* x_1 *in* I *at which* W *is not* 0, *then* y_1, y_2 *are linearly independent on* I.

PROOF **(a)** Let y_1 and y_2 be linearly dependent on I. Then (5a) or (5b) holds on I. If (5a) holds, then

$$W(y_1, y_2) = y_1y_2' - y_2y_1' = ky_2y_2' - y_2ky_2' = 0.$$

Similarly if (5b) holds.

(b) Conversely, we let $W(y_1, y_2) = 0$ for some $x = x_0$ and show that this implies linear dependence of y_1 and y_2 on I. We consider the linear system of equations in the unknowns k_1, k_2

$$(7) \qquad \begin{aligned} k_1y_1(x_0) + k_2y_2(x_0) &= 0 \\ k_1y_1'(x_0) + k_2y_2'(x_0) &= 0. \end{aligned}$$

To eliminate k_2, multiply the first equation by y_2' and the second by $-y_2$ and add the resulting equations. This gives

$$k_1y_1(x_0)y_2'(x_0) - k_1y_1'(x_0)y_2(x_0) = k_1W(y_1(x_0), y_2(x_0)) = 0.$$

Similarly, to eliminate k_1, multiply the first equation by $-y_1'$ and the second by y_1 and add the resulting equations. This gives

$$k_2W(y_1(x_0), y_2(x_0)) = 0.$$

If W were not 0 at x_0, we could divide by W and conclude that $k_1 = k_2 = 0$. Since W is 0, division is not possible, and the system has a solution for which k_1 and k_2 are not both 0. Using *these numbers* k_1, k_2, we introduce the function

$$y(x) = k_1 y_1(x) + k_2 y_2(x).$$

Since (1) is homogeneous linear, Fundamental Theorem 1 in Sec. 2.1 (the superposition principle) implies that this function is a solution of (1) on I. From (7) we see that it satisfies the initial conditions $y(x_0) = 0$, $y'(x_0) = 0$. Now another solution of (1) satisfying the same initial conditions is $y^* \equiv 0$. Since the coefficients p and q of (1) are continuous, Theorem 1 applies and gives uniqueness, that is, $y \equiv y^*$, written out

$$k_1 y_1 + k_2 y_2 \equiv 0 \qquad \text{on } I.$$

Now since k_1 and k_2 are not both zero, this means linear dependence of y_1, y_2 on I.

(c) We prove the last statement of the theorem. If $W(x_0) = 0$ at an x_0 in I, we have linear dependence of y_1, y_2 on I by part (b), hence $W \equiv 0$ by part (a) of this proof. Hence in the case of linear dependence it cannot happen that $W(x_1) \neq 0$ at an x_1 in I. If it does happen, it thus implies linear independence as claimed. ∎

Remark. **Determinants.** Students familiar with second-order determinants may have noticed that

$$W(y_1, y_2) = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix} = y_1 y_2' - y_2 y_1'.$$

This determinant is called the *Wronski determinant*[5] or, briefly, the **Wronskian,** of two solutions y_1 and y_2 of (1), as has already been mentioned in (6). Note that its four entries occupy the same positions as in the linear system (7).

EXAMPLE 1 **Illustration of Theorem 2**

The functions $y_1 = \cos \omega x$ and $y_2 = \sin \omega x$ are solutions of $y'' + \omega^2 y = 0$. Their Wronskian is

$$W(\cos \omega x, \sin \omega x) = \begin{vmatrix} \cos \omega x & \sin \omega x \\ -\omega \sin \omega x & \omega \cos \omega x \end{vmatrix} = y_1 y_2' - y_2 y_1' = \omega \cos^2 \omega x + \omega \sin^2 \omega x = \omega.$$

Theorem 2 shows that these solutions are linearly independent if and only if $\omega \neq 0$. Of course, we can see this directly from the quotient $y_2/y_1 = \tan \omega x$. For $\omega = 0$ we have $y_2 \equiv 0$, which implies linear dependence (why?). ∎

EXAMPLE 2 **Illustration of Theorem 2 for a Double Root**

A general solution of $y'' - 2y' + y = 0$ on any interval is $y = (c_1 + c_2 x)e^x$. (Verify!). The corresponding Wronskian is not 0, which shows linear independence of e^x and xe^x on any interval. Namely,

$$W(x, xe^x) = \begin{vmatrix} e^x & xe^x \\ e^x & (x+1)e^x \end{vmatrix} = (x+1)e^{2x} - xe^{2x} = e^{2x} \neq 0.$$ ∎

[5]Introduced by WRONSKI (JOSEF MARIA HÖNE, 1776–1853), Polish mathematician.

A General Solution of (1) Includes All Solutions

This will be our second main result, as announced at the beginning. Let us start with existence.

THEOREM 3

Existence of a General Solution

If $p(x)$ and $q(x)$ are continuous on an open interval I, then (1) *has a general solution on I.*

PROOF By Theorem 1, the ODE (1) has a solution $y_1(x)$ on I satisfying the initial conditions

$$y_1(x_0) = 1, \qquad y_1'(x_0) = 0$$

and a solution $y_2(x)$ on I satisfying the initial conditions

$$y_2(x_0) = 0, \qquad y_2'(x_0) = 1.$$

The Wronskian of these two solutions has at $x = x_0$ the value

$$W(y_1(0), y_2(0)) = y_1(x_0)y_2'(x_0) - y_2(x_0)y_1'(x_0) = 1.$$

Hence, by Theorem 2, these solutions are linearly independent on I. They form a basis of solutions of (1) on I, and $y = c_1y_1 + c_2y_2$ with arbitrary c_1, c_2 is a general solution of (1) on I, whose existence we wanted to prove. ■

We finally show that a general solution is as general as it can possibly be.

THEOREM 4

A General Solution Includes All Solutions

If the ODE (1) *has continuous coefficients $p(x)$ and $q(x)$ on some open interval I, then every solution $y = Y(x)$ of* (1) *on I is of the form*

$$Y(x) = C_1y_1(x) + C_2y_2(x) \tag{8}$$

where y_1, y_2 is any basis of solutions of (1) *on I and C_1, C_2 are suitable constants.*

Hence (1) *does not have* **singular solutions** *(that is, solutions not obtainable from a general solution).*

PROOF Let $y = Y(x)$ be any solution of (1) on I. Now, by Theorem 3 the ODE (1) has a general solution

$$y(x) = c_1y_1(x) + c_2y_2(x) \tag{9}$$

on I. We have to find suitable values of c_1, c_2 such that $y(x) = Y(x)$ on I. We choose any x_0 in I and show first that we can find values of c_1, c_2 such that we reach agreement at x_0, that is, $y(x_0) = Y(x_0)$ and $y'(x_0) = Y'(x_0)$. Written out in terms of (9), this becomes

$$\begin{aligned} &\text{(a)} \quad c_1y_1(x_0) + c_2y_2(x_0) = Y(x_0) \\ &\text{(b)} \quad c_1y_1'(x_0) + c_2y_2'(x_0) = Y'(x_0). \end{aligned} \tag{10}$$

We determine the unknowns c_1 and c_2. To eliminate c_2, we multiply (10a) by $y_2'(x_0)$ and (10b) by $-y_2(x_0)$ and add the resulting equations. This gives an equation for c_1. Then we multiply (10a) by $-y_1'(x_0)$ and (10b) by $y_1(x_0)$ and add the resulting equations. This gives an equation for c_2. These new equations are as follows, where we take the values of y_1, y_1', y_2, y_2', Y, Y' at x_0,

$$c_1(y_1y_2' - y_2y_1') = c_1W(y_1, y_2) = Yy_2' - y_2Y'$$
$$c_2(y_1y_2' - y_2y_1') = c_2W(y_1, y_2) = y_1Y' - Yy_1'.$$

Since y_1, y_2 is a basis, the Wronskian W in these equations is not 0, and we can solve for c_1 and c_2. We call the (unique) solution $c_1 = C_1$, $c_2 = C_2$. By substituting it into (9) we obtain from (9) the particular solution

$$y^*(x) = C_1y_1(x) + C_2y_2(x).$$

Now since C_1, C_2 is a solution of (10), we see from (10) that

$$y^*(x_0) = Y(x_0), \qquad y^{*\prime}(x_0) = Y'(x_0).$$

From the uniqueness stated in Theorem 1 this implies that y^* and Y must be equal everywhere on I, and the proof is complete. ■

Looking back at he content of this section, we see that homogeneous linear ODEs with continuous variable coefficients have a conceptually and structurally rather transparent existence and uniqueness theory of solutions. Important in itself, this theory will also provide the foundation of an investigation of nonhomogeneous linear ODEs, whose theory and engineering applications we shall study in the remaining four sections of this chapter.

PROBLEM SET 2.6

1–17 BASES OF SOLUTIONS. CORRESPONDING ODEs. WRONSKIANS

Find an ODE (1) for which the given functions are solutions. Show linear independence (a) by considering quotients, (b) by Theorem 2.

1. $e^{0.5x}$, $e^{-0.5x}$
2. $\cos \pi x$, $\sin \pi x$
3. e^{kx}, xe^{kx}
4. x^3, x^{-2}
5. $x^{0.25}$, $x^{0.25} \ln x$
6. $e^{3.4x}$, $e^{-2.5x}$
7. $\cos (2 \ln x)$, $\sin (2 \ln x)$
8. e^{-2x}, xe^{-2x}
9. $x^{1.5}$, $x^{-0.5}$
10. x^{-3}, $x^{-3} \ln x$
11. $\cosh 2.5x$, $\sinh 2.5x$
12. $e^{-2x} \cos \omega x$, $e^{-2x} \sin \omega x$
13. $e^{-x} \cos 0.8x$, $e^{-x} \sin 0.8x$
14. $x^{-1} \cos (\ln x)$, $x^{-1} \sin (\ln x)$
15. $e^{-2.5x} \cos 0.3x$, $e^{-2.5x} \sin 0.3x$
16. $e^{-kx} \cos \pi x$, $e^{-kx} \sin \pi x$
17. $e^{-3.8\pi x}$, $xe^{-3.8\pi x}$

18. **TEAM PROJECT. Consequences of the Present Theory.** This concerns some noteworthy general properties of solutions. Assume that the coefficients p and q of the ODE (1) are continuous on some open interval I, to which the subsequent statements refer.

(A) Solve $y'' - y = 0$ (a) by exponential functions, (b) by hyperbolic functions. How are the constants in the corresponding general solutions related?

(B) Prove that the solutions of a basis cannot be 0 at the same point.

(C) Prove that the solutions of a basis cannot have a maximum or minimum at the same point.

(D) Express $(y_2/y_1)'$ by a formula involving the Wronskian W. Why is it likely that such a formula should exist? Use it to find W in Prob. 10.

(E) Sketch $y_1(x) = x^3$ if $x \geqq 0$ and 0 if $x < 0$, $y_2(x) = 0$ if $x \geqq 0$ and x^3 if $x < 0$. Show linear independence on $-1 < x < 1$. What is their Wronskian? What Euler–Cauchy equation do y_1, y_2 satisfy? Is there a contradiction to Theorem 2?

(F) Prove **Abel's formula**[6]

$$W(y_1(x), y_2(x)) = c \exp\left[-\int_{x_0}^{x} p(t)\,dt\right]$$

where $c = W(y_1(x_0), y_2(x_0))$. Apply it to Prob. 12. *Hint:* Write (1) for y_1 and for y_2. Eliminate q algebraically from these two ODEs, obtaining a first-order linear ODE. Solve it.

2.7 Nonhomogeneous ODEs

Method of Undetermined Coefficients

In this section we proceed from homogeneous to nonhomogeneous linear ODEs

$$y'' + p(x)y' + q(x)y = r(x) \tag{1}$$

where $r(x) \not\equiv 0$. We shall see that a "general solution" of (1) is the sum of a general solution of the corresponding homogeneous ODE

$$y'' + p(x)y' + q(x)y = 0 \tag{2}$$

and a "particular solution" of (1). These two new terms "general solution of (1)" and "particular solution of (1)" are defined as follows.

DEFINITION

General Solution, Particular Solution

A **general solution** of the nonhomogeneous ODE (1) on an open interval I is a solution of the form

$$y(x) = y_h(x) + y_p(x); \tag{3}$$

here, $y_h = c_1y_1 + c_2y_2$ is a general solution of the homogeneous ODE (2) on I and y_p is any solution of (1) on I containing no arbitrary constants.

A **particular solution** of (1) on I is a solution obtained from (3) by assigning specific values to the arbitrary constants c_1 and c_2 in y_h.

Our task is now twofold, first to justify these definitions and then to develop a method for finding a solution y_p of (1).

Accordingly, we first show that a general solution as just defined satisfies (1) and that the solutions of (1) and (2) are related in a very simple way.

THEOREM 1

Relations of Solutions of (1) to Those of (2)

(a) *The sum of a solution y of* (1) *on some open interval I and a solution $\tilde{y}$ of* (2) *on I is a solution of* (1) *on I. In particular,* (3) *is a solution of* (1) *on I.*

(b) *The difference of two solutions of* (1) *on I is a solution of* (2) *on I.*

[6]NIELS HENRIK ABEL (1802–1829), Norwegian mathematician.

PROOF **(a)** Let $L[y]$ denote the left side of (1). Then for any solutions y of (1) and $\tilde{y}$ of (2) on I,

$$L[y + \tilde{y}] = L[y] + L[\tilde{y}] = r + 0 = r.$$

(b) For any solutions y and y^* of (1) on I we have $L[y - y^*] = L[y] - L[y^*] = r - r = 0$. ∎

Now for *homogeneous ODEs* (2) we know that general solutions include all solutions. We show that the same is true for nonhomogeneous ODEs (1).

THEOREM 2

A General Solution of a Nonhomogeneous ODE Includes All Solutions

If the coefficients $p(x)$, $q(x)$, and the function $r(x)$ in (1) *are continuous on some open interval I, then every solution of* (1) *on I is obtained by assigning suitable values to the arbitrary constants c_1 and c_2 in a general solution* (3) *of* (1) *on I.*

PROOF Let y^* be any solution of (1) on I and x_0 any x in I. Let (3) be any general solution of (1) on I. This solution exists. Indeed, $y_h = c_1y_1 + c_2y_2$ exists by Theorem 3 in Sec. 2.6 because of the continuity assumption, and y_p exists according to a construction to be shown in Sec. 2.10. Now, by Theorem 1(b) just proved, the difference $Y = y^* - y_p$ is a solution of (2) on I. At x_0 we have

$$Y(x_0) = y^*(x_0) - y_p(x_0), \qquad Y'(x_0) = y^{*\prime}(x_0) - y_p'(x_0).$$

Theorem 1 in Sec. 2.6 implies that for these conditions, as for any other initial conditions in I, there exists a unique particular solution of (2) obtained by assigning suitable values to c_1, c_2 in y_h. From this and $y^* = Y + y_p$ the statement follows. ∎

Method of Undetermined Coefficients

Our discussion suggests the following. *To solve the nonhomogeneous ODE* (1) *or an initial value problem for* (1), *we have to solve the homogeneous ODE* (2) *and find any solution y_p of* (1), so that we obtain a general solution (3) of (1).

How can we find a solution y_p of (1)? One method is the so-called **method of undetermined coefficients.** It is much simpler than another, more general method (to be discussed in Sec. 2.10). Since it applies to models of vibrational systems and electric circuits to be shown in the next two sections, it is frequently used in engineering.

More precisely, the method of undetermined coefficients is suitable for linear ODEs with ***constant coefficients a and b***

$$y'' + ay' + by = r(x) \tag{4}$$

when $r(x)$ is an exponential function, a power of x, a cosine or sine, or sums or products of such functions. These functions have derivatives similar to $r(x)$ itself. This gives the idea. We choose a form for y_p similar to $r(x)$, but with unknown coefficients to be determined by substituting that y_p and its derivatives into the ODE. Table 2.1 on p. 80 shows the choice of y_p for practically important forms of $r(x)$. Corresponding rules are as follows.

Choice Rules for the Method of Undetermined Coefficients

(a) Basic Rule. *If $r(x)$ in (4) is one of the functions in the first column in Table 2.1, choose y_p in the same line and determine its undetermined coefficients by substituting y_p and its derivatives into (4).*

(b) Modification Rule. *If a term in your choice for y_p happens to be a solution of the homogeneous ODE corresponding to (4), multiply your choice of y_p by x (or by x^2 if this solution corresponds to a double root of the characteristic equation of the homogeneous ODE).*

(c) Sum Rule. *If $r(x)$ is a sum of functions in the first column of Table 2.1, choose for y_p the sum of the functions in the corresponding lines of the second column.*

The Basic Rule applies when $r(x)$ is a single term. The Modification Rule helps in the indicated case, and to recognize such a case, we have to solve the homogeneous ODE first. The Sum Rule follows by noting that the sum of two solutions of (1) with $r = r_1$ and $r = r_2$ (and the same left side!) is a solution of (1) with $r = r_1 + r_2$. (Verify!)

The method is self-correcting. A false choice for y_p or one with too few terms will lead to a contradiction. A choice with too many terms will give a correct result, with superfluous coefficients coming out zero.

Let us illustrate Rules (a)–(c) by the typical Examples 1–3.

Table 2.1 Method of Undetermined Coefficients

Term in $r(x)$	Choice for $y_p(x)$
$ke^{\gamma x}$	$Ce^{\gamma x}$
kx^n $(n = 0, 1, \cdots)$	$K_n x^n + K_{n-1}x^{n-1} + \cdots + K_1 x + K_0$
$k \cos \omega x$ $k \sin \omega x$	$K \cos \omega x + M \sin \omega x$
$ke^{\alpha x} \cos \omega x$ $ke^{\alpha x} \sin \omega x$	$e^{\alpha x}(K \cos \omega x + M \sin \omega x)$

EXAMPLE 1 Application of the Basic Rule (a)

Solve the initial value problem

$$y'' + y = 0.001x^2, \qquad y(0) = 0, \qquad y'(0) = 1.5. \tag{5}$$

Solution. ***Step 1. General solution of the homogeneous ODE.*** The ODE $y'' + y = 0$ has the general solution

$$y_h = A \cos x + B \sin x.$$

Step 2. Solution y_p of the nonhomogeneous ODE. We first try $y_p = Kx^2$. Then $y_p'' = 2K$. By substitution, $2K + Kx^2 = 0.001x^2$. For this to hold for all x, the coefficient of each power of x (x^2 and x^0) must be the same on both sides; thus $K = 0.001$ and $2K = 0$, a contradiction.

The second line in Table 2.1 suggests the choice

$$y_p = K_2x^2 + K_1x + K_0. \qquad \text{Then} \qquad y_p'' + y_p = 2K_2 + K_2x^2 + K_1x + K_0 = 0.001x^2.$$

Equating the coefficients of x^2, x, x^0 on both sides, we have $K_2 = 0.001$, $K_1 = 0$, $2K_2 + K_0 = 0$. Hence $K_0 = -2K_2 = -0.002$. This gives $y_p = 0.001x^2 - 0.002$, and

$$y = y_h + y_p = A \cos x + B \sin x + 0.001x^2 - 0.002.$$

Step 3. Solution of the initial value problem. Setting $x = 0$ and using the first initial condition gives $y(0) = A - 0.002 = 0$, hence $A = 0.002$. By differentiation and from the second initial condition,

$$y' = y_h' + y_p' = -A \sin x + B \cos x + 0.002x \qquad \text{and} \qquad y'(0) = B = 1.5.$$

This gives the answer (Fig. 49)

$$y = 0.002 \cos x + 1.5 \sin x + 0.001x^2 - 0.002.$$

Figure 49 shows y as well as the quadratic parabola y_p about which y is oscillating, practically like a sine curve since the cosine term is smaller by a factor of about 1/1000.

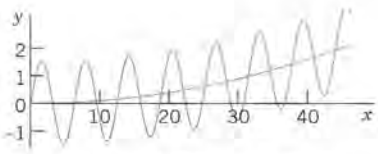

Fig. 49. Solution in Example 1

EXAMPLE 2 Application of the Modification Rule (b)

Solve the initial value problem

$$(6) \qquad y'' + 3y' + 2.25y = -10\, e^{-1.5x}, \qquad y(0) = 1, \qquad y'(0) = 0.$$

Solution. ***Step 1. General solution of the homogeneous ODE.*** The characteristic equation of the homogeneous ODE is $\lambda^2 + 3\lambda + 2.25 = (\lambda + 1.5)^2 = 0$. Hence the homogeneous ODE has the general solution

$$y_h = (c_1 + c_2 x)e^{-1.5x}.$$

Step 2. Solution y_p of the nonhomogeneous ODE. The function $e^{-1.5x}$ on the right would normally require the choice $Ce^{-1.5x}$. But we see from y_h that this function is a solution of the homogeneous ODE, which corresponds to a *double root* of the characteristic equation. Hence, according to the Modification Rule we have to multiply our choice function by x^2. That is, we choose

$$y_p = Cx^2e^{-1.5x}. \qquad \text{Then} \qquad y_p' = C(2x - 1.5x^2)e^{-1.5x}, \qquad y_p'' = C(2 - 3x - 3x + 2.25x^2)e^{-1.5x}.$$

We substitute these expressions into the given ODE and omit the factor $e^{-1.5x}$. This yields

$$C(2 - 6x + 2.25x^2) + 3C(2x - 1.5x^2) + 2.25Cx^2 = -10.$$

Comparing the coefficients of x^2, x, x^0 gives $0 = 0$, $0 = 0$, $2C = -10$, hence $C = -5$. This gives the solution $y_p = -5x^2e^{-1.5x}$. Hence the given ODE has the general solution

$$y = y_h + y_p = (c_1 + c_2 x)e^{-1.5x} - 5x^2e^{-1.5x}.$$

Step 3. Solution of the initial value problem. Setting $x = 0$ in y and using the first initial condition, we obtain $y(0) = c_1 = 1$. Differentiation of y gives

$$y' = (c_2 - 1.5c_1 - 1.5c_2x)e^{-1.5x} - 10xe^{-1.5x} + 7.5x^2e^{-1.5x}.$$

From this and the second initial condition we have $y'(0) = c_2 - 1.5c_1 = 0$. Hence $c_2 = 1.5c_1 = 1.5$. This gives the answer (Fig. 50)

$$y = (1 + 1.5x)\, e^{-1.5x} - 5x^2e^{-1.5x} = (1 + 1.5x - 5x^2)e^{-1.5x}.$$

The curve begins with a horizontal tangent, crosses the x-axis at $x = 0.6217$ (where $1 + 1.5x - 5x^2 = 0$) and approaches the axis from below as x increases.

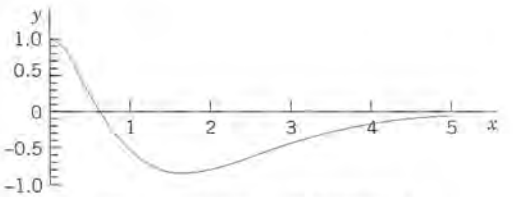

Fig. 50. Solution in Example 2

EXAMPLE 3 Application of the Sum Rule (c)

Solve the initial value problem

$$(7) \qquad y'' + 2y' + 5y = e^{0.5x} + 40\cos 10x - 190\sin 10x, \qquad y(0) = 0.16, \qquad y'(0) = 40.08.$$

Solution. ***Step 1. General solution of the homogeneous ODE.*** The characteristic equation

$$\lambda^2 + 2\lambda + 5 = (\lambda + 1 + 2i)(\lambda + 1 - 2i) = 0$$

shows that a real general solution of the homogeneous ODE is

$$y_h = e^{-x}(A\cos 2x + B\sin 2x).$$

Step 2. Solution of the nonhomogeneous ODE. We write $y_p = y_{p1} + y_{p2}$, where y_{p1} corresponds to the exponential term and y_{p2} to the sum of the other two terms. We set

$$y_{p1} = Ce^{0.5x}. \qquad \text{Then} \qquad y'_{p1} = 0.5Ce^{0.5x} \qquad \text{and} \qquad y''_{p1} = 0.25Ce^{0.5x}.$$

Substitution into the given ODE and omission of the exponential factor gives $(0.25 + 2 \cdot 0.5 + 5)C = 1$, hence $C = 1/6.25 = 0.16$, and $y_{p1} = 0.16e^{0.5x}$.

We now set $y_{p2} = K\cos 10x + M\sin 10x$, as in Table 2.1, and obtain

$$y'_{p2} = -10K\sin 10x + 10M\cos 10x, \qquad y''_{p2} = -100K\cos 10x - 100M\sin 10x.$$

Substitution into the given ODE gives for the cosine terms and for the sine terms

$$-100K + 2 \cdot 10M + 5K = 40, \qquad -100M - 2 \cdot 10K + 5M = -190$$

or, by simplification,

$$-95K + 20M = 40, \qquad -20K - 95M = -190.$$

The solution is $K = 0$, $M = 2$. Hence $y_{p2} = 2\sin 10x$. Together,

$$y = y_h + y_{p1} + y_{p2} = e^{-x}(A\cos 2x + B\sin 2x) + 0.16e^{0.5x} + 2\sin 10x.$$

Step 3. Solution of the initial value problem. From y and the first initial condition, $y(0) = A + 0.16 = 0.16$, hence $A = 0$. Differentiation gives

$$y' = e^{-x}(-A\cos 2x - B\sin 2x - 2A\sin 2x + 2B\cos 2x) + 0.08e^{0.5x} + 20\cos 10x.$$

From this and the second initial condition we have $y'(0) = -A + 2B + 0.08 + 20 = 40.08$, hence $B = 10$. This gives the solution (Fig. 51)

$$y = 10e^{-x}\sin 2x + 0.16e^{0.5x} + 2\sin 10x.$$

The first term goes to 0 relatively fast. When $x = 4$, it is practically 0, as the dashed curves $\pm 10e^{-x} + 0.16e^{0.5x}$ show. From then on, the last term, $2\sin 10x$, gives an oscillation about $0.16e^{0.5x}$, the monotone increasing dashed curve. ■

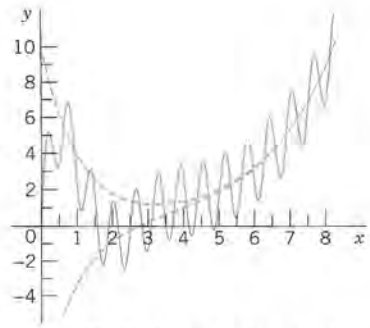

Fig. 51. Solution in Example 3

Stability. The following is important. If (and only if) all the roots of the characteristic equation of the homogeneous ODE $y'' + ay' + by = 0$ in (4) are negative, or have a negative real part, then a general solution y_h of this ODE goes to 0 as $x \to \infty$, so that the **"transient solution"** $y = y_h + y_p$ of (4) approaches the **"steady-state solution"** y_p. In this case the nonhomogeneous ODE and the physical or other system modeled by the ODE are called **stable;** otherwise they are called **unstable.** For instance, the ODE in Example 1 is unstable.

Basic applications follow in the next two sections.

PROBLEM SET 2.7

1–14 GENERAL SOLUTIONS OF NONHOMOGENEOUS ODEs

Find a (real) general solution. Which rule are you using? (Show each step of your calculation.)

1. $y'' + 3y' + 2y = 30e^{2x}$
2. $y'' + 4y' + 3.75y = 109 \cos 5x$
3. $y'' - 16y = 19.2e^{4x} + 60e^{x}$
4. $y'' + 9y = \cos x + \frac{1}{3} \cos 3x$
5. $y'' + y' - 6y = 6x^3 - 3x^2 + 12x$
6. $y'' + 4y' + 4y = e^{-2x} \sin 2x$
7. $y'' + 6y' + 73y = 80e^{x} \cos 4x$
8. $y'' + 10y' + 25y = 100 \sinh 5x$
9. $y'' - 0.16y = 32 \cosh 0.4x$
10. $y'' + 4y' + 6.25y = 3.125(x + 1)^2$
11. $y'' + 1.44y = 24 \cos 1.2x$
12. $y'' + 9y = 18x + 36 \sin 3x$
13. $y'' + 4y' + 5y = 25x^2 + 13 \sin 2x$
14. $y'' + 2y' + y = 2x \sin x$

15–20 INITIAL VALUE PROBLEMS FOR NONHOMOGENEOUS ODEs

Solve the initial value problem. State which rules you are using. Show each step of your calculation in detail.

15. $y'' + 4y = 16 \cos 2x, \quad y(0) = 0, \quad y'(0) = 0$
16. $y'' - 3y' + 2.25y = 27(x^2 - x), \quad y(0) = 20, \quad y'(0) = 30$
17. $y'' + 0.2y' + 0.26y = 1.22e^{0.5x}, \quad y(0) = 3.5, \quad y'(0) = 0.35$
18. $y'' - 2y' = 12e^{2x} - 8e^{-2x}, \quad y(0) = -2, \quad y'(0) = 12$
19. $y'' - y' - 12y = 144x^3 + 12.5, \quad y(0) = 5, \quad y'(0) = -0.5$
20. $y'' + 2y' + 10y = 17 \sin x - 37 \sin 3x, \quad y(0) = 6.6, \quad y'(0) = -2.2$

21. **WRITING PROJECT. Initial Value Problem.** Write out all the details of Example 3 in your own words. Discuss Fig. 51 in more detail. Why is it that some of the "half-waves" do not reach the dashed curves, whereas others preceding them (and, of course, all later ones) excede the dashed curves?

22. **TEAM PROJECT. Extensions of the Method of Undetermined Coefficients. (a)** Extend the method to products of the function in Table 2.1. **(b)** Extend the method to Euler–Cauchy equations. Comment on the practical significance of such extensions.

23. **CAS PROJECT. Structure of Solutions of Initial Value Problems.** Using the present method, find, graph, and discuss the solutions y of initial value problems of your own choice. Explore effects on solutions caused by

changes of initial conditions. Graph y_p, y, $y - y_p$ separately, to see the separate effects. Find a problem in which (a) the part of y resulting from y_h decreases to zero, (b) increases, (c) is not present in the answer y. Study a problem with $y(0) = 0$, $y'(0) = 0$. Consider a problem in which you need the Modification Rule (a) for a simple root, (b) for a double root. Make sure that your problems cover all three Cases I, II, III (see Sec. 2.2).

2.8 Modeling: Forced Oscillations. Resonance

In Sec. 2.4 we considered vertical motions of a mass-spring system (vibration of a mass m on an elastic spring, as in Figs. 32 and 52) and modeled it by the ***homogeneous*** linear ODE

$$\textbf{(1)} \qquad my'' + cy' + ky = 0.$$

Here $y(t)$ as a function of time t is the displacement of the body of mass m from rest. These were **free motions,** that is, motions in the absence of *external forces* (outside forces) caused solely by *internal forces,* forces within the system. These are the force of inertia my'', the damping force cy' (if $c > 0$), and the spring force ky acting as a restoring force.

We now extend our model by including an external force, call it $r(t)$, on the right. Then we have

$$(2^*) \qquad my'' + cy' + ky = r(t).$$

Mechanically this means that at each instant t the resultant of the internal forces is in equilibrium with $r(t)$. The resulting motion is called a **forced motion** with **forcing function** $r(t)$, which is also known as **input** or **driving force,** and the solution $y(t)$ to be obtained is called the **output** or the **response** *of the system to the driving force.*

Of special interest are periodic external forces, and we shall consider a driving force of the form

$$r(t) = F_0 \cos \omega t \qquad (F_0 > 0,\ \omega > 0).$$

Then we have the nonhomogeneous ODE

$$\textbf{(2)} \qquad my'' + cy' + ky = F_0 \cos \omega t.$$

Its solution will familiarize us with further interesting facts fundamental in engineering mathematics, in particular with resonance.

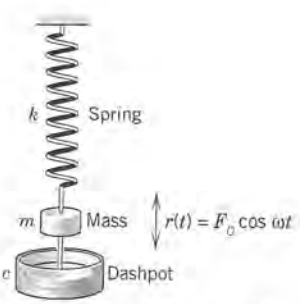

Fig. 52. Mass on a spring

Solving the Nonhomogeneous ODE (2)

From Sec. 2.7 we know that a general solution of (2) is the sum of a general solution y_h of the homogeneous ODE (1) plus any solution y_p of (2). To find y_p, we use the method of undetermined coefficients (Sec. 2.7), starting from

$$y_p(t) = a \cos \omega t + b \sin \omega t. \tag{3}$$

By differentiating this function (chain rule!) we obtain

$$y_p' = -\omega a \sin \omega t + \omega b \cos \omega t,$$
$$y_p'' = -\omega^2 a \cos \omega t - \omega^2 b \sin \omega t.$$

Substituting y_p, y_p', and y_p'' into (2) and collecting the cosine and the sine terms, we get

$$[(k - m\omega^2)a + \omega c b] \cos \omega t + [-\omega c a + (k - m\omega^2)b] \sin \omega t = F_0 \cos \omega t.$$

The cosine terms on both sides must be equal, and the coefficient of the sine term on the left must be zero since there is no sine term on the right. This gives the two equations

$$\begin{aligned} (k - m\omega^2)a + \quad \omega c b \quad &= F_0 \\ -\omega c a \quad + (k - m\omega^2)b &= 0 \end{aligned} \tag{4}$$

for determining the unknown coefficients a and b. This is a linear system. We can solve it by elimination. To eliminate b, multiply the first equation by $k - m\omega^2$ and the second by $-\omega c$ and add the results, obtaining

$$(k - m\omega^2)^2 a + \omega^2 c^2 a = F_0(k - m\omega^2).$$

Similarly, to eliminate a, multiply the first equation by ωc and the second by $k - m\omega^2$ and add to get

$$\omega^2 c^2 b + (k - m\omega^2)^2 b = F_0 \omega c.$$

If the factor $(k - m\omega^2)^2 + \omega^2 c^2$ is not zero, we can divide by this factor and solve for a and b,

$$a = F_0 \frac{k - m\omega^2}{(k - m\omega^2)^2 + \omega^2 c^2}, \qquad b = F_0 \frac{\omega c}{(k - m\omega^2)^2 + \omega^2 c^2}.$$

If we set $\sqrt{k/m} = \omega_0$ (> 0) as in Sec. 2.4, then $k = m\omega_0^2$ and we obtain

$$a = F_0 \frac{m(\omega_0^2 - \omega^2)}{m^2(\omega_0^2 - \omega^2)^2 + \omega^2 c^2}, \qquad b = F_0 \frac{\omega c}{m^2(\omega_0^2 - \omega^2)^2 + \omega^2 c^2}. \tag{5}$$

We thus obtain the general solution of the nonhomogeneous ODE (2) in the form

$$y(t) = y_h(t) + y_p(t). \tag{6}$$

Here y_h is a general solution of the homogeneous ODE (1) and y_p is given by (3) with coefficients (5).

We shall now discuss the behavior of the mechanical system, distinguishing between the two cases $c = 0$ (no damping) and $c > 0$ (damping). These cases will correspond to two basically different types of output.

Case 1. Undamped Forced Oscillations. Resonance

If the damping of the physical system is so small that its effect can be neglected over the time interval considered, we can set $c = 0$. Then (5) reduces to $a = F_0/[m(\omega_0^2 - \omega^2)]$ and $b = 0$. Hence (3) becomes (use $\omega_0^2 = k/m$)

$$y_p(t) = \frac{F_0}{m(\omega_0^2 - \omega^2)} \cos \omega t = \frac{F_0}{k[1 - (\omega/\omega_0)^2]} \cos \omega t. \tag{7}$$

Here we must assume that $\omega^2 \neq \omega_0^2$; physically, the frequency $\omega/(2\pi)$ [cycles/sec] of the driving force is different from the *natural frequency* $\omega_0/(2\pi)$ of the system, which is the frequency of the free undamped motion [see (4) in Sec. 2.4]. From (7) and from (4*) in Sec. 2.4 we have the general solution of the "undamped system"

$$y(t) = C \cos(\omega_0 t - \delta) + \frac{F_0}{m(\omega_0^2 - \omega^2)} \cos \omega t. \tag{8}$$

We see that this output is a ***superposition of two harmonic oscillations*** *of the frequencies just mentioned.*

Resonance. We discuss (7). We see that the maximum amplitude of y_p is (put $\cos \omega t = 1$)

$$a_0 = \frac{F_0}{k} \rho \qquad \text{where} \qquad \rho = \frac{1}{1 - (\omega/\omega_0)^2}. \tag{9}$$

a_0 depends on ω and ω_0. If $\omega \to \omega_0$, then ρ and a_0 tend to infinity. This excitation of large oscillations by matching input and natural frequencies ($\omega = \omega_0$) is called **resonance.** ρ is called the **resonance factor** (Fig. 53), and from (9) we see that $\rho/k = a_0/F_0$ is the ratio of the amplitudes of the particular solution y_p and of the input $F_0 \cos \omega t$. We shall see later in this section that resonance is of basic importance in the study of vibrating systems.

In the case of resonance the nonhomogeneous ODE (2) becomes

$$y'' + \omega_0^2 y = \frac{F_0}{m} \cos \omega_0 t. \tag{10}$$

Then (7) is no longer valid, and from the Modification Rule in Sec. 2.7 we conclude that a particular solution of (10) is of the form

$$y_p(t) = t(a \cos \omega_0 t + b \sin \omega_0 t).$$

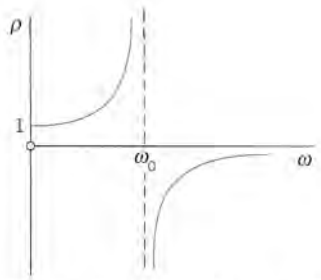

Fig. 53. Resonance factor $p(\omega)$

By substituting this into (10) we find $a = 0$ and $b = F_0/(2m\omega_0)$. Hence (Fig. 54)

$$y_p(t) = \frac{F_0}{2m\omega_0}\, t \sin \omega_0 t. \tag{11}$$

We see that because of the factor t the amplitude of the vibration becomes larger and larger. Practically speaking, systems with very little damping may undergo large vibrations that can destroy the system. We shall return to this practical aspect of resonance later in this section.

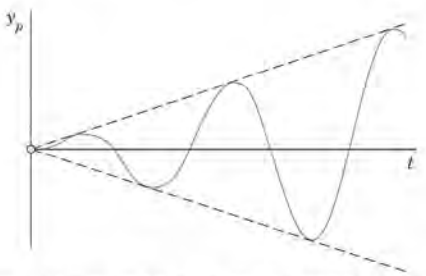

Fig. 54. Particular solution in the case of resonance

Beats. Another interesting and highly important type of oscillation is obtained if ω is close to ω_0. Take, for example, the particular solution [see (8)]

$$y(t) = \frac{F_0}{m(\omega_0^2 - \omega^2)} (\cos \omega t - \cos \omega_0 t) \qquad (\omega \neq \omega_0). \tag{12}$$

Using (12) in App. 3.1, we may write this as

$$y(t) = \frac{2F_0}{m(\omega_0^2 - \omega^2)} \sin\left(\frac{\omega_0 + \omega}{2}\, t\right) \sin\left(\frac{\omega_0 - \omega}{2}\, t\right).$$

Since ω is close to ω_0, the difference $\omega_0 - \omega$ is small. Hence the period of the last sine function is large, and we obtain an oscillation of the type shown in Fig. 55, the dashed curve resulting from the first sine factor. This is what musicians are listening to when they ***tune*** their instruments.

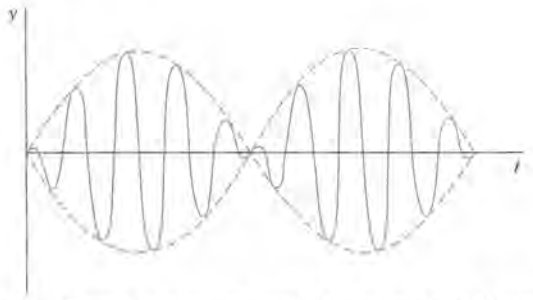

Fig. 55. Forced undamped oscillation when the difference of the input and natural frequencies is small **("beats")**

Case 2. Damped Forced Oscillations

If the damping of the mass-spring system is not negligibly small, we have $c > 0$ and a damping term cy' in (1) and (2). Then the general solution y_h of the homogeneous ODE (1) approaches zero as t goes to infinity, as we know from Sec. 2.4. Practically, it is zero after a sufficiently long time. Hence the **"transient solution"** (6) of (2), given by $y = y_h + y_p$, approaches the **"steady-state solution"** y_p. This proves the following.

THEOREM 1

Steady-State Solution

After a sufficiently long time the output of a damped vibrating system under a purely sinusoidal driving force [see (2)] will practically be a harmonic oscillation whose frequency is that of the input.

Amplitude of the Steady-State Solution. Practical Resonance

Whereas in the undamped case the amplitude of y_p approaches infinity as ω approaches ω_0, this will not happen in the damped case. In this case the amplitude will always be finite. But it may have a maximum for some ω depending on the damping constant c. This may be called **practical resonance.** It is of great importance because if c is not too large, then some input may excite oscillations large enough to damage or even destroy the system. Such cases happened, in particular in earlier times when less was known about resonance. Machines, cars, ships, airplanes, bridges, and high-rising buildings are vibrating mechanical systems, and it is sometimes rather difficult to find constructions that are completely free of undesired resonance effects, caused, for instance, by an engine or by strong winds.

To study the amplitude of y_p as a function of ω, we write (3) in the form

$$y_p(t) = C^* \cos(\omega t - \eta). \tag{13}$$

C^* is called the **amplitude** of y_p and η the **phase angle** or **phase lag** because it measures the lag of the output behind the input. According to (5), these quantities are

$$C^*(\omega) = \sqrt{a^2 + b^2} = \frac{F_0}{\sqrt{m^2(\omega_0^2 - \omega^2)^2 + \omega^2 c^2}},$$

$$\tan \eta(\omega) = \frac{b}{a} = \frac{\omega c}{m(\omega_0^2 - \omega^2)}. \tag{14}$$

Let us see whether $C^*(\omega)$ has a maximum and, if so, find its location and then its size. We denote the radicand in the second root in C^* by R. Equating the derivative of C^* to zero, we obtain

$$\frac{dC^*}{d\omega} = F_0\left(-\frac{1}{2}\,R^{-3/2}\right)[2m^2(\omega_0{}^2 - \omega^2)(-2\omega) + 2\omega c^2].$$

The expression in the brackets [. . .] is zero if

$$c^2 = 2m^2(\omega_0{}^2 - \omega^2) \qquad (\omega_0{}^2 = k/m). \tag{15}$$

By reshuffling terms we have

$$2m^2\omega^2 = 2m^2\omega_0{}^2 - c^2 = 2mk - c^2.$$

The right side of this equation becomes negative if $c^2 > 2mk$, so that then (15) has no real solution and C^* decreases monotone as ω increases, as the lowest curve in Fig. 56 on p. 90 shows. If c is smaller, $c^2 < 2mk$, then (15) has a real solution $\omega = \omega_{\max}$, where

$$\omega_{\max}^2 = \omega_0{}^2 - \frac{c^2}{2m^2}\,. \tag{15*}$$

From (15*) we see that this solution increases as c decreases and approaches ω_0 as c approaches zero. See also Fig. 56.

The size of $C^*(\omega_{\max})$ is obtained from (14), with $\omega^2 = \omega_{\max}^2$ given by (15*). For this ω^2 we obtain in the second radicand in (14) from (15*)

$$m^2(\omega_0{}^2 - \omega_{\max}^2)^2 = \frac{c^4}{4m^2} \qquad \text{and} \qquad \omega_{\max}^2 c^2 = \left(\omega_0{}^2 - \frac{c^2}{2m^2}\right)c^2.$$

The sum of the right sides of these two formulas is

$$(c^4 + 4m^2\omega_0{}^2c^2 - 2c^4)/(4m^2) = c^2(4m^2\omega_0{}^2 - c^2)/(4m^2).$$

Substitution into (14) gives

$$C^*(\omega_{\max}) = \frac{2mF_0}{c\sqrt{4m^2\omega_0{}^2 - c^2}}\,. \tag{16}$$

We see that $C^*(\omega_{\max})$ is always finite when $c > 0$. Furthermore, since the expression

$$c^2 4m^2\omega_0{}^2 - c^4 = c^2(4mk - c^2)$$

in the denominator of (16) decreases monotone to zero as c^2 ($< 2mk$) goes to zero, the maximum amplitude (16) increases monotone to infinity, in agreement with our result in Case 1. Figure 56 shows the **amplification** C^*/F_0 (ratio of the amplitudes of output and input) as a function of ω for $m = 1$, $k = 1$, hence $\omega_0 = 1$, and various values of the damping constant c.

Figure 57 shows the phase angle (the lag of the output behind the input), which is less than $\pi/2$ when $\omega < \omega_0$, and greater than $\pi/2$ for $\omega > \omega_0$.

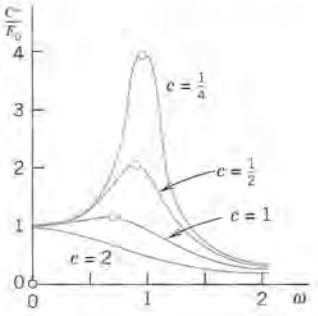

Fig. 56. Amplification C^*/F_0 as a function of ω for $m = 1$, $k = 1$, and various values of the damping constant c

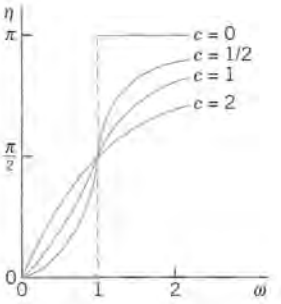

Fig. 57. Phase lag η as a function of ω for $m = 1$, $k = 1$, thus $\omega_0 = 1$, and various values of the damping constant c

PROBLEM SET 2.8

1–8 STEADY-STATE SOLUTIONS

Find the steady-state oscillation of the mass–spring system modeled by the given ODE. Show the details of your calculations.

1. $y'' + 6y' + 8y = 130 \cos 3t$
2. $4y'' + 8y' + 13y = 8 \sin 1.5t$
3. $y'' + y' + 4.25y = 221 \cos 4.5t$
4. $y'' + 4y' + 5y = \cos t - \sin t$
5. $(D^2 + 2D + I)y = -\sin 2t$
6. $(D^2 + 4D + 3I)y = \cos t + \frac{1}{3}\cos 3t$
7. $(D^2 + 6D + 18I)y = \cos 3t - 3 \sin 3t$
8. $(D^2 + 2D + 10I)y = -25 \sin 4t$

9–14 TRANSIENT SOLUTIONS

Find the transient motion of the mass–spring system modeled by the given ODE. (Show the details of your work.)

9. $y'' + 2y' + 0.75y = 13 \sin t$
10. $y'' + 4y' + 4y = \cos 4t$
11. $4y'' + 12y' + 9y = 75 \sin 3t$
12. $(D^2 + 5D + 4I)y = \sin 2t$
13. $(D^2 + 3D + 3.25I)y = 13 - 39 \cos 2t$
14. $(D^2 + 2D + 5I)y = 1 + \sin t$

15–20 INITIAL VALUE PROBLEMS

Find the motion of the mass–spring system modeled by the ODE and initial conditions. Sketch or graph the solution curve. In addition, sketch or graph the curve of $y - y_p$ to see when the system practically reaches the steady state.

15. $y'' + 2y' + 26y = 13 \cos 3t$, $y(0) = 1$, $y'(0) = 0.4$
16. $y'' + 64y = \cos t$, $y(0) = 0$, $y'(0) = 1$
17. $y'' + 6y' + 8y = 4 \sin 2t$, $y(0) = 0.7$, $y'(0) = -11.8$
18. $(D^2 + 2D + I)y = 75(\sin t - \frac{1}{2}\sin 2t + \frac{1}{3}\sin 3t)$, $y(0) = 0$, $y'(0) = 1$
19. $(4D^2 + 12D + 13I)y = 12 \cos t - 6 \sin t$, $y(0) = 1$, $y'(0) = -1$
20. $y'' + 25y = 99 \cos 4.9t$, $y(0) = 2$, $y'(0) = 0$
21. **(Beats)** Derive the formula after (12) from (12). Can there be beats if the system has damping?
22. **(Beats)** How does the graph of the solution in Prob. 20 change if you change (a) $y(0)$, (b) the frequency of the driving force?
23. **WRITING PROJECT. Free and Forced Vibrations.** Write a condensed report of 2–3 pages on the most important facts about free and forced vibrations.
24. **CAS EXPERIMENT. Undamped Vibrations.** **(a)** Solve the initial value problem $y'' + y = \cos \omega t$, $\omega^2 \neq 1$, $y(0) = 0$, $y'(0) = 0$. Show that the solution can be written

$$y(t) = \frac{2}{1 - \omega^2} \sin\left[\frac{1}{2}(1 + \omega)t\right] \times \sin\left[\frac{1}{2}(1 - \omega)t\right]. \tag{17}$$

(b) Experiment with (17) by changing ω to see the change of the curves from those for small ω (> 0) to beats, to resonance and to large values of ω (see Fig. 58).

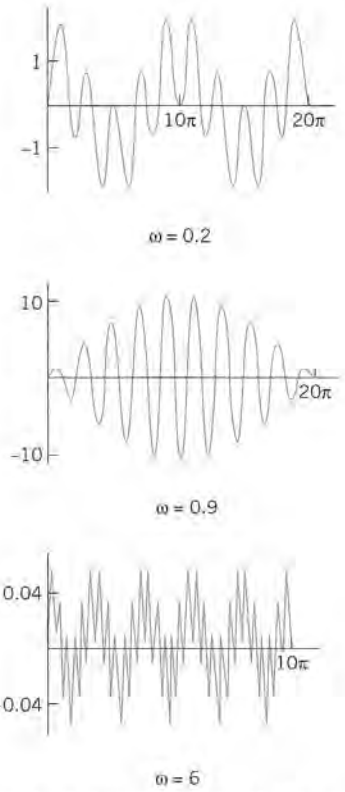

Fig. 58. Typical solution curves in CAS Experiment 24

25. TEAM PROJECT. Practical Resonance. (a) Give a detailed derivation of the crucial formula (16).

(b) By considering dC^*/dc show that $C^*(\omega_{\max})$ increases as c ($\leqq \sqrt{2mk}$) decreases.

(c) Illustrate practical resonance with an ODE of your own in which you vary c, and sketch or graph corresponding curves as in Fig. 56.

(d) Take your ODE with c fixed and an input of two terms, one with frequency close to the practical resonance frequency and the other not. Discuss and sketch or graph the output.

(e) Give other applications (not in the book) in which resonance is important.

26. (Gun barrel) Solve

$$y'' + y = \begin{cases} 1 - t^2/\pi^2 & \text{if } 0 \leqq t \leqq \pi \\ 0 & \text{if } t > \pi, \end{cases}$$

$$y(0) = y'(0) = 0.$$

This models an undamped system on which a force F acts during some interval of time (see Fig. 59), for instance, the force on a gun barrel when a shell is fired, the barrel being braked by heavy springs (and then damped by a dashpot, which we disregard for simplicity). *Hint.* At π both y and y' must be continuous.

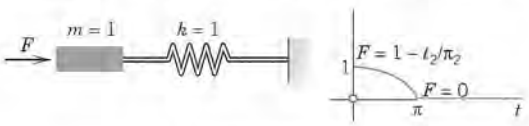

Fig. 59. Problem 26

2.9 Modeling: Electric Circuits

Designing good models is a task the computer cannot do. Hence setting up models has become an important task in modern applied mathematics. The best way to gain experience is to consider models from various fields. Accordingly, modeling electric circuits to be discussed will be *profitable for all students*, not just for electrical engineers and computer scientists.

We have just seen that linear ODEs have important applications in mechanics (see also Sec. 2.4). Similarly, they are models of electric circuits, as they occur as portions of large networks in computers and elsewhere. The circuits we shall consider here are basic building blocks of such networks. They contain three kinds of components, namely, resistors, inductors, and capacitors. Figure 60 on p. 92 shows such an ***RLC*-circuit**, as they are called. In it a resistor of resistance R Ω (ohms), an inductor of inductance L H (henrys), and a capacitor of capacitance C F (farads) are wired in series as shown, and connected to an electromotive force $E(t)$ V (volts) (a generator, for instance), sinusoidal as in Fig. 60, or of some other kind. R, L, C, and E are given and we want to find the current $I(t)$ A (amperes) in the circuit.

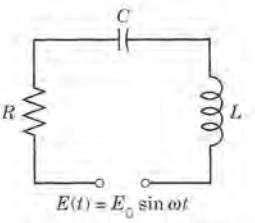

Fig. 60. *RLC*-circuit

An ODE for the current $I(t)$ in the *RLC*-circuit in Fig. 60 is obtained from the following law (which is the analog of Newton's second law, as we shall see later).

Kirchhoff's Voltage Law (KVL).[7] *The voltage (the electromotive force) impressed on a closed loop is equal to the sum of the voltage drops across the other elements of the loop.*

In Fig. 60 the circuit is a closed loop, and the impressed voltage $E(t)$ equals the sum of the voltage drops across the three elements R, L, C of the loop.

Voltage Drops. Experiments show that a current I flowing through a resistor, inductor or capacitor causes a voltage drop (voltage difference, measured in volts) at the two ends; these drops are

RI **(Ohm's law)** Voltage drop for a resistor of resistance R ohms (Ω),

$LI' = L\dfrac{dI}{dt}$ Voltage drop for an inductor of inductance L henrys (H),

$\dfrac{Q}{C}$ Voltage drop for a capacitor of capacitance C farads (F).

Here Q coulombs is the charge on the capacitor, related to the current by

$$I(t) = \frac{dQ}{dt}, \qquad \text{equivalently,} \qquad Q(t) = \int I(t)\,dt.$$

This is summarized in Fig. 61.

According to KVL we thus have in Fig. 60 for an *RLC*-circuit with electromotive force $E(t) = E_0 \sin \omega t$ (E_0 constant) as a model the **"integro-differential equation"**

$$(1') \qquad LI' + RI + \frac{1}{C}\int I\,dt = E(t) = E_0 \sin \omega t.$$

---

[7]GUSTAV ROBERT KIRCHHOFF (1824–1887), German physicist. Later we shall also need **Kirchhoff's current law (KCL):**

At any point of a circuit, the sum of the inflowing currents is equal to the sum of the outflowing currents.

The units of measurement of electrical quantities are named after ANDRÉ MARIE AMPÈRE (1775–1836), French physicist, CHARLES AUGUSTIN DE COULOMB (1736–1806), French physicist and engineer, MICHAEL FARADAY (1791–1867), English physicist, JOSEPH HENRY (1797–1878), American physicist, GEORG SIMON OHM (1789–1854), German physicist, and ALESSANDRO VOLTA (1745–1827), Italian physicist.

Name	Symbol		Notation	Unit	Voltage Drop
Ohm's resistor		R	Ohm's resistance	ohms (Ω)	RI
Inductor		L	Inductance	henrys (H)	$L\frac{dI}{dt}$
Capacitor		C	Capacitance	farads (F)	Q/C

Fig. 61. Elements in an *RLC*-circuit

To get rid of the integral, we differentiate (1′) with respect to t, obtaining

$$\textbf{(1)} \qquad LI'' + RI' + \frac{1}{C}I = E'(t) = E_0\omega \cos \omega t.$$

This shows that the current in an *RLC*-circuit is obtained as the solution of this nonhomogeneous second-order ODE (1) with constant coefficients.

From (1′), using $I = Q'$, hence $I' = Q''$, we also have directly

$$(1'') \qquad LQ'' + RQ' + \frac{1}{C}Q = E_0 \sin \omega t.$$

But in most practical problems the current $I(t)$ is more important than the charge $Q(t)$, and for this reason we shall concentrate on (1) rather than on (1″).

Solving the ODE (1) for the Current. Discussion of Solution

A general solution of (1) is the sum $I = I_h + I_p$, where I_h is a general solution of the homogeneous ODE corresponding to (1) and I_p is a particular solution of (1). We first determine I_p by the method of undetermined coefficients, proceeding as in the previous section. We substitute

$$(2) \qquad \begin{aligned} I_p &= a \cos \omega t + b \sin \omega t \\ I_p' &= \omega(-a \sin \omega t + b \cos \omega t) \\ I_p'' &= \omega^2(-a \cos \omega t - b \sin \omega t) \end{aligned}$$

into (1). Then we collect the cosine terms and equate them to $E_0\omega \cos \omega t$ on the right, and we equate the sine terms to zero because there is no sine term on the right,

$$\begin{aligned} L\omega^2(-a) + R\omega b + a/C &= E_0\omega \qquad \text{(Cosine terms)} \\ L\omega^2(-b) + R\omega(-a) + b/C &= 0 \qquad \text{(Sine terms).} \end{aligned}$$

To solve this system for a and b, we first introduce a combination of L and C, called the **reactance**

$$\textbf{(3)} \qquad S = \omega L - \frac{1}{\omega C}.$$

Dividing the previous two equations by ω, ordering them, and substituting S gives

$$-Sa + Rb = E_0$$

$$-Ra - Sb = 0.$$

We now eliminate b by multiplying the first equation by S and the second by R, and adding. Then we eliminate a by multiplying the first equation by R and the second by $-S$, and adding. This gives

$$-(S^2 + R^2)a = E_0 S, \qquad (R^2 + S^2)b = E_0 R.$$

In any practical case the resistance R is different from zero, so that we can solve for a and b,

$$a = \frac{-E_0 S}{R^2 + S^2}, \qquad b = \frac{E_0 R}{R^2 + S^2}. \tag{4}$$

Equation (2) with coefficients a and b given by (4) is the desired particular solution I_p of the nonhomogeneous ODE (1) governing the current I in an RLC-circuit with sinusoidal electromotive force.

Using (4), we can write I_p in terms of "physically visible" quantities, namely, amplitude I_0 and phase lag θ of the current behind the electromotive force, that is,

$$I_p(t) = I_0 \sin(\omega t - \theta) \tag{5}$$

where [see (14) in App. A3.1]

$$I_0 = \sqrt{a^2 + b^2} = \frac{E_0}{\sqrt{R^2 + S^2}}, \qquad \tan\theta = -\frac{a}{b} = \frac{S}{R}.$$

The quantity $\sqrt{R^2 + S^2}$ is called the **impedance.** Our formula shows that the impedance equals the ratio E_0/I_0. This is somewhat analogous to $E/I = R$ (Ohm's law).

A general solution of the homogeneous equation corresponding to (1) is

$$I_h = c_1 e^{\lambda_1 t} + c_2 e^{\lambda_2 t}$$

where λ_1 and λ_2 are the roots of the characteristic equation

$$\lambda^2 + \frac{R}{L}\lambda + \frac{1}{LC} = 0.$$

We can write these roots in the form $\lambda_1 = -\alpha + \beta$ and $\lambda_2 = -\alpha - \beta$, where

$$\alpha = \frac{R}{2L}, \qquad \beta = \sqrt{\frac{R^2}{4L^2} - \frac{1}{LC}} = \frac{1}{2L}\sqrt{R^2 - \frac{4L}{C}}.$$

Now in an actual circuit, R is never zero (hence $R > 0$). From this it follows that I_h approaches zero, theoretically as $t \to \infty$, but practically after a relatively short time. (This is as for the motion in the previous section.) Hence the transient current $I = I_h + I_p$ tends

to the steady-state current I_p, and after some time the output will practically be a harmonic oscillation, which is given by (5) and whose frequency is that of the input (of the electromotive force).

EXAMPLE 1 **RLC-Circuit**

Find the current $I(t)$ in an RLC-circuit with $R = 11\ \Omega$ (ohms), $L = 0.1$ H (henry), $C = 10^{-2}$F (farad), which is connected to a source of voltage $E(t) = 100 \sin 400t$ (hence $63\frac{2}{3}$ Hz $= 63\frac{2}{3}$ cycles/sec, because $400 = 63\frac{2}{3} \cdot 2\pi$). Assume that current and charge are zero when $t = 0$.

Solution. ***Step 1. General solution of the homogeneous ODE.*** Substituting R, L, C, and the derivative $E'(t)$ into (1), we obtain

$$0.1I'' + 11I' + 100I = 100 \cdot 400 \cos 400t.$$

Hence the homogeneous ODE is $0.1I'' + 11I' + 100I = 0$. Its characteristic equation is

$$0.1\lambda^2 + 11\lambda + 100 = 0.$$

The roots are $\lambda_1 = -10$ and $\lambda_2 = -100$. The corresponding general solution of the homogeneous ODE is

$$I_h(t) = c_1e^{-10t} + c_2e^{-100t}.$$

Step 2. Particular solution I_p of (1). We calculate the reactance $S = 40 - 1/4 = 39.75$ and the steady-state current

$$I_p(t) = a \cos 400t + b \sin 400t$$

with coefficients obtained from (4)

$$a = \frac{-100 \cdot 39.75}{11^2 + 39.75^2} = -2.3368, \qquad b = \frac{100 \cdot 11}{11^2 + 39.75^2} = 0.6467.$$

Hence in our present case, a general solution of the nonhomogeneous ODE (1) is

$$I(t) = c_1e^{-10t} + c_2e^{-100t} - 2.3368 \cos 400t + 0.6467 \sin 400t. \tag{6}$$

Step 3. Particular solution satisfying the initial conditions. How to use $Q(0) = 0$? We finally determine c_1 and c_2 from the initial conditions $I(0) = 0$ and $Q(0) = 0$. From the first condition and (6) we have

$$I(0) = c_1 + c_2 - 2.3368 = 0. \qquad \text{hence} \qquad c_2 = 2.3368 - c_1. \tag{7}$$

Furthermore, using (1′) with $t = 0$ and noting that the integral equals $Q(t)$ (see the formula before (1′)), we obtain

$$LI'(0) + R \cdot 0 + \frac{1}{C} \cdot 0 = 0, \qquad \text{hence} \qquad I'(0) = 0.$$

Differentiating (6) and setting $t = 0$, we thus obtain

$$I'(0) = -10c_1 - 100c_2 + 0 + 0.6467 \cdot 400 = 0, \qquad \text{hence} \qquad -10c_1 = 100(2.3368 - c_1) - 258.68.$$

The solution of this and (7) is $c_1 = -0.2776$, $c_2 = 2.6144$. Hence the answer is

$$I(t) = -0.2776e^{-10t} + 2.6144e^{-100t} - 2.3368 \cos 400t + 0.6467 \sin 400t.$$

Figure 62 on p. 96 shows $I(t)$ as well as $I_p(t)$, which practically coincide, except for a very short time near $t = 0$ because the exponential terms go to zero very rapidly. Thus after a very short time the current will practically execute harmonic oscillations of the input frequency $63\frac{2}{3}$ Hz $= 63\frac{2}{3}$ cycles/sec. Its maximum amplitude and phase lag can be seen from (5), which here takes the form

$$I_p(t) = 2.4246 \sin (400t - 1.3008).$$

■

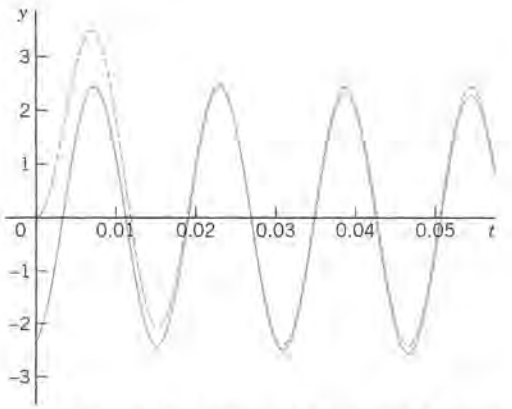

Fig. 62. Transient and steady-state currents in Example 1

Analogy of Electrical and Mechanical Quantities

Entirely different physical or other systems may have the same mathematical model. For instance, we have seen this from the various applications of the ODE $y' = ky$ in Chap. 1. Another impressive demonstration of this ***unifying power of mathematics*** is given by the ODE (1) for an electric RLC-circuit and the ODE (2) in the last section for a mass–spring system. Both equations

$$LI'' + RI' + \frac{1}{C}I = E_0\omega \cos \omega t \qquad \text{and} \qquad my'' + cy' + ky = F_0 \cos \omega t$$

are of the same form. Table 2.2 shows the analogy between the various quantities involved. The inductance L corresponds to the mass m and, indeed, an inductor opposes a change in current, having an "inertia effect" similar to that of a mass. The resistance R corresponds to the damping constant c, and a resistor causes loss of energy, just as a damping dashpot does. And so on.

This analogy is ***strictly quantitative*** in the sense that to a given mechanical system we can construct an electric circuit whose current will give the exact values of the displacement in the mechanical system when suitable scale factors are introduced.

The ***practical importance*** of this analogy is almost obvious. The analogy may be used for constructing an "electrical model" of a given mechanical model, resulting in substantial savings of time and money because electric circuits are easy to assemble, and electric quantities can be measured much more quickly and accurately than mechanical ones.

Table 2.2 **Analogy of Electrical and Mechanical Quantities**

Electrical System	Mechanical System
Inductance L	Mass m
Resistance R	Damping constant c
Reciprocal $1/C$ of capacitance	Spring modulus k
Derivative $E_0\omega \cos \omega t$ of electromotive force	Driving force $F_0 \cos \omega t$
Current $I(t)$	Displacement $y(t)$

PROBLEM SET 2.9

1. **(RL-circuit)** Model the RL-circuit in Fig. 63. Find the general solution when R, L, E are any constants. Graph or sketch solutions when $L = 0.1$ H, $R = 5\ \Omega$, $E = 12$ V.
2. **(RL-circuit)** Solve Prob. 1 when $E = E_0 \sin \omega t$ and R, L, E_0, ω are arbitrary. Sketch a typical solution.
3. **(RC-circuit)** Model the RC-circuit in Fig. 66. Find the current due to a constant E.
4. **(RC-circuit)** Find the current in the RC-circuit in Fig. 66 with $E = E_0 \sin \omega t$ and arbitrary R, C, E_0, and ω.

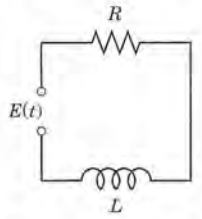

Fig. 63. RL-circuit

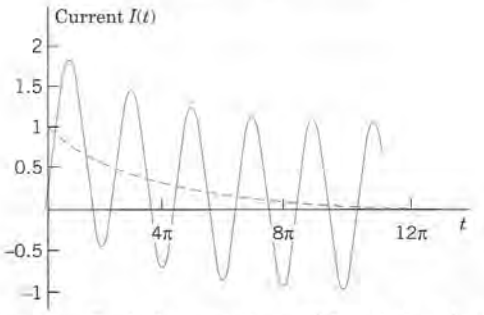

Fig. 65. Typical current $I = e^{-0.1t} + \sin(t - \frac{1}{4}\pi)$ in Problem 2

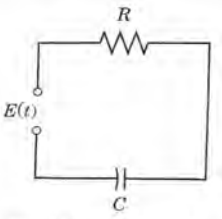

Fig. 66. RC-circuit

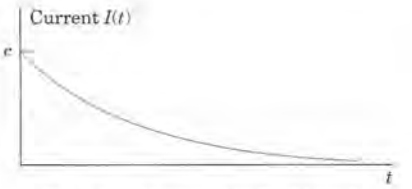

Fig. 67. Current I in Problem 3

5. **(LC-circuit)** This is an RLC-circuit with negligibly small R (analog of an undamped mass–spring system). Find the current when $L = 0.2$ H, $C = 0.05$ F, and $E = \sin t$ V, assuming zero initial current and charge.
6. **(LC-circuit)** Find the current when $L = 0.5$ H, $C = 8 \cdot 10^{-4}$ F, $E = t^2$ V and initial current and charge zero.

7–9 RLC-CIRCUITS (FIG. 60, P. 92)

7. **(Tuning)** In tuning a stereo system to a radio station, we adjust the tuning control (turn a knob) that changes C (or perhaps L) in an RLC-circuit so that the amplitude of the steady-state current (5) becomes maximum. For what C will this happen?
8. **(Transient current)** Prove the claim in the text that if $R \neq 0$ (hence $R > 0$), then the transient current approaches I_p as $t \to \infty$.
9. **(Cases of damping)** What are the conditions for an RLC-circuit to be (I) overdamped, (II) critically damped, (III) underdamped? What is the critical resistance R_{crit} (the analog of the critical damping constant $2\sqrt{mk}$)?

10–12 Find the **steady-state current** in the RLC-circuit in Fig. 60 on p. 92 for the given data. (Show the details of your work.)

10. $R = 8\ \Omega$, $L = 0.5$ H, $C = 0.1$ F, $E = 100 \sin 2t$ V
11. $R = 1\ \Omega$, $L = 0.25$ H, $C = 5 \cdot 10^{-5}$ F, $E = 110$ V
12. $R = 2\ \Omega$, $L = 1$ H, $C = 0.05$ F, $E = \frac{157}{9} \sin 3t$ V

13–15 Find the **transient current** (a general solution) in the RLC-circuit in Fig. 60 for the given data. (Show the details of your work.)

13. $R = 6\ \Omega$, $L = 0.2$ H, $C = 0.025$ F, $E = 110 \sin 10t$ V
14. $R = 0.2\ \Omega$, $L = 0.1$ H, $C = 2$ F, $E = 754 \sin 0.5t$ V
15. $R = 1/10\ \Omega$, $L = 1/2$ H, $C = 100/13$ F, $E = e^{-4t}(1.932 \cos \frac{1}{2}t + 0.246 \sin \frac{1}{2}t)$ V

16–18 Solve the **initial value problem** for the RLC-circuit in Fig. 60 with the given data, assuming zero initial current and charge. Graph or sketch the solution. (Show the details of your work.)

16. $R = 4\ \Omega$, $L = 0.1$ H, $C = 0.025$ F, $E = 10 \sin 10t$ V
17. $R = 6\ \Omega$, $L = 1$ H, $C = 0.04$ F, $E = 600(\cos t + 4 \sin t)$ V
18. $R = 3.6\ \Omega$, $L = 0.2$ H, $C = 0.0625$ F, $E = 164 \cos 10t$ V

19. **WRITING PROJECT. Analogy of *RLC*-Circuits and Damped Mass–Spring Systems.** **(a)** Write an essay of 2–3 pages based on Table 2.2. Describe the analogy in more detail and indicate its practical significance.

(b) What *RLC*-circuit with $L = 1$ H is the analog of the mass–spring system with mass 5 kg, damping constant 10 kg/sec, spring constant 60 kg/sec^2, and driving force $220 \cos 10t$?

(c) Illustrate the analogy with another example of your own choice.

20. **TEAM PROJECT. Complex Method for Particular Solutions.** **(a)** Find a particular solution of the **complex ODE**

$$\textbf{(8)} \qquad L\tilde{I}'' + R\tilde{I}' + \frac{1}{C}\tilde{I} = E_0\omega e^{i\omega t} \qquad (i = \sqrt{-1})$$

by substituting $\tilde{I}_p = Ke^{i\omega t}$ (K unknown) and its derivatives into (8), and then take the real part I_p of $\tilde{I}_p$, showing that I_p agrees with (2), (4). *Hint.* Use the Euler formula $e^{i\omega t} = \cos \omega t + i \sin \omega t$ [(11) in Sec. 2.2 with ωt instead of t]. Note that $E_0\omega \cos \omega t$ in (1) is the real part of $E_0\omega e^{i\omega t}$ in (8). Use $i^2 = -1$.

(b) The **complex impedance** Z is defined by

$$Z = R + iS = R + i\left(\omega L - \frac{1}{\omega C}\right).$$

Show that K obtained in (a) can be written as

$$K = \frac{E_0}{iZ}.$$

Note that the real part of Z is R, the imaginary part is the reactance S, and the absolute value is the impedance $|Z| = \sqrt{R^2 + S^2}$ as defined before. See Fig. 68.

(c) Find the steady-state solution of the ODE $I'' + 2I' + 3I = 20 \cos t$, first by the real method and then by the complex method, and compare. (Show the details of your work.)

(d) Apply the complex method to an *RLC*-circuit of your choice.

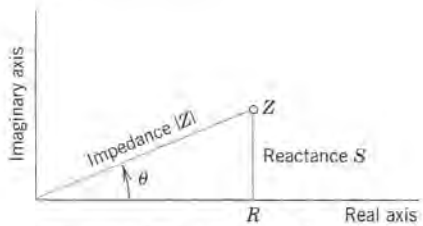

Fig. 68. Complex impedance Z

2.10 Solution by Variation of Parameters

We continue our discussion of nonhomogeneous linear ODEs

$$\textbf{(1)} \qquad y'' + p(x)y' + q(x)y = r(x).$$

In Sec. 2.6 we have seen that a general solution of (1) is the sum of a general solution y_h of the corresponding homogeneous ODE and any particular solution y_p of (1). To obtain y_p when $r(x)$ is not too complicated, we can often use the *method of undetermined coefficients*, as we have shown in Sec. 2.7 and applied to basic engineering models in Secs. 2.8 and 2.9.

However, since this method is restricted to functions $r(x)$ whose derivatives are of a form similar to $r(x)$ itself (powers, exponential functions, etc.), it is desirable to have a method valid for more general ODEs (1), which we shall now develop. It is called the **method of variation of parameters** and is credited to Lagrange (Sec. 2.1). Here p, q, r in (1) may be variable (given functions of x), but we assume that they are continuous on some open interval I.

Lagrange's method gives a particular solution y_p of (1) on I in the form

$$\textbf{(2)} \qquad y_p(x) = -y_1\int \frac{y_2 r}{W}\,dx + y_2\int \frac{y_1 r}{W}\,dx$$

where y_1, y_2 form a basis of solutions of the corresponding homogeneous ODE

$$y'' + p(x)y' + q(x)y = 0 \tag{3}$$

on I, and W is the Wronskian of y_1, y_2,

$$W = y_1y_2' - y_2y_1' \qquad \text{(see Sec. 2.6).} \tag{4}$$

CAUTION! The solution formula (2) is obtained under the assumption that the ODE is written in standard form, with y'' as the first term as shown in (1). If it starts with $f(x)y''$, divide first by $f(x)$.

The integration in (2) may often cause difficulties, and so may the determination of y_1, y_2 if (1) has variable coefficients. If you have a choice, use the previous method. It is simpler. Before deriving (2) let us work an example for which you *do need* the new method. (Try otherwise.)

EXAMPLE 1 Method of Variation of Parameters

Solve the nonhomogeneous ODE

$$y'' + y = \sec x = \frac{1}{\cos x}.$$

Solution. A basis of solutions of the homogeneous ODE on any interval is $y_1 = \cos x$, $y_2 = \sin x$. This gives the Wronskian

$$W(y_1, y_2) = \cos x \cos x - \sin x\,(-\sin x) = 1.$$

From (2), choosing zero constants of integration, we get the particular solution of the given ODE

$$\begin{aligned} y_p &= -\cos x \int \sin x \sec x\, dx + \sin x \int \cos x \sec x\, dx \\ &= \cos x \ln |\cos x| + x \sin x \end{aligned} \qquad \text{(Fig. 69).}$$

Figure 69 shows y_p and its first term, which is small, so that $x \sin x$ essentially determines the shape of the curve of y_p. (Recall from Sec. 2.8 that we have seen $x \sin x$ in connection with resonance, except for notation.) From y_p and the general solution $y_h = c_1y_1 + c_2y_2$ of the homogeneous ODE we obtain the *answer*

$$y = y_h + y_p = (c_1 + \ln |\cos x|) \cos x + (c_2 + x) \sin x.$$

Had we included integration constants $-c_1$, c_2 in (2), then (2) would have given the additional $c_1 \cos x + c_2 \sin x = c_1y_1 + c_2y_2$, that is, a general solution of the given ODE directly from (2). This will always be the case. ■

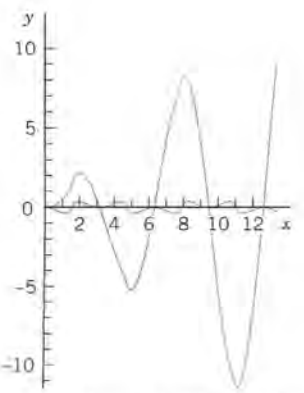

Fig. 69. Particular solution y_p and its first term in Example 1

Idea of the Method. Derivation of (2)

What idea did Lagrange have? What gave the method the name? Where do we use the continuity assumptions?

The idea is to start from a general solution

$$y_h(x) = c_1y_1(x) + c_2y_2(x)$$

of the homogeneous ODE (3) on an open interval I and to replace the constants ("the parameters") c_1 and c_2 by functions $u(x)$ and $v(x)$; this suggests the name of the method. We shall determine u and v so that the resulting function

$$y_p(x) = u(x)y_1(x) + v(x)y_2(x) \tag{5}$$

is a particular solution of the nonhomogeneous ODE (1). Note that y_h exists by Theorem 3 in Sec. 2.6 because of the continuity of p and q on I. (The continuity of r will be used later.)

We determine u and v by substituting (5) and its derivatives into (1). Differentiating (5), we obtain

$$y_p' = u'y_1 + uy_1' + v'y_2 + vy_2'.$$

Now y_p must satisfy (1). This is *one* condition for *two* functions u and v. It seems plausible that we may impose a *second* condition. Indeed, our calculation will show that we can determine u and v such that y_p satisfies (1) and u and v satisfy as a second condition the equation

$$u'y_1 + v'y_2 = 0. \tag{6}$$

This reduces the first derivative y_p' to the simpler form

$$y_p' = uy_1' + vy_2'. \tag{7}$$

Differentiating (7), we obtain

$$y_p'' = u'y_1' + uy_1'' + v'y_2' + vy_2''. \tag{8}$$

We now substitute y_p and its derivatives according to (5), (7), (8) into (1). Collecting terms in u and terms in v, we obtain

$$u(y_1'' + py_1' + qy_1) + v(y_2'' + py_2' + qy_2) + u'y_1' + v'y_2' = r.$$

Since y_1 and y_2 are solutions of the homogeneous ODE (3), this reduces to

$$u'y_1' + v'y_2' = r. \tag{9a}$$

Equation (6) is

$$u'y_1 + v'y_2 = 0. \tag{9b}$$

This is a linear system of two algebraic equations for the unknown functions u' and v'. We can solve it by elimination as follows (or by Cramer's rule in Sec. 7.6). To eliminate v', we multiply (9a) by $-y_2$ and (9b) by y_2' and add, obtaining

$$u'(y_1y_2' - y_2y_1') = -y_2r, \qquad \text{thus} \qquad u'W = -y_2r.$$

Here, W is the Wronskian (4) of y_1, y_2. To eliminate u' we multiply (9a) by y_1, and (9b) by $-y_1'$ and add, obtaining

$$v'(y_1y_2' - y_2y_1') = y_1r, \qquad \text{thus} \qquad v'W = y_1r.$$

Since y_1, y_2 form a basis, we have $W \neq 0$ (by Theorem 2 in Sec. 2.6) and can divide by W,

$$u' = -\frac{y_2r}{W}, \qquad v' = \frac{y_1r}{W}. \tag{10}$$

By integration,

$$u = -\int \frac{y_2r}{W}\,dx, \qquad v = \int \frac{y_1r}{W}\,dx.$$

These integrals exist because $r(x)$ is continuous. Inserting them into (5) gives (2) and completes the derivation. ∎

PROBLEM SET 2.10

1–17 GENERAL SOLUTION

Solve the given nonhomogeneous ODE by variation of parameters or undetermined coefficients. Give a general solution. (Show the details of your work.)

1. $y'' + y = \csc x$
2. $y'' - 4y' + 4y = x^2e^x$
3. $x^2y'' - 2xy' + 2y = x^3\cos x$
4. $y'' - 2y' + y = e^x \sin x$
5. $y'' + y = \tan x$
6. $x^2y'' - xy' + y = x \ln |x|$
7. $y'' + y = \cos x + \sec x$
8. $y'' - 4y' + 4y = 12e^{2x}/x^4$
9. $(D^2 - 2D + I)y = x^2 + x^{-2}e^x$
10. $(D^2 - I)y = 1/\cosh x$
11. $(D^2 + 4I)y = \cosh 2x$
12. $(x^2D^2 + xD - \frac{1}{4}I)y = 3x^{-1} + 3x$
13. $(x^2D^2 - 2xD + 2I)y = x^3 \sin x$
14. $(x^2D^2 + xD - 4I)y = 1/x^2$
15. $(D^2 + I)y = \sec x - 10 \sin 5x$
16. $(x^2D^2 + xD + (x^2 - \frac{1}{4})I)y = x^{3/2}\cos x$.
    Hint. To find y_1, y_2 set $y = ux^{-1/2}$.
17. $(x^2D^2 + xD + (x^2 - \frac{1}{4})I)y = x^{3/2}\sin x$.
    Hint: As in Prob. 16.
18. **TEAM PROJECT. Comparison of Methods.** The undetermined-coefficient method should be used whenever possible because it is simpler. Compare it with the present method as follows.

    (a) Solve $y'' + 2y' - 15y = 17 \sin 5x$ by both methods, showing all details, and compare.

    (b) Solve $y'' + 9y = r_1 + r_2$, $r_1 = \sec 3x$, $r_2 = \sin 3x$ by applying each method to a suitable function on the right.

    (c) Invent an undetermined-coefficient method for nonhomogeneous Euler–Cauchy equations by experimenting.

CHAPTER 2 REVIEW QUESTIONS AND PROBLEMS

1. What general properties make *linear* ODEs particularly attractive?
2. What is a general solution of a linear ODE? A basis of solutions?
3. How would you obtain a general solution of a nonhomogeneous linear ODE if you knew a general solution of the corresponding homogeneous ODE?
4. What does an initial value problem for a second-order ODE look like?
5. What is a particular solution and why is it more common than a general solution as the answer to practical problems?
6. Why are second-order ODEs more important in modeling than ODEs of higher order?
7. Describe the applications of ODEs in mechanical vibrating systems. What are the electrical analogs of those systems?
8. If a construction, such as a bridge, shows undesirable resonance, what could you do?

9–18 GENERAL SOLUTION

Find a general solution. Indicate the method you are using and show the details of your calculation.

9. $y'' - 2y' - 8y = 52 \cos 6x$
10. $y'' + 6y' + 9y = e^{-3x} - 27x^2$
11. $y'' + 8y' + 25y = 26 \sin 3x$
12. $yy'' = 2y'^2$
13. $(x^2D^2 + 2xD - 12I)y = 1/x^3$
14. $(x^2D^2 + 6xD + 6I)y = x^2$
15. $(D^2 - 2D + I)y = x^{-3}e^x$
16. $(D^2 - 4D + 5I)y = e^{2x} \csc x$
17. $(D^2 - 2D + 2I)y = e^x \csc x$
18. $(4x^2D^2 - 24xD + 49I)y = 36x^5$

19–25 INITIAL VALUE PROBLEMS

Solve the following initial value problems. Sketch or graph the solution. (Show the details of your work.)

19. $y'' + 5y' - 14y = 0, \quad y(0) = 6, \quad y'(0) = -6$
20. $y'' + 6y' + 18y = 0, \quad y(0) = 5, \quad y'(0) = -21$
21. $x^2y'' - xy' - 24y = 0, \quad y(1) = 15, \quad y'(1) = 0$
22. $x^2y'' + 15xy' + 49y = 0, \quad y(1) = 2, \quad y'(1) = -11$
23. $y'' + 5y' + 6y = 108x^2, \quad y(0) = 18, \quad y'(0) = -26$
24. $y'' + y' + 2.5y = 13 \cos x, \; y(0) = 8.0, \; y'(0) = 4.5$
25. $(x^2D^2 + xD - 4I)y = x^3, \; y(1) = -4/5, \; y'(1) = 93/5$

26–34 APPLICATIONS

26. Find the steady-state solution of the system in Fig. 70 when $m = 4$, $c = 4$, $k = 17$ and the driving force is $202 \cos 3t$.
27. Find the motion of the system in Fig. 70 with mass 0.25 kg, no damping, spring constant 1 kg/sec^2, and driving force $15 \cos 0.5t - 7 \sin 1.5t$ nt, assuming zero initial displacement and velocity. For what frequency of the driving force would you get resonance?
28. In Prob. 26 find the solution corresponding to initial displacement 10 and initial velocity 0.
29. Show that the system in Fig. 70 with $m = 4$, $c = 0$, $k = 36$, and driving force $61 \cos 3.1t$ exhibits beats. *Hint:* Choose zero initial conditions.
30. In Fig. 70 let $m = 2$, $c = 6$, $k = 27$, and $r(t) = 10 \cos \omega t$. For what ω will you obtain the steady-state vibration of maximum possible amplitude? Determine this amplitude. Then use this ω and the undetermined-coefficient method to see whether you obtain the same amplitude.
31. Find an electrical analog of the mass–spring system in Fig. 70 with mass 0.5 kg, spring constant 40 kg/sec^2, damping constant 9 kg/sec, and driving force $102 \cos 6t$ nt. Solve the analog, assuming zero initial current and charge.
32. Find the current in the *RLC*-circuit in Fig. 71 when $L = 0.1$ H, $R = 20\ \Omega$, $C = 2 \cdot 10^{-4}$ F, and $E(t) = 110 \sin 415t$ V (66 cycles/sec).
33. Find the current in the *RLC*-circuit when $L = 0.4$ H, $R = 40\ \Omega$, $C = 10^{-4}$ F, and $E(t) = 220 \sin 314t$ V (50 cycles/sec).
34. Find a particular solution in Prob. 33 by the complex method. (See Team Project 20 in Sec. 2.9.)

SUMMARY OF CHAPTER 2
Second-Order Linear ODEs

Second-order linear ODEs are particularly important in applications, for instance, in mechanics (Secs. 2.4, 2.8) and electrical engineering (Sec. 2.9). A second-order ODE is called **linear** if it can be written

(1) $$y'' + p(x)y' + q(x)y = r(x) \qquad \text{(Sec. 2.1).}$$

(If the first term is, say, $f(x)y''$, divide by $f(x)$ to get the **"standard form"** (1) with y'' as the first term.) Equation (1) is called **homogeneous** if $r(x)$ is zero for all x considered, usually in some open interval; this is written $r(x) \equiv 0$. Then

(2) $$y'' + p(x)y' + q(x)y = 0.$$

Equation (1) is called **nonhomogeneous** if $r(x) \not\equiv 0$ (meaning $r(x)$ is not zero for some x considered).

For the homogeneous ODE (2) we have the important **superposition principle** (Sec. 2.1) that a linear combination $y = ky_1 + ly_2$ of two solutions y_1, y_2 is again a solution.

Two *linearly independent* solutions y_1, y_2 of (2) on an open interval I form a **basis** (or **fundamental system**) of solutions on I, and $y = c_1y_1 + c_2y_2$ with arbitrary constants c_1, c_2 is a **general solution** of (2) on I. From it we obtain a **particular solution** if we specify numeric values (numbers) for c_1 and c_2, usually by prescribing two **initial conditions**

(3) $$y(x_0) = K_0, \qquad y'(x_0) = K_1 \qquad (x_0, K_0, K_1 \text{ given numbers; Sec. 2.1}).$$

(2) and (3) together form an **initial value problem.** Similarly for (1) and (3).

For a nonhomogeneous ODE (1) a **general solution** is of the form

(4) $$y = y_h + y_p \qquad \text{(Sec. 2.7).}$$

Here y_h is a general solution of (2) and y_p is a particular solution of (1). Such a y_p can be determined by a general method (**variation of parameters,** Sec. 2.10) or in many practical cases by the **method of undetermined coefficients.** The latter applies when (1) has constant coefficients p and q, and $r(x)$ is a power of x, sine, cosine, etc. (Sec. 2.7). Then we write (1) as

(5) $$y'' + ay' + by = r(x) \qquad \text{(Sec. 2.7).}$$

The corresponding homogeneous ODE $y' + ay' + by = 0$ has solutions $y = e^{\lambda x}$, where λ is a root of

(6) $$\lambda^2 + a\lambda + b = 0.$$

Hence there are three cases (Sec. 2.2):

Case	Type of Roots	General Solution
I	Distinct real λ_1, λ_2	$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$
II	Double $-\frac{1}{2}a$	$y = (c_1 + c_2 x) e^{-ax/2}$
III	Complex $-\frac{1}{2}a \pm i\omega^*$	$y = e^{-ax/2}(A \cos \omega^* x + B \sin \omega^* x)$

Important applications of (5) in mechanical and electrical engineering in connection with **vibrations** and **resonance** are discussed in Secs. 2.4, 2.7, and 2.8.

Another large class of ODEs solvable "algebraically" consists of the **Euler–Cauchy equations**

$$x^2y'' + axy' + by = 0 \qquad \text{(Sec. 2.5).} \tag{7}$$

These have solutions of the form $y = x^m$, where m is a solution of the auxiliary equation

$$m^2 + (a - 1)m + b = 0. \tag{8}$$

Existence and uniqueness of solutions of (1) and (2) is discussed in Secs. 2.6 and 2.7, and **reduction of order** in Sec. 2.1.

CHAPTER 3

Higher Order Linear ODEs

In this chapter we extend the concepts and methods of Chap. 2 for linear ODEs from order $n = 2$ to arbitrary order n. This will be straightforward and needs no new ideas. However, the formulas become more involved, the variety of roots of the characteristic equation (in Sec. 3.2) becomes much larger with increasing n, and the Wronskian plays a more prominent role.

Prerequisite: Secs. 2.1, 2.2, 2.6, 2.7, 2.10.
References and Answers to Problems: App. 1 Part A, and App. 2.

3.1 Homogeneous Linear ODEs

Recall from Sec. 1.1 that an ODE is of ***n*th order** if the nth derivative $y^{(n)} = d^n y/dx^n$ of the unknown function $y(x)$ is the highest occurring derivative. Thus the ODE is of the form

$$F(x, y, y', \cdots, y^{(n)}) = 0 \qquad \left(y^{(n)} = \frac{d^n y}{dx^n}\right)$$

where lower order derivatives and y itself may or may not occur. Such an ODE is called **linear** if it can be written

$$\textbf{(1)} \qquad y^{(n)} + p_{n-1}(x)y^{(n-1)} + \cdots + p_1(x)y' + p_0(x)y = r(x).$$

(For $n = 2$ this is (1) in Sec. 2.1 with $p_1 = p$ and $p_0 = q$). The **coefficients** $p_0, \cdots, p_{n-1}$ and the function r on the right are any given functions of x, and y is unknown. $y^{(n)}$ has coefficient 1. This is practical. We call this the **standard form.** (If you have $p_n(x)y^{(n)}$, divide by $p_n(x)$ to get this form.) An nth-order ODE that cannot be written in the form (1) is called **nonlinear.**

If $r(x)$ is identically zero, $r(x) \equiv 0$ (zero for all x considered, usually in some open interval I), then (1) becomes

$$\textbf{(2)} \qquad y^{(n)} + p_{n-1}(x)y^{(n-1)} + \cdots + p_1(x)y' + p_0(x)y = 0$$

and is called **homogeneous.** If $r(x)$ is not identically zero, then the ODE is called **nonhomogeneous.** This is as in Sec. 2.1.

A **solution** of an nth-order (linear or nonlinear) ODE on some open interval I is a function $y = h(x)$ that is defined and n times differentiable on I and is such that the ODE becomes an identity if we replace the unknown function y and its derivatives by h and its corresponding derivatives.

Homogeneous Linear ODE: Superposition Principle, General Solution

Sections 3.1–3.2 will be devoted to homogeneous linear ODEs and Sec. 3.3 to nonhomogeneous linear ODEs. The basic **superposition or linearity principle** in Sec. 2.1 extends to nth order homogeneous linear ODEs as follows.

THEOREM 1

Fundamental Theorem for the Homogeneous Linear ODE (2)

For a homogeneous linear ODE (2), *sums and constant multiples of solutions on some open interval I are again solutions on I.* (This does ***not*** hold for a nonhomogeneous or nonlinear ODE!)

The proof is a simple generalization of that in Sec. 2.1 and we leave it to the student.

Our further discussion parallels and extends that for second-order ODEs in Sec. 2.1. So we define next a general solution of (2), which will require an extension of linear independence from 2 to n functions.

DEFINITION

General Solution, Basis, Particular Solution

A **general solution** of (2) on an open interval I is a solution of (2) on I of the form

$$y(x) = c_1y_1(x) + \cdots + c_ny_n(x) \qquad (c_1, \cdots, c_n \text{ arbitrary}) \tag{3}$$

where $y_1, \cdots, y_n$ is a **basis** (or **fundamental system**) of solutions of (2) on I; that is, these solutions are linearly independent on I, as defined below.

A **particular solution** of (2) on I is obtained if we assign specific values to the n constants $c_1, \cdots, c_n$ in (3).

DEFINITION

Linear Independence and Dependence

n functions $y_1(x), \cdots, y_n(x)$ are called **linearly independent** *on some interval I* where they are defined if the equation

$$k_1y_1(x) + \cdots + k_ny_n(x) = 0 \qquad \text{on } I \tag{4}$$

implies that all $k_1, \cdots, k_n$ are zero. These functions are called **linearly dependent** on I if this equation also holds on I for some $k_1, \cdots, k_n$ not all zero.

(As in Secs. 1.1 and 2.1, the arbitrary constants $c_1, \cdots, c_n$ must sometimes be restricted to some interval.)

If and only if $y_1, \cdots, y_n$ are linearly dependent on I, we can express (at least) one of these functions on I as a **"linear combination"** of the other $n - 1$ functions, that is, as a sum of those functions, each multiplied by a constant (zero or not). This motivates the term "linearly dependent." For instance, if (4) holds with $k_1 \neq 0$, we can divide by k_1 and express y_1 as the linear combination

$$y_1 = -\frac{1}{k_1}(k_2y_2 + \cdots + k_ny_n).$$

Note that when $n = 2$, these concepts reduce to those defined in Sec. 2.1.

EXAMPLE 1 **Linear Dependence**

Show that the functions $y_1 = x^2$, $y_2 = 5x$, $y_3 = 2x$ are linearly dependent on any interval.

Solution. $y_2 = 0y_1 + 2.5y_3$. This proves linear dependence on any interval. ■

EXAMPLE 2 **Linear Independence**

Show that $y_1 = x$, $y_2 = x^2$, $y_3 = x^3$ are linearly independent on any interval, for instance, on $-1 \leqq x \leqq 2$.

Solution. Equation (4) is $k_1x + k_2x^2 + k_3x^3 = 0$. Taking (a) $x = -1$, (b) $x = 1$, (c) $x = 2$, we get

$$\text{(a) } -k_1 + k_2 - k_3 = 0, \qquad \text{(b) } k_1 + k_2 + k_3 = 0, \qquad \text{(c) } 2k_1 + 4k_2 + 8k_3 = 0.$$

$k_2 = 0$ from (a) + (b). Then $k_3 = 0$ from (c) -2(b). Then $k_1 = 0$ from (b). This proves linear independence.

A better method for testing linear independence of solutions of ODEs will soon be explained. ■

EXAMPLE 3 **General Solution. Basis**

Solve the fourth-order ODE

$$y^{\text{iv}} - 5y'' + 4y = 0 \qquad (\text{where } y^{\text{iv}} = d^4y/dx^4).$$

Solution. As in Sec. 2.2 we try and substitute $y = e^{\lambda x}$. Omitting the common factor $e^{\lambda x}$, we obtain the characteristic equation

$$\lambda^4 - 5\lambda^2 + 4 = 0.$$

This is a quadratic equation in $\mu = \lambda^2$, namely,

$$\mu^2 - 5\mu + 4 = (\mu - 1)(\mu - 4) = 0.$$

The roots are $\mu = 1$ and 4. Hence $\lambda = -2, -1, 1, 2$. This gives four solutions. A general solution on any interval is

$$y = c_1e^{-2x} + c_2e^{-x} + c_3e^{x} + c_4e^{2x}$$

provided those four solutions are linearly independent. This is true but will be shown later. ■

Initial Value Problem. Existence and Uniqueness

An **initial value problem** for the ODE (2) consists of (2) and n **initial conditions**

$$\textbf{(5)} \qquad y(x_0) = K_0, \qquad y'(x_0) = K_1, \qquad \cdots, \qquad y^{(n-1)}(x_0) = K_{n-1}$$

with given x_0 in the open interval I considered, and given $K_0, \cdots, K_{n-1}$.

In extension of the existence and uniqueness theorem in Sec. 2.6 we now have the following.

THEOREM 2 **Existence and Uniqueness Theorem for Initial Value Problems**

If the coefficients $p_0(x), \cdots, p_{n-1}(x)$ of (2) are continuous on some open interval I and x_0 is in I, then the initial value problem (2), (5) has a unique solution $y(x)$ on I.

Existence is proved in Ref. [A11] in App. 1. Uniqueness can be proved by a slight generalization of the uniqueness proof at the beginning of App. 4.

EXAMPLE 4 **Initial Value Problem for a Third-Order Euler–Cauchy Equation**

Solve the following initial value problem on any open interval I on the positive x-axis containing $x = 1$.

$$x^3y''' - 3x^2y'' + 6xy' - 6y = 0, \qquad y(1) = 2, \quad y'(1) = 1, \quad y''(1) = -4.$$

Solution. ***Step 1. General solution.*** As in Sec. 2.5 we try $y = x^m$. By differentiation and substitution,

$$m(m-1)(m-2)x^m - 3m(m-1)x^m + 6mx^m - 6x^m = 0.$$

Dropping x^m and ordering gives $m^3 - 6m^2 + 11m - 6 = 0$. If we can guess the root $m = 1$, we can divide by $m - 1$ and find the other roots 2 and 3, thus obtaining the solutions x, x^2, x^3, which are linearly independent on I (see Example 2). [In general one shall need a root-finding method, such as Newton's (Sec. 19.2), also available in a CAS (Computer Algebra System).] Hence a general solution is

$$y = c_1x + c_2x^2 + c_3x^3$$

valid on any interval I, even when it includes $x = 0$ where the coefficients of the ODE divided by x^3 (to have the standard form) are not continuous.

Step 2. Particular solution. The derivatives are $y' = c_1 + 2c_2x + 3c_3x^2$ and $y'' = 2c_2 + 6c_3x$. From this and y and the initial conditions we get by setting $x = 1$

$$\begin{aligned} \text{(a)}\ y(1) &= c_1 + c_2 + c_3 = 2 \\ \text{(b)}\ y'(1) &= c_1 + 2c_2 + 3c_3 = 1 \\ \text{(c)}\ y''(1) &= 2c_2 + 6c_3 = -4. \end{aligned}$$

This is solved by Cramer's rule (Sec. 7.6), or by elimination, which is simple, as follows. (b) − (a) gives (d) $c_2 + 2c_3 = -1$. Then (c) − 2(d) gives $c_3 = -1$. Then (c) gives $c_2 = 1$. Finally $c_1 = 2$ from (a).
Answer: $y = 2x + x^2 - x^3$. ■

Linear Independence of Solutions. Wronskian

Linear independence of solutions is crucial for obtaining general solutions. Although it can often be seen by inspection, it would be good to have a criterion for it. Now Theorem 2 in Sec. 2.6 extends from order $n = 2$ to any n. This extended criterion uses the **Wronskian** W of n solutions $y_1, \cdots, y_n$ defined as the nth order determinant

$$\textbf{(6)} \qquad W(y_1, \cdots, y_n) = \begin{vmatrix} y_1 & y_2 & \cdots & y_n \\ y_1' & y_2' & \cdots & y_n' \\ \cdot & \cdot & \cdots & \cdot \\ y_1^{(n-1)} & y_2^{(n-1)} & \cdots & y_n^{(n-1)} \end{vmatrix}.$$

Note that W depends on x since $y_1, \cdots, y_n$ does. The criterion states that these solutions form a basis if and only if W is not zero; more precisely:

THEOREM 3 **Linear Dependence and Independence of Solutions**

Let the ODE (2) *have continuous coefficients* $p_0(x), \cdots, p_{n-1}(x)$ *on an open interval* I. *Then* n *solutions* $y_1, \cdots, y_n$ *of* (2) *on* I *are linearly dependent on* I *if and only if their Wronskian is zero for some* $x = x_0$ *in* I. *Furthermore, if* W *is zero for* $x = x_0$, *then* W *is identically zero on* I. *Hence if there is an* x_1 *in* I *at which* W *is not zero, then* $y_1, \cdots, y_n$ *are linearly independent on* I, *so that they form a basis of solutions of* (2) *on* I.

PROOF **(a)** Let $y_1, \cdots, y_n$ be linearly dependent solutions of (2) on I. Then, by definition, there are constants $k_1, \cdots, k_n$ *not all zero*, such that for all x in I,

$$k_1 y_1 + \cdots + k_n y_n = 0. \tag{7}$$

By $n - 1$ differentiations of (7) we obtain for all x in I

$$\begin{aligned} k_1 y_1' + \cdots + k_n y_n' &= 0 \\ &\vdots \\ k_1 y_1^{(n-1)} + \cdots + k_n y_n^{(n-1)} &= 0. \end{aligned} \tag{8}$$

(7), (8) is a homogeneous linear system of algebraic equations with a nontrivial solution $k_1, \cdots, k_n$. Hence its coefficient determinant must be zero for every x on I, by Cramer's theorem (Sec. 7.7). But that determinant is the Wronskian W, as we see from (6). Hence W is zero for every x on I.

(b) Conversely, if W is zero at an x_0 in I, then the system (7), (8) with $x = x_0$ has a solution $k_1^*, \cdots, k_n^*$, not all zero, by the same theorem. With these constants we define the solution $y^* = k_1^* y_1 + \cdots + k_n^* y_n$ of (2) on I. By (7), (8) this solution satisfies the initial conditions $y^*(x_0) = 0, \cdots, y^{*(n-1)}(x_0) = 0$. But another solution satisfying the same conditions is $y \equiv 0$. Hence $y^* \equiv y$ by Theorem 2, which applies since the coefficients of (2) are continuous. Together, $y^* = k_1^* y_1 + \cdots + k_n^* y_n \equiv 0$ on I. This means linear dependence of $y_1, \cdots, y_n$ on I.

(c) If W is zero at an x_0 in I, we have linear dependence by (b) and then $W \equiv 0$ by (a). Hence if W is not zero at an x_1 in I, the solutions $y_1, \cdots, y_n$ must be linearly independent on I. ■

EXAMPLE 5 **Basis, Wronskian**

We can now prove that in Example 3 we do have a basis. In evaluating W, pull out the exponential functions columnwise. In the result, subtract Column 1 from Columns 2, 3, 4 (without changing Column 1). Then expand by Row 1. In the resulting third-order determinant, subtract Column 1 from Column 2 and expand the result by Row 2:

$$W = \begin{vmatrix} e^{-2x} & e^{-x} & e^{x} & e^{2x} \\ -2e^{-2x} & -e^{-x} & e^{x} & 2e^{2x} \\ 4e^{-2x} & e^{-x} & e^{x} & 4e^{2x} \\ -8e^{-2x} & -e^{-x} & e^{x} & 8e^{2x} \end{vmatrix} = \begin{vmatrix} 1 & 1 & 1 & 1 \\ -2 & -1 & 1 & 2 \\ 4 & 1 & 1 & 4 \\ -8 & -1 & 1 & 8 \end{vmatrix} = \begin{vmatrix} 1 & 3 & 4 \\ -3 & -3 & 0 \\ 7 & 9 & 16 \end{vmatrix} = 72. \quad ■$$

A General Solution of (2) Includes All Solutions

Let us first show that general solutions always exist. Indeed, Theorem 3 in Sec. 2.6 extends as follows.

THEOREM 4

Existence of a General Solution

If the coefficients $p_0(x), \cdots, p_{n-1}(x)$ of (2) are continuous on some open interval I, then (2) has a general solution on I.

PROOF We choose any fixed x_0 in I. By Theorem 2 the ODE (2) has n solutions $y_1, \cdots, y_n$, where y_j satisfies initial conditions (5) with $K_{j-1} = 1$ and all other K's equal to zero. Their Wronskian at x_0 equals 1. For instance, when $n = 3$, then $y_1(x_0) = 1$, $y_2'(x_0) = 1$, $y_3''(x_0) = 1$, and the other initial values are zero. Thus, as claimed,

$$W(y_1(x_0), y_2(x_0), y_3(x_0)) = \begin{vmatrix} y_1(x_0) & y_2(x_0) & y_3(x_0) \\ y_1'(x_0) & y_2'(x_0) & y_3'(x_0) \\ y_1''(x_0) & y_2''(x_0) & y_3''(x_0) \end{vmatrix} = \begin{vmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{vmatrix} = 1.$$

Hence for any n those solutions $y_1, \cdots, y_n$ are linearly independent on I, by Theorem 3. They form a basis on I, and $y = c_1y_1 + \cdots + c_ny_n$ is a general solution of (2) on I. ■

We can now prove the basic property that from a general solution of (2) every solution of (2) can be obtained by choosing suitable values of the arbitrary constants. Hence an nth order ***linear*** ODE has no **singular solutions,** that is, solutions that cannot be obtained from a general solution.

THEOREM 5

General Solution Includes All Solutions

If the ODE (2) *has continuous coefficients* $p_0(x), \cdots, p_{n-1}(x)$ *on some open interval* I, *then every solution* $y = Y(x)$ *of* (2) *on* I *is of the form*

$$Y(x) = C_1y_1(x) + \cdots + C_ny_n(x) \tag{9}$$

where $y_1, \cdots, y_n$ *is a basis of solutions of* (2) *on* I *and* $C_1, \cdots, C_n$ *are suitable constants.*

PROOF Let Y be a given solution and $y = c_1y_1 + \cdots + c_ny_n$ a general solution of (2) on I. We choose any fixed x_0 in I and show that we can find constants $c_1, \cdots, c_n$ for which y and its first $n - 1$ derivatives agree with Y and its corresponding derivatives at x_0. That is, we should have at $x = x_0$

$$\begin{aligned} c_1y_1 + \cdots + c_ny_n &= Y \\ c_1y_1' + \cdots + c_ny_n' &= Y' \\ &\vdots \\ c_1y_1^{(n-1)} + \cdots + c_ny_n^{(n-1)} &= Y^{(n-1)}. \end{aligned} \tag{10}$$

But this is a linear system of equations in the unknowns $c_1, \cdots, c_n$. Its coefficient determinant is the Wronskian W of $y_1, \cdots, y_n$ at x_0. Since $y_1, \cdots, y_n$ form a basis, they are linearly independent, so that W is not zero by Theorem 3. Hence (10) has a unique solution $c_1 = C_1, \cdots, c_n = C_n$ (by Cramer's theorem in Sec. 7.7). With these values we obtain the particular solution

$$y^*(x) = C_1y_1(x) + \cdots + C_ny_n(x)$$

on I. Equation (10) shows that y^* and its first $n - 1$ derivatives agree at x_0 with Y and its corresponding derivatives. That is, y^* and Y satisfy at x_0 the same initial conditions.

The uniqueness theorem (Theorem 2) now implies that $y^* \equiv Y$ on I. This proves the theorem. ■

This completes our theory of the homogeneous linear ODE (2). Note that for $n = 2$ it is identical with that in Sec. 2.6. This had to be expected.

PROBLEM SET 3.1

1–5 TYPICAL EXAMPLES OF BASES

To get a feel for higher order ODEs, show that the given functions are solutions and form a basis on any interval. Use Wronskians. (In Prob. 2, $x > 0$.)

1. $1, x, x^2, x^3, \qquad y^{\text{iv}} = 0$
2. $1, x^2, x^4, \qquad x^2y''' - 3xy'' + 3y' = 0$
3. $e^x, xe^x, x^2e^x, \qquad y''' - 3y'' + 3y' - y = 0$
4. $e^{2x}\cos x, e^{2x}\sin x, e^{-2x}\cos x, e^{-2x}\sin x, \quad y^{\text{iv}} - 6y'' + 25y = 0.$
5. $1, x, \cos 3x, \sin 3x, \qquad y^{\text{iv}} + 9y'' = 0$
6. **TEAM PROJECT. General Properties of Solutions of Linear ODEs.** These properties are important in obtaining new solutions from given ones. Therefore extend Team Project 34 in Sec. 2.2 to nth-order ODEs. Explore statements on sums and multiples of solutions of (1) and (2) systematically and with proofs. Recognize clearly that no new ideas are needed in this extension from $n = 2$ to general n.

7–19 LINEAR INDEPENDENCE AND DEPENDENCE

Are the given functions linearly independent or dependent on the positive x-axis? (Give a reason.)

7. $1, e^x, e^{-x}$
8. $x + 1, x + 2, x$
9. $\ln x, \ln x^2, (\ln x)^2$
10. $e^x, e^{-x}, \sinh 2x$
11. $x^2, x|x|, x$
12. $x, 1/x, 0$
13. $\sin 2x, \sin x, \cos x$
14. $\cos^2 x, \sin^2 x, \cos 2x$
15. $\tan x, \cot x, 1$
16. $(x - 1)^2, (x + 1)^2, x$
17. $\sin x, \sin \frac{1}{2}x$
18. $\cosh x, \sinh x, \cosh^2 x$
19. $\cos^2 x, \sin^2 x, 2\pi$
20. **TEAM PROJECT. Linear Independence and Dependence. (a)** Investigate the given question about a set S of functions on an interval I. Give an example. Prove your answer.

    (1) If S contains the zero function, can S be linearly independent?

    (2) If S is linearly independent on a subinterval J of I, is it linearly independent on I?

    (3) If S is linearly dependent on a subinterval J of I, is it linearly dependent on I?

    (4) If S is linearly independent on I, is it linearly independent on a subinterval J?

    (5) If S is linearly dependent on I, is it linearly independent on a subinterval J?

    (6) If S is linearly dependent on I, and if T contains S, is T linearly dependent on I?

    (b) In what cases can you use the Wronskian for testing linear independence? By what other means can you perform such a test?

3.2 Homogeneous Linear ODEs with Constant Coefficients

In this section we consider nth-order homogeneous linear ODEs with constant coefficients, which we write in the form

$$y^{(n)} + a_{n-1}y^{(n-1)} + \cdots + a_1y' + a_0y = 0 \tag{1}$$

where $y^{(n)} = d^ny/dx^n$, etc. We shall see that this extends the case $n = 2$ discussed in Sec. 2.2. Substituting $y = e^{\lambda x}$ (as in Sec. 2.2), we obtain the characteristic equation

$$\lambda^n + a_{n-1}\lambda^{(n-1)} + \cdots + a_1\lambda + a_0 = 0 \tag{2}$$

of (1). If λ is a root of (2), then $y = e^{\lambda x}$ is a solution of (1). To find these roots, you may need a numeric method, such as Newton's in Sec. 19.2, also available on the usual CASs. For general n there are more cases than for $n = 2$. We shall discuss all of them and illustrate them with typical examples.

Distinct Real Roots

If all the n roots $\lambda_1, \cdots, \lambda_n$ of (2) are real and different, then the n solutions

$$y_1 = e^{\lambda_1 x}, \quad \cdots, \quad y_n = e^{\lambda_n x} \tag{3}$$

constitute a basis for all x. The corresponding general solution of (1) is

$$y = c_1 e^{\lambda_1 x} + \cdots + c_n e^{\lambda_n x}. \tag{4}$$

Indeed, the solutions in (3) are linearly independent, as we shall see after the example.

EXAMPLE 1 **Distinct Real Roots**

Solve the ODE $y''' - 2y'' - y' + 2y = 0$.

Solution. The characteristic equation is $\lambda^3 - 2\lambda^2 - \lambda + 2 = 0$. It has the roots -1, 1, 2; if you find one of them by inspection, you can obtain the other two roots by solving a quadratic equation (explain!). The corresponding general solution (4) is $y = c_1 e^{-x} + c_2 e^{x} + c_3 e^{2x}$. ■

Linear Independence of (3). Students familiar with nth-order determinants may verify that by pulling out all exponential functions from the columns and denoting their product by E, thus $E = \exp[(\lambda_1 + \cdots + \lambda_n)x]$, the Wronskian of the solutions in (3) becomes

$$W = \begin{vmatrix} e^{\lambda_1 x} & e^{\lambda_2 x} & \cdots & e^{\lambda_n x} \\ \lambda_1 e^{\lambda_1 x} & \lambda_2 e^{\lambda_2 x} & \cdots & \lambda_n e^{\lambda_n x} \\ \lambda_1^2 e^{\lambda_1 x} & \lambda_2^2 e^{\lambda_2 x} & \cdots & \lambda_n^2 e^{\lambda_n x} \\ \cdot & \cdot & \cdots & \cdot \\ \lambda_1^{n-1} e^{\lambda_1 x} & \lambda_2^{n-1} e^{\lambda_2 x} & \cdots & \lambda_n^{n-1} e^{\lambda_n x} \end{vmatrix}$$

$$= E \begin{vmatrix} 1 & 1 & \cdots & 1 \\ \lambda_1 & \lambda_2 & \cdots & \lambda_n \\ \lambda_1^2 & \lambda_2^2 & \cdots & \lambda_n^2 \\ \cdot & \cdot & \cdots & \cdot \\ \lambda_1^{n-1} & \lambda_2^{n-1} & \cdots & \lambda_n^{n-1} \end{vmatrix}. \tag{5}$$

The exponential function E is never zero. Hence $W = 0$ if and only if the determinant on the right is zero. This is a so-called **Vandermonde** or **Cauchy determinant**[1]. It can be shown that it equals

[1]ALEXANDRE THÉOPHILE VANDERMONDE (1735–1796), French mathematician, who worked on solution of equations by determinants. For CAUCHY see footnote 4, in Sec. 2.5.

(6) $$(-1)^{n(n-1)/2}V$$

where V is the product of all factors $\lambda_j - \lambda_k$ with $j < k$ ($\leqq n$); for instance, when $n = 3$ we get $-V = -(\lambda_1 - \lambda_2)(\lambda_1 - \lambda_3)(\lambda_2 - \lambda_3)$. This shows that the Wronskian is not zero if and only if all the n roots of (2) are different and thus gives the following.

THEOREM 1

Basis

Solutions $y_1 = e^{\lambda_1 x}, \cdots, y_n = e^{\lambda_n x}$ of (1) (with any real or complex λ_j's) form a basis of solutions of (1) on any open interval if and only if all n roots of (2) are different.

Actually, Theorem 1 is an important special case of our more general result obtained from (5) and (6):

THEOREM 2

Linear Independence

Any number of solutions of (1) of the form $e^{\lambda x}$ are linearly independent on an open interval I if and only if the corresponding λ are all different.

Simple Complex Roots

If complex roots occur, they must occur in conjugate pairs since the coefficients of (1) are real. Thus, if $\lambda = \gamma + i\omega$ is a simple root of (2), so is the conjugate $\bar{\lambda} = \gamma - i\omega$, and two corresponding linearly independent solutions are (as in Sec. 2.2, except for notation)

$$y_1 = e^{\gamma x} \cos \omega x, \qquad y_2 = e^{\gamma x} \sin \omega x.$$

EXAMPLE 2 **Simple Complex Roots. Initial Value Problem**

Solve the initial value problem

$$y''' - y'' + 100y' - 100y = 0, \qquad y(0) = 4, \qquad y'(0) = 11, \qquad y''(0) = -299.$$

Solution. The characteristic equation is $\lambda^3 - \lambda^2 + 100\lambda - 100 = 0$. It has the root 1, as can perhaps be seen by inspection. Then division by $\lambda - 1$ shows that the other roots are $\pm 10i$. Hence a general solution and its derivatives (obtained by differentiation) are

$$y = c_1 e^x + A \cos 10x + B \sin 10x,$$
$$y' = c_1 e^x - 10A \sin 10x + 10B \cos 10x,$$
$$y'' = c_1 e^x - 100A \cos 10x - 100B \sin 10x.$$

From this and the initial conditions we obtain by setting $x = 0$

$$\text{(a)} \quad c_1 + A = 4, \qquad \text{(b)} \quad c_1 + 10B = 11, \qquad \text{(c)} \quad c_1 - 100A = -299.$$

We solve this system for the unknowns A, B, c_1. Equation (a) minus Equation (c) gives $101A = 303$, $A = 3$. Then $c_1 = 1$ from (a) and $B = 1$ from (b). The solution is (Fig. 72)

$$y = e^x + 3 \cos 10x + \sin 10x.$$

This gives the solution curve, which oscillates about e^x (dashed in Fig. 72 on p. 114). ■

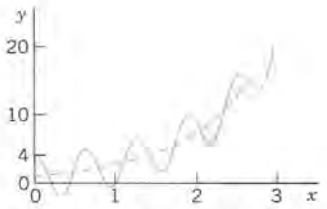

Fig. 72. Solution in Example 2

Multiple Real Roots

If a real double root occurs, say, $\lambda_1 = \lambda_2$, then $y_1 = y_2$ in (3), and we take y_1 and xy_1 as corresponding linearly independent solutions. This is as in Sec. 2.2.

More generally, if λ is a real root of order m, then m corresponding linearly independent solutions are

$$e^{\lambda x}, \quad xe^{\lambda x}, \quad x^2e^{\lambda x}, \quad \cdots, \quad x^{m-1}e^{\lambda x}. \tag{7}$$

We derive these solutions after the next example and indicate how to prove their linear independence.

EXAMPLE 3 **Real Double and Triple Roots**

Solve the ODE $y^v - 3y^{iv} + 3y''' - y'' = 0$.

Solution. The characteristic equation $\lambda^5 - 3\lambda^4 + 3\lambda^3 - \lambda^2 = 0$ has the roots $\lambda_1 = \lambda_2 = 0$ and $\lambda_3 = \lambda_4 = \lambda_5 = 1$, and the answer is

$$y = c_1 + c_2x + (c_3 + c_4x + c_5x^2)e^x. \tag{8}$$

■

***Derivation of* (7).** We write the left side of (1) as

$$L[y] = y^{(n)} + a_{n-1}y^{(n-1)} + \cdots + a_0y.$$

Let $y = e^{\lambda x}$. Then by performing the differentiations we have

$$L[e^{\lambda x}] = (\lambda^n + a_{n-1}\lambda^{n-1} + \cdots + a_0)e^{\lambda x}.$$

Now let λ_1 be a root of mth order of the polynomial on the right, where $m \leqq n$. For $m < n$ let $\lambda_{m+1}, \cdots, \lambda_n$ be the other roots, all different from λ_1. Writing the polynomial in product form, we then have

$$L[e^{\lambda x}] = (\lambda - \lambda_1)^m h(\lambda)e^{\lambda x}$$

with $h(\lambda) = 1$ if $m = n$, and $h(\lambda) = (\lambda - \lambda_{m+1}) \cdots (\lambda - \lambda_n)$ if $m < n$. Now comes the key idea: We differentiate on both sides with respect to λ,

$$\frac{\partial}{\partial \lambda} L[e^{\lambda x}] = m(\lambda - \lambda_1)^{m-1}h(\lambda)e^{\lambda x} + (\lambda - \lambda_1)^m \frac{\partial}{\partial \lambda} [h(\lambda)e^{\lambda x}]. \tag{9}$$

The differentiations with respect to x and λ are independent and the occurring derivatives are continuous, so that we can interchange their order on the left:

$$\frac{\partial}{\partial \lambda} L[e^{\lambda x}] = L\left[\frac{\partial}{\partial \lambda} e^{\lambda x}\right] = L[xe^{\lambda x}]. \tag{10}$$

The right side of (9) is zero for $\lambda = \lambda_1$ because of the factors $\lambda - \lambda_1$ (and $m \geqq 2$ since we have a multiple root!). Hence $L[xe^{\lambda_1 x}] = 0$ by (9) and (10). This proves that $xe^{\lambda_1 x}$ is a solution of (1).

We can repeat this step and produce $x^2 e^{\lambda_1 x}, \cdots, x^{m-1} e^{\lambda_1 x}$ by another $m - 2$ such differentiations with respect to λ. Going one step further would no longer give zero on the right because the lowest power of $\lambda - \lambda_1$ would then be $(\lambda - \lambda_1)^0$, multiplied by $m!h(\lambda)$ and $h(\lambda_1) \neq 0$ because $h(\lambda)$ has no factors $\lambda - \lambda_1$; so we get *precisely* the solutions in (7).

We finally show that the solutions (7) are linearly independent. For a specific n this can be seen by calculating their Wronskian, which turns out to be nonzero. For arbitrary m we can pull out the exponential functions from the Wronskian. This gives $(e^{\lambda x})^m = e^{\lambda m x}$ times a determinant which by "row operations" can be reduced to the Wronskian of $1, x, \cdots, x^{m-1}$. The latter is constant and different from zero (equal to $1!2! \cdots (m-1)!$). These functions are solutions of the ODE $y^{(m)} = 0$, so that linear independence follows from Theroem 3 in Sec. 3.1. ∎

Multiple Complex Roots

In this case, real solutions are obtained as for complex simple roots above. Consequently, if $\lambda = \gamma + i\omega$ is a **complex double root,** so is the conjugate $\bar{\lambda} = \gamma - i\omega$. Corresponding linearly independent solutions are

$$\textbf{(11)} \qquad e^{\gamma x} \cos \omega x, \qquad e^{\gamma x} \sin \omega x, \qquad xe^{\gamma x} \cos \omega x, \qquad xe^{\gamma x} \sin \omega x.$$

The first two of these result from $e^{\lambda x}$ and $e^{\bar{\lambda} x}$ as before, and the second two from $xe^{\lambda x}$ and $xe^{\bar{\lambda} x}$ in the same fashion. Obviously, the corresponding general solution is

$$y = e^{\gamma x}[(A_1 + A_2 x) \cos \omega x + (B_1 + B_2 x) \sin \omega x]. \tag{12}$$

For *complex triple roots* (which hardly ever occur in applications), one would obtain two more solutions $x^2 e^{\lambda x} \cos \omega x$, $x^2 e^{\gamma x} \sin \omega x$, and so on.

PROBLEM SET 3.2

1–6 ODE FOR GIVEN BASIS

Find an ODE (1) for which the given functions form a basis of solutions.

1. e^x, e^{2x}, e^{3x}
2. $e^{-2x}, xe^{-2x}, x^2e^{-2x}$
3. $e^x, e^{-x}, \cos x, \sin x$
4. $\cos x, \sin x, x \cos x, x \sin x$
5. $1, x, \cos 2x, \sin 2x$
6. $e^{-2x}, e^{-x}, e^x, e^{2x}, 1$

7–12 GENERAL SOLUTION

Solve the given ODE. (Show the details of your work.)

7. $y''' + y' = 0$
8. $y^{iv} - 29y'' + 100y = 0$
9. $y''' + y'' - y' - y = 0$
10. $16y^{iv} - 8y'' + y = 0$
11. $y''' - 3y'' - 4y' + 6y = 0$
12. $y^{iv} + 3y'' - 4y = 0$

13–18 INITIAL VALUE PROBLEMS

Solve by a CAS, giving a general solution and the particular solution and its graph.

13. $y^{iv} + 0.45y''' - 0.165y'' + 0.0045y' - 0.00175y = 0$, $y(0) = 17.4$, $y'(0) = -2.82$, $y''(0) = 2.0485$, $y'''(0) = -1.458675$

14. $4y''' + 8y'' + 41y' + 37y = 0$, $y(0) = 9$, $y'(0) = -6.5$, $y''(0) = -39.75$

15. $y''' + 3.2y'' + 4.81y' = 0$, $y(0) = 3.4$, $y'(0) = -4.6$, $y''(0) = 9.91$

16. $y^{iv} + 4y = 0$, $y(0) = \frac{1}{2}$, $y'(0) = -\frac{3}{2}$, $y''(0) = \frac{5}{2}$, $y'''(0) = -\frac{7}{2}$

17. $y^{iv} - 9y'' - 400y = 0$, $y(0) = 0$, $y'(0) = 0$, $y''(0) = 41$, $y'''(0) = 0$

18. $y''' + 7.5y'' + 14.25y' - 9.125y = 0$, $y(0) = 10.05$, $y'(0) = -54.975$, $y''(0) = 257.5125$

19. CAS PROJECT. Wronskians. Euler–Cauchy Equations of Higher Order. Although Euler–Cauchy equations have *variable* coefficients (powers of x), we include them here because they fit quite well into the present methods.

(a) Write a program for calculating Wronskians.

(b) Apply the program to some bases of third-order and fourth-order constant-coefficient ODEs. Compare the results with those obtained by the program most likely available for Wronskians in your CAS.

(c) Extend the solution method in Sec. 2.5 to any order n. Solve $x^3y''' + 2x^2y'' - 4xy' + 4y = 0$ and another ODE of your choice. In each case calculate the Wronskian.

20. PROJECT. Reduction of Order. This is of practical interest since a single solution of an ODE can often be guessed. For second order, see Example 7 in Sec. 2.1.

(a) How could you reduce the order of a linear constant-coefficient ODE if a solution is known?

(b) Extend the method to a variable-coefficient ODE

$$y''' + p_2(x)y'' + p_1(x)y' + p_0(x)y = 0.$$

Assuming a solution y_1 to be known, show that another solution is $y_2(x) = u(x)y_1(x)$ with $u(x) = \int z(x)\,dx$ and z obtained by solving

$$y_1z'' + (3y_1' + p_2y_1)z' + (3y_1'' + 2p_2y_1' + p_1y_1)z = 0.$$

(c) Reduce

$$x^3y''' - 3x^2y'' + (6 - x^2)xy' - (6 - x^2)y = 0,$$

using $y_1 = x$ (perhaps obtainable by inspection).

21. CAS EXPERIMENT. Reduction of Order. Starting with a basis, find third-order ODEs with variable coefficients for which the reduction to second order turns out to be relatively simple.

3.3 Nonhomogeneous Linear ODEs

We now turn from homogeneous to nonhomogeneous linear ODEs of nth order. We write them in standard form

$$y^{(n)} + p_{n-1}(x)y^{(n-1)} + \cdots + p_1(x)y' + p_0(x)y = r(x) \tag{1}$$

with $y^{(n)} = d^ny/dx^n$ as the first term, which is practical, and $r(x) \not\equiv 0$. As for second-order ODEs, a general solution of (1) on an open interval I of the x-axis is of the form

$$y(x) = y_h(x) + y_p(x). \tag{2}$$

Here $y_h(x) = c_1y_1(x) + \cdots + c_ny_n(x)$ is a general solution of the corresponding homogeneous ODE

$$y^{(n)} + p_{n-1}(x)y^{(n-1)} + \cdots + p_1(x)y' + p_0(x)y = 0 \tag{3}$$

on I. Also, y_p is any solution of (1) on I containing no arbitrary constants. If (1) has continuous coefficients and a continuous $r(x)$ on I, then a general solution of (1) exists and includes all solutions. Thus (1) has no singular solutions.

An **initial value problem** for (1) consists of (1) and n **initial conditions**

$$\textbf{(4)} \qquad y(x_0) = K_0, \quad y'(x_0) = K_1, \quad \cdots, \quad y^{(n-1)}(x_0) = K_{n-1}$$

with x_0 in I. Under those continuity assumptions it has a unique solution. The ideas of proof are the same as those for $n = 2$ in Sec. 2.7.

Method of Undetermined Coefficients

Equation (2) shows that for solving (1) we have to determine a particular solution of (1). For a constant-coefficient equation

$$\textbf{(5)} \qquad y^{(n)} + a_{n-1}y^{(n-1)} + \cdots + a_1y' + a_0y = r(x)$$

($a_0, \cdots, a_{n-1}$ constant) and special $r(x)$ as in Sec. 2.7, such a $y_p(x)$ can be determined by the **method of undetermined coefficients,** as in Sec. 2.7, using the following rules.

(A) Basic Rule as in Sec. 2.7.

(B) Modification Rule. *If a term in your choice for $y_p(x)$ is a solution of the homogeneous equation* (3)*, then multiply $y_p(x)$ by x^k, where k is the smallest positive integer such that no term of $x^k y_p(x)$ is a solution of* (3).

(C) Sum Rule as in Sec. 2.7.

The practical application of the method is the same as that in Sec. 2.7. It suffices to illustrate the typical steps of solving an initial value problem and, in particular, the new Modification Rule, which includes the old Modification Rule as a particular case (with $k = 1$ or 2). We shall see that the technicalities are the same as for $n = 2$, perhaps except for the more involved determination of the constants.

EXAMPLE 7 **Initial Value Problem. Modification Rule**

Solve the initial value problem

$$(6) \qquad y''' + 3y'' + 3y' + y = 30e^{-x}, \quad y(0) = 3, \quad y'(0) = -3, \quad y''(0) = -47.$$

Solution. ***Step 1.*** The characteristic equation is $\lambda^3 + 3\lambda^2 + 3\lambda + 1 = (\lambda + 1)^3 = 0$. It has the triple root $\lambda = -1$. Hence a general solution of the homogeneous ODE is

$$\begin{aligned} y_h &= c_1e^{-x} + c_2xe^{-x} + c_3x^2e^{-x} \\ &= (c_1 + c_2x + c_3x^2)e^{-x}. \end{aligned}$$

Step 2. If we try $y_p = Ce^{-x}$, we get $-C + 3C - 3C + C = 30$, which has no solution. Try Cxe^{-x} and Cx^2e^{-x}. The Modification Rule calls for

$$y_p = Cx^3e^{-x}.$$

Then

$$\begin{aligned} y_p' &= C(3x^2 - x^3)e^{-x}, \\ y_p'' &= C(6x - 6x^2 + x^3)e^{-x}, \\ y_p''' &= C(6 - 18x + 9x^2 - x^3)e^{-x}. \end{aligned}$$

Substitution of these expressions into (6) and omission of the common factor e^{-x} gives

$$C(6 - 18x + 9x^2 - x^3) + 3C(6x - 6x^2 + x^3) + 3C(3x^2 - x^3) + Cx^3 = 30.$$

The linear, quadratic, and cubic terms drop out, and $6C = 30$. Hence $C = 5$. This gives $y_p = 5x^3e^{-x}$.

Step 3. We now write down $y = y_h + y_p$, the general solution of the given ODE. From it we find c_1 by the first initial condition. We insert the value, differentiate, and determine c_2 from the second initial condition, insert the value, and finally determine c_3 from $y''(0)$ and the third initial condition:

$$y = y_h + y_p = (c_1 + c_2x + c_3x^2)e^{-x} + 5x^3e^{-x}, \qquad y(0) = c_1 = 3$$

$$y' = [-3 + c_2 + (-c_2 + 2c_3)x + (15 - c_3)x^2 - 5x^3]e^{-x}, \qquad y'(0) = -3 + c_2 = -3, \qquad c_2 = 0$$

$$y'' = [3 + 2c_3 + (30 - 4c_3)x + (-30 + c_3)x^2 + 5x^3]e^{-x}, \qquad y''(0) = 3 + 2c_3 = -47, \qquad c_3 = -25.$$

Hence the *answer* to our problem is (Fig. 73)

$$y = (3 - 25x^2)e^{-x} + 5x^3e^{-x}.$$

The curve of y begins at (0, 3) with a negative slope, as expected from the initial values, and approaches zero as $x \to \infty$. The dashed curve in Fig. 73 is y_p. ■

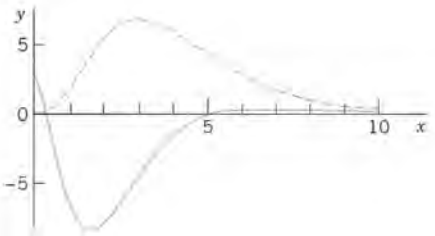

Fig. 73. y and y_p (dashed) in Example 1

Method of Variation of Parameters

The method of variation of parameters (see Sec. 2.10) also extends to arbitrary order n. It gives a particular solution y_p for the nonhomogeneous equation (1) (in standard form with $y^{(n)}$ as the first term!) by the formula

$$(7) \qquad y_p(x) = \sum_{k=1}^{n} y_k(x) \int \frac{W_k(x)}{W(x)}\, r(x)\, dx$$

$$= y_1(x) \int \frac{W_1(x)}{W(x)}\, r(x)\, dx + \cdots + y_n(x) \int \frac{W_n(x)}{W(x)}\, r(x)\, dx$$

on an open interval I on which the coefficients of (1) and $r(x)$ are continuous. In (7) the functions $y_1, \cdots, y_n$ form a basis of the homogeneous ODE (3), with Wronskian W, and W_j ($j = 1, \cdots, n$) is obtained from W by replacing the jth column of W by the column $[0 \quad 0 \quad \cdots \quad 0 \quad 1]^T$. Thus, when $n = 2$, this becomes identical with (2) in Sec. 2.10,

$$W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}, \qquad W_1 = \begin{vmatrix} 0 & y_2 \\ 1 & y_2' \end{vmatrix} = -y_2, \qquad W_2 = \begin{vmatrix} y_1 & 0 \\ y_1' & 1 \end{vmatrix} = y_1.$$

The proof of (7) uses an extension of the idea of the proof of (2) in Sec. 2.10 and can be found in Ref [A11] listed in App. 1.

EXAMPLE 2 Variation of Parameters. Nonhomogeneous Euler–Cauchy Equation

Solve the nonhomogeneous Euler–Cauchy equation

$$x^3y''' - 3x^2y'' + 6xy' - 6y = x^4 \ln x \qquad (x > 0).$$

Solution. ***Step 1. General solution of the homogeneous ODE.*** Substitution of $y = x^m$ and the derivatives into the homogeneous ODE and deletion of the factor x^m gives

$$m(m-1)(m-2) - 3m(m-1) + 6m - 6 = 0.$$

The roots are 1, 2, 3 and give as a basis

$$y_1 = x, \qquad y_2 = x^2, \qquad y_3 = x^3.$$

Hence the corresponding general solution of the homogeneous ODE is

$$y_h = c_1x + c_2x^2 + c_3x^3.$$

***Step 2. Determinants needed in* (7).** These are

$$W = \begin{vmatrix} x & x^2 & x^3 \\ 1 & 2x & 3x^2 \\ 0 & 2 & 6x \end{vmatrix} = 2x^3$$

$$W_1 = \begin{vmatrix} 0 & x^2 & x^3 \\ 0 & 2x & 3x^2 \\ 1 & 2 & 6x \end{vmatrix} = x^4$$

$$W_2 = \begin{vmatrix} x & 0 & x^3 \\ 1 & 0 & 3x^2 \\ 0 & 1 & 6x \end{vmatrix} = -2x^3$$

$$W_3 = \begin{vmatrix} x & x^2 & 0 \\ 1 & 2x & 0 \\ 0 & 2 & 1 \end{vmatrix} = x^2.$$

Step 3. Integration. In (7) we also need the right side $r(x)$ of our ODE in standard form, obtained by division of the given equation by the coefficient x^3 of y'''; thus, $r(x) = (x^4 \ln x)/x^3 = x \ln x$. In (7) we have the simple quotients $W_1/W = x/2$, $W_2/W = -1$, $W_3/W = 1/(2x)$. Hence (7) becomes

$$y_p = x\int \frac{x}{2}\, x \ln x\, dx - x^2 \int x \ln x\, dx + x^3 \int \frac{1}{2x}\, x \ln x\, dx$$

$$= \frac{x}{2}\left(\frac{x^3}{3}\ln x - \frac{x^3}{9}\right) - x^2\left(\frac{x^2}{2}\ln x - \frac{x^2}{4}\right) + \frac{x^3}{2}(x \ln x - x).$$

Simplification gives $y_p = \frac{1}{6}x^4(\ln x - \frac{11}{6})$. Hence the answer is

$$y = y_h + y_p = c_1x + c_2x^2 + c_3x^3 + \tfrac{1}{6}x^4(\ln x - \tfrac{11}{6}).$$

Figure 74 shows y_p. Can you explain the shape of this curve? Its behavior near $x = 0$? The occurrence of a minimum? Its rapid increase? Why would the method of undetermined coefficients not have given the solution? ■

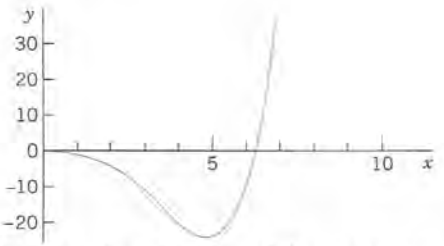

Fig. 74. Particular solution y_p of the nonhomogeneous Euler–Cauchy equation in Example 2

Application: Elastic Beams

Whereas second-order ODEs have various applications, some of the more important ones we have seen, higher order ODEs occur much more rarely in engineering work. An important fourth-order ODE governs the bending of elastic beams, such as wooden or iron girders in a building or a bridge.

Vibrations of beams will be considered in Sec. 12.3.

EXAMPLE 3 **Bending of an Elastic Beam under a Load**

We consider a beam B of length L and constant (e.g., **rectangular**) cross section and homogeneous elastic material (e.g., steel); see Fig. 75. We assume that under its own weight the beam is bent so little that it is practically straight. If we apply a load to B in a vertical plane through the axis of symmetry (the x-axis in Fig. 75), B is bent. Its axis is curved into the so-called **elastic curve** C (or **deflection curve**). It is shown in elasticity theory that the bending moment $M(x)$ is proportional to the curvature $k(x)$ of C. We assume the bending to be small, so that the deflection $y(x)$ and its derivative $y'(x)$ (determining the tangent direction of C) are small. Then, by calculus, $k = y''/(1 + y'^2)^{3/2} \approx y''$. Hence

$$M(x) = EIy''(x).$$

EI is the constant of proportionality. E is *Young's modulus of elasticity* of the material of the beam. I is the moment of inertia of the cross section about the (horizontal) z-axis in Fig. 75.

Elasticity theory shows further that $M''(x) = f(x)$, where $f(x)$ is the load per unit length. Together,

$$EIy^{\text{iv}} = f(x). \tag{8}$$

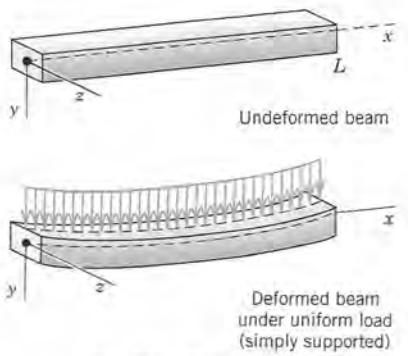

Fig. 75. Elastic Beam

The practically most important supports and corresponding boundary conditions are as follows (see Fig. 76).

(A)	Simply supported	$y = y'' = 0$ at $x = 0$ and L
(B)	Clamped at both ends	$y = y' = 0$ at $x = 0$ and L
(C)	Clamped at $x = 0$, free at $x = L$	$y(0) = y'(0) = 0,\ y''(L) = y'''(L) = 0.$

The boundary condition $y = 0$ means no displacement at that point, $y' = 0$ means a horizontal tangent, $y'' = 0$ means no bending moment, and $y''' = 0$ means no shear force.

Let us apply this to the uniformly loaded simply supported beam in Fig. 75. The load is $f(x) \equiv f_0 = const.$ Then (8) is

$$y^{\mathrm{iv}} = k, \qquad k = \frac{f_0}{EI}. \tag{9}$$

This can be solved simply by calculus. Two integrations give

$$y'' = \frac{k}{2}\,x^2 + c_1 x + c_2.$$

$y''(0) = 0$ gives $c_2 = 0$. Then $y''(L) = L(\frac{1}{2}kL + c_1) = 0$, $c_1 = -kL/2$ (since $L \neq 0$). Hence

$$y'' = \frac{k}{2}(x^2 - Lx).$$

Integrating this twice, we obtain

$$y = \frac{k}{2}\left(\frac{1}{12}\,x^4 - \frac{L}{6}\,x^3 + c_3 x + c_4\right)$$

with $c_4 = 0$ from $y(0) = 0$. Then

$$y(L) = \frac{kL}{2}\left(\frac{L^3}{12} - \frac{L^3}{6} + c_3\right) = 0, \qquad c_3 = \frac{L^3}{12}.$$

Inserting the expression for k, we obtain as our solution

$$y = \frac{f_0}{24EI}\,(x^4 - 2Lx^3 + L^3 x).$$

Since the boundary conditions at both ends are the same, we expect the deflection $y(x)$ to be "symmetric" with respect to $L/2$, that is, $y(x) = y(L - x)$. Verify this directly or set $x = u + L/2$ and show that y becomes an even function of u,

$$y = \frac{f_0}{24EI}\left(u^2 - \frac{1}{4}\,L^2\right)\left(u^2 - \frac{5}{4}\,L^2\right).$$

From this we can see that the maximum deflection in the middle at $u = 0$ ($x = L/2$) is $5f_0L^4/(16 \cdot 24EI)$. Recall that the positive direction points downward. ■

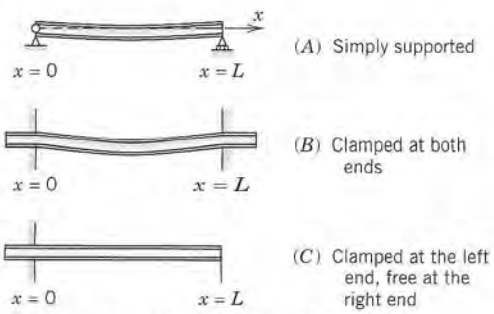

Fig. 76. Supports of a Beam

PROBLEM SET 3.3

1–8 GENERAL SOLUTION

Solve the following ODEs. (Show the details of your work.)

1. $y''' - 2y'' - 4y' + 8y = e^{-3x} + 8x^2$
2. $y''' + 3y'' - 5y' - 39y = 30 \cos x$
3. $y^{iv} + 0.5y'' + 0.0625y = e^{-x} \cos 0.5x$
4. $y''' + 2y'' - 5y' - 6y = 100e^{-3x} + 18e^{-x}$
5. $x^3y''' + 0.75xy' - 0.75y = 9x^{5.5}$
6. $(xD^3 + 4D^2)y = 8e^x$
7. $(D^4 + 10D^2 + 9I)y = 13 \cosh 2x$
8. $(D^3 - 2D^2 - 9D + 18I)y = e^{2x}$

9–14 INITIAL VALUE PROBLEMS

Solve the following initial value problems. (Show the details.)

9. $y''' - 9y'' + 27y' - 27y = 54 \sin 3x, \quad y(0) = 3.5, \quad y'(0) = 13.5, \quad y''(0) = 38.5$
10. $y^{iv} - 16y = 128 \cosh 2x, \quad y(0) = 1, \quad y'(0) = 24, \quad y''(0) = 20, \quad y'''(0) = -160$
11. $(x^3D^3 - x^2D^2 - 7xD + 16I)y = 9x \ln x, \quad y(1) = 6, \quad Dy(1) = 18, \quad D^2y(1) = 65$
12. $(D^4 - 26D^2 + 25I)y = 50(x + 1)^2, \quad y(0) = 12.16, \quad Dy(0) = -6, \quad D^2y(0) = 34, \quad D^3y(0) = -130$
13. $(D^3 + 4D^2 + 85D)y = 135xe^x, \quad y(0) = 10.4, \quad Dy(0) = -18.1, \quad D^2y(0) = -691.6$
14. $(2D^3 - D^2 - 8D + 4I)y = \sin x, \quad y(0) = 1, \quad Dy(0) = 0, \quad D^2y(0) = 0$
15. **WRITING PROJECT. Comparison of Methods.** Write a report on the method of undetermined coefficients and the method of variation of parameters, discussing and comparing the advantages and disadvantages of each method. Illustrate your findings with typical examples. Try to show that the method of undetermined coefficients, say, for a third-order ODE with constant coefficients and an exponential function on the right, can be derived from the method of variation of parameters.
16. **CAS EXPERIMENT. Undetermined Coefficients.** Since variation of parameters is generally complicated, it seems worthwhile to try to extend the other method. Find out experimentally for what ODEs this is possible and for what not. *Hint:* Work backward, solving ODEs with a CAS and then looking whether the solution could be obtained by undetermined coefficients. For example, consider

$$y''' - 12y'' + 48y' - 64y = x^{1/2}e^{4x} \quad \text{and}$$

$$x^3y''' + x^2y'' - 6xy' + 6y = x \ln x.$$

CHAPTER 3 REVIEW QUESTIONS AND PROBLEMS

1. What is the superposition or linearity principle? For what nth-order ODEs does it hold?
2. List some other basic theorems that extend from second-order to nth-order ODEs.
3. If you know a general solution of a homogeneous linear ODE, what do you need to obtain from it a general solution of a corresponding nonhomogeneous linear ODE?
4. What is an initial value problem for an nth-order linear ODE?
5. What is the Wronskian? What is it used for?

6–15 GENERAL SOLUTION

Solve the given ODE. (Show the details of your work.)

6. $y''' + 6y'' + 18y' + 40y = 0$
7. $4x^2y''' + 12xy'' + 3y' = 0$
8. $y^{iv} + 10y'' + 9y = 0$
9. $8y''' + 12y'' - 2y' - 3y = 0$
10. $(D^3 + 3D^2 + 3D + I)y = x^2$
11. $(xD^4 + D^3)y = 150x^4$
12. $(D^4 - 2D^3 - 8D^2)y = 16 \cos 2x$
13. $(D^3 + I)y = 9e^{x/2}$
14. $(x^3D^3 - 3x^2D^2 + 6xD - 6I)y = 30x^{-2}$
15. $(D^3 - D^2 - D + I)y = e^x$

16–20 INITIAL VALUE PROBLEMS

Solve the given problem. (Show the details.)

16. $y''' - 2y'' + 4y' - 8y = 0, \quad y(0) = -1, \quad y'(0) = 30, \quad y''(0) = 28$
17. $x^3y''' + 7x^2y'' - 2xy' - 10y = 0, \quad y(1) = 1, \quad y'(1) = -7, \quad y''(1) = 44$
18. $(D^3 + 25D)y = 32 \cos^2 4x, \quad y(0) = 0, \quad Dy(0) = 0, \quad D^2y(0) = 0$
19. $(D^4 + 40D^2 - 441I)y = 8 \cosh x, \quad y(0) = 1.98, \quad Dy(0) = 3, \quad D^2y(0) = -40.02, \quad D^3y(0) = 27$
20. $(x^3D^3 + 5x^2D^2 + 2xD - 2I)y = 7x^{3/2}, \quad y(1) = 10.6, \quad Dy(1) = -3.6, \quad D^2y(1) = 31.2$

SUMMARY OF CHAPTER 3
Higher Order Linear ODEs

Compare with the similar Summary of Chap. 2 (the case n = 2).
Chapter 3 extends Chap. 2 from order $n = 2$ to arbitrary order n. An **nth-order linear ODE** is an ODE that can be written

$$(1) \qquad y^{(n)} + p_{n-1}(x)y^{(n-1)} + \cdots + p_1(x)y' + p_0(x)y = r(x)$$

with $y^{(n)} = d^n y/dx^n$ as the first term; we again call this the **standard form.** Equation (1) is called **homogeneous** if $r(x) \equiv 0$ on a given open interval I considered, **nonhomogeneous** if $r(x) \not\equiv 0$ on I. For the homogeneous ODE

$$(2) \qquad y^{(n)} + p_{n-1}(x)y^{(n-1)} + \cdots + p_1(x)y' + p_0(x)y = 0$$

the **superposition principle** (Sec. 3.1) holds, just as in the case $n = 2$. A **basis** or **fundamental system** of solutions of (2) on I consists of n linearly independent solutions $y_1, \cdots, y_n$ of (2) on I. A **general solution** of (2) on I is a linear combination of these,

$$(3) \qquad y = c_1y_1 + \cdots + c_ny_n \qquad (c_1, \cdots, c_n \text{ arbitrary constants}).$$

A **general solution** of the nonhomogeneous ODE (1) on I is of the form

$$(4) \qquad y = y_h + y_p \qquad \text{(Sec. 3.3)}.$$

Here, y_p is a particular solution of (1) and is obtained by two methods (**undetermined coefficients** or **variation of parameters**) explained in Sec. 3.3.

An **initial value problem** for (1) or (2) consists of one of these ODEs and n initial conditions (Secs. 3.1, 3.3)

$$(5) \qquad y(x_0) = K_0, \quad y'(x_0) = K_1, \quad \cdots, \quad y^{(n-1)}(x_0) = K_{n-1}$$

with given x_0 in I and given $K_0, \cdots, K_{n-1}$. If $p_0, \cdots, p_{n-1}$, r are continuous on I, then general solutions of (1) and (2) on I exist, and initial value problems (1), (5) or (2), (5) have a unique solution.

CHAPTER 4

Systems of ODEs. Phase Plane. Qualitative Methods

Systems of ODEs have various applications (see, for instance, Secs. 4.1 and 4.5). Their theory is outlined in Sec. 4.2 and includes that of a single ODE. The practically important conversion of a single nth-order ODE to a system is shown in Sec. 4.1.

Linear systems (Secs. 4.3, 4.4, 4.6) are best treated by the use of vectors and matrices, of which, however, only a few elementary facts will be needed here, as given in Sec. 4.0 and probably familiar to most students.

Qualitative methods. In addition to actually solving systems (Sec. 4.3, 4.6), which is often difficult or even impossible, we shall explain a totally different method, namely, the powerful method of investigating the general behavior of whole families of solutions in the **phase plane** (Sec. 4.3). This approach to systems of ODEs is called a **qualitative method** because it does not need actual solutions (in contrats to a *"quantitative method"* of actually solving a system).

This *phase plane method,* as it is called, also gives information on **stability** of solutions, which is of general importance in control theory, circuit theory, population dynamics, and so on. Here, *stability of a physical system* means that, roughly speaking, a small change at some instant causes only small changes in the behavior of the system at all later times.

Phase plane methods can be extended to nonlinear systems, for which they are particularly useful. We will show this in Sec. 4.5, which includes a discussion of the pendulum equation and the Lotka-Volterra population model. We finally discuss nonhomogeneous linear systems in Sec. 4.6.

NOTATION. Analogous to Chaps. 1–3, we continue to denote unknown functions by y; thus, $y_1(t)$, $y_2(t)$. This seems preferable to suddenly using x for functions, $x_1(t)$, $x_2(t)$, as is sometimes done in systems of ODEs.

Prerequisite: Chap. 2.
References and Answers to Problems: App. 1 Part A, and App. 2.

4.0 Basics of Matrices and Vectors

In discussing *linear* systems of ODEs we shall use matrices and vectors. This simplifies formulas and clarifies ideas. But we shall need only a few elementary facts (by no means the bulk of material in Chaps. 7 and 8). These facts will very likely be at the disposal of most students. Hence ***this section is for reference only. Begin with Sec. 4.1 and consult 4.0 as needed.***

Most of our linear systems will consist of two ODEs in two unknown functions $y_1(t)$, $y_2(t)$,

$$(1)\qquad \begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2, \\ y_2' &= a_{21}y_1 + a_{22}y_2, \end{aligned} \qquad \text{for example,} \qquad \begin{aligned} y_1' &= -5y_1 + 2y_2 \\ y_2' &= 13y_1 + \tfrac{1}{2}y_2 \end{aligned}$$

(perhaps with additional *given* functions $g_1(t)$, $g_2(t)$ in the two ODEs on the right).

Similarly, a linear system of n first-order ODEs in n unknown functions $y_1(t), \cdots, y_n(t)$ is of the form

$$(2)\qquad \begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2 + \cdots + a_{1n}y_n \\ y_2' &= a_{21}y_1 + a_{22}y_2 + \cdots + a_{2n}y_n \\ &\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ y_n' &= a_{n1}y_1 + a_{n2}y_2 + \cdots + a_{nn}y_n \end{aligned}$$

(perhaps with an additional given function in each ODE on the right).

Some Definitions and Terms

Matrices. In (1) the (constant or variable) coefficients form a **2 × 2 matrix A,** that is, an array

$$(3)\qquad \mathbf{A} = [a_{jk}] = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}, \qquad \text{for example,} \qquad \mathbf{A} = \begin{bmatrix} -5 & 2 \\ 13 & \frac{1}{2} \end{bmatrix}.$$

Similarly, the coefficients in (2) form an ***n* × *n* matrix**

$$(4)\qquad \mathbf{A} = [a_{jk}] = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}.$$

The a_{11}, a_{12}, $\cdots$ are called **entries,** the horizontal lines **rows,** and the vertical lines **columns.** Thus, in (3) the first row is $[a_{11} \quad a_{12}]$, the second row is $[a_{21} \quad a_{22}]$, and the first and second columns are

$$\begin{bmatrix} a_{11} \\ a_{21} \end{bmatrix} \qquad \text{and} \qquad \begin{bmatrix} a_{12} \\ a_{22} \end{bmatrix}.$$

In the ***"double subscript notation"*** for entries, the first subscript denotes the *row* and the second the *column* in which the entry stands. Similarly in (4). The **main diagonal** is the diagonal $a_{11} \quad a_{22} \quad \cdots \quad a_{nn}$ in (4), hence $a_{11} \quad a_{22}$ in (3).

We shall need only **square matrices,** that is, matrices with the same number of rows and columns, as in (3) and (4).

Vectors. A **column vector x** with n **components** $x_1, \cdots, x_n$ is of the form

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \cdot \\ \cdot \\ \cdot \\ x_n \end{bmatrix}, \qquad \text{thus if } n = 2, \qquad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}.$$

Similarly, a **row vector v** is of the form

$$\mathbf{v} = [v_1 \quad \cdots \quad v_n], \qquad \text{thus if } n = 2, \text{ then} \qquad \mathbf{v} = [v_1, \quad v_2].$$

Calculations with Matrices and Vectors

Equality. Two $n \times n$ matrices are *equal* if and only if corresponding entries are equal. Thus for $n = 2$, let

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \qquad \text{and} \qquad \mathbf{B} = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix}.$$

Then $\mathbf{A} = \mathbf{B}$ if and only if

$$a_{11} = b_{11}, \qquad a_{12} = b_{12}$$
$$a_{21} = b_{21}, \qquad a_{22} = b_{22}.$$

Two column vectors (or two row vectors) are *equal* if and only if they both have n components and corresponding components are equal. Thus, let

$$\mathbf{v} = \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} \quad \text{and} \quad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}. \qquad \text{Then} \qquad \mathbf{v} = \mathbf{x} \quad \text{if and only if} \quad \begin{matrix} v_1 = x_1 \\ v_2 = x_2. \end{matrix}$$

Addition is performed by adding corresponding entries (or components); here, matrices must both be $n \times n$, and vectors must both have the same number of components. Thus for $n = 2$,

$$\text{(5)} \qquad \mathbf{A} + \mathbf{B} = \begin{bmatrix} a_{11} + b_{11} & a_{12} + b_{12} \\ a_{21} + b_{21} & a_{22} + b_{22} \end{bmatrix}, \qquad \mathbf{v} + \mathbf{x} = \begin{bmatrix} v_1 + x_1 \\ v_2 + x_2 \end{bmatrix}.$$

Scalar multiplication (multiplication by a number c) is performed by multiplying each entry (or component) by c. For example, if

$$\mathbf{A} = \begin{bmatrix} 9 & 3 \\ -2 & 0 \end{bmatrix}, \qquad \text{then} \qquad -7\mathbf{A} = \begin{bmatrix} -63 & -21 \\ 14 & 0 \end{bmatrix}.$$

If

$$\mathbf{v} = \begin{bmatrix} 0.4 \\ -13 \end{bmatrix}, \qquad \text{then} \qquad 10\mathbf{v} = \begin{bmatrix} 4 \\ -130 \end{bmatrix}.$$

Matrix Multiplication. The product $\mathbf{C} = \mathbf{AB}$ (in this order) of two $n \times n$ matrices $\mathbf{A} = [a_{jk}]$ and $\mathbf{B} = [b_{jk}]$ is the $n \times n$ matrix $\mathbf{C} = [c_{jk}]$ with entries

$$(6) \qquad c_{jk} = \sum_{m=1}^{n} a_{jm} b_{mk} \qquad \begin{matrix} j = 1, \cdots, n \\ k = 1, \cdots, n, \end{matrix}$$

that is, multiply each entry in the jth *row* of $\mathbf{A}$ by the corresponding entry in the kth *column* of $\mathbf{B}$ and then add these n products. One says briefly that this is a "multiplication of rows into columns." For example,

$$\begin{bmatrix} 9 & 3 \\ -2 & 0 \end{bmatrix} \begin{bmatrix} 1 & -4 \\ 2 & 5 \end{bmatrix} = \begin{bmatrix} 9 \cdot 1 + 3 \cdot 2 & 9 \cdot (-4) + 3 \cdot 5 \\ -2 \cdot 1 + 0 \cdot 2 & (-2) \cdot (-4) + 0 \cdot 5 \end{bmatrix} = \begin{bmatrix} 15 & -21 \\ -2 & 8 \end{bmatrix}.$$

CAUTION! Matrix multiplication is ***not commutative,*** $\mathbf{AB} \neq \mathbf{BA}$ in general. In our example,

$$\begin{bmatrix} 1 & -4 \\ 2 & 5 \end{bmatrix} \begin{bmatrix} 9 & 3 \\ -2 & 0 \end{bmatrix} = \begin{bmatrix} 1 \cdot 9 + (-4) \cdot (-2) & 1 \cdot 3 + (-4) \cdot 0 \\ 2 \cdot 9 + 5 \cdot (-2) & 2 \cdot 3 + 5 \cdot 0 \end{bmatrix} = \begin{bmatrix} 17 & 3 \\ 8 & 6 \end{bmatrix}.$$

Multiplication of an $n \times n$ matrix $\mathbf{A}$ by a vector $\mathbf{x}$ with n components is defined by the same rule: $\mathbf{v} = \mathbf{Ax}$ is the vector with the n components

$$v_j = \sum_{m=1}^{n} a_{jm} x_m \qquad j = 1, \cdots, n.$$

For example,

$$\begin{bmatrix} 12 & 7 \\ -8 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 12x_1 + 7x_2 \\ -8x_1 + 3x_2 \end{bmatrix}.$$

Systems of ODEs as Vector Equations

Differentiation. The *derivative* of a matrix (or vector) with variable entries (or components) is obtained by differentiating each entry (or component). Thus, if

$$\mathbf{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \end{bmatrix} = \begin{bmatrix} e^{-2t} \\ \sin t \end{bmatrix}, \quad \text{then} \quad \mathbf{y}'(t) = \begin{bmatrix} y_1'(t) \\ y_2'(t) \end{bmatrix} = \begin{bmatrix} -2e^{-2t} \\ \cos t \end{bmatrix}.$$

Using matrix multiplication and differentiation, we can now write (1) as

$$(7) \quad \mathbf{y}' = \begin{bmatrix} y_1' \\ y_2' \end{bmatrix} = \mathbf{Ay} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}, \quad \text{e.g.,} \quad \mathbf{y}' = \begin{bmatrix} -5 & 2 \\ 13 & \frac{1}{2} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}.$$

Similarly for (2) by means of an $n \times n$ matrix $\mathbf{A}$ and a column vector $\mathbf{y}$ with n components, namely, $\mathbf{y}' = \mathbf{Ay}$. The vector equation (7) is equivalent to two equations for the components, and these are precisely the two ODEs in (1).

Some Further Operations and Terms

Transposition is the operation of writing columns as rows and conversely and is indicated by T. Thus the transpose $\mathbf{A}^T$ of the 2×2 matrix

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = \begin{bmatrix} -5 & 2 \\ 13 & \frac{1}{2} \end{bmatrix} \quad \text{is} \quad \mathbf{A}^T = \begin{bmatrix} a_{11} & a_{21} \\ a_{12} & a_{22} \end{bmatrix} = \begin{bmatrix} -5 & 13 \\ 2 & \frac{1}{2} \end{bmatrix}.$$

The transpose of a column vector, say,

$$\mathbf{v} = \begin{bmatrix} v_1 \\ v_2 \end{bmatrix}, \qquad \text{is a row vector,} \qquad \mathbf{v}^T = [v_1 \quad v_2],$$

and conversely.

Inverse of a Matrix. The $n \times n$ **unit matrix I** is the $n \times n$ matrix with main diagonal $1, 1, \cdots, 1$ and all other entries zero. If for a given $n \times n$ matrix $\mathbf{A}$ there is an $n \times n$ matrix $\mathbf{B}$ such that $\mathbf{AB} = \mathbf{BA} = \mathbf{I}$, then $\mathbf{A}$ is called **nonsingular** and $\mathbf{B}$ is called the **inverse** of $\mathbf{A}$ and is denoted by $\mathbf{A}^{-1}$; thus

$$\mathbf{A}\mathbf{A}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I}. \tag{8}$$

If $\mathbf{A}$ has no inverse, it is called **singular.** For $n = 2$,

$$\mathbf{A}^{-1} = \frac{1}{\det \mathbf{A}} \begin{bmatrix} a_{22} & -a_{12} \\ -a_{21} & a_{11} \end{bmatrix}, \tag{9}$$

where the **determinant** of $\mathbf{A}$ is

$$\det \mathbf{A} = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{12}a_{21}. \tag{10}$$

(For general n, see Sec. 7.7, but this will not be needed in this chapter.)

Linear Independence. r given vectors $\mathbf{v}^{(1)}, \cdots, \mathbf{v}^{(r)}$ with n components are called a *linearly independent set* or, more briefly, **linearly independent,** if

$$c_1\mathbf{v}^{(1)} + \cdots + c_r\mathbf{v}^{(r)} = \mathbf{0} \tag{11}$$

implies that all scalars $c_1, \cdots, c_r$ must be zero; here, $\mathbf{0}$ denotes the **zero vector,** whose n components are all zero. If (11) also holds for scalars not all zero (so that at least one of these scalars is not zero), then these vectors are called a *linearly dependent set* or, briefly, **linearly dependent,** because then at least one of them can be expressed as

a **linear combination** of the others; that is, if, for instance, $c_1 \neq 0$ in (11), then we can obtain

$$\mathbf{v}^{(1)} = -\frac{1}{c_1}\,(c_2\mathbf{v}^{(2)} + \cdots + c_r\mathbf{v}^{(r)}).$$

Eigenvalues, Eigenvectors

Eigenvalues and eigenvectors will be very important in this chapter (and, as a matter of fact, throughout mathematics).

Let $\mathbf{A} = [a_{jk}]$ be an $n \times n$ matrix. Consider the equation

$$\mathbf{Ax} = \lambda\mathbf{x} \tag{12}$$

where λ is a scalar (a real or complex number) to be determined and $\mathbf{x}$ is a vector to be determined. Now for every λ a solution is $\mathbf{x} = \mathbf{0}$. A scalar λ such that (12) holds for some vector $\mathbf{x} \neq \mathbf{0}$ is called an **eigenvalue** of $\mathbf{A}$, and this vector is called an **eigenvector** of $\mathbf{A}$ corresponding to this eigenvalue λ.

We can write (12) as $\mathbf{Ax} - \lambda\mathbf{x} = \mathbf{0}$ or

$$(\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}. \tag{13}$$

These are n linear algebraic equations in the n unknowns $x_1, \cdots, x_n$ (the components of $\mathbf{x}$). For these equations to have a solution $\mathbf{x} \neq \mathbf{0}$, the determinant of the coefficient matrix $\mathbf{A} - \lambda\mathbf{I}$ must be zero. This is proved as a basic fact in linear algebra (Theorem 4 in Sec. 7.7). In this chapter we need this only for $n = 2$. Then (13) is

$$\begin{bmatrix} a_{11} - \lambda & a_{12} \\ a_{21} & a_{22} - \lambda \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}; \tag{14}$$

in components,

$$\begin{aligned} (a_{11} - \lambda)x_1 + \quad a_{12}x_2 \quad &= 0 \\ a_{21}x_1 \quad + (a_{22} - \lambda)x_2 &= 0. \end{aligned} \tag{14*}$$

Now $\mathbf{A} - \lambda\mathbf{I}$ is singular if and only if its determinant $\det(\mathbf{A} - \lambda\mathbf{I})$, called the **characteristic determinant** of $\mathbf{A}$ (also for general n), is zero. This gives

$$\begin{aligned} \det(\mathbf{A} - \lambda\mathbf{I}) &= \begin{vmatrix} a_{11} - \lambda & a_{12} \\ a_{21} & a_{22} - \lambda \end{vmatrix} \\ &= (a_{11} - \lambda)(a_{22} - \lambda) - a_{12}a_{21} \\ &= \lambda^2 - (a_{11} + a_{22})\lambda + a_{11}a_{22} - a_{12}a_{21} = 0. \end{aligned} \tag{15}$$

This quadratic equation in λ is called the **characteristic equation** of $\mathbf{A}$. Its solutions are the eigenvalues λ_1 and λ_2 of $\mathbf{A}$. First determine these. Then use (14*) with $\lambda = \lambda_1$ to determine an eigenvector $\mathbf{x}^{(1)}$ of $\mathbf{A}$ corresponding to λ_1. Finally use (14*) with $\lambda = \lambda_2$ to find an eigenvector $\mathbf{x}^{(2)}$ of $\mathbf{A}$ corresponding to λ_2. Note that if $\mathbf{x}$ is an eigenvector of $\mathbf{A}$, so is $k\mathbf{x}$ for any $k \neq 0$.

EXAMPLE 1 **Eigenvalue Problem**

Find the eigenvalues and eigenvectors of the matrix

$$\mathbf{A} = \begin{bmatrix} -4.0 & 4.0 \\ -1.6 & 1.2 \end{bmatrix}. \tag{16}$$

Solution. The characteristic equation is the quadratic equation

$$\det [\mathbf{A} - \lambda \mathbf{I}] = \begin{vmatrix} -4 - \lambda & 4 \\ -1.6 & 1.2 - \lambda \end{vmatrix} = \lambda^2 + 2.8\lambda + 1.6 = 0.$$

It has the solutions $\lambda_1 = -2$ and $\lambda_2 = -0.8$. These are the eigenvalues of $\mathbf{A}$.

Eigenvectors are obtained from (14*). For $\lambda = \lambda_1 = -2$ we have from (14*)

$$\begin{aligned} (-4.0 + 2.0)x_1 + \quad 4.0x_2 \quad &= 0 \\ -1.6x_1 \quad + (1.2 + 2.0)x_2 &= 0. \end{aligned}$$

A solution of the first equation is $x_1 = 2$, $x_2 = 1$. This also satisfies the second equation. (Why?). Hence an eigenvector of $\mathbf{A}$ corresponding to $\lambda_1 = -2.0$ is

$$\mathbf{x}^{(1)} = \begin{bmatrix} 2 \\ 1 \end{bmatrix}. \qquad \text{Similarly,} \qquad \mathbf{x}^{(2)} = \begin{bmatrix} 1 \\ 0.8 \end{bmatrix} \tag{17}$$

is an eigenvector of $\mathbf{A}$ corresponding to $\lambda_2 = -0.8$, as obtained from (14*) with $\lambda = \lambda_2$. Verify this. ■

4.1 Systems of ODEs as Models

We first illustrate with a few typical examples that systems of ODEs can serve as models in various applications. We further show that a higher order ODE (with the highest derivative standing alone on one side) can be reduced to a first-order system. Both facts account for the practical importance of these systems.

EXAMPLE 1 **Mixing Problem Involving Two Tanks**

A mixing problem involving a single tank is modeled by a single ODE, and you may first review the corresponding Example 3 in Sec. 1.3 because the principle of modeling will be the same for two tanks. The model will be a system of two first-order ODEs.

Tank T_1 and T_2 in Fig. 77 contain initially 100 gal of water each. In T_1 the water is pure, whereas 150 lb of fertilizer are dissolved in T_2. By circulating liquid at a rate of 2 gal/min and stirring (to keep the mixture uniform) the amounts of fertilizer $y_1(t)$ in T_1 and $y_2(t)$ in T_2 change with time t. How long should we let the liquid circulate so that T_1 will contain at least half as much fertilizer as there will be left in T_2?

Solution. ***Step 1.*** **Setting up the model.** As for a single tank, the time rate of change $y_1'(t)$ of $y_1(t)$ equals inflow minus outflow. Similarly for tank T_2. From Fig. 77 we see that

$$y_1' = \text{Inflow/min} - \text{Outflow/min} = \frac{2}{100}y_2 - \frac{2}{100}y_1 \qquad \text{(Tank } T_1\text{)}$$

$$y_2' = \text{Inflow/min} - \text{Outflow/min} = \frac{2}{100}y_1 - \frac{2}{100}y_2 \qquad \text{(Tank } T_2\text{).}$$

Hence the mathematical model of our mixture problem is the system of first-order ODEs

$$\begin{aligned} y_1' &= -0.02y_1 + 0.02y_2 \qquad \text{(Tank } T_1\text{)} \\ y_2' &= \quad 0.02y_1 - 0.02y_2 \qquad \text{(Tank } T_2\text{).} \end{aligned}$$

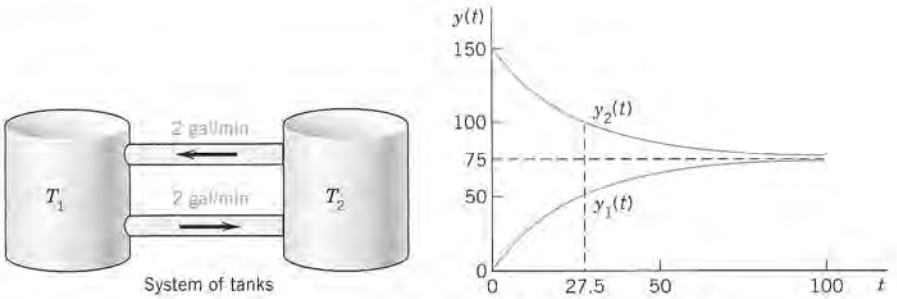

Fig. 77. Fertilizer content in Tanks T_1 (lower curve) and T_2

As a vector equation with column vector $\mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$ and matrix $\mathbf{A}$ this becomes

$$\mathbf{y}' = \mathbf{A}\mathbf{y}, \qquad \text{where} \qquad \mathbf{A} = \begin{bmatrix} -0.02 & 0.02 \\ 0.02 & -0.02 \end{bmatrix}.$$

Step 2. **General solution.** As for a single equation, we try an exponential function of t,

$$\mathbf{y} = \mathbf{x}e^{\lambda t}. \qquad \text{Then} \qquad \mathbf{y}' = \lambda \mathbf{x}e^{\lambda t} = \mathbf{A}\mathbf{x}e^{\lambda t}. \tag{1}$$

Dividing the last equation $\lambda \mathbf{x}e^{\lambda t} = \mathbf{A}\mathbf{x}e^{\lambda t}$ by $e^{\lambda t}$ and interchanging the left and right sides, we obtain

$$\mathbf{A}\mathbf{x} = \lambda \mathbf{x}.$$

We need nontrivial solutions (solutions that are not identically zero). Hence we have to look for eigenvalues and eigenvectors of $\mathbf{A}$. The eigenvalues are the solutions of the characteristic equation

$$\det (\mathbf{A} - \lambda \mathbf{I}) = \begin{vmatrix} -0.02 - \lambda & 0.02 \\ 0.02 & -0.02 - \lambda \end{vmatrix} = (-0.02 - \lambda)^2 - 0.02^2 = \lambda(\lambda + 0.04) = 0. \tag{2}$$

We see that $\lambda_1 = 0$ (which can very well happen—don't get mixed up—it is eigen*vectors* that must not be zero) and $\lambda_2 = -0.04$. Eigenvectors are obtained from (14*) in Sec. 4.0 with $\lambda = 0$ and $\lambda = -0.04$. For our present $\mathbf{A}$ this gives [we need only the first equation in (14*)]

$$-0.02x_1 + 0.02x_2 = 0 \qquad \text{and} \qquad (-0.02 + 0.04)x_1 + 0.02x_2 = 0,$$

respectively. Hence $x_1 = x_2$ and $x_1 = -x_2$, respectively, and we can take $x_1 = x_2 = 1$ and $x_1 = -x_2 = 1$. This gives two eigenvectors corresponding to $\lambda_1 = 0$ and $\lambda_2 = -0.04$, respectively, namely,

$$\mathbf{x}^{(1)} = \begin{bmatrix} 1 \\ 1 \end{bmatrix} \qquad \text{and} \qquad \mathbf{x}^{(2)} = \begin{bmatrix} 1 \\ -1 \end{bmatrix}.$$

From (1) and the superposition principle (which continues to hold for systems of homogeneous linear ODEs) we thus obtain a solution

$$\mathbf{y} = c_1\mathbf{x}^{(1)}e^{\lambda_1 t} + c_2\mathbf{x}^{(2)}e^{\lambda_2 t} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-0.04t} \tag{3}$$

where c_1 and c_2 are arbitrary constants. Later we shall call this a **general solution.**

Step 3. **Use of initial conditions.** The initial conditions are $y_1(0) = 0$ (no fertilizer in tank T_1) and $y_2(0) = 150$. From this and (3) with $t = 0$ we obtain

$$\mathbf{y}(0) = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} = \begin{bmatrix} c_1 + c_2 \\ c_1 - c_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 150 \end{bmatrix}.$$

In components this is $c_1 + c_2 = 0$, $c_1 - c_2 = 150$. The solution is $c_1 = 75$, $c_2 = -75$. This gives the answer

$$\mathbf{y} = 75\mathbf{x}^{(1)} - 75\mathbf{x}^{(2)}e^{-0.04t} = 75\begin{bmatrix}1\\1\end{bmatrix} - 75\begin{bmatrix}1\\-1\end{bmatrix}e^{-0.04t}.$$

In components,

$$y_1 = 75 - 75e^{-0.04t} \qquad \text{(Tank } T_1\text{, lower curve)}$$

$$y_2 = 75 + 75e^{-0.04t} \qquad \text{(Tank } T_2\text{, upper curve).}$$

Figure 77 shows the exponential increase of y_1 and the exponential decrease of y_2 to the common limit 75 lb. Did you expect this for physical reasons? Can you physically explain why the curves look "symmetric"? Would the limit change if T_1 initially contained 100 lb of fertilizer and T_2 contained 50 lb?

***Step 4.* Answer.** T_1 contains half the fertilizer amount of T_2 if it contains 1/3 of the total amount, that is, 50 lb. Thus

$$y_1 = 75 - 75e^{-0.04t} = 50, \qquad e^{-0.04t} = \tfrac{1}{3}, \qquad t = (\ln 3)/0.04 = 27.5.$$

Hence the fluid should circulate for at least about half an hour. ■

EXAMPLE 2 **Electrical Network**

Find the currents $I_1(t)$ and $I_2(t)$ in the network in Fig. 78. Assume all currents and charges to be zero at $t = 0$, the instant when the switch is closed.

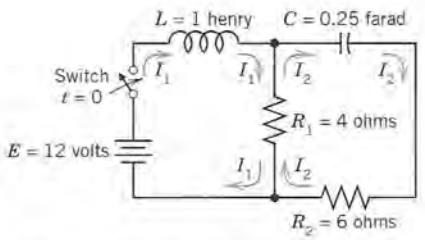

Fig. 78. Electrical network in Example 2

***Solution.* *Step 1.* Setting up the mathematical model.** The model of this network is obtained from Kirchhoff's voltage law, as in Sec. 2.9 (where we considered single circuits). Let $I_1(t)$ and $I_2(t)$ be the currents in the left and right loops, respectively. In the left loop the voltage drops are $LI_1' = I_1'$ [V] over the inductor and $R_1(I_1 - I_2) = 4(I_1 - I_2)$ [V] over the resistor, the difference because I_1 and I_2 flow through the resistor in opposite directions. By Kirchhoff's voltage law the sum of these drops equals the voltage of the battery; that is, $I_1' + 4(I_1 - I_2) = 12$, hence

$$I_1' = -4I_1 + 4I_2 + 12. \tag{4a}$$

In the right loop the voltage drops are $R_2I_2 = 6I_2$ [V] and $R_1(I_2 - I_1) = 4(I_2 - I_1)$ [V] over the resistors and $(1/C)\int I_2\,dt = 4\int I_2\,dt$ [V] over the capacitor, and their sum is zero,

$$6I_2 + 4(I_2 - I_1) + 4\int I_2\,dt = 0 \qquad \text{or} \qquad 10I_2 - 4I_1 + 4\int I_2\,dt = 0.$$

Division by 10 and differentiation gives $I_2' - 0.4I_1' + 0.4I_2 = 0$.

To simplify the solution process, we first get rid of $0.4I_1'$, which by (4a) equals $0.4(-4I_1 + 4I_2 + 12)$. Substitution into the present ODE gives

$$I_2' = 0.4I_1' - 0.4I_2 = 0.4(-4I_1 + 4I_2 + 12) - 0.4I_2$$

and by simplification

(4b) $$I_2' = -1.6I_1 + 1.2I_2 + 4.8.$$

In matrix form, (4) is (we write **J** since **I** is the unit matrix)

(5) $$\mathbf{J}' = \mathbf{AJ} + \mathbf{g}, \quad \text{where} \quad \mathbf{J} = \begin{bmatrix} I_1 \\ I_2 \end{bmatrix}, \quad \mathbf{A} = \begin{bmatrix} -4.0 & 4.0 \\ -1.6 & 1.2 \end{bmatrix}, \quad \mathbf{g} = \begin{bmatrix} 12.0 \\ 4.8 \end{bmatrix}.$$

***Step 2.* Solving (5).** Because of the vector **g** this is a *nonhomogeneous* system, and we try to proceed as for a single ODE, solving first the *homogeneous* system $\mathbf{J}' = \mathbf{AJ}$ (thus $\mathbf{J}' - \mathbf{AJ} = \mathbf{0}$) by substituting $\mathbf{J} = \mathbf{x}e^{\lambda t}$. This gives

$$\mathbf{J}' = \lambda \mathbf{x}e^{\lambda t} = \mathbf{A}\mathbf{x}e^{\lambda t}, \qquad \text{hence} \qquad \mathbf{Ax} = \lambda \mathbf{x}.$$

Hence to obtain a nontrivial solution, we again need the eigenvalues and eigenvectors. For the present matrix **A** they are derived in Example 1 in Sec. 4.0:

$$\lambda_1 = -2, \quad \mathbf{x}^{(1)} = \begin{bmatrix} 2 \\ 1 \end{bmatrix}; \qquad \lambda_2 = -0.8, \quad \mathbf{x}^{(2)} = \begin{bmatrix} 1 \\ 0.8 \end{bmatrix}.$$

Hence a "general solution" of the homogeneous system is

$$\mathbf{J}_h = c_1\mathbf{x}^{(1)}e^{-2t} + c_2\mathbf{x}^{(2)}e^{-0.8t}.$$

For a particular solution of the nonhomogeneous system (5), since **g** is constant, we try a constant column vector $\mathbf{J}_p = \mathbf{a}$ with components a_1, a_2. Then $\mathbf{J}_p' = \mathbf{0}$, and substitution into (5) gives $\mathbf{Aa} + \mathbf{g} = \mathbf{0}$; in components,

$$\begin{aligned} -4.0a_1 + 4.0a_2 + 12.0 &= 0 \\ -1.6a_1 + 1.2a_2 + 4.8 &= 0. \end{aligned}$$

The solution is $a_1 = 3$, $a_2 = 0$; thus $\mathbf{a} = \begin{bmatrix} 3 \\ 0 \end{bmatrix}$. Hence

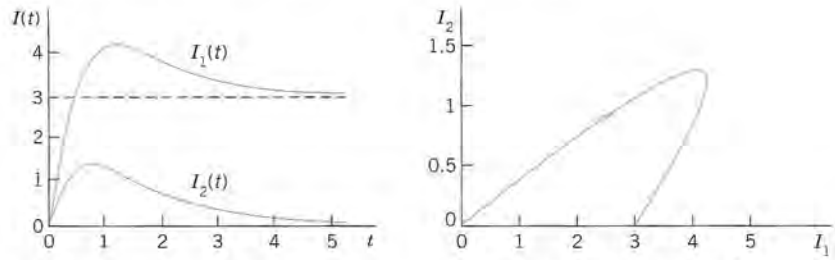
(6) $$\mathbf{J} = \mathbf{J}_h + \mathbf{J}_p = c_1\mathbf{x}^{(1)}e^{-2t} + c_2\mathbf{x}^{(2)}e^{-0.8t} + \mathbf{a};$$

in components,

$$\begin{aligned} I_1 &= 2c_1e^{-2t} + c_2e^{-0.8t} + 3 \\ I_2 &= c_1e^{-2t} + 0.8c_2e^{-0.8t}. \end{aligned}$$

The initial conditions give

$$\begin{aligned} I_1(0) &= 2c_1 + c_2 + 3 = 0 \\ I_2(0) &= c_1 + 0.8c_2 = 0. \end{aligned}$$



Hence $c_1 = -4$ and $c_2 = 5$. As the solution of our problem we thus obtain

(7) $$\mathbf{J} = -4\mathbf{x}^{(1)}e^{-2t} + 5\mathbf{x}^{(2)}e^{-0.8t} + \mathbf{a}.$$

In components (Fig. 79b),

$$\begin{aligned} I_1 &= -8e^{-2t} + 5e^{-0.8t} + 3 \\ I_2 &= -4e^{-2t} + 4e^{-0.8t}. \end{aligned}$$

Now comes an important idea, on which we shall elaborate further, beginning in Sec. 4.3. Figure 79a shows $I_1(t)$ and $I_2(t)$ as two separate curves. Figure 79b shows these two currents as a single curve $[I_1(t), I_2(t)]$ in the I_1I_2-plane. This is a parametric representation with time t as the parameter. It is often important to know in which sense such a curve is traced. This can be indicated by an arrow in the sense of increasing t, as is shown. The I_1I_2-plane is called the **phase plane** of our system (5), and the curve in Fig. 79b is called a **trajectory.** We shall see that such **"phase plane representations"** are far more important than graphs as in Fig. 79a because they will give a much better qualitative overall impression of the general behavior of whole families of solutions, not merely of one solution as in the present case. ■

(a) Currents I_1 (upper curve) and I_2

(b) Trajectory $[I_1(t), I_2(t)]^T$ in the I_1I_2-plane (the "phase plane")

Fig. 79. Currents in Example 2

Conversion of an *n*th-Order ODE to a System

We show that an *n*th-order ODE of the general form (8) (see Theorem 1) can be converted to a system of n first-order ODEs. This is practically and theoretically important—practically because it permits the study and solution of single ODEs by methods for systems, and theoretically because it opens a way of including the theory of higher order ODEs into that of first-order systems. This conversion is another reason for the importance of systems, in addition to their use as models in various basic applications. The idea of the conversion is simple and straightforward, as follows.

THEOREM 1

Conversion of an ODE

An nth-order ODE

$$y^{(n)} = F(t, y, y', \cdots, y^{(n-1)}) \tag{8}$$

can be converted to a system of n first-order ODEs by setting

$$y_1 = y, \quad y_2 = y', \quad y_3 = y'', \cdots, y_n = y^{(n-1)}. \tag{9}$$

This system is of the form

$$\begin{aligned} y_1' &= y_2 \\ y_2' &= y_3 \\ &\vdots \\ y_{n-1}' &= y_n \\ y_n' &= F(t, y_1, y_2, \cdots, y_n). \end{aligned} \tag{10}$$

PROOF The first $n - 1$ of these n ODEs follow immediately from (9) by differentiation. Also, $y_n' = y^{(n)}$ by (9), so that the last equation in (10) results from the given ODE (8). ■

EXAMPLE 3 Mass on a Spring

To gain confidence in the conversion method, let us apply it to an old friend of ours, modeling the free motions of a mass on a spring (see Sec. 2.4)

$$my'' + cy' + ky = 0 \qquad \text{or} \qquad y'' = -\frac{c}{m}y' - \frac{k}{m}y.$$

For this ODE (8) the system (10) is linear and homogeneous,

$$y_1' = y_2$$
$$y_2' = -\frac{k}{m}y_1 - \frac{c}{m}y_2.$$

Setting $\mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$, we get in matrix form

$$\mathbf{y}' = \mathbf{A}\mathbf{y} = \begin{bmatrix} 0 & 1 \\ -\frac{k}{m} & -\frac{c}{m} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}.$$

The characteristic equation is

$$\det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} -\lambda & 1 \\ -\frac{k}{m} & -\frac{c}{m} - \lambda \end{vmatrix} = \lambda^2 + \frac{c}{m}\lambda + \frac{k}{m} = 0.$$

It agrees with that in Sec. 2.4. For an illustrative computation, let $m = 1$, $c = 2$, and $k = 0.75$. Then

$$\lambda^2 + 2\lambda + 0.75 = (\lambda + 0.5)(\lambda + 1.5) = 0.$$

This gives the eigenvalues $\lambda_1 = -0.5$ and $\lambda_2 = -1.5$. Eigenvectors follow from the first equation in $\mathbf{A} - \lambda\mathbf{I} = \mathbf{0}$, which is $-\lambda x_1 + x_2 = 0$. For λ_1 this gives $0.5x_1 + x_2 = 0$, say, $x_1 = 2$, $x_2 = -1$. For $\lambda_2 = -1.5$ it gives $1.5x_1 + x_2 = 0$, say, $x_1 = 1$, $x_2 = -1.5$. These eigenvectors

$$\mathbf{x}^{(1)} = \begin{bmatrix} 2 \\ -1 \end{bmatrix}, \quad \mathbf{x}^{(2)} = \begin{bmatrix} 1 \\ -1.5 \end{bmatrix} \qquad \text{give} \qquad \mathbf{y} = c_1 \begin{bmatrix} 2 \\ -1 \end{bmatrix} e^{-0.5t} + c_2 \begin{bmatrix} 1 \\ -1.5 \end{bmatrix} e^{-1.5t}.$$

This vector solution has the first component

$$y = y_1 = 2c_1 e^{-0.5t} + c_2 e^{-1.5t}$$

which is the expected solution. The second component is its derivative

$$y_2 = y_1' = y' = -c_1 e^{-0.5t} - 1.5c_2 e^{-1.5t}.$$

■

PROBLEM SET 4.1

1–6 MIXING PROBLEMS

1. Find out without calculation whether doubling the flow rate in Example 1 has the same effect as halfing the tank sizes. (Give a reason.)
2. What happens in Example 1 if we replace T_2 by a tank containing 500 gal of water and 150 lb of fertilizer dissolved in it?
3. Derive the eigenvectors in Example 1 without consulting this book.
4. In Example 1 find a "general solution" for any ratio $a = (\textit{flow rate})/(\textit{tank size})$, tank sizes being equal. Comment on the result.
5. If you extend Example 1 by a tank T_3 of the same size as the others and connected to T_2 by two tubes with

flow rates as between T_1 and T_2, what system of ODEs will you get?

6. Find a "general solution" of the system in Prob. 5.

7–10 ELECTRICAL NETWORKS

7. Find the currents in Example 2 if the initial currents are 0 and −3 A (minus meaning that $I_2(0)$ flows against the direction of the arrow).
8. Find the currents in Example 2 if the resistance of R_1 and R_2 is doubled (general solution only). First, guess.
9. What are the limits of the currents in Example 2? Explain them in terms of physics.
10. Find the currents in Example 2 if the capacitance is changed to $C = 1/5.4$ F (farad).

11–15 CONVERSION TO SYSTEMS

Find a general solution of the given ODE (a) by first converting it to a system, (b), as given. (Show the details of your work.)

11. $y'' - 4y = 0$
12. $y'' + 2y' - 24y = 0$
13. $y'' - y' = 0$
14. $y'' + 15y' + 50y = 0$
15. $64y'' - 48y' - 7y = 0$

16. **TEAM PROJECT. Two Masses on Springs. (a)** Set up the model for the (undamped) system in Fig. 80.

(b) Solve the system of ODEs obtained. *Hint.* Try $\mathbf{y} = \mathbf{x}e^{\omega t}$ and set $\omega^2 = \lambda$. Proceed as in Example 1 or 2.

(c) Describe the influence of initial conditions on the possible kind of motions.

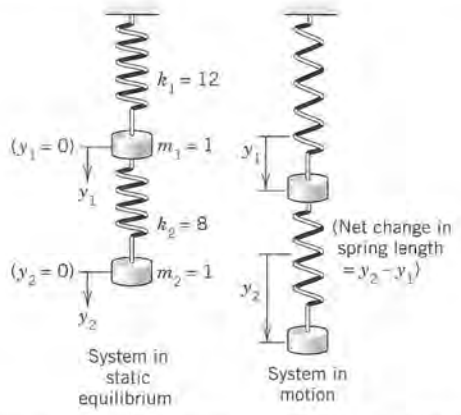


Fig. 80. Mechanical system in Team Project 16

4.2 Basic Theory of Systems of ODEs

In this section we discuss some basic concepts and facts about systems of ODEs that are quite similar to those for single ODEs.

The first-order systems in the last section were special cases of the more general system

$$\begin{aligned} y_1' &= f_1(t, y_1, \cdots, y_n) \\ y_2' &= f_2(t, y_1, \cdots, y_n) \\ &\cdots \\ y_n' &= f_n(t, y_1, \cdots, y_n). \end{aligned} \tag{1}$$

We can write the system (1) as a vector equation by introducing the column vectors $\mathbf{y} = [y_1 \quad \cdots \quad y_n]^\mathsf{T}$ and $\mathbf{f} = [f_1 \quad \cdots \quad f_n]^\mathsf{T}$ (where T means *transposition* and saves us the space that would be needed for writing $\mathbf{y}$ and $\mathbf{f}$ as columns). This gives

$$\mathbf{y}' = \mathbf{f}(t, \mathbf{y}). \tag{1}$$

This system (1) includes almost all cases of practical interest. For $n = 1$ it becomes $y_1' = f_1(t, y_1)$ or, simply, $y' = f(t, y)$, well known to us from Chap. 1.

A **solution** of (1) on some interval $a < t < b$ is a set of n differentiable functions

$$y_1 = h_1(t), \quad \cdots, \quad y_n = h_n(t)$$

on $a < t < b$ that satisfy (1) throughout this interval. In vector form, introducing the *"solution vector"* $\mathbf{h} = [h_1 \ \cdots \ h_n]^T$ (a column vector!) we can write

$$\mathbf{y} = \mathbf{h}(t).$$

An **initial value problem** for (1) consists of (1) and n given **initial conditions**

$$(2) \qquad y_1(t_0) = K_1, \qquad y_2(t_0) = K_2, \qquad \cdots, \qquad y_n(t_0) = K_n,$$

in vector form, $\mathbf{y}(t_0) = \mathbf{K}$, where t_0 is a specified value of t in the interval considered and the components of $\mathbf{K} = [K_1 \ \cdots \ K_n]^T$ are given numbers. Sufficient conditions for the existence and uniqueness of a solution of an initial value problem (1), (2) are stated in the following theorem, which extends the theorems in Sec. 1.7 for a single equation. (For a proof, see Ref. [A7].)

THEOREM 1

Existence and Uniqueness Theorem

Let $f_1, \cdots, f_n$ in (1) be continuous functions having continuous partial derivatives $\partial f_1/\partial y_1, \cdots, \partial f_1/\partial y_n, \cdots, \partial f_n/\partial y_n$ in some domain R of $ty_1y_2 \cdots y_n$-space containing the point $(t_0, K_1, \cdots, K_n)$. Then (1) has a solution on some interval $t_0 - \alpha < t < t_0 + \alpha$ satisfying (2), and this solution is unique.

Linear Systems

Extending the notion of a *linear* ODE, we call (1) a **linear system** if it is linear in $y_1 \cdots, y_n$; that is, if it can be written

$$(3) \qquad \begin{aligned} y_1' &= a_{11}(t)y_1 + \cdots + a_{1n}(t)y_n + g_1(t) \\ &\vdots \\ y_n' &= a_{n1}(t)y_1 + \cdots + a_{nn}(t)y_n + g_n(t). \end{aligned}$$

In vector form, this becomes

$$(3) \qquad \mathbf{y}' = \mathbf{A}\mathbf{y} + \mathbf{g}$$

where $$\mathbf{A} = \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \cdot & \cdots & \cdot \\ a_{n1} & \cdots & a_{nn} \end{bmatrix}, \qquad \mathbf{y} = \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix}, \qquad \mathbf{g} = \begin{bmatrix} g_1 \\ \vdots \\ g_n \end{bmatrix}.$$

This system is called **homogeneous** if $\mathbf{g} = \mathbf{0}$, so that it is

$$(4) \qquad \mathbf{y}' = \mathbf{A}\mathbf{y}.$$

If $\mathbf{g} \neq \mathbf{0}$, then (3) is called **nonhomogeneous.** The system in Example 1 in the last section is homogeneous and in Example 2 nonhomogeneous. The system in Example 3 is homogeneous.

For a linear system (3) we have $\partial f_1/\partial y_1 = a_{11}(t), \cdots, \partial f_n/\partial y_n = a_{nn}(t)$ in Theorem 1. Hence for a linear system we simply obtain the following.

THEOREM 2

Existence and Uniqueness in the Linear Case

Let the a_{jk}'s and g_j's in (3) *be continuous functions of t on an open interval $\alpha < t < \beta$ containing the point $t = t_0$. Then* (3) *has a solution* $\mathbf{y}(t)$ *on this interval satisfying* (2)*, and this solution is unique.*

As for a single homogeneous linear ODE we have

THEOREM 3

Superposition Principle or Linearity Principle

If $\mathbf{y}^{(1)}$ *and* $\mathbf{y}^{(2)}$ *are solutions of the* ***homogeneous linear*** *system* (4) *on some interval, so is any linear combination* $\mathbf{y} = c_1\mathbf{y}^{(1)} + c_2\mathbf{y}^{(2)}$.

PROOF Differentiating and using (4), we obtain

$$\begin{aligned}\mathbf{y}' &= \left[c_1\mathbf{y}^{(1)} + c_2\mathbf{y}^{(2)}\right]' \\ &= c_1\mathbf{y}^{(1)\prime} + c_2\mathbf{y}^{(2)\prime} \\ &= c_1\mathbf{A}\mathbf{y}^{(1)} + c_2\mathbf{A}\mathbf{y}^{(2)} \\ &= \mathbf{A}(c_1\mathbf{y}^{(1)} + c_2\mathbf{y}^{(2)}) = \mathbf{A}\mathbf{y}.\end{aligned}$$

■

The general theory of linear systems of ODEs is quite similar to that of a single linear ODE in Secs. 2.6 and 2.7. To see this, we explain the most basic concepts and facts. For proofs we refer to more advanced texts, such as [A7].

Basis. General Solution. Wronskian

By a **basis** or a **fundamental system** of solutions of the homogeneous system (4) on some interval J we mean a linearly independent set of n solutions $\mathbf{y}^{(1)}, \cdots, \mathbf{y}^{(n)}$ of (4) on that interval. (We write J because we need $\mathbf{I}$ to denote the unit matrix.) We call a corresponding linear combination

$$\mathbf{y} = c_1\mathbf{y}^{(1)} \cdots + c_n\mathbf{y}^{(n)} \qquad (c_1, \cdots, c_n \text{ arbitrary}) \tag{5}$$

a **general solution** of (4) on J. It can be shown that if the $a_{jk}(t)$ in (4) are continuous on J, then (4) has a basis of solutions on J, hence a general solution, which includes every solution of (4) on J.

We can write n solutions $\mathbf{y}^{(1)}, \cdots, \mathbf{y}^{(n)}$ of (4) on some interval J as columns of an $n \times n$ matrix

$$\mathbf{Y} = \begin{bmatrix}\mathbf{y}^{(1)} & \cdots & \mathbf{y}^{(n)}\end{bmatrix}. \tag{6}$$

The determinant of $\mathbf{Y}$ is called the **Wronskian** of $\mathbf{y}^{(1)}, \cdots, \mathbf{y}^{(n)}$, written

$$(7) \quad W(\mathbf{y}^{(1)}, \cdots, \mathbf{y}^{(n)}) = \begin{vmatrix} y_1^{(1)} & y_1^{(2)} & \cdots & y_1^{(n)} \\ y_2^{(1)} & y_2^{(2)} & \cdots & y_2^{(n)} \\ \cdot & \cdot & \cdots & \cdot \\ y_n^{(1)} & y_n^{(2)} & \cdots & y_n^{(n)} \end{vmatrix}.$$

The columns are these solutions, each in terms of components. These solutions form a basis on J if and only if W is not zero at any t_1 in this interval. W either is identically zero or is nowhere zero in J. (This is similar to Secs. 2.6 and 3.1.)

If the solutions $\mathbf{y}^{(1)}, \cdots, \mathbf{y}^{(n)}$ in (5) form a basis (a fundamental system), then (6) is often called a **fundamental matrix.** Introducing a column vector $\mathbf{c} = [c_1 \quad c_2 \quad \cdots \quad c_n]^T$, we can now write (5) simply as

$$(8) \qquad \mathbf{y} = \mathbf{Yc}.$$

Furthermore, we can relate (7) to Sec. 2.6, as follows. If y and z are solutions of a second-order homogeneous linear ODE, their Wronskian is

$$W(y, z) = \begin{vmatrix} y & z \\ y' & z' \end{vmatrix}.$$

To write this ODE as a system, we have to set $y = y_1$, $y' = y_1' = y_2$ and similarly for z (see Sec. 4.1). But then $W(y, z)$ becomes (7), except for notation.

4.3 Constant-Coefficient Systems. Phase Plane Method

Continuing, we now assume that our homogeneous linear system

$$(1) \qquad \mathbf{y}' = \mathbf{Ay}$$

under discussion has ***constant coefficients,*** so that the $n \times n$ matrix $\mathbf{A} = [a_{jk}]$ has entries not depending on t. We want to solve (1). Now a single ODE $y' = ky$ has the solution $y = Ce^{kt}$. So let us try

$$(2) \qquad \mathbf{y} = \mathbf{x}e^{\lambda t}.$$

Substitution into (1) gives $\mathbf{y}' = \lambda \mathbf{x}e^{\lambda t} = \mathbf{Ay} = \mathbf{A}\mathbf{x}e^{\lambda t}$. Dividing by $e^{\lambda t}$, we obtain the **eigenvalue problem**

$$(3) \qquad \mathbf{Ax} = \lambda \mathbf{x}.$$

Thus the nontrivial solutions of (1) (solutions that are not zero vectors) are of the form (2), where λ is an eigenvalue of $\mathbf{A}$ and $\mathbf{x}$ is a corresponding eigenvector.

We assume that $\mathbf{A}$ has a linearly independent set of n eigenvectors. This holds in most applications, in particular if $\mathbf{A}$ is symmetric ($a_{kj} = a_{jk}$) or skew-symmetric ($a_{kj} = -a_{jk}$) or has n *different* eigenvalues.

Let those eigenvectors be $\mathbf{x}^{(1)}, \cdots, \mathbf{x}^{(n)}$ and let them correspond to eigenvalues $\lambda_1, \cdots, \lambda_n$ (which may be all different, or some—or even all—may be equal). Then the corresponding solutions (2) are

$$\mathbf{(4)} \qquad \mathbf{y}^{(1)} = \mathbf{x}^{(1)}e^{\lambda_1 t}, \quad \cdots, \quad \mathbf{y}^{(n)} = \mathbf{x}^{(n)}e^{\lambda_n t}.$$

Their Wronskian $W = W(\mathbf{y}^{(1)}, \cdots, \mathbf{y}^{(n)})$ [(7) in Sec. 4.2] is given by

$$W = (\mathbf{y}^{(1)}, \cdots, \mathbf{y}^{(n)}) = \begin{vmatrix} x_1^{(1)}e^{\lambda_1 t} & \cdots & x_1^{(n)}e^{\lambda_n t} \\ x_2^{(1)}e^{\lambda_1 t} & \cdots & x_2^{(n)}e^{\lambda_n t} \\ \cdot & \cdots & \cdot \\ x_n^{(1)}e^{\lambda_1 t} & \cdots & x_n^{(n)}e^{\lambda_n t} \end{vmatrix} = e^{\lambda_1 t + \cdots + \lambda_n t} \begin{vmatrix} x_1^{(1)} & \cdots & x_1^{(n)} \\ x_2^{(1)} & \cdots & x_2^{(n)} \\ \cdot & \cdots & \cdot \\ x_n^{(1)} & \cdots & x_n^{(n)} \end{vmatrix}.$$

On the right, the exponential function is never zero, and the determinant is not zero either because its columns are the n linearly independent eigenvectors. This proves the following theorem, whose assumption is true if the matrix $\mathbf{A}$ is symmetric or skew-symmetric, or if the n eigenvalues of $\mathbf{A}$ are all different.

THEOREM 1

General Solution

If the constant matrix $\mathbf{A}$ *in the system* (1) *has a linearly independent set of* n *eigenvectors, then the corresponding solutions* $\mathbf{y}^{(1)}, \cdots, \mathbf{y}^{(n)}$ *in* (4) *form a basis of solutions of* (1)*, and the corresponding general solution is*

$$\mathbf{(5)} \qquad \mathbf{y} = c_1\mathbf{x}^{(1)}e^{\lambda_1 t} + \cdots + c_n\mathbf{x}^{(n)}e^{\lambda_n t}.$$

How to Graph Solutions in the Phase Plane

We shall now concentrate on systems (1) with constant coefficients consisting of two ODEs

$$\mathbf{(6)} \qquad \mathbf{y}' = \mathbf{Ay}; \quad \text{in components,} \quad \begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2 \\ y_2' &= a_{21}y_1 + a_{22}y_2. \end{aligned}$$

Of course, we can graph solutions of (6),

$$(7) \qquad \mathbf{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \end{bmatrix},$$

as two curves over the t-axis, one for each component of $\mathbf{y}(t)$. (Figure 79a in Sec. 4.1 shows an example.) But we can also graph (7) as a single curve in the y_1y_2-plane. This is a *parametric representation* (*parametric equation*) with parameter t. (See Fig. 79b for an example. Many more follow. Parametric equations also occur in calculus.) Such a curve is called a **trajectory** (or sometimes an *orbit* or *path*) of (6). The y_1y_2-plane is called the **phase plane.**[1] If we fill the phase plane with trajectories of (6), we obtain the so-called **phase portrait** of (6).

EXAMPLE 1 **Trajectories in the Phase Plane (Phase Portrait)**

In order to see what is going on, let us find and graph solutions of the system

$$\mathbf{y}' = \mathbf{A}\mathbf{y} = \begin{bmatrix} -3 & 1 \\ 1 & -3 \end{bmatrix} \mathbf{y}, \quad \text{thus} \quad \begin{aligned} y_1' &= -3y_1 + y_2 \\ y_2' &= y_1 - 3y_2. \end{aligned} \tag{8}$$

Solution. By substituting $\mathbf{y} = \mathbf{x}e^{\lambda t}$ and $\mathbf{y}' = \lambda \mathbf{x}e^{\lambda t}$ and dropping the exponential function we get $\mathbf{A}\mathbf{x} = \lambda\mathbf{x}$. The characteristic equation is

$$\det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} -3 - \lambda & 1 \\ 1 & -3 - \lambda \end{vmatrix} = \lambda^2 + 6\lambda + 8 = 0.$$

This gives the eigenvalues $\lambda_1 = -2$ and $\lambda_2 = -4$. Eigenvectors are then obtained from

$$(-3 - \lambda)x_1 + x_2 = 0.$$

For $\lambda_1 = -2$ this is $-x_1 + x_2 = 0$. Hence we can take $\mathbf{x}^{(1)} = [1 \quad 1]^\mathsf{T}$. For $\lambda_2 = -4$ this becomes $x_1 + x_2 = 0$, and an eigenvector is $\mathbf{x}^{(2)} = [1 \quad -1]^\mathsf{T}$. This gives the general solution

$$\mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = c_1\mathbf{y}^{(1)} + c_2\mathbf{y}^{(2)} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-2t} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-4t}.$$

Figure 81 on p. 142 shows a phase portrait of some of the trajectories (to which more trajectories could be added if so desired). The two straight trajectories correspond to $c_1 = 0$ and $c_2 = 0$ and the others to other choices of c_1, c_2. ■

Studies of solutions in the phase plane have recently become quite important, along with advances in computer graphics, because a phase portrait gives a good general qualitative impression of the entire family of solutions. This method becomes particularly valuable in the frequent cases when solving an ODE or a system is inconvenient or impossible.

Critical Points of the System (6)

The point $\mathbf{y} = \mathbf{0}$ in Fig. 81 seems to be a common point of all trajectories, and we want to explore the reason for this remarkable observation. The answer will follow by calculus. Indeed, from (6) we obtain

$$\frac{dy_2}{dy_1} = \frac{y_2'\,dt}{y_1'\,dt} = \frac{y_2'}{y_1'} = \frac{a_{21}y_1 + a_{22}y_2}{a_{11}y_1 + a_{12}y_2}. \tag{9}$$

---

[1] A name that comes from physics, where it is the y-(mv)-plane, used to plot a motion in terms of position y and velocity $y' = v$ (m = mass); but the name is now used quite generally for the y_1y_2-plane.

The use of the phase plane is a **qualitative method,** a method of obtaining general qualitative information on solutions without actually solving an ODE or a system. This method was created by HENRI POINCARÉ (1854–1912), a great French mathematician, whose work was also fundamental in complex analysis, divergent series, topology, and astronomy.

This associates with every point P: (y_1, y_2) a unique tangent direction dy_2/dy_1 of the trajectory passing through P, except for the point $P = P_0$: (0, 0), where the right side of (9) becomes 0/0. This point P_0, at which dy_2/dy_1 becomes undetermined, is called a **critical point** of (6).

Five Types of Critical Points

There are five types of critical points depending on the geometric shape of the trajectories near them. They are called **improper nodes, proper nodes, saddle points, centers,** and **spiral points.** We define and illustrate them in Examples 1–5.

EXAMPLE 1 **(*Continued*) Improper Node (Fig. 81)**

An **improper node** is a critical point P_0 at which all the trajectories, except for two of them, have the same limiting direction of the tangent. The two exceptional trajectories also have a limiting direction of the tangent at P_0 which, however, is different.

The system (8) has an improper node at **0,** as its phase portrait Fig. 81 shows. The common limiting direction at **0** is that of the eigenvector $\mathbf{x}^{(1)} = [1 \quad 1]^T$ because e^{-4t} goes to zero faster than e^{-2t} as t increases. The two exceptional limiting tangent directions are those of $\mathbf{x}^{(2)} = [1 \quad -1]^T$ and $-\mathbf{x}^{(2)} = [-1 \quad 1]^T$. ■

EXAMPLE 2 **Proper Node (Fig. 82)**

A **proper node** is a critical point P_0 at which every trajectory has a definite limiting direction and for any given direction $\mathbf{d}$ at P_0 there is a trajectory having $\mathbf{d}$ as its limiting direction.

The system

$$\mathbf{y}' = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= y_1 \\ y_2' &= y_2 \end{aligned} \tag{10}$$

has a proper node at the origin (see Fig. 82). Indeed, the matrix is the unit matrix. Its characteristic equation $(1 - \lambda)^2 = 0$ has the root $\lambda = 1$. Any $\mathbf{x} \neq \mathbf{0}$ is an eigenvector, and we can take $[1 \quad 0]^T$ and $[0 \quad 1]^T$. Hence a general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 0 \end{bmatrix} e^t + c_2 \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^t \qquad \text{or} \qquad \begin{aligned} y_1 &= c_1 e^t \\ y_2 &= c_2 e^t \end{aligned} \qquad \text{or} \qquad c_1 y_2 = c_2 y_1. \quad ■$$

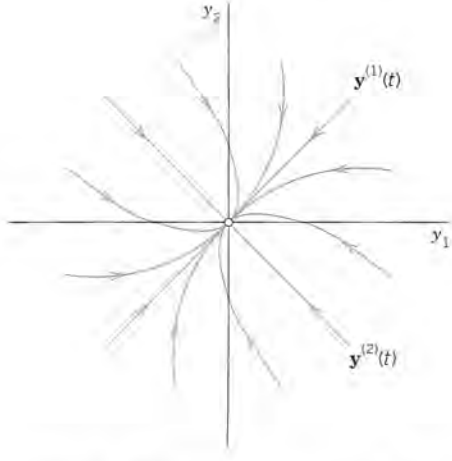

Fig. 81. Trajectories of the system (8) (Improper node)

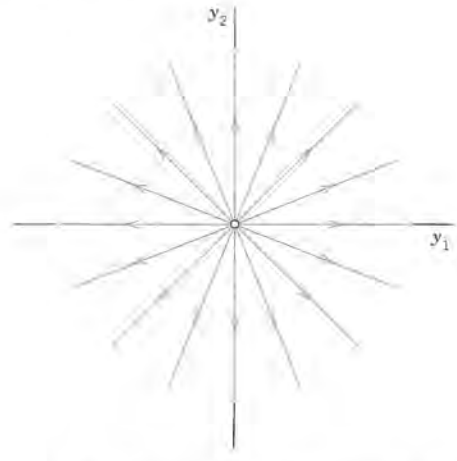

Fig. 82. Trajectories of the system (10) (Proper node)

EXAMPLE 3 **Saddle Point (Fig. 83)**

A **saddle point** is a critical point P_0 at which there are two incoming trajectories, two outgoing trajectories, and all the other trajectories in a neighborhood of P_0 bypass P_0.

The system

$$\mathbf{y}' = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= y_1 \\ y_2' &= -y_2 \end{aligned} \tag{11}$$

has a saddle point at the origin. Its characteristic equation $(1 - \lambda)(-1 - \lambda) = 0$ has the roots $\lambda_1 = 1$ and $\lambda_2 = -1$. For $\lambda = 1$ an eigenvector $[1 \quad 0]^T$ is obtained from the second row of $(\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}$, that is, $0x_1 + (-1 - 1)x_2 = 0$. For $\lambda_2 = -1$ the first row gives $[0 \quad 1]^T$. Hence a general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 0 \end{bmatrix} e^{t} + c_2 \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^{-t} \qquad \text{or} \qquad \begin{aligned} y_1 &= c_1 e^{t} \\ y_2 &= c_2 e^{-t} \end{aligned} \qquad \text{or} \qquad y_1 y_2 = const.$$

This is a family of hyperbolas (and the coordinate axes); see Fig. 83. ■

EXAMPLE 4 **Center (Fig. 84)**

A **center** is a critical point that is enclosed by infinitely many closed trajectories.

The system

$$\mathbf{y}' = \begin{bmatrix} 0 & 1 \\ -4 & 0 \end{bmatrix} \mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= y_2 \\ y_2' &= -4y_1 \end{aligned} \tag{12}$$

has a center at the origin. The characteristic equation $\lambda^2 + 4 = 0$ gives the eigenvalues $2i$ and $-2i$. For $2i$ an eigenvector follows from the first equation $-2ix_1 + x_2 = 0$ of $(\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}$, say, $[1 \quad 2i]^T$. For $\lambda = -2i$ that equation is $-(-2i)x_1 + x_2 = 0$ and gives, say, $[1 \quad -2i]^T$. Hence a complex general solution is

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 2i \end{bmatrix} e^{2it} + c_2 \begin{bmatrix} 1 \\ -2i \end{bmatrix} e^{-2it}, \qquad \text{thus} \qquad \begin{aligned} y_1 &= c_1 e^{2it} + c_2 e^{-2it} \\ y_2 &= 2ic_1 e^{2it} - 2ic_2 e^{-2it}. \end{aligned} \tag{12*}$$

The next step would be the transformation of this solution to real form by the Euler formula (Sec. 2.2). But we were just curious to see what kind of eigenvalues we obtain in the case of a center. Accordingly, we do not continue, but start again from the beginning and use a shortcut. We rewrite the given equations in the form $y_1' = y_2$, $4y_1 = -y_2'$; then the product of the left sides must equal the product of the right sides,

$$4y_1 y_1' = -y_2 y_2'. \qquad \text{By integration,} \qquad 2y_1^2 + \tfrac{1}{2}y_2^2 = const.$$

This is a family of ellipses (see Fig. 84) enclosing the center at the origin. ■

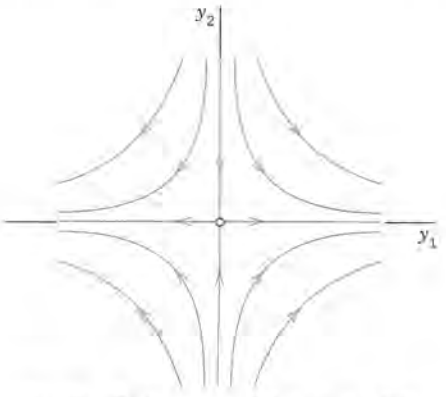

Fig. 83. Trajectories of the system (11) (Saddle point)

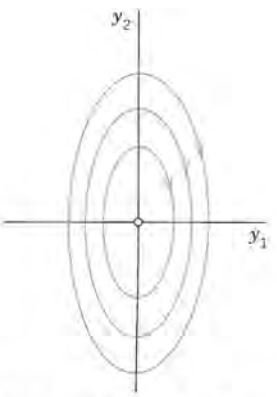

Fig. 84. Trajectories of the system (12) (Center)

EXAMPLE 5 **Spiral Point (Fig. 85)**

A **spiral point** is a critical point P_0 about which the trajectories spiral, approaching P_0 as $t \to \infty$ (or tracing these spirals in the opposite sense, away from P_0).

The system

$$\mathbf{y}' = \begin{bmatrix} -1 & 1 \\ -1 & -1 \end{bmatrix} \mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= -y_1 + y_2 \\ y_2' &= -y_1 - y_2 \end{aligned} \tag{13}$$

has a spiral point at the origin, as we shall see. The characteristic equation is $\lambda^2 + 2\lambda + 2 = 0$. It gives the eigenvalues $-1 + i$ and $-1 - i$. Corresponding eigenvectors are obtained from $(-1 - \lambda)x_1 + x_2 = 0$. For $\lambda = -1 + i$ this becomes $-ix_1 + x_2 = 0$ and we can take $[1 \quad i]^T$ as an eigenvector. Similarly, an eigenvector corresponding to $-1 - i$ is $[1 \quad -i]^T$. This gives the complex general solution

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ i \end{bmatrix} e^{(-1+i)t} + c_2 \begin{bmatrix} 1 \\ -i \end{bmatrix} e^{(-1-i)t}.$$

The next step would be the transformation of this complex solution to a real general solution by the Euler formula. But, as in the last example, we just wanted to see what eigenvalues to expect in the case of a spiral point. Accordingly, we start again from the beginning and instead of that rather lengthy systematic calculation we use a shortcut. We multiply the first equation in (13) by y_1, the second by y_2, and add, obtaining

$$y_1 y_1' + y_2 y_2' = -(y_1^2 + y_2^2).$$

We now introduce polar coordinates r, t, where $r^2 = y_1^2 + y_2^2$. Differentiating this with respect to t gives $2rr' = 2y_1 y_1' + 2y_2 y_2'$. Hence the previous equation can be written

$$rr' = -r^2. \qquad \text{Thus,} \qquad r' = -r, \qquad dr/r = -dt, \qquad \ln|r| = -t + c^*, \qquad r = ce^{-t}.$$

For each real c this is a spiral, as claimed. (see Fig. 85). ■

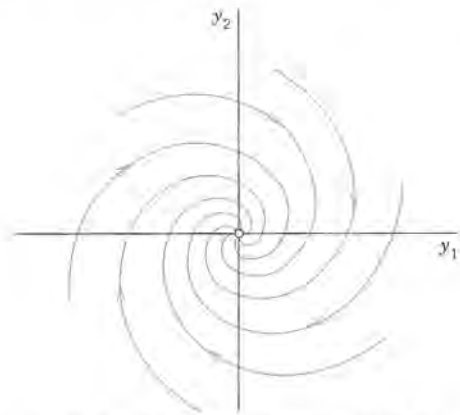

Fig. 85. Trajectories of the system (13) (Spiral point)

EXAMPLE 6 **No Basis of Eigenvectors Available. Degenerate Node (Fig. 86)**

This cannot happen if $\mathbf{A}$ in (1) is symmetric ($a_{kj} = a_{jk}$, as in Examples 1–3) or skew-symmetric ($a_{kj} = -a_{jk}$, thus $a_{jj} = 0$). And it does not happen in many other cases (see Examples 4 and 5). Hence it suffices to explain the method to be used by an example.

Find and graph a general solution of

$$\mathbf{y}' = \mathbf{A}\mathbf{y} = \begin{bmatrix} 4 & 1 \\ -1 & 2 \end{bmatrix} \mathbf{y}. \tag{14}$$

Solution. **A** is not skew-symmetric! Its characteristic equation is

$$\det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} 4 - \lambda & 1 \\ -1 & 2 - \lambda \end{vmatrix} = \lambda^2 - 6\lambda + 9 = (\lambda - 3)^2 = 0.$$

It has a double root $\lambda = 3$. Hence eigenvectors are obtained from $(4 - \lambda)x_1 + x_2 = 0$, thus from $x_1 + x_2 = 0$, say, $\mathbf{x}^{(1)} = [1 \quad -1]^\mathsf{T}$ and nonzero multiples of it (which do not help). The method now is to substitute

$$\mathbf{y}^{(2)} = \mathbf{x}te^{\lambda t} + \mathbf{u}e^{\lambda t}$$

with constant $\mathbf{u} = [u_1 \quad u_2]^\mathsf{T}$ into (14). (The $\mathbf{x}t$-term alone, the analog of what we did in Sec. 2.2 in the case of a double root, would not be enough. Try it.) This gives

$$\mathbf{y}^{(2)\prime} = \mathbf{x}e^{\lambda t} + \lambda\mathbf{x}te^{\lambda t} + \lambda\mathbf{u}e^{\lambda t} = \mathbf{A}\mathbf{y}^{(2)} = \mathbf{A}\mathbf{x}te^{\lambda t} + \mathbf{A}\mathbf{u}e^{\lambda t}.$$

On the right, $\mathbf{A}\mathbf{x} = \lambda\mathbf{x}$. Hence the terms $\lambda\mathbf{x}te^{\lambda t}$ cancel, and then division by $e^{\lambda t}$ gives

$$\mathbf{x} + \lambda\mathbf{u} = \mathbf{A}\mathbf{u}, \qquad \text{thus} \qquad (\mathbf{A} - \lambda\mathbf{I})\mathbf{u} = \mathbf{x}.$$

Here $\lambda = 3$ and $\mathbf{x} = [1 \quad -1]^\mathsf{T}$, so that

$$(\mathbf{A} - 3\mathbf{I})\mathbf{u} = \begin{bmatrix} 4 - 3 & 1 \\ -1 & 2 - 3 \end{bmatrix} \mathbf{u} = \begin{bmatrix} 1 \\ -1 \end{bmatrix}, \qquad \text{thus} \qquad \begin{aligned} u_1 + u_2 &= 1 \\ -u_1 - u_2 &= -1. \end{aligned}$$

A solution, linearly independent of $\mathbf{x} = [1 \quad -1]^\mathsf{T}$, is $\mathbf{u} = [0 \quad 1]^\mathsf{T}$. This yields the answer (Fig. 86)

$$\mathbf{y} = c_1\mathbf{y}^{(1)} + c_2\mathbf{y}^{(2)} = c_1 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{3t} + c_2\left(\begin{bmatrix} 1 \\ -1 \end{bmatrix} t + \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right) e^{3t}.$$

The critical point at the origin is often called a **degenerate node.** $c_1\mathbf{y}^{(1)}$ gives the heavy straight line, with $c_1 > 0$ the lower part and $c_1 < 0$ the upper part of it. $\mathbf{y}^{(2)}$ gives the right part of the heavy curve from 0 through the second, first, and—finally—fourth quadrants. $-\mathbf{y}^{(2)}$ gives the other part of that curve. ■

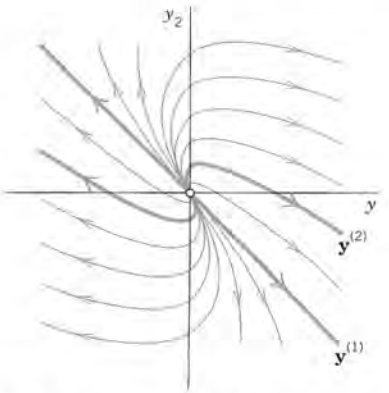

Fig. 86. Degenerate node in Example 6

We mention that for a system (1) with three or more equations and a triple eigenvalue with only one linearly independent eigenvector, one will get two solutions, as just discussed, and a third linearly independent one from

$$\mathbf{y}^{(3)} = \tfrac{1}{2}\mathbf{x}t^2e^{\lambda t} + \mathbf{u}te^{\lambda t} + \mathbf{v}e^{\lambda t} \qquad \text{with } \mathbf{v} \text{ from} \qquad (\mathbf{u} + \lambda\mathbf{v} = \mathbf{A}\mathbf{v}.$$

PROBLEM SET 4.3

1–9 GENERAL SOLUTION

Find a real general solution of the following systems. (Show the details.)

1. $y_1' = 3y_2$
$y_2' = 12y_1$

2. $y_1' = 5y_2$
$y_2' = 5y_1$

3. $y_1' = y_1 + y_2$
$y_2' = y_1 + y_2$

4. $y_1' = 9y_1 + 13.5y_2$
$y_2' = 1.5y_1 + 9y_2$

5. $y_1' = 4y_2$
$y_2' = -4y_1$

6. $y_1' = 2y_1 - 2y_2$
$y_2' = 2y_1 + 2y_2$

7. $y_1' = 2y_1 + 8y_2 - 4y_3$
$y_2' = -4y_1 - 10y_2 + 2y_3$
$y_3' = -4y_1 - 4y_2 - 4y_3$

8. $y_1' = 8y_1 - y_2$
$y_2' = y_1 + 10y_2$

9. $y_1' = -y_1 + y_2 + 0.4y_3$
$y_2' = y_1 - 0.1y_2 + 1.4y_3$
$y_3' = 0.4y_1 + 1.4y_2 + 0.2y_3$

10–15 INITIAL VALUE PROBLEMS

Solve the following initial value problems. (Show the details.)

10. $y_1' = y_1 + y_2$
$y_2' = 4y_1 + y_2$
$y_1(0) = 1,\ y_2(0) = 6$

11. $y_1' = y_1 + 2y_2$
$y_2' = \frac{1}{2}y_1 + y_2$
$y_1(0) = 16,\ y_2(0) = -2$

12. $y_1' = 3y_1 + 2y_2$
$y_2' = 2y_1 + 3y_2$
$y_1(0) = 7,\ y_2(0) = 7$

13. $y_1' = \frac{1}{2}y_1 - 2y_2$
$y_2' = -\frac{3}{2}y_1 + y_2$
$y_1(0) = 0.4,\ y_2(0) = 3.8$

14. $y_1' = -y_1 + 5y_2$
$y_2' = -y_1 + 3y_2$
$y_1(0) = 7,\ y_2(0) = 2$

15. $y_1' = 2y_1 + 5y_2$
$y_2' = 5y_1 + 12.5y_2$
$y_1(0) = 12,\ y_2(0) = 1$

16–17 CONVERSION

Find a general solution by conversion to a single ODE.

16. The system in Prob. 8.

17. The system in Example 5.

18. (Mixing problem, Fig. 87) Each of the two tanks contains 400 gal of water, in which initially 100 lb (Tank T_1) and 40 lb (Tank T_2) of fertilizer are dissolved. The inflow, circulation, and outflow are shown in Fig. 87. The mixture is kept uniform by stirring. Find the fertilizer contents $y_1(t)$ in T_1 and $y_2(t)$ in T_2.

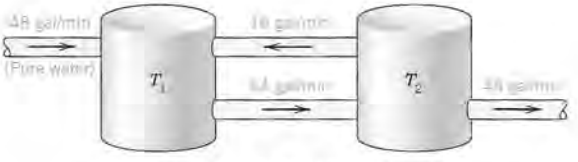

Fig. 87. Tanks in Problem 18

19. (Network) Show that a model for the currents $I_1(t)$ and $I_2(t)$ in Fig. 88 is

$$\frac{1}{C}\int I_1\,dt + R(I_1 - I_2) = 0, \qquad LI_2' + R(I_2 - I_1) = 0.$$

Find a general solution, assuming that $R = 20\ \Omega$, $L = 0.5$ H, $C = 2 \cdot 10^{-4}$ F.

20. CAS PROJECT. Phase Portraits. Graph some of the figures in this section, in particular Fig. 86 on the degenerate node, in which the vector $\mathbf{y}^{(2)}$ depends on t. In each figure highlight a trajectory that satisfies an initial condition of your choice.

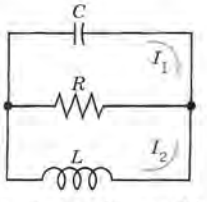

Fig. 88. Network in Problem 19

4.4 Criteria for Critical Points. Stability

We continue our discussion of homogeneous linear systems with constant coefficients

$$(1)\quad \mathbf{y}' = \mathbf{A}\mathbf{y} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \mathbf{y}, \qquad \text{in components,} \qquad \begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2 \\ y_2' &= a_{21}y_1 + a_{22}y_2. \end{aligned}$$

From the examples in the last section we have seen that we can obtain an overview of families of solution curves if we represent them parametrically as $\mathbf{y}(t) = [y_1(t) \quad y_2(t)]^T$ and graph them as curves in the y_1y_2-plane, called the **phase plane.** Such a curve is called a **trajectory** of (1), and their totality is known as the **phase portrait** of (1).

Now we have seen that solutions are of the form

$$\mathbf{y}(t) = \mathbf{x}e^{\lambda t}. \qquad \text{Substitution into (1) gives} \qquad \mathbf{y}'(t) = \lambda\mathbf{x}e^{\lambda t} = \mathbf{A}\mathbf{y} = \mathbf{A}\mathbf{x}e^{\lambda t}.$$

Dropping the common factor $e^{\lambda t}$, we have

$$(2)\qquad \mathbf{A}\mathbf{x} = \lambda\mathbf{x}.$$

Hence $\mathbf{y}(t)$ is a (nonzero) solution of (1) if λ is an eigenvalue of $\mathbf{A}$ and $\mathbf{x}$ a corresponding eigenvector.

Our examples in the last section show that the general form of the phase portrait is determined to a large extent by the type of **critical point** of the system (1) defined as a point at which dy_2/dy_1 becomes undetermined, 0/0; here [see (9) in Sec. 4.3]

$$(3)\qquad \frac{dy_2}{dy_1} = \frac{y_2'\,dt}{y_1'\,dt} = \frac{a_{21}y_1 + a_{22}y_2}{a_{11}y_1 + a_{12}y_2}.$$

We also recall from Sec. 4.3 that there are various types of critical points, and we shall now see how these types are related to the eigenvalues. The latter are solutions $\lambda = \lambda_1$ and λ_2 of the characteristic equation

$$(4)\qquad \det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} a_{11} - \lambda & a_{12} \\ a_{21} & a_{22} - \lambda \end{vmatrix} = \lambda^2 - (a_{11} + a_{22})\lambda + \det\mathbf{A} = 0.$$

This is a quadratic equation $\lambda^2 - p\lambda + q = 0$ with coefficients p, q and discriminant Δ given by

$$(5)\qquad p = a_{11} + a_{22}, \qquad q = \det\mathbf{A} = a_{11}a_{22} - a_{12}a_{21}, \qquad \Delta = p^2 - 4q.$$

From calculus we know that the solutions of this equation are

$$(6)\qquad \lambda_1 = \tfrac{1}{2}(p + \sqrt{\Delta}), \qquad \lambda_2 = \tfrac{1}{2}(p - \sqrt{\Delta}).$$

Furthermore, the product representation of the equation gives

$$\lambda^2 - p\lambda + q = (\lambda - \lambda_1)(\lambda - \lambda_2) = \lambda^2 - (\lambda_1 + \lambda_2)\lambda + \lambda_1\lambda_2.$$

Hence p is the sum and q the product of the eigenvalues. Also $\lambda_1 - \lambda_2 = \sqrt{\Delta}$ from (6). Together,

$$(7) \qquad p = \lambda_1 + \lambda_2, \qquad q = \lambda_1\lambda_2, \qquad \Delta = (\lambda_1 - \lambda_2)^2.$$

This gives the criteria in Table 4.1 for classifying critical points. A derivation will be indicated later in this section.

Table 4.1 Eigenvalue Criteria for Critical Points (Derivation after Table 4.2)

Name	$p = \lambda_1 + \lambda_2$	$q = \lambda_1\lambda_2$	$\Delta = (\lambda_1 - \lambda_2)^2$	Comments on λ_1, λ_2
(a) Node		$q > 0$	$\Delta \geqq 0$	Real, same sign
(b) Saddle point		$q < 0$		Real, opposite sign
(c) Center	$p = 0$	$q > 0$		Pure imaginary
(d) Spiral point	$p \neq 0$		$\Delta < 0$	Complex, not pure imaginary

Stability

Critical points may also be classified in terms of their stability. Stability concepts are basic in engineering and other applications. They are suggested by physics, where **stability** means, roughly speaking, that a small change (a small disturbance) of a physical system at some instant changes the behavior of the system only slightly at all future times t. For critical points, the following concepts are appropriate.

DEFINITIONS

Stable, Unstable, Stable and Attractive

A critical point P_0 of (1) is called **stable**[2] if, roughly, all trajectories of (1) that at some instant are close to P_0 remain close to P_0 at all future times; precisely: if for every disk D_ϵ of radius $\epsilon > 0$ with center P_0 there is a disk D_δ of radius $\delta > 0$ with center P_0 such that every trajectory of (1) that has a point P_1 (corresponding to $t = t_1$, say) in D_δ has all its points corresponding to $t \geqq t_1$ in D_ϵ. See Fig. 89.

P_0 is called **unstable** if P_0 is not stable.

P_0 is called **stable and attractive** (or *asymptotically stable*) if P_0 is stable and every trajectory that has a point in D_δ approaches P_0 as $t \to \infty$. See Fig. 90.

Classification criteria for critical points in terms of stability are given in Table 4.2. Both tables are summarized in the **stability chart** in Fig. 91. In this chart the region of instability is dark blue.

[2]In the sense of the Russian mathematician ALEXANDER MICHAILOVICH LJAPUNOV (1857–1918), whose work was fundamental in stability theory for ODEs. This is perhaps the most appropriate definition of stability (and the only we shall use), but there are others, too.

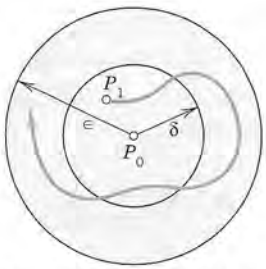

Fig. 89. Stable critical point P_0 of (1) (The trajectory initiating at P_1 stays in the disk of radius ϵ.)

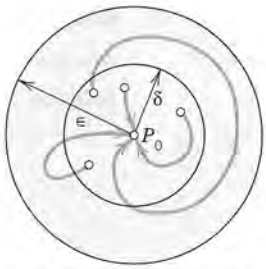

Fig. 90. Stable and attractive critical point P_0 of (1)

Table 4.2 Stability Criteria for Critical Points

Type of Stability	$p = \lambda_1 + \lambda_2$		$q = \lambda_1\lambda_2$
(a) Stable and attractive	$p < 0$		$q > 0$
(b) Stable	$p \leqq 0$		$q > 0$
(c) Unstable	$p > 0$	OR	$q < 0$

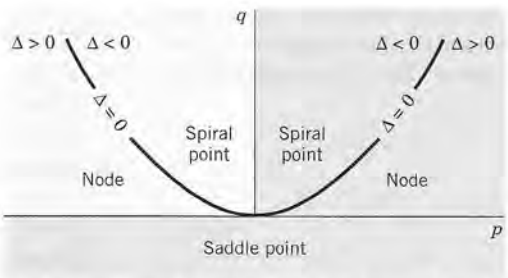

Fig. 91. Stability chart of the system (1) with p, q, Δ defined in (5).
Stable and attractive: The second quadrant without the q-axis.
Stability also on the positive q-axis (which corresponds to centers).
Unstable: Dark blue region

We indicate how the criteria in Tables 4.1 and 4.2 are obtained. If $q = \lambda_1\lambda_2 > 0$, both eigenvalues are positive or both are negative or complex conjugates. If also $p = \lambda_1 + \lambda_2 < 0$, both are negative or have a negative real part. Hence P_0 is stable and attractive. The reasoning for the other two lines in Table 4.2 is similar.

If $\Delta < 0$, the eigenvalues are complex conjugates, say, $\lambda_1 = \alpha + i\beta$ and $\lambda_2 = \alpha - i\beta$. If also $p = \lambda_1 + \lambda_2 = 2\alpha < 0$, this gives a spiral point that is stable and attractive. If $p = 2\alpha > 0$, this gives an unstable spiral point.

If $p = 0$, then $\lambda_2 = -\lambda_1$ and $q = \lambda_1\lambda_2 = -\lambda_1{}^2$. If also $q > 0$, then $\lambda_1{}^2 = -q < 0$, so that λ_1, and thus λ_2, must be pure imaginary. This gives periodic solutions, their trajectories being closed curves around P_0, which is a center.

EXAMPLE 1 Application of the Criteria in Tables 4.1 and 4.2

In Example 1, Sec. 4.3, we have $\mathbf{y}' = \begin{bmatrix} -3 & 1 \\ 1 & -3 \end{bmatrix} \mathbf{y}$, $p = -6$, $q = 8$, $\Delta = 4$, a node by Table 4.1(a), which is stable and attractive by Table 4.2(a). ■

EXAMPLE 2 Free Motions of a Mass on a Spring

What kind of critical point does $my'' + cy' + ky = 0$ in Sec. 2.4 have?

Solution. Division by m gives $y'' = -(k/m)y - (c/m)y'$. To get a system, set $y_1 = y$, $y_2 = y'$ (see Sec. 4.1). Then $y_2' = y'' = -(k/m)y_1 - (c/m)y_2$. Hence

$$\mathbf{y}' = \begin{bmatrix} 0 & 1 \\ -k/m & -c/m \end{bmatrix} \mathbf{y}, \qquad \det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} -\lambda & 1 \\ -k/m & -c/m - \lambda \end{vmatrix} = \lambda^2 + \frac{c}{m}\lambda + \frac{k}{m} = 0.$$

We see that $p = -c/m$, $q = k/m$, $\Delta = (c/m)^2 - 4k/m$. From this and Tables 4.1 and 4.2 we obtain the following results. Note that in the last three cases the discriminant Δ plays an essential role.

No damping. $c = 0$, $p = 0$, $q > 0$, a center.
Underdamping. $c^2 < 4mk$, $p < 0$, $q > 0$, $\Delta < 0$, a stable and attractive spiral point.
Critical damping. $c^2 = 4mk$, $p < 0$, $q > 0$, $\Delta = 0$, a stable and attractive node.
Overdamping. $c^2 > 4mk$, $p < 0$, $q > 0$, $\Delta > 0$, a stable and attractive node. ■

PROBLEM SET 4.4

1–9 TYPE AND STABILITY OF CRITICAL POINT

Determine the type and stability of the critical point. Then find a real general solution and sketch or graph some of the trajectories in the phase plane. (Show the details of your work.)

1. $y_1' = 2y_2$
$y_2' = 8y_1$

2. $y_1' = 4y_1$
$y_2' = 3y_2$

3. $y_1' = 2y_1 + y_2$
$y_2' = y_1 + 2y_2$

4. $y_1' = y_2$
$y_2' = -5y_1 - 2y_2$

5. $y_1' = -4y_1 + y_2$
$y_2' = y_1 - 4y_2$

6. $y_1' = y_1 + 10y_2$
$y_2' = 7y_1 - 8y_2$

7. $y_1' = -2y_2$
$y_2' = 8y_1$

8. $y_1' = 3y_1 + 5y_2$
$y_2' = -5y_1 - 3y_2$

9. $y_1' = y_1 + 2y_2$
$y_2' = 2y_1 + y_2$

10–12 FORM OF TRAJECTORIES

What kind of curves are the trajectories of the following ODEs in the phase plane?

10. $y'' + 5y' = 0$

11. $y'' - k^2y = 0$

12. $y'' + \frac{1}{16}y = 0$

13. (Damped oscillation) Solve $y'' + 4y' + 5y = 0$. What kind of curves do you get as trajectories?

14. (Transformation of variable) What happens to the system (1) and its critical point if you introduce $\tau = -t$ as a new independent variable?

15. (Types of critical points) Discuss the critical points in (10)–(14) in Sec. 4.3 by applying the criteria in Tables 4.1 and 4.2 in this section.

16. (Perturbation of center) If a system has a center as its critical point, what happens if you replace the matrix $\mathbf{A}$ by $\tilde{\mathbf{A}} = \mathbf{A} + k\mathbf{I}$ with any real number $k \neq 0$ (representing measurement errors in the diagonal entries)?

17. (Perturbation) The system in Example 4 in Sec. 4.3 has a center as its critical point. Replace each a_{jk} in Example 4, Sec. 4.3, by $a_{jk} + b$. Find values of b such that you get (a) a saddle point, (b) a stable and attractive node, (c) a stable and attractive spiral, (d) an unstable spiral, (e) an unstable node.

18. CAS EXPERIMENT. Phase Portraits. Graph phase portraits for the systems in Prob. 17 with the values of b suggested in the answer. Try to illustrate how the phase portrait changes "continuously" under a continuous change of b.

19. WRITING EXPERIMENT. Stability. Stability concepts are basic in physics and engineering. Write a two-part report of 3 pages each (A) on general applications in which stability plays a role (be as precise as you can), and (B) on material related to stability in this section. Use your own formulations and examples; do not copy.

20. (Stability chart) Locate the critical points of the systems (10)–(14) in Sec. 4.3 and of Probs. 1, 3, 5 in this problem set on the stability chart.

4.5 Qualitative Methods for Nonlinear Systems

Qualitative methods are methods of obtaining qualitative information on solutions without actually solving a system. These methods are particularly valuable for systems whose solution by analytic methods is difficult or impossible. This is the case for many practically important **nonlinear systems**

$$\text{(1)} \qquad \mathbf{y}' = \mathbf{f}(\mathbf{y}), \qquad \text{thus} \qquad \begin{aligned} y_1' &= f_1(y_1, y_2) \\ y_2' &= f_2(y_1, y_2). \end{aligned}$$

In this section we extend **phase plane methods,** as just discussed, from linear systems to nonlinear systems (1). We assume that (1) is **autonomous,** that is, the independent variable t does not occur explicitly. (All examples in the last section are autonomous.) We shall again exhibit entire families of solutions. This is an advantage over numeric methods, which give only one (approximate) solution at a time.

Concepts needed from the last section are the **phase plane** (the y_1y_2-plane), **trajectories** (solution curves of (1) in the phase plane), the **phase portrait** of (1) (the totality of these trajectories), and **critical points** of (1) (points (y_1, y_2) at which both $f_1(y_1, y_2)$ and $f_2(y_1, y_2)$ are zero).

Now (1) may have several critical points. Then we discuss one after another. As a technical convenience, each time we first move the critical point P_0: (a, b) to be considered to the origin (0, 0). This can be done by a translation

$$\tilde{y}_1 = y_1 - a, \qquad \tilde{y}_2 = y_2 - b$$

which moves P_0 to (0, 0). Thus we can assume P_0 to be the origin (0, 0), and for simplicity we continue to write y_1, y_2 (instead of $\tilde{y}_1$, $\tilde{y}_2$). We also assume that P_0 is **isolated,** that is, it is the only critical point of (1) within a (sufficiently small) disk with center at the origin. If (1) has only finitely many critical points, this is automatically true. (Explain!)

Linearization of Nonlinear Systems

How can we determine the kind and stability property of a critical point P_0: (0, 0) of (1)? In most cases this can be done by **linearization** of (1) near P_0, writing (1) as $\mathbf{y}' = \mathbf{f}(\mathbf{y}) = \mathbf{A}\mathbf{y} + \mathbf{h}(\mathbf{y})$ and dropping $\mathbf{h}(\mathbf{y})$, as follows.

Since P_0 is critical, $f_1(0, 0) = 0$, $f_2(0, 0) = 0$, so that f_1 and f_2 have no constant terms and we can write

$$\text{(2)} \qquad \mathbf{y}' = \mathbf{A}\mathbf{y} + \mathbf{h}(\mathbf{y}), \qquad \text{thus} \qquad \begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2 + h_1(y_1, y_2) \\ y_2' &= a_{21}y_1 + a_{22}y_2 + h_2(y_1, y_2). \end{aligned}$$

$\mathbf{A}$ is constant (independent of t) since (1) is autonomous. One can prove the following (proof in Ref. [A7], pp. 375–388, listed in App. 1).

THEOREM 1

Linearization

If f_1 and f_2 in (1) *are continuous and have continuous partial derivatives in a neighborhood of the critical point P_0:* (0, 0), *and if* det $\mathbf{A} \neq 0$ *in* (2), *then the kind and stability of the critical point of* (1) *are the same as those of the* **linearized system**

$$\mathbf{y}' = \mathbf{A}\mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2 \\ y_2' &= a_{21}y_1 + a_{22}y_2. \end{aligned} \tag{3}$$

Exceptions occur if $\mathbf{A}$ *has equal or pure imaginary eigenvalues; then* (1) *may have the same kind of critical point as* (3) *or a spiral point.*

EXAMPLE 1 **Free Undamped Pendulum. Linearization**

Figure 92a shows a pendulum consisting of a body of mass m (the bob) and a rod of length L. Determine the locations and types of the critical points. Assume that the mass of the rod and air resistance are negligible.

Solution. ***Step 1. Setting up the mathematical model.*** Let θ denote the angular displacement, measured counterclockwise from the equilibrium position. The weight of the bob is mg (g the acceleration of gravity). It causes a restoring force $mg \sin\theta$ tangent to the curve of motion (circular arc) of the bob. By Newton's second law, at each instant this force is balanced by the force of acceleration $mL\theta''$, where $L\theta''$ is the acceleration; hence the resultant of these two forces is zero, and we obtain as the mathematical model

$$mL\theta'' + mg \sin\theta = 0.$$

Dividing this by mL, we have

$$\theta'' + k \sin\theta = 0 \qquad \left(k = \frac{g}{L}\right). \tag{4}$$

When θ is very small, we can approximate $\sin\theta$ rather accurately by θ and obtain as an *approximate* solution $A\cos\sqrt{k}t + B\sin\sqrt{k}t$, but the *exact* solution for any θ is not an elementary function.

Step 2. Critical points $(0, 0)$, $\pm(2\pi, 0)$, $\pm(4\pi, 0)$, $\cdots$, ***Linearization.*** To obtain a system of ODEs, we set $\theta = y_1$, $\theta' = y_2$. Then from (4) we obtain a nonlinear system (1) of the form

$$\begin{aligned} y_1' &= f_1(y_1, y_2) = y_2 \\ y_2' &= f_2(y_1, y_2) = -k \sin y_1. \end{aligned} \tag{4*}$$

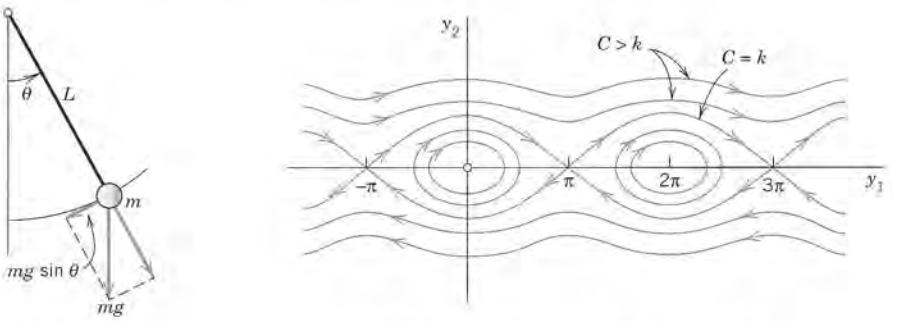
The right sides are both zero when $y_2 = 0$ and $\sin y_1 = 0$. This gives infinitely many critical points $(n\pi, 0)$, where $n = 0, \pm1, \pm2, \cdots$. We consider (0, 0). Since the Maclaurin series is

$$\sin y_1 = y_1 - \tfrac{1}{6}y_1^3 + - \cdots \approx y_1,$$

the linearized system at (0, 0) is

$$\mathbf{y}' = \mathbf{A}\mathbf{y} = \begin{bmatrix} 0 & 1 \\ -k & 0 \end{bmatrix}\mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= y_2 \\ y_2' &= -ky_1. \end{aligned}$$

To apply our criteria in Sec. 4.4 we calculate $p = a_{11} + a_{22} = 0$, $q = \det\mathbf{A} = k = g/L$ (> 0), and $\Delta = p^2 - 4q = -4k$. From this and Table 4.1(c) in Sec. 4.4 we conclude that (0, 0) is a center, which is always stable. Since $\sin\theta = \sin y_1$ is periodic with period 2π, the critical points $(n\pi, 0)$, $n = \pm2, \pm4, \cdots$, are all centers.



Step 3. Critical points $\pm(\pi, 0)$, $\pm(3\pi, 0)$, $\pm(5\pi, 0)$, $\cdots$, ***Linearization.*** We now consider the critical point $(\pi, 0)$, setting $\theta - \pi = y_1$ and $(\theta - \pi)' = \theta' = y_2$. Then in (4),

$$\sin\theta = \sin(y_1 + \pi) = -\sin y_1 = -y_1 + \tfrac{1}{6}y_1^3 - + \cdots \approx -y_1$$

and the linearized system at $(\pi, 0)$ is now

$$\mathbf{y}' = \mathbf{A}\mathbf{y} = \begin{bmatrix} 0 & 1 \\ k & 0 \end{bmatrix} \mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= y_2 \\ y_2' &= k y_1. \end{aligned}$$

We see that $p = 0$, $q = -k\ (< 0)$, and $\Delta = -4q = 4k$. Hence, by Table 4.1(b), this gives a saddle point, which is always unstable. Because of periodicity, the critical points $(n\pi, 0)$, $n = \pm 1, \pm 3, \cdots$, are all saddle points. These results agree with the impression we get from Fig. 92b. ■

(a) Pendulum (b) Solution curves $y_2(y_1)$ of (4) in the phase plane

Fig. 92. Example 1 (C will be explained in Example 4.)

EXAMPLE 2 **Linearization of the Damped Pendulum Equation**

To gain further experience in investigating critical points, as another practically important case, let us see how Example 1 changes when we add a damping term $c\theta'$ (damping proportional to the angular velocity) to equation (4), so that it becomes

$$\theta'' + c\theta' + k \sin \theta = 0 \tag{5}$$

where $k > 0$ and $c \geqq 0$ (which includes our previous case of no damping, $c = 0$). Setting $\theta = y_1$, $\theta' = y_2$, as before, we obtain the nonlinear system (use $\theta'' = y_2'$)

$$\begin{aligned} y_1' &= y_2 \\ y_2' &= -k \sin y_1 - c y_2. \end{aligned}$$

We see that the critical points have the same locations as before, namely, $(0, 0)$, $(\pm\pi, 0)$, $(\pm 2\pi, 0)$, $\cdots$. We consider $(0, 0)$. Linearizing $\sin y_1 \approx y_1$ as in Example 1, we get the linearized system at $(0, 0)$

$$\mathbf{y}' = \mathbf{A}\mathbf{y} = \begin{bmatrix} 0 & 1 \\ -k & -c \end{bmatrix} \mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= y_2 \\ y_2' &= -k y_1 - c y_2. \end{aligned} \tag{6}$$

This is identical with the system in Example 2 of Sec 4.4, except for the (positive!) factor m (and except for the physical meaning of y_1). Hence for $c = 0$ (no damping) we have a center (see Fig. 92b), for small damping we have a spiral point (see Fig. 93), and so on.

We now consider the critical point $(\pi, 0)$. We set $\theta - \pi = y_1$, $(\theta - \pi)' = \theta' = y_2$ and linearize

$$\sin \theta = \sin (y_1 + \pi) = -\sin y_1 \approx -y_1.$$

This gives the new linearized system at $(\pi, 0)$

$$\mathbf{y}' = \mathbf{A}\mathbf{y} = \begin{bmatrix} 0 & 1 \\ k & -c \end{bmatrix} \mathbf{y}, \qquad \text{thus} \qquad \begin{aligned} y_1' &= y_2 \\ y_2' &= k y_1 - c y_2. \end{aligned} \tag{6*}$$

For our criteria in Sec 4.4 we calculate $p = a_{11} + a_{22} = -c$, $q = \det \mathbf{A} = -k$, and $\Delta = p^2 - 4q = c^2 + 4k$. This gives the following results for the critical point at $(\pi, 0)$.

No damping. $c = 0$, $p = 0$, $q < 0$, $\Delta > 0$, a saddle point. See Fig. 92b.
Damping. $c > 0$, $p < 0$, $q < 0$, $\Delta > 0$, a saddle point. See Fig. 93.

Since $\sin y_1$ is periodic with period 2π, the critical points $(\pm 2\pi, 0)$, $(\pm 4\pi, 0)$, $\cdots$ are of the same type as $(0, 0)$, and the critical points $(-\pi, 0)$, $(\pm 3\pi, 0)$, $\cdots$ are of the same type as $(\pi, 0)$, so that our task is finished.

Figure 93 shows the trajectories in the case of damping. What we see agrees with our physical intuition. Indeed, damping means loss of energy. Hence instead of the closed trajectories of periodic solutions in Fig. 92b we now have trajectories spiraling around one of the critical points $(0, 0)$, $(\pm 2\pi, 0)$, $\cdots$. Even the wavy trajectories corresponding to whirly motions eventually spiral around one of these points. Furthermore, there are no more trajectories that connect critical points (as there were in the undamped case for the saddle points). ■

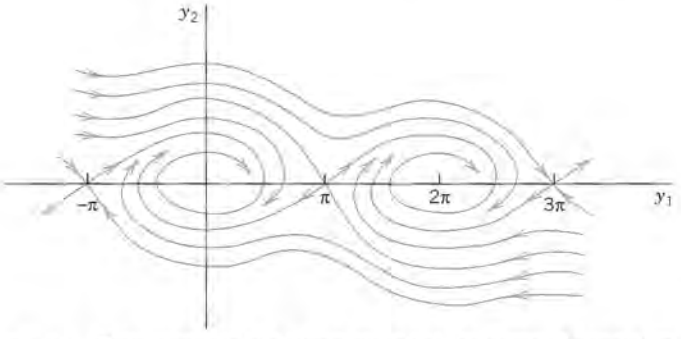


Fig. 93. Trajectories in the phase plane for the damped pendulum in Example 2

Lotka–Volterra Population Model

EXAMPLE 3 **Predator–Prey Population Model**[3]

This model concerns two species, say, rabbits and foxes, and the foxes prey on the rabbits.

Step 1. Setting up the model. We assume the following.

1. Rabbits have unlimited food supply. Hence if there were no foxes, their number $y_1(t)$ would grow exponentially, $y_1' = ay_1$.
2. Actually, y_1 is decreased because of the kill by foxes, say, at a rate proportional to y_1y_2, where $y_2(t)$ is the number of foxes. Hence $y_1' = ay_1 - by_1y_2$, where $a > 0$ and $b > 0$.
3. If there were no rabbits, then $y_2(t)$ would exponentially decrease to zero, $y_2' = -ly_2$. However, y_2 is increased by a rate proportional to the number of encounters between predator and prey; together we have $y_2' = -ly_2 + ky_1y_2$, where $k > 0$ and $l > 0$.

This gives the (nonlinear!) Lotka–Volterra system

$$\begin{aligned} y_1' &= f_1(y_1, y_2) = ay_1 - by_1y_2 \\ y_2' &= f_2(y_1, y_2) = ky_1y_2 - ly_2. \end{aligned} \tag{7}$$

[3]Introduced by ALFRED J. LOTKA (1880–1949), American biophysicist, and VITO VOLTERRA (1860–1940), Italian mathematician, the initiator of functional analysis (see [GR7] in App. 1).

Step 2. Critical point (0, 0), Linearization. We see from (7) that the critical points are the solutions of

$$(7^*) \qquad f_1(y_1, y_2) = y_1(a - by_2) = 0, \qquad f_2(y_1, y_2) = y_2(ky_1 - l) = 0.$$

The solutions are $(y_1, y_2) = (0, 0)$ and $(\frac{l}{k}, \frac{a}{b})$. We consider $(0, 0)$. Dropping $-by_1y_2$ and ky_1y_2 from (7) gives the linearized system

$$\mathbf{y}' = \begin{bmatrix} a & 0 \\ 0 & -l \end{bmatrix} \mathbf{y}.$$

Its eigenvalues are $\lambda_1 = a > 0$ and $\lambda_2 = -l < 0$. They have opposite signs, so that we get a saddle point.

Step 3. Critical point (l/k, a/b), Linearization. We set $y_1 = \tilde{y}_1 + l/k$, $y_2 = \tilde{y}_2 + a/b$. Then the critical point $(l/k, a/b)$ corresponds to $(\tilde{y}_1, \tilde{y}_2) = (0, 0)$. Since $\tilde{y}_1' = y_1'$, $\tilde{y}_2' = y_2'$, we obtain from (7) [factorized as in (8)]

$$\tilde{y}_1' = \left(\tilde{y}_1 + \frac{l}{k}\right)\left[a - b\left(\tilde{y}_2 + \frac{a}{b}\right)\right] = \left(\tilde{y}_1 + \frac{l}{k}\right)(-b\tilde{y}_2)$$

$$\tilde{y}_2' = \left(\tilde{y}_2 + \frac{a}{b}\right)\left[k\left(\tilde{y}_1 + \frac{l}{k}\right) - l\right] = \left(\tilde{y}_2 + \frac{a}{b}\right)k\tilde{y}_1.$$

Dropping the two nonlinear terms $-b\tilde{y}_1\tilde{y}_2$ and $k\tilde{y}_1\tilde{y}_2$, we have the linearized system

$$(7^{**}) \qquad \text{(a)} \quad \tilde{y}_1' = -\frac{lb}{k}\tilde{y}_2 \qquad \text{(b)} \quad \tilde{y}_2' = \frac{ak}{b}\tilde{y}_1.$$

The left side of (a) times the right side of (b) must equal the right side of (a) times the left side of (b),

$$\frac{ak}{b}\tilde{y}_1\tilde{y}_1' = -\frac{lb}{k}\tilde{y}_2\tilde{y}_2'. \qquad \text{By integration,} \qquad \frac{ak}{b}\tilde{y}_1^2 + \frac{lb}{k}\tilde{y}_2^2 = const.$$

This is a family ellipses, so that the critical point $(l/k, a/b)$ of the linearized system (7**) is a center (Fig. 94). It can be shown by a complicated analysis that the nonlinear system (7) also has a center (rather than a spiral point) at $(l/k, a/b)$ surrounded by closed trajectories (not ellipses).

We see that the predators and prey have a cyclic variation about the critical point. Let us move counterclockwise around the ellipse, beginning at the right vertex, where the rabbits have a maximum number. Foxes are sharply increasing in number until they reach a maximum at the upper vertex, and the number of rabbits is then sharply decreasing until it reaches a minimum at the left vertex, and so on. Cyclic variations of this kind have been observed in nature, for example, for lynx and snowshoe hare near the Hudson Bay, with a cycle of about 10 years.

For models of more complicated situations and a systematic discussion, see C. W. Clark, *Mathematical Bioeconomics* (Wiley, 1976). ■

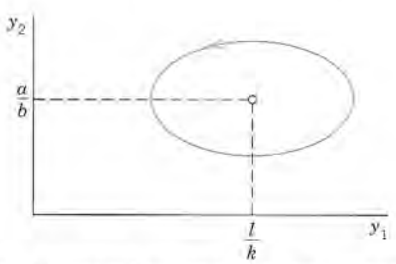

Fig. 94. Ecological equilibrium point and trajectory of the linearized Lotka–Volterra system (7**)

Transformation to a First-Order Equation in the Phase Plane

Another phase plane method is based on the idea of transforming a second-order **autonomous ODE** (an ODE in which t does not occur explicitly)

$$F(y, y', y'') = 0$$

to first order by taking $y = y_1$ as the independent variable, setting $y' = y_2$ and transforming y'' by the chain rule,

$$y'' = y_2' = \frac{dy_2}{dt} = \frac{dy_2}{dy_1}\frac{dy_1}{dt} = \frac{dy_2}{dy_1}\,y_2.$$

Then the ODE becomes of first order,

$$F\left(y_1, y_2, \frac{dy_2}{dy_1}\,y_2\right) = 0 \tag{8}$$

and can sometimes be solved or treated by direction fields. We illustrate this for the equation in Example 1 and shall gain much more insight into the behavior of solutions.

EXAMPLE 4 **An ODE (8) for the Free Undamped Pendulum**

If in (4) $\theta'' + k \sin\theta = 0$ we set $\theta = y_1$, $\theta' = y_2$ (the angular velocity) and use

$$\theta'' = \frac{dy_2}{dt} = \frac{dy_2}{dy_1}\frac{dy_1}{dt} = \frac{dy_2}{dy_1}\,y_2, \qquad \text{we get} \qquad \frac{dy_2}{dy_1}\,y_2 = -k \sin y_1.$$

Separation of variables gives $y_2\,dy_2 = -k \sin y_1\,dy_1$. By integration,

$$\tfrac{1}{2}y_2^2 = k \cos y_1 + C \qquad (C \text{ constant}). \tag{9}$$

Multiplying this by mL^2, we get

$$\tfrac{1}{2}m(Ly_2)^2 - mL^2k \cos y_1 = mL^2C.$$

We see that these three terms are **energies.** Indeed, y_2 is the angular velocity, so that Ly_2 is the velocity and the first term is the kinetic energy. The second term (including the minus sign) is the potential energy of the pendulum, and mL^2C is its total energy, which is constant, as expected from the law of conservation of energy, because there is no damping (no loss of energy). The type of motion depends on the total energy, hence on C, as follows.

Figure 92b on p. 153 shows trajectories for various values of C. These graphs continue periodically with period 2π to the left and to the right. We see that some of them are ellipse-like and closed, others are wavy, and there are two trajectories (passing through the saddle points $(n\pi, 0)$, $n = \pm 1, \pm 3, \cdots$) that separate those two types of trajectories. From (9) we see that the smallest possible C is $C = -k$; then $y_2 = 0$, and $\cos y_1 = 1$, so that the pendulum is at rest. The pendulum will change its direction of motion if there are points at which $y_2 = \theta' = 0$. Then $k \cos y_1 + C = 0$ by (9). If $y_1 = \pi$, then $\cos y_1 = -1$ and $C = k$. Hence if $-k < C < k$, then the pendulum reverses its direction for a $|y_1| = |\theta| < \pi$, and for these values of C with $|C| < k$ the pendulum oscillates. This corresponds to the closed trajectories in the figure. However, if $C > k$, then $y_2 = 0$ is impossible and the pendulum makes a whirly motion that appears as a wavy trajectory in the y_1y_2-plane. Finally, the value $C = k$ corresponds to the two "separating trajectories" in Fig. 92b connecting the saddle points. ■

The phase plane method of deriving a single first-order equation (8) may be of practical interest not only when (8) can be solved (as in Example 4) but also when solution is not possible and we have to utilize direction fields (Sec. 1.2). We illustrate this with a very famous example:

EXAMPLE 5 **Self-Sustained Oscillations. Van der Pol Equation**

There are physical systems such that for small oscillations, energy is fed into the system, whereas for large oscillations, energy is taken from the system. In other words, large oscillations will be damped, whereas for small oscillations there is "negative damping" (feeding of energy into the system). For physical reasons we expect such a system to approach a periodic behavior, which will thus appear as a closed trajectory in the phase plane, called a **limit cycle.** A differential equation describing such vibrations is the famous **van der Pol equation**[4]

$$y'' - \mu(1 - y^2)y' + y = 0 \qquad (\mu > 0, \text{ constant}). \tag{10}$$

It first occurred in the study of electrical circuits containing vacuum tubes. For $\mu = 0$ this equation becomes $y'' + y = 0$ and we obtain harmonic oscillations. Let $\mu > 0$. The damping term has the factor $-\mu(1 - y^2)$. This is negative for small oscillations, when $y^2 < 1$, so that we have "negative damping," is zero for $y^2 = 1$ (no damping), and is positive if $y^2 > 1$ (positive damping, loss of energy). If μ is small, we expect a limit cycle that is almost a circle because then our equation differs but little from $y'' + y = 0$. If μ is large, the limit cycle will probably look different.

Setting $y = y_1$, $y' = y_2$ and using $y'' = (dy_2/dy_1)y_2$ as in (8), we have from (10)

$$\frac{dy_2}{dy_1}\, y_2 - \mu(1 - y_1^2)y_2 + y_1 = 0. \tag{11}$$

The isoclines in the y_1y_2-plane (the phase plane) are the curves $dy_2/dy_1 = K = const$, that is,

$$\frac{dy_2}{dy_1} = \mu(1 - y_1^2) - \frac{y_1}{y_2} = K.$$

Solving algebraically for y_2, we see that the isoclines are given by

$$y_2 = \frac{y_1}{\mu(1 - y_1^2) - K} \qquad \text{(Figs. 95, 96).}$$

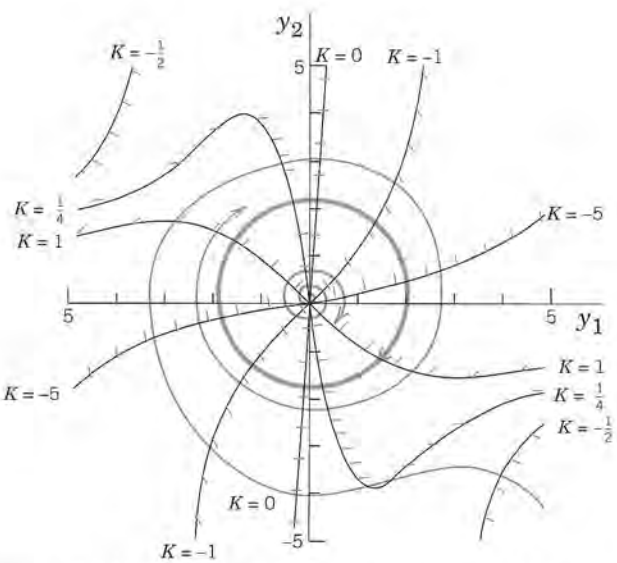

Fig. 95. Direction field for the van der Pol equation with $\mu = 0.1$ in the phase plane, showing also the limit cycle and two trajectories. See also Fig. 8 in Sec. 1.2.

[4]BALTHASAR VAN DER POL (1889–1959), Dutch physicist and engineer.

Figure 95 shows some isoclines when μ is small, $\mu = 0.1$, the limit cycle (almost a circle), and two (blue) trajectories approaching it, one from the outside and the other from the inside, of which only the initial portion, a small spiral, is shown. Due to this approach by trajectories, a limit cycle differs conceptually from a closed curve (a trajectory) surrounding a center, which is not approached by trajectories. For larger μ the limit cycle no longer resembles a circle, and the trajectories approach it more rapidly than for smaller μ. Figure 96 illustrates this for $\mu = 1$.

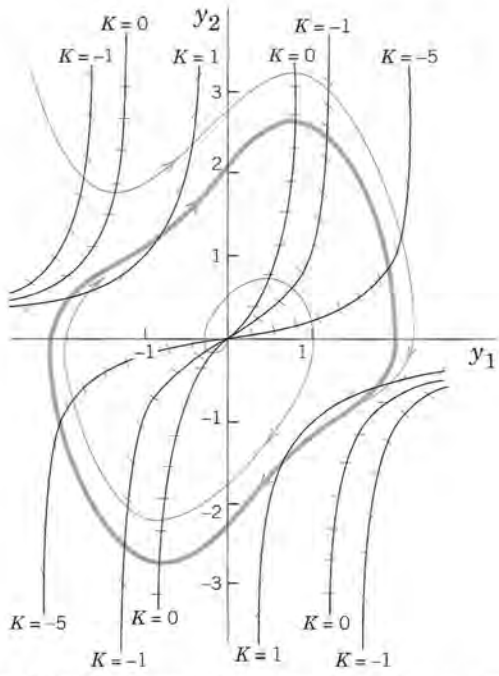

Fig. 96. Direction field for the van der Pol equation with $\mu = 1$ in the phase plane, showing also the limit cycle and two trajectories approaching it

PROBLEM SET 4.5

1–12 CRITICAL POINTS, LINEARIZATION

Determine the location and type of all critical points by linearization. In Probs. 7–12 first transform the ODE to a system. (Show the details of your work.)

1. $y_1' = y_2 + {y_2}^2$
$y_2' = 3y_1$

2. $y_1' = 4y_1 - {y_1}^2$
$y_2' = y_2$

3. $y_1' = 4y_2$
$y_2' = 2y_1 - {y_1}^2$

4. $y_1' = -3y_1 + y_2 - {y_2}^2$
$y_2' = y_1 - 3y_2$

5. $y_1' = -y_1 + y_2 - {y_2}^2$
$y_2' = -y_1 - y_2$

6. $y_1' = y_2 - {y_2}^2$
$y_2' = y_1 - {y_1}^2$

7. $y'' + y - 4y^2 = 0$

8. $y'' + 9y + y^2 = 0$

9. $y'' + \cos y = 0$

10. $y'' + \sin y = 0$

11. $y'' + 4y - y^3 = 0$

12. $y'' + y' + 2y - y^2 = 0$

13. (Trajectories) What kind of curves are the trajectories of $yy'' + 2y'^2 = 0$?

14. (Trajectories) Write the ODE $y'' - 4y + y^3 = 0$ as a system, solve it for y_2 as a function of y_1, and sketch or graph some of the trajectories in the phase plane.

15. (Trajectories) What is the radius of a real general solution of $y'' + y = 0$ in the phase plane?

16. (Trajectories) In Prob. 14 add a linear damping term to get $y'' + 2y' - 4y + y^3 = 0$. Using arguments from mechanics and a comparison with Prob. 14, as well as with Examples 1 and 2, guess the type of each critical point. Then determine these types by linearization. (Show all details of your work.)

17. **(Pendulum)** To what state (position, speed, direction of motion) do the four points of intersection of a closed trajectory with the axes in Fig. 92b correspond? The point of intersection of a wavy curve with the y_2-axis?

18. **(Limit cycle)** What is the essential difference between a limit cycle and a closed trajectory surrounding a center?

19. **CAS EXPERIMENT. Deformation of Limit Cycle.** Convert the van der Pol equation to a system. Graph the limit cycle and some approaching trajectories for $\mu = 0.2, 0.4, 0.6, 0.8, 1.0, 1.5, 2.0$. Try to observe how the limit cycle changes its form continuously if you vary μ continuously. Describe in words how the limit cycle is deformed with growing μ.

20. **TEAM PROJECT. Self-sustained oscillations.** **(a) Van der Pol Equation.** Determine the type of the critical point at (0, 0) when $\mu > 0$, $\mu = 0$, $\mu < 0$. Show that if $\mu \to 0$, the isoclines approach straight lines through the origin. Why is this to be expected?

(b) Rayleigh equation. Show that the so-called Rayleigh equation[5]

$$Y'' - \mu(1 - \tfrac{1}{3}Y'^2)Y' + Y = 0 \quad (\mu > 0)$$

also describes self-sustained oscillations and that by differentiating it and setting $y = Y'$ one obtains the van der Pol equation.

(c) Duffing equation. The Duffing equation is

$$y'' + \omega_0^2 y + \beta y^3 = 0$$

where usually $|\beta|$ is small, thus characterizing a small deviation of the restoring force from linearity. $\beta > 0$ and $\beta < 0$ are called the cases of a *hard spring* and a *soft spring*, respectively. Find the equation of the trajectories in the phase plane. (Note that for $\beta > 0$ all these curves are closed.)

4.6 Nonhomogeneous Linear Systems of ODEs

In this last section of Chap. 4 we discuss methods for solving nonhomogeneous linear systems of ODEs

$$\mathbf{y}' = \mathbf{A}\mathbf{y} + \mathbf{g} \qquad \text{(see Sec. 4.2)} \tag{1}$$

where the vector $\mathbf{g}(t)$ is not identically zero. We assume $\mathbf{g}(t)$ and the entries of the $n \times n$ matrix $\mathbf{A}(t)$ to be continuous on some interval J of the t-axis. From a general solution $\mathbf{y}^{(h)}(t)$ of the homogeneous system $\mathbf{y}' = \mathbf{A}\mathbf{y}$ on J and a **particular solution** $\mathbf{y}^{(p)}(t)$ of (1) on J [i.e., a solution of (1) containing no arbitrary constants], we get a solution of (1),

$$\mathbf{y} = \mathbf{y}^{(h)} + \mathbf{y}^{(p)}. \tag{2}$$

$\mathbf{y}$ is called a **general solution** of (1) on J because it includes every solution of (1) on J. This follows from Theorem 2 in Sec. 4.2 (see Prob. 1 of this section).

Having studied homogeneous linear systems in Secs. 4.1–4.4, our present task will be to explain methods for obtaining particular solutions of (1). We discuss the method of undetermined coefficients and the method of the variation of parameters; these have counterparts for a single ODE, as we know from Secs. 2.7 and 2.10.

---

[5]LORD RAYLEIGH (JOHN WILLIAM STRUTT) (1842–1919), great English physicist and mathematician, professor at Cambridge and London, known by his important contributions to the theory of waves, elasticity theory, hydrodynamics, and various other branches of applied mathematics and theoretical physics. In 1904 he received the Nobel Prize in physics.

Method of Undetermined Coefficients

As for a single ODE, this method is suitable if the entries of $\mathbf{A}$ are constants and the components of $\mathbf{g}$ are constants, positive integer powers of t, exponential functions, or cosines and sines. In such a case a particular solution $\mathbf{y}^{(p)}$ is assumed in a form similar to $\mathbf{g}$; for instance, $\mathbf{y}^{(p)} = \mathbf{u} + \mathbf{v}t + \mathbf{w}t^2$ if $\mathbf{g}$ has components quadratic in t, with $\mathbf{u}, \mathbf{v}, \mathbf{w}$ to be determined by substitution into (1). This is similar to Sec. 2.7, except for the Modification Rule. It suffices to show this by an example.

EXAMPLE 1 **Method of Undetermined Coefficients. Modification Rule**

Find a general solution of

$$\mathbf{y}' = \mathbf{A}\mathbf{y} + \mathbf{g} = \begin{bmatrix} -3 & 1 \\ 1 & -3 \end{bmatrix} \mathbf{y} + \begin{bmatrix} -6 \\ 2 \end{bmatrix} e^{-2t}. \tag{3}$$

Solution. A general equation of the homogeneous system is (see Example 1 in Sec. 4.3)

$$\mathbf{y}^{(h)} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-2t} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-4t}. \tag{4}$$

Since $\lambda = -2$ is an eigenvalue of $\mathbf{A}$, the function e^{-2t} on the right also appears in $\mathbf{y}^{(h)}$, and we must apply the Modification Rule by setting

$$\mathbf{y}^{(p)} = \mathbf{u}te^{-2t} + \mathbf{v}e^{-2t} \qquad \text{(rather than } \mathbf{u}e^{-2t}\text{)}.$$

Note that the first of these two terms is the analog of the modification in Sec. 2.7, but it would not be sufficient here. (Try it.) By substitution,

$$\mathbf{y}^{(p)\prime} = \mathbf{u}e^{-2t} - 2\mathbf{u}te^{-2t} - 2\mathbf{v}e^{-2t} = \mathbf{A}\mathbf{u}te^{-2t} + \mathbf{A}\mathbf{v}e^{-2t} + \mathbf{g}.$$

Equating the te^{-2t}-terms on both sides, we have $-2\mathbf{u} = \mathbf{A}\mathbf{u}$. Hence $\mathbf{u}$ is an eigenvector of $\mathbf{A}$ corresponding to $\lambda = -2$; thus [see (5)] $\mathbf{u} = a[1 \quad 1]^\mathsf{T}$ with any $a \neq 0$. Equating the other terms gives

$$\mathbf{u} - 2\mathbf{v} = \mathbf{A}\mathbf{v} + \begin{bmatrix} -6 \\ 2 \end{bmatrix} \qquad \text{thus} \qquad \begin{bmatrix} a \\ a \end{bmatrix} - \begin{bmatrix} 2v_1 \\ 2v_2 \end{bmatrix} = \begin{bmatrix} -3v_1 + v_2 \\ v_1 - 3v_2 \end{bmatrix} + \begin{bmatrix} -6 \\ 2 \end{bmatrix}.$$

Collecting terms and reshuffling gives

$$\begin{aligned} v_1 - v_2 &= -a - 6 \\ -v_1 + v_2 &= -a + 2. \end{aligned}$$

By addition, $0 = -2a - 4$, $a = -2$, and then $v_2 = v_1 + 4$, say, $v_1 = k$, $v_2 = k + 4$, thus, $\mathbf{v} = [k \quad k + 4]^\mathsf{T}$. We can simply choose $k = 0$. This gives the *answer*

$$\mathbf{y} = \mathbf{y}^{(h)} + \mathbf{y}^{(p)} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-2t} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-4t} - 2 \begin{bmatrix} 1 \\ 1 \end{bmatrix} te^{-2t} + \begin{bmatrix} 0 \\ 4 \end{bmatrix} e^{-2t}. \tag{5}$$

For other k we get other $\mathbf{v}$; for instance, $k = -2$ gives $\mathbf{v} = [-2 \quad 2]^\mathsf{T}$, so that the *answer* becomes

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-2t} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-4t} - 2 \begin{bmatrix} 1 \\ 1 \end{bmatrix} te^{-2t} + \begin{bmatrix} -2 \\ 2 \end{bmatrix} e^{-2t}, \qquad \text{etc.} \tag{5*}$$

■

Method of Variation of Parameters

This method can be applied to nonhomogeneous linear systems

$$\mathbf{y}' = \mathbf{A}(t)\mathbf{y} + \mathbf{g}(t) \tag{6}$$

with variable $\mathbf{A} = \mathbf{A}(t)$ and general $\mathbf{g}(t)$. It yields a particular solution $\mathbf{y}^{(p)}$ of (6) on some open interval J on the t-axis if a general solution of the homogeneous system $\mathbf{y}' = \mathbf{A}(t)\mathbf{y}$ on J is known. We explain the method in terms of the previous example.

EXAMPLE 2 Solution by the Method of Variation of Parameters

Solve (3) in Example 1.

Solution. A basis of solutions of the homogeneous system is $[e^{-2t} \quad e^{-2t}]^\top$ and $[e^{-4t} \quad -e^{-4t}]^\top$. Hence the general solution (4) of the homogenous system may be written

$$\mathbf{y}^{(h)} = \begin{bmatrix} e^{-2t} & e^{-4t} \\ e^{-2t} & -e^{-4t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} = \mathbf{Y}(t)\mathbf{c}. \tag{7}$$

Here, $\mathbf{Y}(t) = \left[\mathbf{y}^{(1)} \quad \mathbf{y}^{(2)}\right]^\top$ is the fundamental matrix (see Sec. 4.2). As in Sec. 2.10 we replace the constant vector $\mathbf{c}$ by a variable vector $\mathbf{u}(t)$ to obtain a particular solution

$$\mathbf{y}^{(p)} = \mathbf{Y}(t)\mathbf{u}(t).$$

Substitution into (3) $\mathbf{y}' = \mathbf{A}\mathbf{y} + \mathbf{g}$ gives

$$\mathbf{Y}'\mathbf{u} + \mathbf{Y}\mathbf{u}' = \mathbf{A}\mathbf{Y}\mathbf{u} + \mathbf{g}. \tag{8}$$

Now since $\mathbf{y}^{(1)}$ and $\mathbf{y}^{(2)}$ are solutions of the homogeneous system, we have

$$\mathbf{y}^{(1)\prime} = \mathbf{A}\mathbf{y}^{(1)}, \qquad \mathbf{y}^{(2)\prime} = \mathbf{A}\mathbf{y}^{(2)}, \qquad \text{thus} \qquad \mathbf{Y}' = \mathbf{A}\mathbf{Y}.$$

Hence $\mathbf{Y}'\mathbf{u} = \mathbf{A}\mathbf{Y}\mathbf{u}$, so that (8) reduces to

$$\mathbf{Y}\mathbf{u}' = \mathbf{g}. \qquad \text{The solution is} \qquad \mathbf{u}' = \mathbf{Y}^{-1}\mathbf{g};$$

here we use that the inverse $\mathbf{Y}^{-1}$ of $\mathbf{Y}$ (Sec. 4.0) exists because the determinant of $\mathbf{Y}$ is the Wronskian W, which is not zero for a basis. Equation (9) in Sec. 4.0 gives the form of $\mathbf{Y}^{-1}$,

$$\mathbf{Y}^{-1} = \frac{1}{-2e^{-6t}} \begin{bmatrix} -e^{-4t} & -e^{-4t} \\ -e^{-2t} & e^{-2t} \end{bmatrix} = \frac{1}{2} \begin{bmatrix} e^{2t} & e^{2t} \\ e^{4t} & -e^{4t} \end{bmatrix}.$$

We multiply this by $\mathbf{g}$, obtaining

$$\mathbf{u}' = \mathbf{Y}^{-1}\mathbf{g} = \frac{1}{2} \begin{bmatrix} e^{2t} & e^{2t} \\ e^{4t} & -e^{4t} \end{bmatrix} \begin{bmatrix} -6e^{-2t} \\ 2e^{-2t} \end{bmatrix} = \frac{1}{2} \begin{bmatrix} -4 \\ -8e^{2t} \end{bmatrix} = \begin{bmatrix} -2 \\ -4e^{2t} \end{bmatrix}.$$

Integration is done componentwise (just as differentiation) and gives

$$\mathbf{u}(t) = \int_0^t \begin{bmatrix} -2 \\ -4e^{2\tilde{t}} \end{bmatrix} d\tilde{t} = \begin{bmatrix} -2t \\ -2e^{2t} + 2 \end{bmatrix}$$

(where $+ 2$ comes from the lower limit of integration). From this and $\mathbf{Y}$ in (7) we obtain

$$\mathbf{Y}\mathbf{u} = \begin{bmatrix} e^{-2t} & e^{-4t} \\ e^{-2t} & -e^{-4t} \end{bmatrix} \begin{bmatrix} -2t \\ -2e^{2t} + 2 \end{bmatrix} = \begin{bmatrix} -2te^{-2t} - 2e^{-2t} + 2e^{-4t} \\ -2te^{-2t} + 2e^{-2t} - 2e^{-4t} \end{bmatrix} = \begin{bmatrix} -2t - 2 \\ -2t + 2 \end{bmatrix} e^{-2t} + \begin{bmatrix} 2 \\ -2 \end{bmatrix} e^{-4t}.$$

The last term on the right is a solution of the homogeneous system. Hence we can absorb it into $\mathbf{y}^{(h)}$. We thus obtain as a general solution of the system (3), in agreement with (5*),

$$\mathbf{y} = c_1 \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{-2t} + c_2 \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{-4t} - 2 \begin{bmatrix} 1 \\ 1 \end{bmatrix} te^{-2t} + \begin{bmatrix} -2 \\ 2 \end{bmatrix} e^{-2t}. \tag{9}$$

■

PROBLEM SET 4.6

1. (General solution) Prove that (2) includes every solution of (1).

2–9 GENERAL SOLUTION

Find a general solution. (Show the details of your work.)

2. $y_1' = y_2 + t$
$y_2' = y_1 - 3t$

3. $y_1' = 4y_2 + 9t$
$y_2' = -4y_1 + 5$

4. $y_1' = y_1 + y_2 + 5\cos t$
$y_2' = 3y_1 - y_2 - 5\sin t$

5. $y_1' = 2y_1 + 2y_2 + 12$
$y_2' = 5y_1 - y_2 - 30$

6. $y_1' = -y_1 + y_2 + e^{-2t}$
$y_2' = -y_1 - y_2 - e^{-2t}$

7. $y_1' = -14y_1 + 10y_2 + 162$
$y_2' = -5y_1 + y_2 - 324t$

8. $y_1' = 10y_1 - 6y_2 + 10(1 - t - t^2)$
$y_2' = 6y_1 - 10y_2 + 4 - 20t - 6t^2$

9. $y_1' = -3y_1 - 4y_2 + 11t + 15$
$y_2' = 5y_1 + 6y_2 + 3e^{-t} - 15t - 20$

10. CAS EXPERIMENT. Undetermined Coefficients. Find out experimentally how general you must choose $\mathbf{y}^{(p)}$, in particular when the components of $\mathbf{g}$ have a different form (e.g., as in Prob. 9). Write a short report, covering also the situation in the case of the modification rule.

11–16 INITIAL VALUE PROBLEM

Solve (showing details):

11. $y_1' = -2y_2 + 4t$
$y_2' = 2y_1 - 2t$
$y_1(0) = 4,\ y_2(0) = \frac{1}{2}$

12. $y_1' = 4y_2 + 5e^t$
$y_2' = -y_1 - 20e^{-t}$
$y_1(0) = 1,\ y_2(0) = 0$

13. $y_1' = y_1 + 2y_2 + e^{2t} - 2t$
$y_2' = -y_2 + 1 + t$
$y_1(0) = 1,\ y_2(0) = -4$

14. $y_1' = 3y_1 - 4y_2 + 20\cos t$
$y_2' = y_1 - 2y_2$
$y_1(0) = 0,\ y_2(0) = 8$

15. $y_1' = 4y_2 + 3e^{3t}$
$y_2' = 2y_2 - 15e^{-3t}$
$y_1(0) = 2,\ y_2(0) = 2$

16. $y_1' = 4y_1 + 8y_2 + 2\cos t - 16\sin t$
$y_2' = 6y_1 + 2y_2 + \cos t - 14\sin t$
$y_1(0) = 15,\ y_2(0) = 13$

17. (Network) Find the currents in Fig. 97 when $R = 2.5\ \Omega$, $L = 1$ H, $C = 0.04$ F, $E(t) = 845\sin t$ V, and $I_1(0) = 0$, $I_2(0) = 0$. (Show the details.)

18. (Network) Find the currents in Fig. 97 when $R = 1\ \Omega$, $L = 10$ H, $C = 1.25$ F, $E(t) = 10$ kV, and $I_1(0) = 0$, $I_2(0) = 0$. (Show the details.)

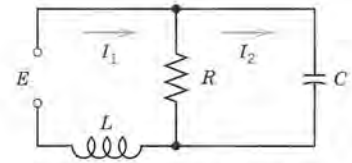

Fig. 97. Network in Probs. 17, 18

19. (Network) Find the currents in Fig. 98 when $R_1 = 2\ \Omega$, $R_2 = 8\ \Omega$, $L = 1$ H, $C = 0.5$ F, $E = 200$ V. (Show the details.)

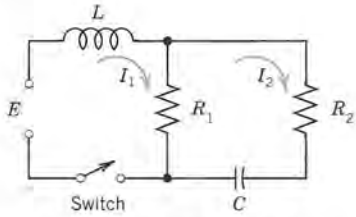

Fig. 98. Network in Prob. 19

20. WRITING PROJECT. Undetermined Coefficients. Write a short report in which you compare the application of the method of undetermined coefficients to a single ODE and to a system of two ODEs, using ODEs and systems of your choice.

CHAPTER 4 REVIEW QUESTIONS AND PROBLEMS

1. State some applications that can be modeled by systems of ODEs.
2. What is population dynamics? Give examples.
3. How can you transform an ODE into a system of ODEs?
4. What are qualitative methods for systems? Why are they important?
5. What is the phase plane? The phase plane method? The phase portrait of a system of ODEs?
6. What is a critical point of a system of ODEs? How did we classify these points?
7. What are eigenvalues? What role did they play in this chapter?
8. What does stability mean in general? In connection with critical points?
9. What does linearization of a system mean? Give an example.
10. What is a limit cycle? When may it occur in mechanics?

11–19 GENERAL SOLUTION. CRITICAL POINTS

Find a general solution. Determine the kind and stability of the critical point. (Show the details of your work.)

11. $y_1' = 4y_2$
$y_2' = 16y_1$

12. $y_1' = 9y_1$
$y_2' = y_2$

13. $y_1' = y_2$
$y_2' = 6y_1 - 5y_2$

14. $y_1' = 3y_1 - 3y_2$
$y_2' = 3y_1 + 3y_2$

15. $y_1' = 1.5y_1 - 6y_2$
$y_2' = -4.5y_1 + 3y_2$

16. $y_1' = -3y_1 - 2y_2$
$y_2' = -2y_1 - 3y_2$

17. $y_1' = 3y_1 + 2y_2$
$y_2' = 2y_1 + 3y_2$

18. $y_1' = 3y_1 + 5y_2$
$y_2' = -5y_1 - 3y_2$

19. $y_1' = -y_1 + 2y_2$
$y_2' = -2y_1 - y_2$

20–25 NONHOMOGENEOUS SYSTEMS

Find a general solution. (Show the details.)

20. $y_1' = 3y_2 + 6t$
$y_2' = 12y_1 + 1$

21. $y_1' = y_1 + 2y_2 + e^{2t}$
$y_2' = -y_2 + 1.5e^{-2t}$

22. $y_1' = y_1 + y_2 + \sin t$
$y_2' = 4y_1 + y_2$

23. $y_1' = 4y_1 + 3y_2 + 2$
$y_2' = -6y_1 - 5y_2 + 4e^{-t}$

24. $y_1' = y_1 - 2y_2 - \sin t$
$y_2' = 3y_1 - 4y_2 - \cos t$

25. $y_1' = y_1 + 2y_2 + t^2$
$y_2' = 2y_1 + y_2 - t^2$

26. (Mixing problem) Tank T_1 in Fig. 99 contains initially 200 gal of water in which 160 lb of salt are dissolved. Tank T_2 contains initially 100 gal of pure water. Liquid is pumped through the system as indicated, and the mixtures are kept uniform by stirring. Find the amounts of salt $y_1(t)$ and $y_2(t)$ in T_1 and T_2, respectively.

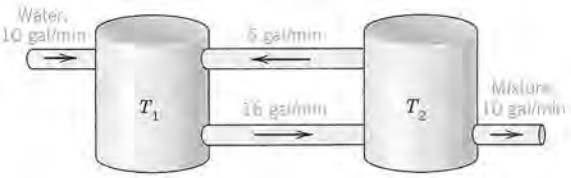

Fig. 99. Tanks in Problem 26

27. (Critical point) What kind of critical point does $\mathbf{y}' = \mathbf{Ay}$ have if $\mathbf{A}$ has the eigenvalues -6 and 1?

28. (Network) Find the currents in Fig. 100, where $R_1 = 0.5\ \Omega$, $R_2 = 0.7\ \Omega$, $L_1 = 0.4$ H, $L_2 = 0.5$ H, $E = 1$ kV $= 1000$ V, and $I_1(0) = 0$, $I_2(0) = 0$.

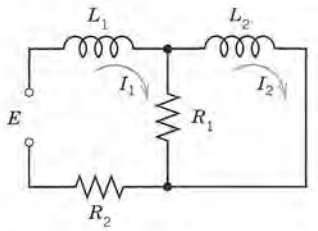

Fig. 100. Network in Problem 28

29. (Network) Find the currents in Fig. 101 when $R = 10\ \Omega$, $L = 1.25$ H, $C = 0.002$ F, and $I_1(0) = I_2(0) = 3$ A.

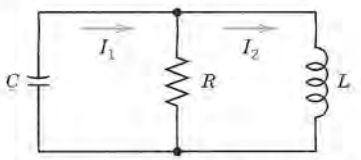

Fig. 101. Network in Problem 29

30–33 LINEARIZATION

Determine the location and kind of all critical points of the given nonlinear system by linearization.

30. $y_1' = y_2$
$y_2' = 4y_1 - y_1^3$

31. $y_1' = -9y_2$
$y_2' = \sin y_1$

32. $y_1' = \cos y_2$
$y_2' = 3y_1$

33. $y_1' = y_2 - 2y_2^2$
$y_2' = y_1 - 2y_1^2$

SUMMARY OF CHAPTER 4
Systems of ODEs. Phase Plane. Qualitative Methods

Whereas single electric circuits or single mass–spring systems are modeled by single ODEs (Chap. 2), networks of several circuits, systems of several masses and springs, and other engineering problems lead to **systems of ODEs,** involving several unknown functions $y_1(t), \cdots, y_n(t)$. Of central interest are **first-order systems** (Sec. 4.2):

$$\mathbf{y}' = \mathbf{f}(t, \mathbf{y}), \qquad \text{in components,} \qquad \begin{aligned} y_1' &= f_1(t, y_1, \cdots, y_n) \\ &\vdots \\ y_n' &= f_n(t, y_1, \cdots, y_n), \end{aligned}$$

to which higher order ODEs and systems of ODEs can be reduced (Sec. 4.1). In this summary we let $n = 2$, so that

$$(1) \qquad \mathbf{y}' = \mathbf{f}(t, \mathbf{y}), \qquad \text{in components,} \qquad \begin{aligned} y_1' &= f_1(t, y_1, y_2) \\ y_2' &= f_2(t, y_1, y_2) \end{aligned}$$

Then we can represent solution curves as **trajectories** in the **phase plane** (the y_1y_2-plane), investigate their totality [the **"phase portrait"** of (1)], and study the kind and **stability** of the **critical points** (points at which both f_1 and f_2 are zero), and classify them as **nodes, saddle points, centers,** or **spiral points** (Secs. 4.3, 4.4). These phase plane methods are **qualitative;** with their use we can discover various general properties of solutions without actually solving the system. They are primarily used for **autonomous systems,** that is, systems in which t does not occur explicitly.

A **linear system** is of the form

$$(2) \quad \mathbf{y}' = \mathbf{A}\mathbf{y} + \mathbf{g}, \quad \text{where} \quad \mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}, \quad \mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}, \quad \mathbf{g} = \begin{bmatrix} g_1 \\ g_2 \end{bmatrix}.$$

If $\mathbf{g} = \mathbf{0}$, the system is called **homogeneous** and is of the form

$$(3) \qquad \mathbf{y}' = \mathbf{A}\mathbf{y}.$$

If $a_{11}, \cdots, a_{22}$ are constants, it has solutions $\mathbf{y} = \mathbf{x}e^{\lambda t}$, where λ is a solution of the quadratic equation

$$\begin{vmatrix} a_{11} - \lambda & a_{12} \\ a_{21} & a_{22} - \lambda \end{vmatrix} = (a_{11} - \lambda)(a_{22} - \lambda) - a_{12}a_{21} = 0$$

and $\mathbf{x} \neq \mathbf{0}$ has components x_1, x_2 determined up to a multiplicative constant by

$$(a_{11} - \lambda)x_1 + a_{12}x_2 = 0.$$

(These λ's are called the **eigenvalues** and these vectors **x eigenvectors** of the matrix **A.** Further explanation is given in Sec. 4.0.)

A system (2) with $\mathbf{g} \neq \mathbf{0}$ is called **nonhomogeneous.** Its general solution is of the form $\mathbf{y} = \mathbf{y}_h + \mathbf{y}_p$, where $\mathbf{y}_h$ is a general solution of (3) and $\mathbf{y}_p$ a particular solution of (2). Methods of determining the latter are discussed in Sec. 4.6.

The discussion of critical points of linear systems based on eigenvalues is summarized in Tables 4.1 and 4.2 in Sec. 4.4. It also applies to nonlinear systems if the latter are first linearized. The key theorem for this is Theorem 1 in Sec. 4.5, which also includes three famous applications, namely the pendulum and van der Pol equations and the Lotka–Volterra predator–prey population model.

CHAPTER 5

Series Solutions of ODEs. Special Functions

In Chaps. 2 and 3 we have seen that linear ODEs with *constant* coefficients can be solved by functions known from calculus. However, if a linear ODE has *variable* coefficients (functions of x), it must usually be solved by other methods, as we shall see in this chapter.

Legendre polynomials, Bessel functions, and eigenfunction expansions are the three main topics in this chapter. These are of greatest importance to the applied mathematician.

Legendre's ODE and **Legendre polynomials** (Sec. 5.3) are likely to occur in problems showing *spherical symmetry*. They are obtained by the **power series method** (Secs. 5.1, 5.2), which gives solutions of ODEs in power series.

Bessel's ODE and **Bessel functions** (Secs. 5.5, 5.6) are likely to occur in problems showing *cylindrical symmetry*. They are obtained by the **Frobenius method** (Sec. 5.4), an extension of the power series method which gives solutions of ODEs in power series, possibly multiplied by a logarithmic term or by a fractional power.

Eigenfunction expansions (Sec. 5.8) are infinite series obtained by the **Sturm–Liouville theory** (Sec. 5.7). The terms of these series may be Legendre polynomials or other functions, and their coefficients are obtained by the **orthogonality** of those functions. These expansions include **Fourier series** in terms of cosine and sine, which are so important that we shall devote a whole chapter (Chap. 11) to them.

Special functions (also called **higher functions**) is a name for more advanced functions not considered in calculus. If a function occurs in many applications, it gets a name, and its properties and values are investigated in all details, resulting in hundreds of formulas which together with the underlying theory often fill whole books. This is what has happened to the gamma, Legendre, Bessel, and several other functions (take a look into Refs. [GR1], [GR10], [A11] in App. 1).

Your CAS knows most of the special functions and corresponding formulas that you will ever need in your later work in industry, and this chapter will give you a feel for the basics of their theory and their application in modeling.

COMMENT. You can study this chapter directly after Chap. 2 because it needs no material from Chaps. 3 or 4.

Prerequisite: Chap. 2.
Sections that may be omitted in a shorter course: 5.2, 5.6–5.8.
References and Answers to Problems: App. 1 Part A, and App. 2.

5.1 Power Series Method

The **power series method** is the standard method for solving linear ODEs with ***variable*** coefficients. It gives solutions in the form of power series. These series can be used for computing values, graphing curves, proving formulas, and exploring properties of solutions, as we shall see. In this section we begin by explaining the idea of the power series method.

Power Series

From calculus we recall that a **power series** (in powers of $x - x_0$) is an infinite series of the form

$$\textbf{(1)} \qquad \sum_{m=0}^{\infty} a_m(x - x_0)^m = a_0 + a_1(x - x_0) + a_2(x - x_0)^2 + \cdots.$$

Here, x is a variable. a_0, a_1, a_2, $\cdots$ are constants, called the **coefficients** of the series. x_0 is a constant, called the **center** of the series. In particular, if $x_0 = 0$, we obtain a **power series in powers of x**

$$\textbf{(2)} \qquad \sum_{m=0}^{\infty} a_m x^m = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + \cdots.$$

We shall assume that all variables and constants are real.

Familiar examples of power series are the Maclaurin series

$$\frac{1}{1 - x} = \sum_{m=0}^{\infty} x^m = 1 + x + x^2 + \cdots \qquad (|x| < 1, \textbf{ geometric series})$$

$$e^x = \sum_{m=0}^{\infty} \frac{x^m}{m!} = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots$$

$$\cos x = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{(2m)!} = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - + \cdots$$

$$\sin x = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+1}}{(2m + 1)!} = x - \frac{x^3}{3!} + \frac{x^5}{5!} - + \cdots.$$

We note that the term "power series" usually refers to a series of the form (1) [or (2)] but ***does not include*** series of negative or fractional powers of x. We use m as the summation letter, reserving n as a standard notation in the Legendre and Bessel equations for integer values of the parameter.

Idea of the Power Series Method

The idea of the power series method for solving ODEs is simple and natural. We describe the practical procedure and illustrate it for two ODEs whose solution we know, so that

we can see what is going on. The mathematical justification of the method follows in the next section.

For a given ODE

$$y'' + p(x)y' + q(x)y = 0$$

we first represent $p(x)$ and $q(x)$ by power series in powers of x (or of $x - x_0$ if solutions in powers of $x - x_0$ are wanted). Often $p(x)$ and $q(x)$ are polynomials, and then nothing needs to be done in this first step. Next we assume a solution in the form of a power series with unknown coefficients,

$$y = \sum_{m=0}^{\infty} a_m x^m = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + \cdots \tag{3}$$

and insert this series and the series obtained by termwise differentiation,

$$\text{(a)} \quad y' = \sum_{m=1}^{\infty} m a_m x^{m-1} = a_1 + 2a_2 x + 3a_3 x^2 + \cdots$$

$$\text{(b)} \quad y'' = \sum_{m=2}^{\infty} m(m-1) a_m x^{m-2} = 2a_2 + 3 \cdot 2a_3 x + 4 \cdot 3a_4 x^2 + \cdots \tag{4}$$

into the ODE. Then we collect like powers of x and equate the sum of the coefficients of each occurring power of x to zero, starting with the constant terms, then taking the terms containing x, then the terms in x^2, and so on. This gives equations from which we can determine the unknown coefficients of (3) successively.

Let us show this for two simple ODEs that can also be solved by elementary methods, so that we would not need power series.

EXAMPLE 1 Solve the following ODE by power series. To grasp the idea, do this by hand; do not use your CAS (for which you could program the whole process).

$$y' = 2xy.$$

Solution. We insert (3) and (4a) into the given ODE, obtaining

$$a_1 + 2a_2 x + 3a_3 x^2 + \cdots = 2x(a_0 + a_1 x + a_2 x^2 + \cdots).$$

We must perform the multiplication by $2x$ on the right and can write the resulting equation conveniently as

$$\begin{aligned} a_1 + 2a_2 x + 3a_3 x^2 + 4a_4 x^3 + 5a_5 x^4 + 6a_6 x^5 + \cdots \\ = \quad 2a_0 x + 2a_1 x^2 + 2a_2 x^3 + 2a_3 x^4 + 2a_4 x^5 + \cdots. \end{aligned}$$

For this equation to hold, the two coefficients of every power of x on both sides must be equal, that is,

$$a_1 = 0, \quad 2a_2 = 2a_0, \quad 3a_3 = 2a_1, \quad 4a_4 = 2a_2, \quad 5a_5 = 2a_3, \quad 6a_6 = 2a_4, \cdots.$$

Hence $a_3 = 0$, $a_5 = 0$, $\cdots$ and for the coefficients with even subscripts,

$$a_2 = a_0, \quad a_4 = \frac{a_2}{2} = \frac{a_0}{2!}, \quad a_6 = \frac{a_4}{3} = \frac{a_0}{3!}, \cdots;$$

a_0 remains arbitrary. With these coefficients the series (3) gives the following solution, which you should confirm by the method of separating variables.

$$y = a_0\left(1 + x^2 + \frac{x^4}{2!} + \frac{x^6}{3!} + \frac{x^8}{4!} + \cdots\right) = a_0 e^{x^2}.$$

More rapidly, (3) and (4) give for the ODE $y' = 2xy$

$$1 \cdot a_1 x^0 + \sum_{m=2}^{\infty} m a_m x^{m-1} = 2x \sum_{m=0}^{\infty} a_m x^m = \sum_{m=0}^{\infty} 2a_m x^{m+1}.$$

Now, to get the same general power on both sides, we make a **"shift of index"** on the left by setting $m = s + 2$, thus $m - 1 = s + 1$. Then a_m becomes a_{s+2} and x^{m-1} becomes x^{s+1}. Also the summation, which started with $m = 2$, now starts with $s = 0$ because $s = m - 2$. On the right we simply make a change of notation $m = s$, hence $a_m = a_s$ and $x^{m+1} = x^{s+1}$; also the summation now starts with $s = 0$. This altogether gives

$$a_1 + \sum_{s=0}^{\infty} (s + 2)a_{s+2}x^{s+1} = \sum_{s=0}^{\infty} 2a_s x^{s+1}.$$

Every occurring power of x must have the same coefficient on both sides; hence

$$a_1 = 0 \qquad \text{and} \qquad (s + 2)a_{s+2} = 2a_s \qquad \text{or} \qquad a_{s+2} = \frac{2}{s + 2}a_s.$$

For $s = 0, 1, 2, \cdots$ we thus have $a_2 = (2/2)a_0$, $a_3 = (2/3)a_1 = 0$, $a_4 = (2/4)a_2, \cdots$ as before. ■

EXAMPLE 2 Solve

$$y'' + y = 0.$$

Solution. By inserting (3) and (4b) into the ODE we have

$$\sum_{m=2}^{\infty} m(m - 1)a_m x^{m-2} + \sum_{m=0}^{\infty} a_m x^m = 0.$$

To obtain the same general power on both series, we set $m = s + 2$ in the first series and $m = s$ in the second, and then we take the latter to the right side. This gives

$$\sum_{s=0}^{\infty} (s + 2)(s + 1)a_{s+2}x^s = -\sum_{s=0}^{\infty} a_s x^s.$$

Each power x^s must have the same coefficient on both sides. Hence $(s + 2)(s + 1)a_{s+2} = -a_s$. This gives the **recursion formula**

$$a_{s+2} = -\frac{a_s}{(s + 2)(s + 1)} \qquad (s = 0, 1, \cdots).$$

We thus obtain successively

$$a_2 = -\frac{a_0}{2 \cdot 1} = -\frac{a_0}{2!}, \qquad a_3 = -\frac{a_1}{3 \cdot 2} = -\frac{a_1}{3!}$$

$$a_4 = -\frac{a_2}{4 \cdot 3} = \frac{a_0}{4!}, \qquad a_5 = -\frac{a_3}{5 \cdot 4} = \frac{a_1}{5!}.$$

and so on. a_0 and a_1 remain arbitrary. With these coefficients the series (3) becomes

$$y = a_0 + a_1 x - \frac{a_0}{2!}x^2 - \frac{a_1}{3!}x^3 + \frac{a_0}{4!}x^4 + \frac{a_1}{5!}x^5 + \cdots.$$

Reordering terms (which is permissible for a power series), we can write this in the form

$$y = a_0\left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - + \cdots\right) + a_1\left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - + \cdots\right)$$

and we recognize the familiar general solution

$$y = a_0 \cos x + a_1 \sin x.$$ ■

Do we need the power series method for these or similar ODEs? Of course not; we used them just for explaining the idea of the method. What happens if we apply the method to an ODE not of the kind considered so far, even to an innocent-looking one such as $y'' + xy = 0$ ("Airy's equation")? We most likely end up with new special functions given by power series. And if such an ODE and its solutions are of practical (or theoretical) interest, we name and investigate them in terms of formulas and graphs and by numeric methods.

We shall discuss Legendre's, Bessel's, and the hypergeometric equations and their solutions, to mention just the most prominent of these ODEs. To do this with a good understanding, also in the light of your CAS, we first explain the power series method (and later an extension, the Frobenius method) in more detail.

PROBLEM SET 5.1

1–10 POWER SERIES METHOD: TECHNIQUE, FEATURES

Apply the power series method. Do this by hand, not by a CAS, so that you get a feel for the method, e.g., why a series may terminate, or has even powers only, or has no constant or linear terms, etc. Show the details of your work.

1. $y' - y = 0$

2. $y' + xy = 0$

3. $y'' + 4y = 0$

4. $y'' - y = 0$

5. $(2 + x)y' = y$

6. $y' + 3(1 + x^2)y = 0$

7. $y' = y + x$

8. $(x^5 + 4x^3)y' = (5x^4 + 12x^2)y$

9. $y'' - y' = 0$

10. $y'' - xy' + y = 0$

11–16 CAS PROBLEMS. INITIAL VALUE PROBLEMS

Solve the initial value problems by a power series. Graph the partial sum s of the powers up to and including x^5. Find the value of s (5 digits) at x_1.

11. $y' + 4y = 1$, $y(0) = 1.25$, $x_1 = 0.2$

12. $y' = 1 + y^2$, $y(0) = 0$, $x_1 = \frac{1}{4}\pi$

13. $y' = y - y^2$, $y(0) = \frac{1}{2}$, $x_1 = 1$

14. $(x - 2)y' = xy$, $y(0) = 4$, $x_1 = 2$

15. $y'' + 3xy' + 2y = 0$, $y(0) = 1$, $y'(0) = 1$, $x_1 = 0.5$

16. $(1 - x^2)y'' - 2xy' + 30y = 0$, $y(0) = 0$, $y'(0) = 1.875$, $x_1 = 0.5$

17. WRITING PROJECT. Power Series. Write a review (2–3 pages) on power series as they are discussed in calculus, using your own formulation and examples—do not just copy passages from calculus texts.

18. LITERATURE PROJECT. Maclaurin Series. Collect Maclaurin series of the functions known from calculus and arrange them systematically in a list that you can use for your work.

5.2 Theory of the Power Series Method

In the last section we saw that the power series method gives solutions of ODEs in the form of power series. In this section we justify the method mathematically as follows. We first review relevant facts on power series from calculus. Then we list the operations on power series needed in the method (differentiation, addition, multiplication, etc.). Near the end we state the basic existence theorem for power series solutions of ODEs.

Basic Concepts

Recall from calculus that a power series is an infinite series of the form

$$\textbf{(1)} \qquad \sum_{m=0}^{\infty} a_m(x - x_0)^m = a_0 + a_1(x - x_0) + a_2(x - x_0)^2 + \cdots$$

As before, we assume the variable x, the **center** x_0, and the **coefficients** $a_0, a_1, \cdots$ to be real. The ***n*th partial sum** of (1) is

$$\textbf{(2)} \qquad s_n(x) = a_0 + a_1(x - x_0) + a_2(x - x_0)^2 + \cdots + a_n(x - x_0)^n$$

where $n = 0, 1, \cdots$. Clearly, if we omit the terms of s_n from (1), the remaining expression is

$$\textbf{(3)} \qquad R_n(x) = a_{n+1}(x - x_0)^{n+1} + a_{n+2}(x - x_0)^{n+2} + \cdots.$$

This expression is called the **remainder** *of* (1) *after the term* $a_n(x - x_0)^n$.

For example, in the case of the geometric series

$$1 + x + x^2 + \cdots + x^n + \cdots$$

we have

$$\begin{aligned} s_0 &= 1, & R_0 &= x + x^2 + x^3 + \cdots, \\ s_1 &= 1 + x, & R_1 &= x^2 + x^3 + x^4 + \cdots, \\ s_2 &= 1 + x + x^2, & R_2 &= x^3 + x^4 + x^5 + \cdots, \qquad \text{etc.} \end{aligned}$$

In this way we have now associated with (1) the sequence of the partial sums $s_0(x), s_1(x), s_2(x), \cdots$. If for some $x = x_1$ this sequence converges, say,

$$\lim_{n\to\infty} s_n(x_1) = s(x_1),$$

then the series (1) is called **convergent** *at* $x = x_1$, the number $s(x_1)$ is called the **value** or *sum* of (1) at x_1, and we write

$$s(x_1) = \sum_{m=0}^{\infty} a_m(x_1 - x_0)^m.$$

Then we have for every n,

$$(4) \qquad s(x_1) = s_n(x_1) + R_n(x_1).$$

If that sequence diverges at $x = x_1$, the series (1) is called **divergent** at $x = x_1$.

In the case of convergence, for any positive ϵ there is an N (depending on ϵ) such that, by (4),

$$(5) \qquad |R_n(x_1)| = |s(x_1) - s_n(x_1)| < \epsilon \qquad \text{for all } n > N.$$

Geometrically, this means that all $s_n(x_1)$ with $n > N$ lie between $s(x_1) - \epsilon$ and $s(x_1) + \epsilon$ (Fig. 102). Practically, this means that in the case of convergence we can approximate the sum $s(x_1)$ of (1) at x_1 by $s_n(x_1)$ as accurately as we please, by taking n large enough.

Convergence Interval. Radius of Convergence

With respect to the convergence of the power series (1) there are three cases, the useless Case 1, the usual Case 2, and the best Case 3, as follows.

Case 1. The series (1) always converges at $x = x_0$, because for $x = x_0$ all its terms are zero, perhaps except for the first one, a_0. In exceptional cases $x = x_0$ may be the only x for which (1) converges. Such a series is of no practical interest.

Case 2. If there are further values of x for which the series converges, these values form an interval, called the **convergence interval.** If this interval is finite, it has the midpoint x_0, so that it is of the form

$$|x - x_0| < R \qquad \text{(Fig. 103)} \tag{6}$$

and the series (1) converges for all x such that $|x - x_0| < R$ and diverges for all x such that $|x - x_0| > R$. (No general statement about convergence or divergence can be made for $x - x_0 = R$ or $-R$.) The number R is called the **radius of convergence** of (1). (R is called "radius" because for a *complex* power series it is the radius of a disk of convergence.) R can be obtained from either of the formulas

$$\text{(a)}\quad R = 1\Big/\lim_{m\to\infty} \sqrt[m]{|a_m|} \qquad \text{(b)}\quad R = 1\Big/\lim_{m\to\infty} \left|\frac{a_{m+1}}{a_m}\right| \tag{7}$$

provided these limits exist and are not zero. [If these limits are infinite, then (1) converges only at the center x_0.]

Case 3. The convergence interval may sometimes be infinite, that is, (1) converges for all x. For instance, if the limit in (7a) or (7b) is zero, this case occurs. One then writes $R = \infty$, for convenience. (Proofs of all these facts can be found in Sec. 15.2.)

For each x for which (1) converges, it has a certain value $s(x)$. We say that (1) **represents** the function $s(x)$ in the convergence interval and write

$$s(x) = \sum_{m=0}^{\infty} a_m(x - x_0)^m \qquad (|x - x_0| < R).$$

Let us illustrate these three possible cases with typical examples.

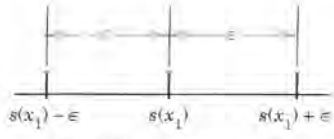

Fig. 102. Inequality (5)

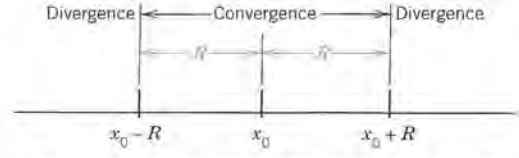

Fig. 103. Convergence interval (6) of a power series with center x_0

EXAMPLE 1 The Useless Case 1 of Convergence Only at the Center

In the case of the series

$$\sum_{m=0}^{\infty} m!x^m = 1 + x + 2x^2 + 6x^3 + \cdots$$

we have $a_m = m!$, and in (7b),

$$\frac{a_{m+1}}{a_m} = \frac{(m+1)!}{m!} = m + 1 \to \infty \qquad \text{as } m \to \infty.$$

Thus this series converges only at the center $x = 0$. Such a series is useless. ■

EXAMPLE 2 The Usual Case 2 of Convergence in a Finite Interval. Geometric Series

For the **geometric series** we have

$$\frac{1}{1-x} = \sum_{m=0}^{\infty} x^m = 1 + x + x^2 + \cdots \qquad (|x| < 1).$$

In fact, $a_m = 1$ for all m, and from (7) we obtain $R = 1$, that is, the geometric series converges and represents $1/(1 - x)$ when $|x| < 1$. ■

EXAMPLE 3 The Best Case 3 of Convergence for All *x*

In the case of the series

$$e^x = \sum_{m=0}^{\infty} \frac{x^m}{m!} = 1 + x + \frac{x^2}{2!} + \cdots$$

we have $a_m = 1/m!$. Hence in (7b),

$$\frac{a_{m+1}}{a_m} = \frac{1/(m+1)!}{1/m!} = \frac{1}{m+1} \to 0 \qquad \text{as } m \to \infty,$$

so that the series converges for all x. ■

EXAMPLE 4 Hint for Some of the Problems

Find the radius of convergence of the series

$$\sum_{m=0}^{\infty} \frac{(-1)^m}{8^m} x^{3m} = 1 - \frac{x^3}{8} + \frac{x^6}{64} - \frac{x^9}{512} + - \cdots.$$

Solution. This is a series in powers of $t = x^3$ with coefficients $a_m = (-1)^m/8^m$, so that in (7b),

$$\left| \frac{a_{m+1}}{a_m} \right| = \frac{8^m}{8^{m+1}} = \frac{1}{8}.$$

Thus $R = 8$. Hence the series converges for $|t| = |x^3| < 8$, that is, $|x| < 2$. ■

Operations on Power Series

In the power series method we differentiate, add, and multiply power series. These three operations are permissible, in the sense explained in what follows. We also list a condition about the vanishing of all coefficients of a power series, which is a basic tool of the power series method. (Proofs can be found in Sec. 15.3.)

Termwise Differentiation

A power series may be differentiated term by term. More precisely: if

$$y(x) = \sum_{m=0}^{\infty} a_m(x - x_0)^m$$

converges for $|x - x_0| < R$, where $R > 0$, then the series obtained by differentiating term by term also converges for those x and represents the derivative y' of y for those x, that is,

$$y'(x) = \sum_{m=1}^{\infty} m a_m(x - x_0)^{m-1} \qquad (|x - x_0| < R).$$

Similarly,

$$y''(x) = \sum_{m=2}^{\infty} m(m-1) a_m(x - x_0)^{m-2} \qquad (|x - x_0| < R), \text{ etc.}$$

Termwise Addition

Two power series may be added term by term. More precisely: if the series

$$(8) \qquad \sum_{m=0}^{\infty} a_m(x - x_0)^m \qquad \text{and} \qquad \sum_{m=0}^{\infty} b_m(x - x_0)^m$$

have positive radii of convergence and their sums are $f(x)$ and $g(x)$, then the series

$$\sum_{m=0}^{\infty} (a_m + b_m)(x - x_0)^m$$

converges and represents $f(x) + g(x)$ for each x that lies in the interior of the convergence interval of each of the two given series.

Termwise Multiplication

Two power series may be multiplied term by term. More precisely: Suppose that the series (8) have positive radii of convergence and let $f(x)$ and $g(x)$ be their sums. Then the series obtained by multiplying each term of the first series by each term of the second series and collecting like powers of $x - x_0$, that is,

$$\sum_{m=0}^{\infty} (a_0 b_m + a_1 b_{m-1} + \cdots + a_m b_0)(x - x_0)^m$$
$$= a_0 b_0 + (a_0 b_1 + a_1 b_0)(x - x_0) + (a_0 b_2 + a_1 b_1 + a_2 b_0)(x - x_0)^2 + \cdots$$

converges and represents $f(x)g(x)$ for each x in the interior of the convergence interval of each of the two given series.

Vanishing of All Coefficients

If a power series has a positive radius of convergence and a sum that is identically zero throughout its interval of convergence, then each coefficient of the series must be zero.

Existence of Power Series Solutions of ODEs. Real Analytic Functions

The properties of power series just discussed form the foundation of the power series method. The remaining question is whether an ODE has power series solutions at all. An answer is simple: If the coefficients p and q and the function r on the right side of

$$y'' + p(x)y' + q(x)y = r(x) \tag{9}$$

have power series representations, then (9) has power series solutions. The same is true if $\tilde{h}$, $\tilde{p}$, $\tilde{q}$, and $\tilde{r}$ in

$$\tilde{h}(x)y'' + \tilde{p}(x)y' + \tilde{q}(x)y = \tilde{r}(x) \tag{10}$$

have power series representations and $\tilde{h}(x_0) \neq 0$ (x_0 the center of the series). Almost all ODEs in practice have polynomials as coefficients (thus terminating power series), so that (when $r(x) \equiv 0$ or is a power series, too) those conditions are satisfied, except perhaps the condition $\tilde{h}(x_0) \neq 0$. If $\tilde{h}(x_0) \neq 0$, division of (10) by $\tilde{h}(x)$ gives (9) with $p = \tilde{p}/\tilde{h}$, $q = \tilde{q}/\tilde{h}$, $r = \tilde{r}/\tilde{h}$. This motivates our notation in (10).

To formulate all this in a precise and simple way, we use the following concept (which is of general interest).

DEFINITION

Real Analytic Function

A real function $f(x)$ is called **analytic** *at a point* $x = x_0$ if it can be represented by a power series in powers of $x - x_0$ with radius of convergence $R > 0$.

Using this concept, we can state the following basic theorem.

THEOREM 1

Existence of Power Series Solutions

If p, q, and r in (9) *are analytic at $x = x_0$, then every solution of* (9) *is analytic at $x = x_0$ and can thus be represented by a power series in powers of $x - x_0$ with radius of convergence $R > 0$. Hence the same is true if $\tilde{h}$, $\tilde{p}$, $\tilde{q}$, and $\tilde{r}$ in* (10) *are analytic at $x = x_0$ and $\tilde{h}(x_0) \neq 0$.*

The proof of this theorem requires advanced methods of complex analysis and can be found in Ref. [A11] listed in App. 1.

We mention that the radius of convergence R in Theorem 1 is at least equal to the distance from the point $x = x_0$ to the point (or points) closest to x_0 at which one of the functions p, q, r, as functions of a *complex variable,* is not analytic. (Note that that point may not lie on the x-axis but somewhere in the complex plane.)

PROBLEM SET 5.2

1–12 RADIUS OF CONVERGENCE

Determine the radius of convergence. (Show the details.)

1. $\sum_{m=0}^{\infty} \frac{x^m}{c^m} \quad (c \neq 0)$
2. $\sum_{m=0}^{\infty} \frac{(-1)^m}{3^m(m+1)^2}(x+1)^{2m}$
3. $\sum_{m=1}^{\infty} \frac{(m+1)m}{2^m}(x-3)^{2m}$
4. $\sum_{m=0}^{\infty} (-1)^m x^{4m}$
5. $\sum_{m=0}^{\infty} \frac{(2m)!}{(2m+2)(2m+4)} x^m$
6. $\sum_{m=0}^{\infty} \frac{(-1)^m}{(m!)^2} x^{2m+10}$
7. $\sum_{m=2}^{\infty} \frac{(-1)^m}{4^m}(x-1)^{2m}$
8. $\sum_{m=1}^{\infty} \frac{(4m)!}{(m!)^4} x^m$
9. $\sum_{m=4}^{\infty} \frac{(m+3)^2}{(m-3)^4} x^m$
10. $\sum_{m=1}^{\infty} \frac{(2m)!}{m^2} x^m$
11. $\sum_{m=1}^{\infty} \frac{1}{\pi^m}(x-\frac{1}{2}\pi)^m$
12. $\sum_{m=1}^{\infty} \frac{(m+1)m}{(2m+1)!} x^{2m+1}$

13–15 SHIFTING SUMMATION INDICES (CF. SEC. 5.1)

This is often convenient or necessary in the power series method. Shift the index so that the power under the summation sign is x^s. Check by writing the first few terms explicitly. Also determine the radius of convergence R.

13. $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{5n} x^{n+2}$
14. $\sum_{m=3}^{\infty} \frac{(-1)^{m+1}}{4^m} x^{m-3}$
15. $\sum_{p=1}^{\infty} \frac{p^2}{(p+1)!} x^{p+4}$

16–23 POWER SERIES SOLUTIONS

Find a power series solution in powers of x. (Show the details of your work.)

16. $y'' + xy = 0$
17. $y'' - y' + x^2y = 0$
18. $y'' - y' + xy = 0$
19. $y'' + 4xy' = 0$
20. $y'' + 2xy' + y = 0$
21. $y'' + (1 + x^2)y = 0$
22. $y'' - 4xy' + (4x^2 - 2)y = 0$
23. $(2x^2 - 3x + 1)y'' + 2xy' - 2y = 0$

24. **TEAM PROJECT. Properties from Power Series.** In the next sections we shall define new functions (Legendre functions, etc.) by power series, deriving properties of the functions directly from the series. To understand this idea, do the same for functions familiar from calculus, using Maclaurin series.

    (a) Show that $\cosh x + \sinh x = e^x$. Show that $\cosh x > 0$ for all x. Show that $e^x \geqq e^{-x}$ for all $x \geqq 0$.

    (b) Derive the differentiation formulas for e^x, $\cos x$, $\sin x$, $1/(1-x)$ and other functions of your choice. Show that $(\cos x)'' = -\cos x$, $(\cosh x)'' = \cosh x$. Consider integration similarly.

    (c) What can you conclude if a series contains only odd powers? Only even powers? No constant term? If all its coefficients are positive? Give examples.

    (d) What properties of $\cos x$ and $\sin x$ are *not* obvious from the Maclaurin series? What properties of other functions?

25. **CAS EXPERIMENT. Information from Graphs of Partial Sums.** In connection with power series in numerics we use partial sums. To get a feel for the accuracy for various x, experiment with $\sin x$ and graphs of partial sums of the Maclaurin series of an increasing number of terms, describing qualitatively the "breakaway points" of these graphs from the graph of $\sin x$. Consider other examples of your own choice.

5.3 Legendre's Equation. Legendre Polynomials $P_n(x)$

In order to first gain skill, we have applied the power series method to ODEs that can also be solved by other methods. We now turn to the first "big" equation of physics, for which we do need the power series method. This is **Legendre's equation**[1]

$$(1) \qquad (1 - x^2)y'' - 2xy' + n(n + 1)y = 0$$

where n is a given constant. Legendre's equation arises in numerous problems, particularly in boundary value problems for spheres (take a quick look at Example 1 in Sec. 12.10). The **parameter** n in (1) is a given real number. Any solution of (1) is called a **Legendre function.** The study of these and other "higher" functions not occurring in calculus is called the **theory of special functions.** Further special functions will occur in the next sections.

Dividing (1) by the coefficient $1 - x^2$ of y'', we see that the coefficients $-2x/(1 - x^2)$ and $n(n + 1)/(1 - x^2)$ of the new equation are analytic at $x = 0$. Hence by Theorem 1, in Sec. 5.2, Legendre's equation has power series solutions of the form

$$(2) \qquad y = \sum_{m=0}^{\infty} a_m x^m.$$

Substituting (2) and its derivatives into (1), and denoting the constant $n(n + 1)$ simply by k, we obtain

$$(1 - x^2) \sum_{m=2}^{\infty} m(m - 1)a_m x^{m-2} - 2x \sum_{m=1}^{\infty} m a_m x^{m-1} + k \sum_{m=0}^{\infty} a_m x^m = 0.$$

By writing the first expression as two separate series we have the equation

$$\sum_{m=2}^{\infty} m(m - 1)a_m x^{m-2} - \sum_{m=2}^{\infty} m(m - 1)a_m x^m - \sum_{m=1}^{\infty} 2m a_m x^m + \sum_{m=0}^{\infty} k a_m x^m = 0.$$

To obtain the same general power x^s in all four series, we set $m - 2 = s$ (thus $m = s + 2$) in the first series and simply write s instead of m in the other three series. This gives

$$\sum_{s=0}^{\infty} (s + 2)(s + 1)a_{s+2} x^s - \sum_{s=2}^{\infty} s(s - 1)a_s x^s - \sum_{s=1}^{\infty} 2s a_s x^s + \sum_{s=0}^{\infty} k a_s x^s = 0.$$

---

[1]ADRIEN-MARIE LEGENDRE (1752–1833), French mathematician, who became a professor in Paris in 1775 and made important contributions to special functions, elliptic integrals, number theory, and the calculus of variations. His book *Éléments de géométrie* (1794) became very famous and had 12 editions in less than 30 years.

Formulas on Legendre functions may be found in Refs. [GR1] and [GR10].

(Note that in the first series the summation begins with $s = 0$.) Since this equation with right side 0 must be an identity in x if (2) is to be a solution of (1), the sum of the coefficients of each power of x on the left must be zero. Now x^0 occurs in the first and fourth series and gives [remember that $k = n(n + 1)$]

$$2 \cdot 1a_2 + n(n + 1)a_0 = 0. \tag{3a}$$

x^1 occurs in the first, third, and fourth series and gives

$$3 \cdot 2a_3 + [-2 + n(n + 1)]a_1 = 0. \tag{3b}$$

The higher powers $x^2, x^3, \cdots$ occur in all four series and give

$$(s + 2)(s + 1)a_{s+2} + [-s(s - 1) - 2s + n(n + 1)]a_s = 0. \tag{3c}$$

The expression in the brackets $[\cdots]$ can be written $(n - s)(n + s + 1)$, as you may readily verify. Solving (3a) for a_2 and (3b) for a_3 as well as (3c) for a_{s+2}, we obtain the general formula

$$\mathbf{(4)} \qquad a_{s+2} = -\frac{(n - s)(n + s + 1)}{(s + 2)(s + 1)}\, a_s \qquad (s = 0, 1, \cdots).$$

This is called a **recurrence relation** or **recursion formula.** (Its derivation you may verify with your CAS.) It gives each coefficient in terms of the second one preceding it, except for a_0 and a_1, which are left as arbitrary constants. We find successively

$$a_2 = -\frac{n(n + 1)}{2!}\, a_0 \qquad a_3 = -\frac{(n - 1)(n + 2)}{3!}\, a_1$$

$$a_4 = -\frac{(n - 2)(n + 3)}{4 \cdot 3}\, a_2 \qquad a_5 = -\frac{(n - 3)(n + 4)}{5 \cdot 4}\, a_3$$

$$= \frac{(n - 2)n(n + 1)(n + 3)}{4!}\, a_0 \qquad = \frac{(n - 3)(n - 1)(n + 2)(n + 4)}{5!}\, a_1$$

and so on. By inserting these expressions for the coefficients into (2) we obtain

$$\mathbf{(5)} \qquad y(x) = a_0 y_1(x) + a_1 y_2(x)$$

where

$$\mathbf{(6)} \qquad y_1(x) = 1 - \frac{n(n + 1)}{2!}\, x^2 + \frac{(n - 2)n(n + 1)(n + 3)}{4!}\, x^4 - + \cdots$$

$$\mathbf{(7)} \qquad y_2(x) = x - \frac{(n - 1)(n + 2)}{3!}\, x^3 + \frac{(n - 3)(n - 1)(n + 2)(n + 4)}{5!}\, x^5 - + \cdots.$$

These series converge for $|x| < 1$ (see Prob. 4; or they may terminate, see below). Since (6) contains even powers of x only, while (7) contains odd powers of x only, the ratio y_1/y_2 is not a constant, so that y_1 and y_2 are not proportional and are thus linearly independent solutions. Hence (5) is a general solution of (1) on the interval $-1 < x < 1$.

Legendre Polynomials $P_n(x)$

In various applications, power series solutions of ODEs reduce to polynomials, that is, they terminate after finitely many terms. This is a great advantage and is quite common for special functions, leading to various important families of polynomials (see Refs. [GR1] or [GR10] in App. 1). For Legendre's equation this happens when the parameter n is a nonnegative integer because then the right side of (4) is zero for $s = n$, so that $a_{n+2} = 0$, $a_{n+4} = 0$, $a_{n+6} = 0, \cdots$. Hence if n is even, $y_1(x)$ reduces to a polynomial of degree n. If n is odd, the same is true for $y_2(x)$. These polynomials, multiplied by some constants, are called **Legendre polynomials** and are denoted by $P_n(x)$. The standard choice of a constant is done as follows. We choose the coefficient a_n of the highest power x^n as

$$a_n = \frac{(2n)!}{2^n(n!)^2} = \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{n!} \quad (n \text{ a positive integer}) \tag{8}$$

(and $a_n = 1$ if $n = 0$). Then we calculate the other coefficients from (4), solved for a_s in terms of a_{s+2}, that is,

$$a_s = -\frac{(s+2)(s+1)}{(n-s)(n+s+1)}\, a_{s+2} \qquad (s \leqq n-2). \tag{9}$$

The choice (8) makes $P_n(1) = 1$ for every n (see Fig. 104 on p. 180); this motivates (8). From (9) with $s = n - 2$ and (8) we obtain

$$a_{n-2} = -\frac{n(n-1)}{2(2n-1)}\, a_n = -\frac{n(n-1)(2n)!}{2(2n-1)2^n(n!)^2}.$$

Using $(2n)! = 2n(2n-1)(2n-2)!$, $n! = n(n-1)!$, and $n! = n(n-1)(n-2)!$, we obtain

$$a_{n-2} = -\frac{n(n-1)2n(2n-1)(2n-2)!}{2(2n-1)2^n n(n-1)!\, n(n-1)(n-2)!}.$$

$n(n-1)2n(2n-1)$ cancels, so that we get

$$a_{n-2} = -\frac{(2n-2)!}{2^n(n-1)!\,(n-2)!}.$$

Similarly,

$$a_{n-4} = -\frac{(n-2)(n-3)}{4(2n-3)}\, a_{n-2}$$

$$= \frac{(2n-4)!}{2^n 2!\,(n-2)!\,(n-4)!}$$

and so on, and in general, when $n - 2m \geqq 0$,

$$a_{n-2m} = (-1)^m \frac{(2n-2m)!}{2^n m!\,(n-m)!\,(n-2m)!}. \tag{10}$$

The resulting solution of Legendre's differential equation (1) is called the **Legendre polynomial** *of degree n* and is denoted by $P_n(x)$.

From (10) we obtain

$$\textbf{(11)} \qquad P_n(x) = \sum_{m=0}^{M} (-1)^m \frac{(2n-2m)!}{2^n m!\,(n-m)!\,(n-2m)!}\, x^{n-2m}$$

$$= \frac{(2n)!}{2^n (n!)^2}\, x^n - \frac{(2n-2)!}{2^n 1!\,(n-1)!\,(n-2)!}\, x^{n-2} + - \cdots$$

where $M = n/2$ or $(n-1)/2$, whichever is an integer. The first few of these functions are (Fig. 104)

$$\textbf{(11')} \qquad \begin{aligned} &P_0(x) = 1, && P_1(x) = x \\ &P_2(x) = \tfrac{1}{2}(3x^2 - 1), && P_3(x) = \tfrac{1}{2}(5x^3 - 3x) \\ &P_4(x) = \tfrac{1}{8}(35x^4 - 30x^2 + 3), && P_5(x) = \tfrac{1}{8}(63x^5 - 70x^3 + 15x) \end{aligned}$$

and so on. You may now program (11) on your CAS and calculate $P_n(x)$ as needed.

The so-called **orthogonality** of the Legendre polynomials will be considered in Secs. 5.7 and 5.8.

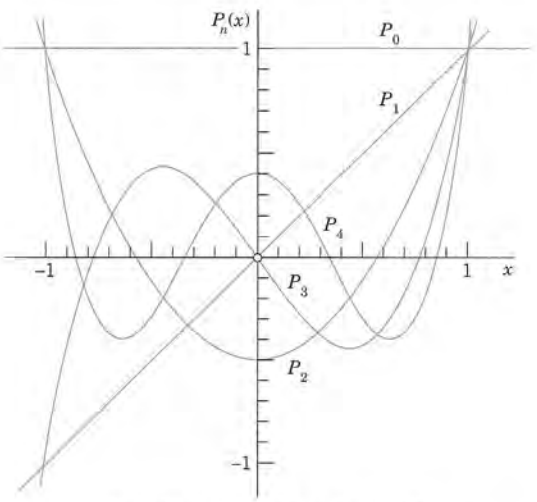

Fig. 104. Legendre polynomials

PROBLEM SET 5.3

1. Verify that the polynomials in (11′) satisfy Legendre's equation.
2. Derive (11′) from (11).
3. Obtain P_6 and P_7 from (11).
4. **(Convergence)** Show that for any n for which (6) or (7) does not reduce to a polynomial, the series has radius of convergence 1.
5. **(Legendre function $Q_0(x)$ for $n = 0$)** Show that (6) with $n = 0$ gives $y_1(x) = P_0(x) = 1$ and (7) gives

$$y_2(x) = x + \frac{2}{3!}\, x^3 + \frac{(-3)(-1)\cdot 2\cdot 4}{5!}\, x^5 + \cdots$$

$$= x + \frac{x^3}{3} + \frac{x^5}{5} + \cdots = \frac{1}{2} \ln \frac{1+x}{1-x}.$$

Verify this by solving (1) with $n = 0$, setting $z = y'$ and separating variables.

6. **(Legendre function $-Q_1(x)$ for $n = 1$)** Show that (7) with $n = 1$ gives $y_2(x) = P_1(x) = x$ and (6) gives $y_1(x) = -Q_1(x)$ (the minus sign in the notation being conventional),

$$y_1(x) = 1 - \frac{x^2}{1} - \frac{x^4}{3} - \frac{x^6}{5} - \cdots$$
$$= 1 - x\left(x + \frac{x^3}{3} + \frac{x^5}{5} + \cdots\right)$$
$$= 1 - \frac{1}{2}\,x \ln \frac{1+x}{1-x}.$$

7. **(ODE)** Find a solution of $(a^2 - x^2)y'' - 2xy' + n(n+1)y = 0$, $a \neq 0$, by reduction to the Legendre equation.

8. **[Rodrigues's formula (12)][2]** Applying the binomial theorem to $(x^2 - 1)^n$, differentiating it n times term by term, and comparing the result with (11), show that

$$\textbf{(12)} \qquad P_n(x) = \frac{1}{2^n n!}\,\frac{d^n}{dx^n}\left[(x^2 - 1)^n\right].$$

9. **(Rodrigues's formula)** Obtain (11′) from (12).

10–13 CAS PROBLEMS

10. Graph $P_2(x), \cdots, P_{10}(x)$ on common axes. For what x (approximately) and $n = 2, \cdots, 10$ is $|P_n(x)| < \frac{1}{2}$?

11. From what n on will your CAS no longer produce faithful graphs of $P_n(x)$? Why?

12. Graph $Q_0(x)$, $Q_1(x)$, and some further Legendre functions.

13. Substitute $a_s x^s + a_{s+1}x^{s+1} + a_{s+2}x^{s+2}$ into Legendre's equation and obtain the coefficient recursion (4).

14. **TEAM PROJECT. Generating Functions.** Generating functions play a significant role in modern applied mathematics (see [GR5]). The idea is simple. If we want to study a certain sequence $(f_n(x))$ and can find a function

$$G(u, x) = \sum_{n=0}^{\infty} f_n(x)u^n,$$

we may obtain properties of $(f_n(x))$ from those of G, which "generates" this sequence and is called a **generating function** of the sequence.

(a) Legendre polynomials. Show that

$$\textbf{(13)} \qquad G(u, x) = \frac{1}{\sqrt{1 - 2xu + u^2}} = \sum_{n=0}^{\infty} P_n(x)u^n$$

is a generating function of the Legendre polynomials. *Hint:* Start from the binomial expansion of $1/\sqrt{1 - v}$, then set $v = 2xu - u^2$, multiply the powers of $2xu - u^2$ out, collect all the terms involving u^n, and verify that the sum of these terms is $P_n(x)u^n$.

(b) Potential theory. Let A_1 and A_2 be two points in space (Fig. 105, $r_2 > 0$). Using (13), show that

$$\frac{1}{r} = \frac{1}{\sqrt{r_1^2 + r_2^2 - 2r_1 r_2 \cos\theta}} = \frac{1}{r_2}\sum_{m=0}^{\infty} P_m(\cos\theta)\left(\frac{r_1}{r_2}\right)^m.$$

This formula has applications in potential theory. (Q/r is the electrostatic potential at A_2 due to a charge Q located at A_1. And the series expresses $1/r$ in terms of the distances of A_1 and A_2 from any origin O and the angle θ between the segments OA_1 and OA_2.)

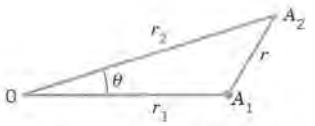

Fig. 105. Team Project 14

(c) Further applications of (13). Show that $P_n(1) = 1$, $P_n(-1) = (-1)^n$, $P_{2n+1}(0) = 0$, and

$$P_{2n}(0) = (-1)^n \cdot 1 \cdot 3 \cdots (2n-1)/[2 \cdot 4 \cdots (2n)].$$

(d) Bonnet's recursion.[3] Differentiating (13) with respect to u, using (13) in the resulting formula, and comparing coefficients of u^n, obtain the *Bonnet recursion*

$$(14) \quad (n+1)P_{n+1}(x) = (2n+1)xP_n(x) - nP_{n-1}(x),$$

where $n = 1, 2, \cdots$. This formula is useful for computations, the loss of significant digits being small (except near zeros). Try (14) out for a few computations of your own choice.

[2] OLINDE RODRIGUES (1794–1851), French mathematician and economist.
[3] OSSIAN BONNET (1819–1892), French mathematician, whose main work was in differential geometry.

15. (Associated Legendre functions) The associated Legendre functions $P_n^k(x)$ play a role in quantum physics. They are defined by

$$P_n^k(x) = (1 - x^2)^{k/2} \frac{d^k P_n}{dx^k} \tag{15}$$

and are solutions of the ODE

$$(1 - x^2)y'' - 2xy' + \left[n(n + 1) - \frac{k^2}{1 - x^2}\right] y = 0. \tag{16}$$

Find $P_1^1(x)$, $P_2^1(x)$, $P_2^2(x)$, and $P_4^2(x)$ and verify that they satisfy (16).

5.4 Frobenius Method

Several second-order ODEs of considerable practical importance—the famous Bessel equation among them—have coefficients that are not analytic (definition in Sec. 5.2), but are "not too bad," so that these ODEs can still be solved by series (power series times a logarithm or times a fractional power of x, etc.). Indeed, the following theorem permits an extension of the power series method that is called the **Frobenius method.** The latter—as well as the power series method itself—has gained in significance due to the use of software in the actual calculations.

THEOREM 1

Frobenius Method

Let $b(x)$ and $c(x)$ be any functions that are analytic at $x = 0$. Then the ODE

$$y'' + \frac{b(x)}{x} y' + \frac{c(x)}{x^2} y = 0 \tag{1}$$

has at least one solution that can be represented in the form

$$y(x) = x^r \sum_{m=0}^{\infty} a_m x^m = x^r(a_0 + a_1 x + a_2 x^2 + \cdots) \qquad (a_0 \neq 0) \tag{2}$$

where the exponent r may be any (real or complex) number (and r is chosen so that $a_0 \neq 0$).

The ODE (1) also has a second solution (such that these two solutions are linearly independent) that may be similar to (2) (with a different r and different coefficients) or may contain a logarithmic term. (Details in Theorem 2 below.)[4]

For example, Bessel's equation (to be discussed in the next section)

$$y'' + \frac{1}{x} y' + \left(\frac{x^2 - \nu^2}{x^2}\right) y = 0 \qquad (\nu \text{ a parameter})$$

[4]GEORG FROBENIUS (1849–1917), German mathematician, also known for his work on matrices and in group theory.

In this theorem we may replace x by $x - x_0$ with any number x_0. The condition $a_0 \neq 0$ is no restriction; it simply means that we factor out the highest possible power of x.

The singular point of (1) at $x = 0$ is sometimes called a **regular singular point,** a term confusing to the student, which we shall not use.

is of the form (1) with $b(x) = 1$ and $c(x) = x^2 - \nu^2$ analytic at $x = 0$, so that the theorem applies. This ODE could not be handled in full generality by the power series method.

Similarly, the so-called hypergeometric differential equation (see Problem Set 5.4) also requires the Frobenius method.

The point is that in (2) we have a power series times a single power of x whose exponent r is not restricted to be a nonnegative integer. (The latter restriction would make the whole expression a power series, by definition; see Sec. 5.1.)

The proof of the theorem requires advanced methods of complex analysis and can be found in Ref. [A11] listed in App. 1.

Regular and Singular Points

The following commonly used terms are practical. A **regular point** of

$$y'' + p(x)y' + q(x)y = 0$$

is a point x_0 at which the coefficients p and q are analytic. Then the power series method can be applied. If x_0 is not regular, it is called **singular.** Similarly, a **regular point** of the ODE

$$\tilde{h}(x)y'' + \tilde{p}(x)y'(x) + \tilde{q}(x)y = 0$$

is an x_0 at which $\tilde{h}$, $\tilde{p}$, $\tilde{q}$ are analytic and $\tilde{h}(x_0) \neq 0$ (so what we can divide by $\tilde{h}$ and get the previous standard form). If x_0 is not regular, it is called **singular.**

Indicial Equation, Indicating the Form of Solutions

We shall now explain the Frobenius method for solving (1). Multiplication of (1) by x^2 gives the more convenient form

$$\textbf{(1')} \qquad x^2y'' + xb(x)y' + c(x)y = 0.$$

We first expand $b(x)$ and $c(x)$ in power series,

$$b(x) = b_0 + b_1x + b_2x^2 + \cdots, \qquad c(x) = c_0 + c_1x + c_2x^2 + \cdots$$

or we do nothing if $b(x)$ and $c(x)$ are polynomials. Then we differentiate (2) term by term, finding

$$y'(x) = \sum_{m=0}^{\infty} (m + r)a_m x^{m+r-1} = x^{r-1}\,[ra_0 + (r + 1)a_1x + \cdots]$$

$$\textbf{(2*)} \qquad y''(x) = \sum_{m=0}^{\infty} (m + r)(m + r - 1)a_m x^{m+r-2}$$

$$= x^{r-2}[r(r - 1)a_0 + (r + 1)ra_1x + \cdots].$$

By inserting all these series into (1′) we readily obtain

$$\textbf{(3)} \qquad x^r[r(r - 1)a_0 + \cdots] + (b_0 + b_1x + \cdots)x^r(ra_0 + \cdots) + (c_0 + c_1x + \cdots)x^r(a_0 + a_1x + \cdots) = 0.$$

We now equate the sum of the coefficients of each power $x^r, x^{r+1}, x^{r+2}, \cdots$ to zero. This yields a system of equations involving the unknown coefficients a_m. The equation corresponding to the power x^r is

$$[r(r-1) + b_0 r + c_0]a_0 = 0.$$

Since by assumption $a_0 \neq 0$, the expression in the brackets $[\cdots]$ must be zero. This gives

$$\textbf{(4)} \qquad r(r-1) + b_0 r + c_0 = 0.$$

This important quadratic equation is called the **indicial equation** of the ODE (1). Its role is as follows.

The Frobenius method yields a basis of solutions. One of the two solutions will always be of the form (2), where r is a root of (4). The other solution will be of a form indicated by the indicial equation. There are three cases:

Case 1. Distinct roots not differing by an integer 1, 2, 3, $\cdots$.

Case 2. A double root.

Case 3. Roots differing by an integer 1, 2, 3, $\cdots$.

Cases 1 and 2 are not unexpected because of the Euler–Cauchy equation (Sec. 2.5), the simplest ODE of the form (1). Case 1 includes complex conjugate roots r_1 and $r_2 = \bar{r}_1$ because $r_1 - r_2 = r_1 - \bar{r}_1 = 2i \operatorname{Im} r_1$ is imaginary, so it cannot be a *real* integer. The form of a basis will be given in Theorem 2 (which is proved in App. 4), without a general theory of convergence, but convergence of the occurring series can be tested in each individual case as usual. Note that in Case 2 we ***must*** have a logarithm, whereas in Case 3 we *may* or *may not*.

THEOREM 2

Frobenius Method. Basis of Solutions. Three Cases

Suppose that the ODE (1) *satisfies the assumptions in Theorem* 1. *Let* r_1 *and* r_2 *be the roots of the indicial equation* (4). *Then we have the following three cases.*

Case* 1. *Distinct Roots Not Differing by an Integer. *A basis is*

$$\textbf{(5)} \qquad y_1(x) = x^{r_1}(a_0 + a_1 x + a_2 x^2 + \cdots)$$

and

$$\textbf{(6)} \qquad y_2(x) = x^{r_2}(A_0 + A_1 x + A_2 x^2 + \cdots)$$

with coefficients obtained successively from (3) *with* $r = r_1$ *and* $r = r_2$, *respectively.*

Case 2. Double Root $r_1 = r_2 = r$. *A basis is*

$$\textbf{(7)} \qquad y_1(x) = x^r(a_0 + a_1 x + a_2 x^2 + \cdots) \qquad \left[r = \tfrac{1}{2}(1 - b_0)\right]$$

(*of the same general form as before*) *and*

$$\textbf{(8)} \qquad y_2(x) = y_1(x) \ln x + x^r(A_1 x + A_2 x^2 + \cdots) \qquad (x > 0).$$

Case 3. Roots Differing by an Integer. *A basis is*

$$y_1(x) = x^{r_1}(a_0 + a_1x + a_2x^2 + \cdots) \tag{9}$$

(of the same general form as before) and

$$y_2(x) = ky_1(x) \ln x + x^{r_2}(A_0 + A_1x + A_2x^2 + \cdots), \tag{10}$$

where the roots are so denoted that $r_1 - r_2 > 0$ and k may turn out to be zero.

Typical Applications

Technically, the Frobenius method is similar to the power series method, once the roots of the indicial equation have been determined. However, (5)–(10) merely indicate the general form of a basis, and a second solution can often be obtained more rapidly by reduction of order (Sec. 2.1).

EXAMPLE 1 **Euler–Cauchy Equation, Illustrating Cases 1 and 2 and Case 3 without a Logarithm**

For the Euler–Cauchy equation (Sec. 2.5)

$$x^2y'' + b_0xy' + c_0y = 0 \qquad (b_0, c_0 \text{ constant})$$

substitution of $y = x^r$ gives the auxiliary equation

$$r(r - 1) + b_0r + c_0 = 0,$$

which is the indicial equation [and $y = x^r$ is a very special form of (2)!]. For different roots r_1, r_2 we get a basis $y_1 = x^{r_1}$, $y_2 = x^{r_2}$, and for a double root r we get a basis x^r, $x^r \ln x$. Accordingly, for this simple ODE, Case 3 plays no extra role. ■

EXAMPLE 2 **Illustration of Case 2 (Double Root)**

Solve the ODE

$$x(x - 1)y'' + (3x - 1)y' + y = 0. \tag{11}$$

(This is a special hypergeometric equation, as we shall see in the problem set.)

Solution. Writing (11) in the standard form (1), we see that it satisfies the assumptions in Theorem 1. [What are $b(x)$ and $c(x)$ in (11)?] By inserting (2) and its derivatives (2*) into (11) we obtain

$$\begin{aligned}\sum_{m=0}^{\infty} (m + r)(m + r - 1)a_mx^{m+r} - \sum_{m=0}^{\infty} (m + r)(m + r - 1)a_mx^{m+r-1} \\ + 3\sum_{m=0}^{\infty} (m + r)a_mx^{m+r} - \sum_{m=0}^{\infty} (m + r)a_mx^{m+r-1} + \sum_{m=0}^{\infty} a_mx^{m+r} = 0.\end{aligned} \tag{12}$$

The smallest power is x^{r-1}, occurring in the second and the fourth series; by equating the sum of its coefficients to zero we have

$$[-r(r - 1) - r]a_0 = 0, \qquad \text{thus} \qquad r^2 = 0.$$

Hence this indicial equation has the double root $r = 0$.

First Solution. We insert this value $r = 0$ into (12) and equate the sum of the coefficients of the power x^s to zero, obtaining

$$s(s-1)a_s - (s+1)sa_{s+1} + 3sa_s - (s+1)a_{s+1} + a_s = 0$$

thus $a_{s+1} = a_s$. Hence $a_0 = a_1 = a_2 = \cdots$, and by choosing $a_0 = 1$ we obtain the solution

$$y_1(x) = \sum_{m=0}^{\infty} x^m = \frac{1}{1-x} \qquad (|x| < 1).$$

Second Solution. We get a second independent solution y_2 by the method of reduction of order (Sec. 2.1), substituting $y_2 = uy_1$ and its derivatives into the equation. This leads to (9), Sec. 2.1, which we shall use in this example, instead of starting reduction of order from scratch (as we shall do in the next example). In (9) of Sec. 2.1 we have $p = (3x-1)/(x^2 - x)$, the coefficient of y' in (11) ***in standard form.*** By partial fractions,

$$-\int p\,dx = -\int \frac{3x-1}{x(x-1)}\,dx = -\int \left(\frac{2}{x-1} + \frac{1}{x}\right) dx = -2\ln(x-1) - \ln x.$$

Hence (9), Sec. 2.1, becomes

$$u' = U = y_1^{-2}e^{-\int p\,dx} = \frac{(x-1)^2}{(x-1)^2 x} = \frac{1}{x}, \qquad u = \ln x, \qquad y_2 = uy_1 = \frac{\ln x}{1-x}.$$

y_1 and y_2 are shown in Fig. 106. These functions are linearly independent and thus form a basis on the interval $0 < x < 1$ (as well as on $1 < x < \infty$). ■

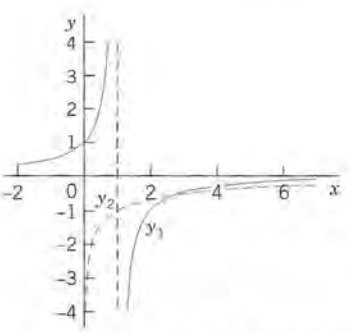

Fig. 106. Solutions in Example 2

EXAMPLE 3 Case 3, Second Solution with Logarithmic Term

Solve the ODE

$$(x^2 - x)y'' - xy' + y = 0. \tag{13}$$

Solution. Substituting (2) and (2*) into (13), we have

$$(x^2 - x)\sum_{m=0}^{\infty}(m+r)(m+r-1)a_m x^{m+r-2} - x\sum_{m=0}^{\infty}(m+r)a_m x^{m+r-1} + \sum_{m=0}^{\infty} a_m x^{m+r} = 0.$$

We now take x^2, x, and x inside the summations and collect all terms with power x^{m+r} and simplify algebraically,

$$\sum_{m=0}^{\infty}(m+r-1)^2 a_m x^{m+r} - \sum_{m=0}^{\infty}(m+r)(m+r-1)a_m x^{m+r-1} = 0.$$

In the first series we set $m = s$ and in the second $m = s+1$, thus $s = m-1$. Then

$$\sum_{s=0}^{\infty}(s+r-1)^2 a_s x^{s+r} - \sum_{s=-1}^{\infty}(s+r+1)(s+r)a_{s+1}x^{s+r} = 0. \tag{14}$$

The lowest power is x^{r-1} (take $s = -1$ in the second series) and gives the indicial equation

$$r(r-1) = 0.$$

The roots are $r_1 = 1$ and $r_2 = 0$. They differ by an integer. This is Case 3.

First Solution. From (14) with $r = r_1 = 1$ we have

$$\sum_{s=0}^{\infty} \left[s^2 a_s - (s+2)(s+1)a_{s+1}\right]x^{s+1} = 0.$$

This gives the recurrence relation

$$a_{s+1} = \frac{s^2}{(s+2)(s+1)}\, a_s \qquad (s = 0, 1, \cdorp).$$

Hence $a_1 = 0$, $a_2 = 0, \cdots$ successively. Taking $a_0 = 1$, we get as a first solution $y_1 = x^{r_1}a_0 = x$.

Second Solution. Applying reduction of order (Sec. 2.1), we substitute $y_2 = y_1 u = xu$, $y_2' = xu' + u$ and $y_2'' = xu'' + 2u'$ into the ODE, obtaining

$$(x^2 - x)(xu'' + 2u') - x(xu' + u) + xu = 0.$$

xu drops out. Division by x and simplification give

$$(x^2 - x)u'' + (x - 2)u' = 0.$$

From this, using partial fractions and integrating (taking the integration constant zero), we get

$$\frac{u''}{u'} = -\frac{x-2}{x^2-x} = -\frac{2}{x} + \frac{1}{x-1}, \qquad \ln u' = \ln\left|\frac{x-1}{x^2}\right|.$$

Taking exponents and integrating (again taking the integration constant zero), we obtain

$$u' = \frac{x-1}{x^2} = \frac{1}{x} - \frac{1}{x^2}, \qquad u = \ln x + \frac{1}{x}, \qquad y_2 = xu = x\ln x + 1.$$

y_1 and y_2 are linearly independent, and y_2 has a logarithmic term. Hence y_1 and y_2 constitute a basis of solutions for positive x. ■

The Frobenius method solves the **hypergeometric equation,** whose solutions include many known functions as special cases (see the problem set). In the next section we use the method for solving Bessel's equation.

PROBLEM SET 5.4

1–17 BASIS OF SOLUTIONS BY THE FROBENIUS METHOD

Find a basis of solutions. Try to identify the series as expansions of known functions. (Show the details of your work.)

1. $xy'' + 2y' - xy = 0$

2. $(x+2)^2y'' - 2y = 0$

3. $xy'' + 5y' + xy = 0$

4. $2xy'' + (3 - 4x)y' + (2x - 3)y = 0$

5. $x^2y'' + 4xy' + (x^2 + 2)y = 0$

6. $4xy'' + 2y' + y = 0$

7. $(x+3)^2y'' - 9(x+3)y' + 25y = 0$

8. $xy'' - y = 0$

9. $xy'' + (2x+1)y' + (x+1)y = 0$

10. $x^2y'' + 2x^3y' + (x^2 - 2)y = 0$

11. $(x^2 + x)y'' + (4x + 2)y' + 2y = 0$

12. $x^2y'' + 6xy' + (4x^2 + 6)y = 0$

13. $2xy'' - (8x - 1)y' + (8x - 2)y = 0$

14. $xy'' + y' - xy = 0$

15. $(x-4)^2y'' - (x-4)y' - 35y = 0$

16. $x^2y'' + 4xy' - (x^2 - 2)y = 0$

17. $y'' + (x - 6)y = 0$

18. TEAM PROJECT. Hypergeometric Equation, Series, and Function. Gauss's **hypergeometric ODE**[5] is

$$x(1-x)y'' + [c - (a+b+1)x]y' - aby = 0. \tag{15}$$

Here, a, b, c are constants. This ODE is of the form $p_2y'' + p_1y' + p_0y = 0$, where p_2, p_1, p_0 are polynomials of degree 2, 1, 0, respectively. These polynomials are written so that the series solution takes a most practical form, namely,

$$y_1(x) = 1 + \frac{ab}{1!\,c}x + \frac{a(a+1)b(b+1)}{2!\,c(c+1)}x^2 + \frac{a(a+1)(a+2)b(b+1)(b+2)}{3!\,c(c+1)(c+2)}x^3 + \cdots. \tag{16}$$

This series is called the **hypergeometric series.** Its sum $y_1(x)$ is called the **hypergeometric function** and is denoted by $F(a, b, c; x)$. Here, $c \neq 0, -1, -2, \cdns$. By choosing specific values of a, b, c we can obtain an incredibly large number of special functions as solutions of (15) [see the small sample of elementary functions in part (c)]. This accounts for the importance of (15).

(a) Hypergeometric series and function. Show that the indicial equation of (15) has the roots $r_1 = 0$ and $r_2 = 1 - c$. Show that for $r_1 = 0$ the Frobenius method gives (16). Motivate the name for (16) by showing that

$$F(1, 1, 1; x) = F(1, b, b; x) = F(a, 1, a; x) = \frac{1}{1-x}.$$

(b) Convergence. For what a or b will (16) reduce to a polynomial? Show that for any other a, b, c ($c \neq 0, -1, -2, \cdots$) the series (16) converges when $|x| < 1$.

(c) Special cases. Show that

$$(1+x)^n = F(-n, b, b; -x),$$
$$(1-x)^n = 1 - nxF(1-n, 1, 2; x),$$
$$\arctan x = xF(\tfrac{1}{2}, 1, \tfrac{3}{2}; -x^2),$$
$$\arcsin x = xF(\tfrac{1}{2}, \tfrac{1}{2}, \tfrac{3}{2}; x^2),$$
$$\ln(1+x) = xF(1, 1, 2; -x),$$
$$\ln\frac{1+x}{1-x} = 2xF(\tfrac{1}{2}, 1, \tfrac{3}{2}; x^2).$$

Find more such relations from the literature on special functions.

(d) Second solution. Show that for $r_2 = 1 - c$ the Frobenius method yields the following solution (where $c \neq 2, 3, 4, \cdots$):

$$y_2(x) = x^{1-c}\left(1 + \frac{(a-c+1)(b-c+1)}{1!\,(-c+2)}x + \frac{(a-c+1)(a-c+2)(b-c+1)(b-c+2)}{2!\,(-c+2)(-c+3)}x^2 + \cdots\right). \tag{17}$$

Show that

$$y_2(x) = x^{1-c}F(a-c+1, b-c+1, 2-c; x).$$

(e) On the generality of the hypergeometric equation. Show that

$$(t^2 + At + B)\ddot{y} + (Ct + D)\dot{y} + Ky = 0 \tag{18}$$

with $\dot{y} = dy/dt$, etc., constant A, B, C, D, K, and $t^2 + At + B = (t - t_1)(t - t_2)$, $t_1 \neq t_2$, can be reduced to the hypergeometric equation with independent variable

$$x = \frac{t - t_1}{t_2 - t_1}$$

and parameters related by $Ct_1 + D = -c(t_2 - t_1)$, $C = a + b + 1$, $K = ab$. From this you see that (15) is a "normalized form" of the more general (18) and that various cases of (18) can thus be solved in terms of hypergeometric functions.

19–24 HYPERGEOMETRIC EQUATIONS

Find a general solution in terms of hypergeometric functions.

19. $x(1-x)y'' + (\frac{1}{2} - 2x)y' - \frac{1}{4}y = 0$

20. $2x(1-x)y'' - (1+6x)y' - 2y = 0$

21. $x(1-x)y'' + \frac{1}{2}y' + 2y = 0$

22. $3t(1+t)\ddot{y} + t\dot{y} - y = 0$

23. $2(t^2 - 5t + 6)\ddot{y} + (2t - 3)\dot{y} - 8y = 0$

24. $4(t^2 - 3t + 2)\ddot{y} - 2\dot{y} + y = 0$

[5]CARL FRIEDRICH GAUSS (1777–1855), great German mathematician. He already made the first of his great discoveries as a student at Helmstedt and Göttingen. In 1807 he became a professor and director of the Observatory at Göttingen. His work was of basic importance in algebra, number theory, differential equations, differential geometry, non-Euclidean geometry, complex analysis, numeric analysis, astronomy, geodesy, electromagnetism, and theoretical mechanics. He also paved the way for a general and systematic use of complex numbers.

5.5 Bessel's Equation. Bessel Functions $J_\nu(x)$

One of the most important ODEs in applied mathematics in **Bessel's equation.**[6]

$$x^2y'' + xy' + (x^2 - \nu^2)y = 0. \tag{1}$$

Its diverse applications range from electric fields to heat conduction and vibrations (see Sec. 12.9). It often appears when a problem shows *cylindrical symmetry* (just as Legendre's equation may appear in cases of *spherical* symmetry). The parameter ν in (1) is a given number. We assume that ν is real and nonnegative.

Bessel's equation can be solved by the Frobenius method, as we mentioned at the beginning of the preceding section, where the equation is written in standard form (obtained by dividing (1) by x^2). Accordingly, we substitute the series

$$y(x) = \sum_{m=0}^{\infty} a_m x^{m+r} \qquad (a_0 \neq 0) \tag{2}$$

with undetermined coefficients and its derivatives into (1). This gives

$$\sum_{m=0}^{\infty} (m + r)(m + r - 1)a_m x^{m+r} + \sum_{m=0}^{\infty} (m + r)a_m x^{m+r} + \sum_{m=0}^{\infty} a_m x^{m+r+2} - \nu^2 \sum_{m=0}^{\infty} a_m x^{m+r} = 0.$$

We equate the sum of the coefficients of x^{s+r} to zero. Note that this power x^{s+r} corresponds to $m = s$ in the first, second, and fourth series, and to $m = s - 2$ in the third series. Hence for $s = 0$ and $s = 1$, the third series does not contribute since $m \geqq 0$. For $s = 2, 3, \cdots$ all four series contribute, so that we get a general formula for all these s. We find

$$\begin{aligned}
&\text{(a)} && r(r - 1)a_0 + ra_0 - \nu^2 a_0 = 0 && (s = 0)\\
&\text{(b)} && (r + 1)ra_1 + (r + 1)a_1 - \nu^2 a_1 = 0 && (s = 1)\\
&\text{(c)} && (s + r)(s + r - 1)a_s + (s + r)a_s + a_{s-2} - \nu^2 a_s = 0 && (s = 2, 3, \cdots).
\end{aligned} \tag{3}$$

From (3a) we obtain the **indicial equation** by dropping a_0,

$$(r + \nu)(r - \nu) = 0. \tag{4}$$

The roots are $r_1 = \nu\ (\geqq 0)$ and $r_2 = -\nu$.

---

[6]FRIEDRICH WILHELM BESSEL (1784–1846), German astronomer and mathematician, studied astronomy on his own in his spare time as an apprentice of a trade company and finally became director of the new Königsberg Observatory.

Formulas on Bessel functions are contained in Ref. [GR1] and the standard treatise [A13].

Coefficient Recursion for $r = r_1 = \nu$. For $r = \nu$, Eq. (3b) reduces to $(2\nu + 1)a_1 = 0$. Hence $a_1 = 0$ since $\nu \geqq 0$. Substituting $r = \nu$ in (3c) and combining the three terms containing a_s gives simply

$$(s + 2\nu)sa_s + a_{s-2} = 0. \tag{5}$$

Since $a_1 = 0$ and $\nu \geqq 0$, it follows from (5) that $a_3 = 0$, $a_5 = 0, \cdots$. Hence we have to deal only with *even-numbered* coefficients a_s with $s = 2m$. For $s = 2m$, Eq. (5) becomes

$$(2m + 2\nu)2ma_{2m} + a_{2m-2} = 0.$$

Solving for a_{2m} gives the recursion formula

$$a_{2m} = -\frac{1}{2^2m(\nu + m)}\, a_{2m-2}, \qquad m = 1, 2, \cdots. \tag{6}$$

From (6) we can now determine $a_2, a_4, \cdots$ successively. This gives

$$a_2 = -\frac{a_0}{2^2(\nu + 1)}$$

$$a_4 = -\frac{a_2}{2^2 2(\nu + 2)} = \frac{a_0}{2^4 2!\,(\nu + 1)(\nu + 2)}$$

and so on, and in general

$$a_{2m} = \frac{(-1)^m a_0}{2^{2m} m!\,(\nu + 1)(\nu + 2)\cdots(\nu + m)}, \qquad m = 1, 2, \cdots. \tag{7}$$

Bessel Functions $J_n(x)$ For Integer $\nu = n$

Integer values of ν are denoted by n. This is standard. For $\nu = n$ the relation (7) becomes

$$a_{2m} = \frac{(-1)^m a_0}{2^{2m} m!\,(n + 1)(n + 2)\cdots(n + m)}, \qquad m = 1, 2, \cdots. \tag{8}$$

a_0 is still arbitrary, so that the series (2) with these coefficients would contain this arbitrary factor a_0. This would be a highly impractical situation for developing formulas or computing values of this new function. Accordingly, we have to make a choice. $a_0 = 1$ would be possible, but more practical turns out to be

$$a_0 = \frac{1}{2^n n!}. \tag{9}$$

because then $n!(n + 1)\cdots(n + m) = (m + n)!$ in (8), so that (8) simply becomes

$$a_{2m} = \frac{(-1)^m}{2^{2m+n} m!\,(n + m)!}, \qquad m = 1, 2, \cdots. \tag{10}$$

This simplicity of the denominator of (10) partially motivates the choice (9). With these coefficients and $r_1 = \nu = n$ we get from (2) a particular solution of (1), denoted by $J_n(x)$ and given by

$$\textbf{(11)} \qquad J_n(x) = x^n \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+n} m!\,(n+m)!}.$$

$J_n(x)$ is called the **Bessel function of the first kind** *of order n*. The series (11) converges for all x, as the ratio test shows. In fact, it converges very rapidly because of the factorials in the denominator.

EXAMPLE 1 **Bessel Functions $J_0(x)$ and $J_1(x)$**

For $n = 0$ we obtain from (11) the **Bessel function of order 0**

$$\textbf{(12)} \qquad J_0(x) = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m}(m!)^2} = 1 - \frac{x^2}{2^2(1!)^2} + \frac{x^4}{2^4(2!)^2} - \frac{x^6}{2^6(3!)^2} + - \cdots$$

which looks similar to a cosine (Fig. 107). For $n = 1$ we obtain the **Bessel function of order 1**

$$\textbf{(13)} \qquad J_1(x) = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+1}}{2^{2m+1} m!\,(m+1)!} = \frac{x}{2} - \frac{x^3}{2^3 1!\,2!} + \frac{x^5}{2^5 2!\,3!} - \frac{x^7}{2^7 3!\,4!} + - \cdots,$$

which looks similar to a sine (Fig. 107). But the zeros of these functions are not completely regularly spaced (see also Table A1 in App. 5) and the height of the "waves" decreases with increasing x. Heuristically, n^2/x^2 in (1) in standard form [(1) divided by x^2] is zero (if $n = 0$) or small in absolute value for large x, and so is y'/x, so that then Bessel's equation comes close to $y'' + y = 0$, the equation of $\cos x$ and $\sin x$; also y'/x acts as a "damping term," in part responsible for the decrease in height. One can show that for large x,

$$\textbf{(14)} \qquad J_n(x) \sim \sqrt{\frac{2}{\pi x}} \cos\left(x - \frac{n\pi}{2} - \frac{\pi}{4}\right)$$

where $\sim$ is read **"asymptotically equal"** and means that *for fixed n* the quotient of the two sides approaches 1 as $x \to \infty$.

Formula (14) is surprisingly accurate even for smaller x (> 0). For instance, it will give you good starting values in a computer program for the basic task of computing zeros. For example, for the first three zeros of J_0 you obtain the values 2.356 (2.405 exact to 3 decimals, error 0.049), 5.498 (5.520, error 0.022), 8.639 (8.654, error 0.015), etc. ■

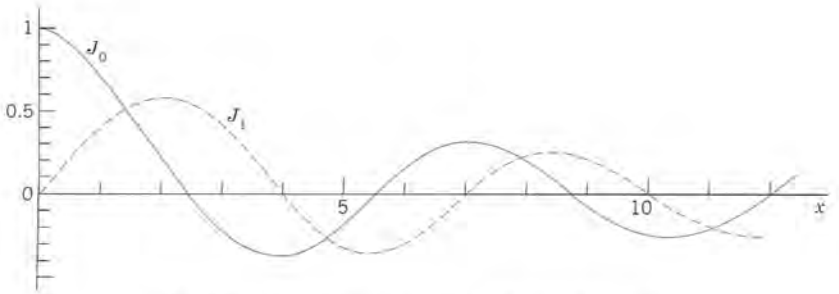

Fig. 107. Bessel functions of the first kind J_0 and J_1

Bessel Functions $J_\nu(x)$ for any $\nu \geqq 0$. Gamma Function

We now extend our discussion from integer $\nu = n$ to any $\nu \geqq 0$. All we need is an extension of the factorials in (9) and (11) to any ν. This is done by the **gamma function** $\Gamma(\nu)$ defined by the integral

(15) $$\Gamma(\nu) = \int_0^\infty e^{-t} t^{\nu-1}\, dt \qquad (\nu > 0).$$

By integration by parts we obtain

$$\Gamma(\nu + 1) = \int_0^\infty e^{-t} t^\nu\, dt = -e^{-t} t^\nu \Big|_0^\infty + \nu \int_0^\infty e^{-t} t^{\nu-1}\, dt.$$

The first expression on the right is zero. The integral on the right is $\Gamma(\nu)$. This yields the basic functional relation

(16) $$\Gamma(\nu + 1) = \nu\, \Gamma(\nu).$$

Now by (15)

$$\Gamma(1) = \int_0^\infty e^{-t}\, dt = -e^{-t} \Big|_0^\infty = 0 - (-1) = 1.$$

From this and (16) we obtain successively $\Gamma(2) = \Gamma(1) = 1!$, $\Gamma(3) = 2\Gamma(2) = 2!$, $\cdots$ and in general

(17) $$\Gamma(n + 1) = n! \qquad (n = 0, 1, \cdots).$$

This shows the ***the gamma function does in fact generalize the factorial function.***

Now in (9) we had $a_0 = 1/(2^n n!)$. This is $1/(2^n \Gamma(n + 1))$ by (17). It suggests to choose, for any ν,

(18) $$a_0 = \frac{1}{2^\nu \Gamma(\nu + 1)}.$$

Then (7) becomes

$$a_{2m} = \frac{(-1)^m}{2^{2m} m!\, (\nu + 1)(\nu + 2) \cdots (\nu + m) 2^\nu \Gamma(\nu + 1)}.$$

But (16) gives in the denominator

$$(\nu + 1)\Gamma(\nu + 1) = \Gamma(\nu + 2), \qquad (\nu + 2)\Gamma(\nu + 2) = \Gamma(\nu + 3)$$

and so on, so that

$$(\nu + 1)(\nu + 2) \cdots (\nu + m)\Gamma(\nu + 1) = \Gamma(\nu + m + 1).$$

Hence because of our (standard!) choice (18) of a_0 the coefficients (7) simply are

$$a_{2m} = \frac{(-1)^m}{2^{2m+\nu} m!\, \Gamma(\nu + m + 1)}. \tag{19}$$

With these coefficients and $r = r_1 = \nu$ we get from (2) a particular solution of (1), denoted by $J_\nu(x)$ and given by

$$J_\nu(x) = x^\nu \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+\nu} m!\, \Gamma(\nu + m + 1)}. \tag{20}$$

$J_\nu(x)$ is called the **Bessel function of the first kind of order ν.** The series (20) converges for all x, as one can verify by the ratio test.

General Solution for Noninteger ν. Solution $J_{-\nu}$

For a general solution, in addition to J_ν we need a second linearly independent solution. For ν not an integer this is easy. Replacing ν by $-\nu$ in (20), we have

$$J_{-\nu}(x) = x^{-\nu} \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m-\nu} m!\, \Gamma(m - \nu + 1)}. \tag{21}$$

Since Bessel's equation involves ν^2, the functions J_ν and $J_{-\nu}$ are solutions of the equation for the same ν. If ν is not an integer, they are linearly independent, because the first term in (20) and the first term in (21) are finite nonzero multiples of x^ν and $x^{-\nu}$, respectively. $x = 0$ must be excluded in (21) because of the factor $x^{-\nu}$ (with $\nu > 0$). This gives

THEOREM 1

General Solution of Bessel's Equation

If ν is not an integer, a general solution of Bessel's equation for all $x \neq 0$ is

$$y(x) = c_1 J_\nu(x) + c_2 J_{-\nu}(x). \tag{22}$$

But if ν is an integer, then (22) is not a general solution because of linear dependence:

THEOREM 2

Linear Dependence of Bessel Functions J_n and J_{-n}

For integer $\nu = n$ the Bessel functions $J_n(x)$ and $J_{-n}(x)$ are linearly dependent, because

$$J_{-n}(x) = (-1)^n J_n(x) \qquad (n = 1, 2, \cdots). \tag{23}$$

PROOF We use (21) and let ν approach a positive integer n. Then the gamma functions in the coefficients of the first n terms become infinite (see Fig. 552 in App. A3.1), the coefficients become zero, and the summation starts with $m = n$. Since in this case $\Gamma(m - n + 1) = (m - n)!$ by (17), we obtain

$$J_{-n}(x) = \sum_{m=n}^{\infty} \frac{(-1)^m x^{2m-n}}{2^{2m-n} m!\,(m-n)!} = \sum_{s=0}^{\infty} \frac{(-1)^{n+s} x^{2s+n}}{2^{2s+n}(n+s)!\,s!} \qquad (m = n + s).$$

The last series represents $(-1)^n J_n(x)$, as you can see from (11) with m replaced by s. This completes the proof. ■

A general solution for integer n will be given in the next section, based on some further interesting ideas.

Discovery of Properties From Series

Bessel functions are a model case for showing how to discover properties and relations of functions from series by which they are *defined*. Bessel functions satisfy an incredibly large number of relationships—look at Ref. [A13] in App. 1; also, find out what your CAS knows. In Theorem 3 we shall discuss four formulas that are backbones in applications.

THEOREM 3

Derivatives, Recursions

The derivative of $J_\nu(x)$ with respect to x can be expressed by $J_{\nu-1}(x)$ or $J_{\nu+1}(x)$ by the formulas

(24)

$$\textbf{(a)} \quad [x^\nu J_\nu(x)]' = x^\nu J_{\nu-1}(x)$$

$$\textbf{(b)} \quad [x^{-\nu} J_\nu(x)]' = -x^{-\nu} J_{\nu+1}(x).$$

Furthermore, $J_\nu(x)$ and its derivative satisfy the recurrence relations

(24)

$$\textbf{(c)} \quad J_{\nu-1}(x) + J_{\nu+1}(x) = \frac{2\nu}{x} J_\nu(x)$$

$$\textbf{(d)} \quad J_{\nu-1}(x) - J_{\nu+1}(x) = 2J_\nu'(x).$$

PROOF **(a)** We multiply (20) by x^ν and take $x^{2\nu}$ under the summation sign. Then we have

$$x^\nu J_\nu(x) = \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m+2\nu}}{2^{2m+\nu} m!\,\Gamma(\nu + m + 1)}.$$

We now differentiate this, cancel a factor 2, pull $x^{2\nu-1}$ out, and use the functional relationship $\Gamma(\nu + m + 1) = (\nu + m)\Gamma(\nu + m)$ [see (16)]. Then (20) with $\nu - 1$ instead of ν shows that we obtain the right side of (24a). Indeed,

$$(x^\nu J_\nu)' = \sum_{m=0}^{\infty} \frac{(-1)^m 2(m+\nu) x^{2m+2\nu-1}}{2^{2m+\nu} m!\,\Gamma(\nu + m + 1)} = x^\nu x^{\nu-1} \sum_{m=0}^{\infty} \frac{(-1)^m x^{2m}}{2^{2m+\nu-1} m!\,\Gamma(\nu + m)}.$$

(b) Similarly, we multiply (20) by $x^{-\nu}$, so that x^ν in (20) cancels. Then we differentiate, cancel $2m$, and use $m! = m(m-1)!$. This gives, with $m = s + 1$,

$$(x^{-\nu}J_\nu)' = \sum_{m=1}^{\infty} \frac{(-1)^m x^{2m-1}}{2^{2m+\nu-1}(m-1)!\,\Gamma(\nu+m+1)} = \sum_{s=0}^{\infty} \frac{(-1)^{s+1}x^{2s+1}}{2^{2s+\nu+1}s!\,\Gamma(\nu+s+2)}.$$

Equation (20) with $\nu + 1$ instead of ν and s instead of m shows that the expression on the right is $-x^{-\nu}J_{\nu+1}(x)$. This proves (24b).

(c), (d) We perform the differentiation in (24a). Then we do the same in (24b) and multiply the result on both sides by $x^{2\nu}$. This gives

$$\text{(a*)} \qquad \nu x^{\nu-1}J_\nu + x^\nu J_\nu' = x^\nu J_{\nu-1}$$

$$\text{(b*)} \qquad -\nu x^{\nu-1}J_\nu + x^\nu J_\nu' = -x^\nu J_{\nu+1}.$$

Substracting (b*) from (a*) and dividing the result by x^ν gives (24c). Adding (a*) and (b*) and dividing the result by x^ν gives (24d). ■

EXAMPLE 2 Application of Theorem 3 in Evaluation and Integration

Formula (24c) can be used recursively in the form

$$J_{\nu+1}(x) = \frac{2\nu}{x}J_\nu(x) - J_{\nu-1}(x)$$

for calculating Bessel functions of higher order from those of lower order. For instance, $J_2(x) = 2J_1(x)/x - J_0(x)$, so that J_2 can be obtained from tables of J_0 and J_1 (in App. 5 or, more accurately, in Ref. [GR1] in App. 1).

To illustrate how Theorem 3 helps in integration, we use (24b) with $\nu = 3$ integrated on both sides. This evaluates, for instance, the integral

$$I = \int_1^2 x^{-3}J_4(x)\,dx = -x^{-3}J_3(x)\Big|_1^2 = -\frac{1}{8}J_3(2) + J_3(1).$$

A table of J_3 (on p. 398 of Ref. [GR1]) or your CAS will give you

$$-\tfrac{1}{8}\cdot 0.128943 + 0.019563 = 0.003445.$$

Your CAS (or a human computer in precomputer times) obtains J_3 from (24), first using (24c) with $\nu = 2$, that is, $J_3 = 4x^{-1}J_2 - J_1$, then (24c) with $\nu = 1$, that is, $J_2 = 2x^{-1}J_1 - J_0$. Together,

$$\begin{aligned} I &= x^{-3}(4x^{-1}(2x^{-1}J_1 - J_0) - J_1)\Big|_1^2 \\ &= -\tfrac{1}{8}[2J_1(2) - 2J_0(2) - J_1(2)] + [8J_1(1) - 4J_0(1) - J_1(1)] \\ &= -\tfrac{1}{8}J_1(2) + \tfrac{1}{4}J_0(2) + 7J_1(1) - 4J_0(1). \end{aligned}$$

This is what you get, for instance, with Maple if you type int(· · ·). And if you type evalf(int(· · ·)), you obtain 0.003445448, in agreement with the result near the beginning of the example. ■

In the theory of special functions it often happens that for certain values of a parameter a higher function becomes elementary. We have seen this in the last problem set, and we now show this for J_ν.

THEOREM 4

Elementary J_ν for Half-Integer Order ν

Bessel functions J_ν of orders $\pm\frac{1}{2}, \pm\frac{3}{2}, \pm\frac{5}{2}, \cdots$ are elementary; they can be expressed by finitely many cosines and sines and powers of x. In particular,

$$\textbf{(25)} \qquad \textbf{(a)} \quad J_{1/2}(x) = \sqrt{\frac{2}{\pi x}}\sin x, \qquad \textbf{(b)} \quad J_{-1/2}(x) = \sqrt{\frac{2}{\pi x}}\cos x.$$

PROOF When $\nu = \frac{1}{2}$, then (20) is

$$J_{1/2}(x) = \sqrt{x}\sum_{m=0}^{\infty}\frac{(-1)^m x^{2m}}{2^{2m+1/2}m!\,\Gamma(m+\frac{3}{2})} = \sqrt{\frac{2}{x}}\sum_{m=0}^{\infty}\frac{(-1)^m x^{2m+1}}{2^{2m+1}m!\,\Gamma(m+\frac{3}{2})}.$$

To simplify the denominator, we first write it out as a product AB, where

$$A = 2^m m! = 2m(2m-2)(2m-4)\cdots 4\cdot 2$$

and [use (16)]

$$B = 2^{m+1}\Gamma(m+\tfrac{3}{2}) = 2^{m+1}(m+\tfrac{1}{2})(m-\tfrac{1}{2})\cdots\tfrac{3}{2}\cdot\tfrac{1}{2}\Gamma(\tfrac{1}{2})$$

$$= (2m+1)(2m-1)\cdots 3\cdot 1\cdot\sqrt{\pi};$$

here we used

$$\textbf{(26)} \qquad \Gamma(\tfrac{1}{2}) = \sqrt{\pi}.$$

We see that the product of the two right sides of A and B is simply $(2m+1)!\sqrt{\pi}$, so that $J_{1/2}$ becomes

$$J_{1/2}(x) = \sqrt{\frac{2}{\pi x}}\sum_{m=0}^{\infty}\frac{(-1)^m x^{2m+1}}{(2m+1)!} = \sqrt{\frac{2}{\pi x}}\sin x,$$

as claimed. Differentiation and the use of (24a) with $\nu = \frac{1}{2}$ now gives

$$\left[\sqrt{x}J_{1/2}(x)\right]' = \sqrt{\frac{2}{\pi}}\cos x = x^{1/2}J_{-1/2}(x).$$

This proves (25b). From (25) follow further formulas successively by (24c), used as in Example 2. This completes the proof. ■

EXAMPLE 3 **Further Elementary Bessel Functions**

From (24c) with $\nu = \frac{1}{2}$ and $\nu = -\frac{1}{2}$ and (25) we obtain

$$J_{3/2}(x) = \frac{1}{x}J_{1/2}(x) - J_{-1/2}(x) = \sqrt{\frac{2}{\pi x}}\left(\frac{\sin x}{x} - \cos x\right)$$

$$J_{-3/2}(x) = -\frac{1}{x}J_{-1/2}(x) - J_{1/2}(x) = -\sqrt{\frac{2}{\pi x}}\left(\frac{\cos x}{x} + \sin x\right)$$

respectively, and so on. ■

We hope that our study has not only helped you to become acquainted with Bessel functions but has also convinced you that series can be quite useful in obtaining various properties of the corresponding functions.

PROBLEM SET 5.5

1. **(Convergence)** Show that the series in (11) converges for all x. Why is the convergence very rapid?
2. **(Approximation)** Show that for small $|x|$ we have $J_0 \approx 1 - 0.25x^2$. From this compute $J_0(x)$ for $x = 0, 0.1, 0.2, \cdots, 1.0$ and determine the error by using Table A1 in App. 5 or your CAS.
3. **("Large" values)** Using (14), compute $J_0(x)$ for $x = 1.0, 2.0, 3.0, \cdots, 8.0$, determine the error by Table A1 or your CAS, and comment.
4. **(Zeros)** Compute the first four positive zeros of $J_0(x)$ and $J_1(x)$ from (14). Determine the error and comment.

5–20 ODEs REDUCIBLE TO BESSEL'S EQUATION

Using the indicated substitutions, find a general solution in terms of J_ν and $J_{-\nu}$ or indicate when this is not possible. (This is just a sample of various ODEs reducible to Bessel's equation. Some more follow in the next problem set. Show the details of your work.)

5. **(ODE with two parameters)** $x^2y'' + xy' + (\lambda^2x^2 - \nu^2)y = 0 \quad (\lambda x = z)$
6. $x^2y'' + xy' + (x^2 - \frac{1}{16})y = 0$
7. $x^2y'' + xy' + \frac{1}{4}(x - \nu^2)y = 0 \quad (\sqrt{x} = z)$
8. $(2x + 1)^2y'' + 2(2x + 1)y' + 16x(x + 1)y = 0 \quad (2x + 1 = z)$
9. $xy'' - y' + 4xy = 0 \quad (y = xu,\ 2x = z)$
10. $x^2y'' + xy' + \frac{1}{4}(x^2 - 1)y = 0 \quad (x = 2z)$
11. $xy'' + (2\nu + 1)y' + xy = 0 \quad (y = x^{-\nu}u)$
12. $x^2y'' + xy' + 4(x^4 - \nu^2)y = 0 \quad (x^2 = z)$
13. $x^2y'' + xy' + 9(x^6 - \nu^2)y = 0 \quad (x^3 = z)$
14. $y'' + (e^{2x} - \frac{1}{9})y = 0 \quad (e^x = z)$
15. $xy'' + y = 0 \quad (y = \sqrt{x}\,u,\ 2\sqrt{x} = z)$
16. $16x^2y'' + 8xy' + (x^{1/2} + \frac{15}{16})y = 0 \quad (y = x^{1/4}u,\ x^{1/4} = z)$
17. $36x^2y'' + 18xy' + \sqrt{x}\,y = 0 \quad (y = x^{1/4}u,\ \frac{2}{3}x^{1/4} = z)$
18. $x^2y'' + xy' + \sqrt{x}\,y = 0 \quad (4x^{1/4} = z)$
19. $x^2y'' + \frac{1}{5}xy' + \sqrt{x}\,y = 0 \quad (y = x^{2/5}u,\ 4x^{1/4} = z)$
20. $x^2y'' + (1 - 2\nu)xy' + \nu^2(x^{2\nu} + 1 - \nu^2)y = 0 \quad (y = x^\nu u,\ x^\nu = z)$

21–28 APPLICATION OF (24): DERIVATIVES, INTEGRALS

Use the powerful formulas (24) to do Probs. 21–28. (Show the details of your work.)

21. **(Derivatives)** Show that $J_0'(x) = -J_1(x)$, $J_1'(x) = J_0(x) - J_1(x)/x$, $J_2'(x) = \frac{1}{2}[J_1(x) - J_3(x)]$.
22. **(Interlacing of zeros)** Using (24) and Rolle's theorem, show that between two consecutive zeros of $J_0(x)$ there is precisely one zero of $J_1(x)$.
23. **(Interlacing of zeros)** Using (24) and Rolle's theorem, show that between any two consecutive positive zeros of $J_n(x)$ there is precisely one zero of $J_{n+1}(x)$.
24. **(Bessel's equation)** Derive (1) from (24).
25. **(Basic integral formulas)** Show that

$$\int x^\nu J_{\nu-1}(x)\,dx = x^\nu J_\nu(x) + c,$$

$$\int x^{-\nu} J_{\nu+1}(x)\,dx = -x^{-\nu} J_\nu(x) + c,$$

$$\int J_{\nu+1}(x)\,dx = \int J_{\nu-1}(x)\,dx - 2J_\nu(x).$$

26. **(Integration)** Evaluate $\int x^{-1}J_4(x)\,dx$. (Use Prob. 25; integrate by parts.)
27. **(Integration)** Show that $\int x^2J_0(x)\,dx = x^2J_1(x) + xJ_0(x) - \int J_0(x)\,dx$. (The last integral is nonelementary; tables exist, e.g. in Ref. [A13] in App. 1.)
28. **(Integration)** Evaluate $\int J_5(x)\,dx$.
29. **(Elimination of first derivative)** Show that $y = uv$ with $v(x) = \exp\left(-\frac{1}{2}\int p(x)\,dx\right)$ gives from the ODE $y'' + p(x)y' + q(x)y = 0$ the ODE

$$u'' + \left[q(x) - \tfrac{1}{4}p(x)^2 - \tfrac{1}{2}p'(x)\right]u = 0$$

no longer containing the first derivative. Show that for the Bessel equation the substitution is $y = ux^{-1/2}$ and gives

(27) $$x^2u'' + (x^2 + \tfrac{1}{4} - \nu^2)u = 0.$$

30. (Elementary Bessel functions) Derive (25) in Theorem 4 from (27).

31. CAS EXPERIMENT. Change of Coefficient. Find and graph (on common axes) the solutions of

$$y'' + kx^{-1}y' + y = 0,\ y(0) = 1,\ y'(0) = 0,$$

for $k = 0, 1, 2, \cdots, 10$ (or as far as you get useful graphs). For what k do you get elementary functions? Why? Try for noninteger k, particularly between 0 and 2, to see the continuous change of the curve. Describe the change of the location of the zeros and of the extrema as k increases from 0. Can you interpret the ODE as a model in mechanics, thereby explaining your observations?

32. TEAM PROJECT. Modeling a Vibrating Cable (Fig. 108). A flexible cable, chain, or rope of length L and density (mass per unit length) ρ is fixed at the upper end ($x = 0$) and allowed to make small vibrations (small angles α in the horizontal displacement $u(x, t)$, t = time) in a vertical plane.

(a) Show the following. The weight of the cable below a point x is $W(x) = \rho g(L - x)$. The restoring force is $F(x) = W \sin \alpha \approx Wu_x$, $u_x = \partial u/\partial x$. The difference in force between x and $x + \Delta x$ is $\Delta x\ (Wu_x)_x$. Newton's second law now gives

$$\rho\ \Delta x\ u_{tt} = \Delta x\ \rho g[(L - x)u_x]_x.$$

For the expected periodic motion $u(x, t) = y(x) \cos(\omega t + \delta)$ the model of the problem is the ODE

$$(L - x)y'' - y' + \lambda^2 y = 0, \qquad \lambda^2 = \omega^2/g.$$

(b) Transform this ODE to $\ddot{y} + s^{-1}\dot{y} + y = 0$, $\dot{y} = dy/ds$, $s = 2\lambda z^{1/2}$, $z = L - x$, so that the solution is

$$y(x) = J_0(2\omega\sqrt{(L - x)/g}).$$

(c) Conclude that possible frequencies $\omega/2\pi$ are those for which $s = 2\omega\sqrt{L/g}$ is a zero of J_0. The corresponding solutions are called **normal modes.** Figure 108 shows the first of them. What does the second normal mode look like? The third? What is the frequency (cycles/min) of a cable of length 2 m? Of length 10 m?

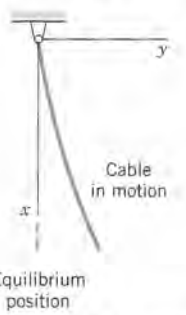

Fig. 108. Vibrating cable in Team Project 32

33. CAS EXPERIMENT. Bessel Functions for Large x.

(a) Graph $J_n(x)$ for $n = 0, \cdots, 5$ on common axes.

(b) Experiment with (14) for integer n. Using graphs, find out from which $x = x_n$ on the curves of (11) and (14) practically coincide. How does x_n change with n?

(c) What happens in (b) if $n = \pm\frac{1}{2}$? (Our usual notation in this case would be ν.)

(d) How does the error of (14) behave as function of x for fixed n? [Error = exact value minus approximation (14).]

(e) Show from the graphs that $J_0(x)$ has extrema where $J_1(x) = 0$. Which formula proves this? Find further relations between zeros and extrema.

(f) Raise and answer questions of your own, for instance, on the zeros of J_0 and J_1. How accurately are they obtained from (14)?

5.6 Bessel Functions of the Second Kind $Y_\nu(x)$

From the last section we know that J_ν and $J_{-\nu}$ form a basis of solutions of Bessel's equation, provided ν is not an integer. But when ν is an integer, these two solutions are linearly dependent on any interval (see Theorem 2 in Sec. 5.5). Hence to have a general solution also when $\nu = n$ is an integer, we need a second linearly independent solution besides J_n. This solution is called a **Bessel function of the second kind** and is denoted by Y_n. We shall now derive such a solution, beginning with the case $n = 0$.

$n = 0$: Bessel Function of the Second Kind $Y_0(x)$

When $n = 0$, Bessel's equation can be written

(1) $$xy'' + y' + xy = 0.$$

Then the indicial equation (4) in Sec. 5.5 has a double root $r = 0$. This is Case 2 in Sec. 5.4. In this case we first have only one solution, $J_0(x)$. From (8) in Sec. 5.4 we see that the desired second solution must be of the form

$$(2) \qquad y_2(x) = J_0(x) \ln x + \sum_{m=1}^{\infty} A_m x^m.$$

We substitute y_2 and its derivatives

$$y_2' = J_0' \ln x + \frac{J_0}{x} + \sum_{m=1}^{\infty} m A_m x^{m-1}$$

$$y_2'' = J_0'' \ln x + \frac{2J_0'}{x} - \frac{J_0}{x^2} + \sum_{m=1}^{\infty} m(m-1) A_m x^{m-2}$$

into (1). Then the sum of the three logarithmic terms $xJ_0'' \ln x$, $J_0' \ln x$, and $xJ_0 \ln x$ is zero because J_0 is a solution of (1). The terms $-J_0/x$ and J_0/x (from xy'' and y') cancel. Hence we are left with

$$2J_0' + \sum_{m=1}^{\infty} m(m-1) A_m x^{m-1} + \sum_{m=1}^{\infty} m A_m x^{m-1} + \sum_{m=1}^{\infty} A_m x^{m+1} = 0.$$

Addition of the first and second series gives $\Sigma m^2 A_m x^{m-1}$. The power series of $J_0'(x)$ is obtained from (12) in Sec. 5.5 and the use of $m!/m = (m-1)!$ in the form

$$J_0'(x) = \sum_{m=1}^{\infty} \frac{(-1)^m 2m x^{2m-1}}{2^{2m}(m!)^2} = \sum_{m=1}^{\infty} \frac{(-1)^m x^{2m-1}}{2^{2m-1} m!\,(m-1)!}.$$

Together with $\Sigma m^2 A_m x^{m-1}$ and $\Sigma A_m x^{m+1}$ this gives

$$(3^*) \qquad \sum_{m=1}^{\infty} \frac{(-1)^m x^{2m-1}}{2^{2m-2} m!\,(m-1)!} + \sum_{m=1}^{\infty} m^2 A_m x^{m-1} + \sum_{m=1}^{\infty} A_m x^{m+1} = 0.$$

First, we show that the A_m with odd subscripts are all zero. The power x^0 occurs only in the second series, with coefficient A_1. Hence $A_1 = 0$. Next, we consider the even powers x^{2s}. The first series contains none. In the second series, $m - 1 = 2s$ gives the term $(2s+1)^2 A_{2s+1} x^{2s}$. In the third series, $m + 1 = 2s$. Hence by equating the sum of the coefficients of x^{2s} to zero we have

$$(2s+1)^2 A_{2s+1} + A_{2s-1} = 0, \qquad s = 1, 2, \cdots.$$

Since $A_1 = 0$, we thus obtain $A_3 = 0$, $A_5 = 0, \cdots$, successively.

We now equate the sum of the coefficients of x^{2s+1} to zero. For $s = 0$ this gives

$$-1 + 4A_2 = 0, \qquad \text{thus} \qquad A_2 = \tfrac{1}{4}.$$

For the other values of s we have in the first series in (3*) $2m - 1 = 2s + 1$, hence $m = s + 1$, in the second $m - 1 = 2s + 1$, and in the third $m + 1 = 2s + 1$. We thus obtain

$$\frac{(-1)^{s+1}}{2^{2s}(s+1)!\,s!} + (2s+2)^2 A_{2s+2} + A_{2s} = 0.$$

For $s = 1$ this yields

$$\frac{1}{8} + 16A_4 + A_2 = 0, \qquad \text{thus} \qquad A_4 = -\frac{3}{128}$$

and in general

$$(3) \qquad A_{2m} = \frac{(-1)^{m-1}}{2^{2m}(m!)^2}\left(1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{m}\right), \qquad m = 1, 2, \cdots.$$

Using the short notations

$$(4) \qquad h_1 = 1 \qquad h_m = 1 + \frac{1}{2} + \cdots + \frac{1}{m} \qquad m = 2, 3, \cdots$$

and inserting (4) and $A_1 = A_3 = \cdots = 0$ into (2), we obtain the result

$$(5) \qquad \begin{aligned} y_2(x) &= J_0(x)\ln x + \sum_{m=1}^{\infty} \frac{(-1)^{m-1}h_m}{2^{2m}(m!)^2}\, x^{2m} \\ &= J_0(x)\ln x + \frac{1}{4}x^2 - \frac{3}{128}x^4 + \frac{11}{13824}x^6 - + \cdots. \end{aligned}$$

Since J_0 and y_2 are linearly independent functions, they form a basis of (1) for $x > 0$. Of course, another basis is obtained if we replace y_2 by an independent particular solution of the form $a(y_2 + bJ_0)$, where a $(\neq 0)$ and b are constants. It is customary to choose $a = 2/\pi$ and $b = \gamma - \ln 2$, where the number $\gamma = 0.577\,215\,664\,90\cdots$ is the so-called **Euler constant,** which is defined as the limit of

$$1 + \frac{1}{2} + \cdots + \frac{1}{s} - \ln s$$

as s approaches infinity. The standard particular solution thus obtained is called the **Bessel function of the second kind** *of order zero* (Fig. 109) or **Neumann's function** *of order zero* and is denoted by $Y_0(x)$. Thus [see (4)]

$$(6) \qquad Y_0(x) = \frac{2}{\pi}\left[J_0(x)\left(\ln\frac{x}{2} + \gamma\right) + \sum_{m=1}^{\infty}\frac{(-1)^{m-1}h_m}{2^{2m}(m!)^2}\, x^{2m}\right].$$

For small $x > 0$ the function $Y_0(x)$ behaves about like $\ln x$ (see Fig. 109, why?), and $Y_0(x) \to -\infty$ as $x \to 0$.

Bessel Functions of the Second Kind $Y_n(x)$

For $\nu = n = 1, 2, \cdots$ a second solution can be obtained by manipulations similar to those for $n = 0$, starting from (10), Sec 5.4. It turns out that in these cases the solution also contains a logarithmic term.

The situation is not yet completely satisfactory, because the second solution is defined differently, depending on whether the order ν is an integer or not. To provide uniformity

of formalism, it is desirable to adopt a form of the second solution that is valid for all values of the order. For this reason we introduce a standard second solution $Y_\nu(x)$ defined for all ν by the formula

$$\textbf{(7)} \qquad \textbf{(a)} \qquad Y_\nu(x) = \frac{1}{\sin \nu\pi} \left[J_\nu(x) \cos \nu\pi - J_{-\nu}(x)\right]$$

$$\textbf{(b)} \qquad Y_n(x) = \lim_{\nu \to n} Y_\nu(x).$$

This function is called the **Bessel function of the second kind** *of order* ν or **Neumann's function**[7] *of order* ν. Figure 109 shows $Y_0(x)$ and $Y_1(x)$.

Let us show that J_ν and Y_ν are indeed linearly independent for all ν (and $x > 0$).

For noninteger order ν, the function $Y_\nu(x)$ is evidently a solution of Bessel's equation because $J_\nu(x)$ and $J_{-\nu}(x)$ are solutions of that equation. Since for those ν the solutions J_ν and $J_{-\nu}$ are linearly independent and Y_ν involves $J_{-\nu}$, the functions J_ν and Y_ν are linearly independent. Furthermore, it can be shown that the limit in (7b) exists and Y_n is a solution of Bessel's equation for integer order; see Ref. [A13] in App. 1. We shall see that the series development of $Y_n(x)$ contains a logarithmic term. Hence $J_n(x)$ and $Y_n(x)$ are linearly independent solutions of Bessel's equation. The series development of $Y_n(x)$ can be obtained if we insert the series (20) and (21), Sec. 5.5, for $J_\nu(x)$ and $J_{-\nu}(x)$ into (7a) and then let ν approach n; for details see Ref. [A13]. The result is

$$\textbf{(8)} \qquad Y_n(x) = \frac{2}{\pi} J_n(x) \left(\ln \frac{x}{2} + \gamma\right) + \frac{x^n}{\pi} \sum_{m=0}^{\infty} \frac{(-1)^{m-1}(h_m + h_{m+n})}{2^{2m+n} m!\,(m+n)!} x^{2m} - \frac{x^{-n}}{\pi} \sum_{m=0}^{n-1} \frac{(n-m-1)!}{2^{2m-n} m!} x^{2m}$$

where $x > 0$, $n = 0, 1, \cdots$, and [as in (4)] $h_0 = 0$, $h_1 = 1$,

$$h_m = 1 + \frac{1}{2} + \cdots + \frac{1}{m}, \qquad h_{m+n} = 1 + \frac{1}{2} + \cdots + \frac{1}{m+n}.$$

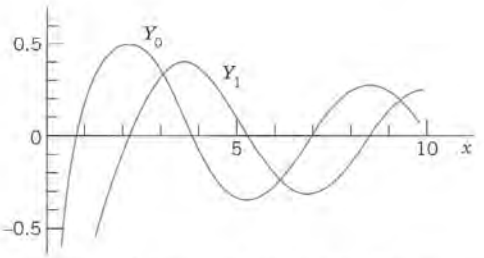

Fig. 109. Bessel functions of the second kind Y_0 and Y_1. (For a small table, see App. 5.)

[7] CARL NEUMANN (1832–1925), German mathematician and physicist. His work on potential theory sparked the development in the field of integral equations by VITO VOLTERRA (1860–1940) of Rome, ERIC IVAR FREDHOLM (1866–1927) of Stockholm, and DAVID HILBERT (1862–1943) of Göttingen (see the footnote in Sec. 7.9).

The solutions $Y_\nu(x)$ are sometimes denoted by $N_\nu(x)$; in Ref. [A13] they are called **Weber's functions;** Euler's constant in (6) is often denoted by C or $\ln \gamma$.

For $n = 0$ the last sum in (8) is to be replaced by 0 [giving agreement with (6)].

Furthermore, it can be shown that

$$Y_{-n}(x) = (-1)^n Y_n(x).$$

Our main result may now be formulated as follows.

THEOREM 1

General Solution of Bessel's Equation

A general solution of Bessel's equation for all values of ν (and $x > 0$) is

$$y(x) = C_1 J_\nu(x) + C_2 Y_\nu(x). \tag{9}$$

We finally mention that there is a practical need for solutions of Bessel's equation that are complex for real values of x. For this purpose the solutions

$$H_\nu^{(1)}(x) = J_\nu(x) + iY_\nu(x)$$
$$H_\nu^{(2)}(x) = J_\nu(x) - iY_\nu(x) \tag{10}$$

are frequently used. These linearly independent functions are called **Bessel functions of the third kind** *of order ν* or *first and second* **Hankel functions**[8] *of order ν.*

This finishes our discussion on Bessel functions, except for their "orthogonality," which we explain in Sec. 5.7. Applications to vibrations follow in Sec. 12.9.

PROBLEM SET 5.6

1–10 SOME FURTHER ODEs REDUCIBLE TO BESSEL'S EQUATIONS

(See also Sec. 5.5.)

Using the indicated substitutions, find a general solution in terms of J_ν and Y_ν. Indicate whether you could also use $J_{-\nu}$ instead of Y_ν. (Show the details of your work.)

1. $x^2y'' + xy' + (x^2 - 25)y = 0$
2. $x^2y'' + xy' + (9x^2 - \frac{1}{9})y = 0 \quad (3x = z)$
3. $4xy'' + 4y' + y = 0 \quad (\sqrt{x} = z)$
4. $xy'' + y' + 36y = 0 \quad (12\sqrt{x} = z)$
5. $x^2y'' + xy' + (4x^4 - 16)y = 0 \quad (x^2 = z)$
6. $x^2y'' + xy' + (x^6 - 1)y = 0 \quad (\frac{1}{3}x^3 = z)$
7. $xy'' + 11y' + xy = 0 \quad (y = x^{-5}u)$
8. $y'' + 4x^2y = 0 \quad (y = u\sqrt{x},\ x^2 = z)$
9. $x^2y'' - 5xy' + 9(x^6 - 8)y = 0 \quad (y = x^3u,\ x^3 = z)$
10. $xy'' + 7y' + 4xy = 0 \quad (y = x^{-3}u,\ 2x = z)$

11. **(Hankel functions)** Show that the Hankel functions (10) form a basis of solutions of Bessel's equation for any ν.

12. **CAS EXPERIMENT. Bessel Functions for Large x.** It can be shown that for large x,

$$Y_n(x) \sim \sqrt{2/(\pi x)} \sin(x - \tfrac{1}{2}n\pi - \tfrac{1}{4}\pi) \tag{11}$$

with $\sim$ defined as in (14) of Sec. 5.5.

(a) Graph $Y_n(x)$ for $n = 0, \cdots, 5$ on common axes. Are there relations between zeros of one function and extrema of another? For what functions?

(b) Find out from graphs from which $x = x_n$ on the curves of (8) and (11) (both obtained from your CAS) practically coincide. How does x_n change with n?

(c) Calculate the first ten zeros x_m, $m = 1, \cdots, 10$, of $Y_0(x)$ from your CAS and from (11). How does the error behave as m increases?

(d) Do (c) for $Y_1(x)$ and $Y_2(x)$. How do the errors compare to those in (c)?

[8] HERMANN HANKEL (1839–1873), German mathematician.

13. Modified Bessel functions of the first kind of order ν are defined by $I_\nu(x) = i^{-\nu}J_\nu(ix)$, $i = \sqrt{-1}$. Show that I_ν satisfies the ODE

$$x^2y'' + xy' - (x^2 + \nu^2)y = 0 \tag{12}$$

and has the representation

$$I_\nu(x) = \sum_{m=0}^{\infty} \frac{x^{2m+\nu}}{2^{2m+\nu}m!\,\Gamma(m + \nu + 1)}. \tag{13}$$

14. (Modified Bessel functions I_n) Show that $I_\nu(x)$ is real for all real x (and real ν), $I_\nu(x) \neq 0$ for all real $x \neq 0$, and $I_{-n}(x) = I_n(x)$, where n is any integer.

15. Modified Bessel functions of the third kind (sometimes called *of the second kind*) are defined by the formula (14) below. Show that they satisfy the ODE (12).

$$K_\nu(x) = \frac{\pi}{2 \sin \nu\pi}\,[I_{-\nu}(x) - I_\nu(x)] \tag{14}$$

5.7 Sturm–Liouville Problems. Orthogonal Functions

So far we have considered initial value problems. We recall from Sec. 2.1 that such a problem consists of an ODE, say, of second order, and initial conditions $y(x_0) = K_0$, $y'(x_0) = K_1$ referring to the *same point* (initial point) $x = x_0$. We now turn to boundary value problems. A **boundary value problem** consists of an ODE and given **boundary conditions** referring to the two boundary points (endpoints) $x = a$ and $x = b$ of a given interval $a \leqq x \leqq b$. To solve such a problem means to find a solution of the ODE on the interval $a \leqq x \leqq b$ satisfying the boundary conditions.

We shall see that Legendre's, Bessel's, and other ODEs of importance in engineering can be written as a **Sturm–Liouville equation**

$$[p(x)y']' + [q(x) + \lambda r(x)]y = 0 \tag{1}$$

involving a parameter λ. The boundary value problem consisting of an ODE (1) and given **Sturm–Liouville boundary conditions**

$$\begin{aligned} &\textbf{(a)} \quad k_1y(a) + k_2y'(a) = 0 \\ &\textbf{(b)} \quad l_1y(b) + l_2y'(b) = 0 \end{aligned} \tag{2}$$

is called a **Sturm–Liouville problem.**[9] We shall see further that these problems lead to useful series developments in terms of particular solutions of (1), (2). Crucial in this connection is *orthogonality* to be discussed later in this section.

In (1) we make the ***assumptions*** that p, q, r, and p' are continuous on $a \leqq x \leqq b$, and

$$r(x) > 0 \qquad (a \leqq x \leqq b).$$

In (2) we assume that k_1, k_2 are given constants, not both zero, and so are l_1, l_2, not both zero.

---

[9]JACQUES CHARLES FRANÇOIS STURM (1803–1855), was born and studied in Switzerland and then moved to Paris, where he later became the successor of Poisson in the chair of mechanics at the Sorbonne (the University of Paris).

JOSEPH LIOUVILLE (1809–1882), French mathematician and professor in Paris, contributed to various fields in mathematics and is particularly known by his important work in complex analysis (Liouville's theorem; Sec. 14.4), special functions, differential geometry, and number theory.

EXAMPLE 1 Legendre's and Bessel's Equations are Sturm–Liouville Equations

Legendre's equation $(1 - x^2)y'' - 2xy' + n(n + 1)y = 0$ may be written

$$[(1 - x^2)y']' + \lambda y = 0 \qquad \lambda = n(n + 1).$$

This is (1) with $p = 1 - x^2$, $q = 0$, and $r = 1$.

In Bessel's equation

$$\tilde{x}^2\ddot{y} + \tilde{x}\dot{y} + (\tilde{x}^2 - n^2)y = 0 \qquad \dot{y} = dy/d\tilde{x}, \quad \text{etc.}$$

as a model in physics or elsewhere, one often likes to have another parameter k in addition to n. For this reason we set $\tilde{x} = kx$. Then by the chain rule $\dot{y} = dy/d\tilde{x} = (dy/dx)\,dx/d\tilde{x} = y'/k$, $\ddot{y} = y''/k^2$. In the first two terms, k^2 and k drop out and we get

$$x^2y'' + xy' + (k^2x^2 - n^2)y = 0.$$

Division by x gives the Sturm–Liouville equation

$$[xy']' + \left(-\frac{n^2}{x} + \lambda x\right)y = 0 \qquad \lambda = k^2.$$

This is (1) with $p = x$, $q = -n^2/x$, and $r = x$. ■

Eigenfunctions, Eigenvalues

Clearly, $y \equiv 0$ is a solution—the **"trivial solution"**—for any λ because (1) is homogeneous and (2) has zeros on the right. This is of no interest. We want to find **eigenfunctions** $y(x)$, that is, solutions of (1) satisfying (2) without being identically zero. We call a number λ for which an eigenfunction exists an **eigenvalue** of the Sturm–Liouville problem (1), (2).

EXAMPLE 2 Trigonometric Functions as Eigenfunctions. Vibrating String

Find the eigenvalues and eigenfunctions of the Sturm–Liouville problem

$$y'' + \lambda y = 0, \qquad y(0) = 0, \quad y(\pi) = 0. \tag{3}$$

This problem arises, for instance, if an elastic string (a violin string, for example) is stretched a little and then fixed at its ends $x = 0$ and $x = \pi$ and allowed to vibrate. Then $y(x)$ is the "space function" of the deflection $u(x, t)$ of the string, assumed in the form $u(x, t) = y(x)w(t)$, where t is time. (This model will be discussed in great detail in Secs. 12.2–12.4.)

Solution. From (1) and (2) we see that $p = 1$, $q = 0$, $r = 1$ in (1), and $a = 0$, $b = \pi$, $k_1 = l_1 = 1$, $k_2 = l_2 = 0$ in (2). For negative $\lambda = -\nu^2$ a general solution of the ODE in (3) is $y(x) = c_1e^{\nu x} + c_2e^{-\nu x}$. From the boundary conditions we obtain $c_1 = c_2 = 0$, so that $y \equiv 0$, which is not an eigenfunction. For $\lambda = 0$ the situation is similar. For positive $\lambda = \nu^2$ a general solution is

$$y(x) = A \cos \nu x + B \sin \nu x.$$

From the first boundary condition we obtain $y(0) = A = 0$. The second boundary condition then yields

$$y(\pi) = B \sin \nu\pi = 0, \qquad \text{thus} \qquad \nu = 0, \pm 1, \pm 2, \cdots.$$

For $\nu = 0$ we have $y \equiv 0$. For $\lambda = \nu^2 = 1, 4, 9, 16, \cdots$, taking $B = 1$, we obtain

$$y(x) = \sin \nu x \qquad (\nu = 1, 2, \cdots).$$

Hence the eigenvalues of the problem are $\lambda = \nu^2$, where $\nu = 1, 2, \cdots$, and corresponding eigenfunctions are $y(x) = \sin \nu x$, where $\nu = 1, 2, \cdots$. ■

Existence of Eigenvalues

Eigenvalues of a Sturm–Liouville problem (1), (2), even infinitely many, exist under rather general conditions on p, q, r in (1). (Sufficient are the conditions in Theorem 1, below, together with $p(x) > 0$ and $r(x) > 0$ on $a < x < b$. Proofs are complicated; see Ref. [A3] or [A11] listed in App. 1.)

Reality of Eigenvalues

Furthermore, if p, q, r, and p' in (1) are real-valued and continuous on the interval $a \leqq x \leqq b$ and r is positive throughout that interval (or negative throughout that interval), then all the eigenvalues of the Sturm–Liouville problem (1), (2) are real. (Proof in App. 4.) This is what the engineer would expect since eigenvalues are often related to frequencies, energies, or other physical quantities that must be real.

Orthogonality

The most remarkable and important property of eigenfunctions of Sturm–Liouville problems is their orthogonality, which will be crucial in series developments in terms of eigenfunctions.

DEFINITION

Orthogonality

Functions $y_1(x), y_2(x), \cdots$ defined on some interval $a \leqq x \leqq b$ are called **orthogonal** on this interval with respect to the **weight function** $r(x) > 0$ if for all m and all n different from m,

$$\int_a^b r(x)\, y_m(x)\, y_n(x)\, dx = 0 \qquad (m \neq n). \tag{4}$$

The **norm** $\|y_m\|$ of y_m is defined by

$$\|y_m\| = \sqrt{\int_a^b r(x) y_m^2(x)\, dx}\,. \tag{5}$$

Note that this is the square root of the integral in (4) with $n = m$.

The functions $y_1, y_2, \cdots$ are called **orthonormal** on $a \leqq x \leqq b$ if they are orthogonal on this interval and all have norm 1.

If $r(x) = 1$, we more briefly call the functions *orthogonal* instead of orthogonal with respect to $r(x) = 1$; similarly for orthonormality. Then

$$\int_a^b y_m(x)\, y_n(x)\, dx = 0 \quad (m \neq n), \qquad \|y_m\| = \sqrt{\int_a^b y_m^2(x)\, dx}\,.$$

EXAMPLE 3 **Orthogonal Functions. Orthonormal Functions**

The functions $y_m(x) = \sin mx$, $m = 1, 2, \cdots$ form an orthogonal set on the interval $-\pi \leqq x \leqq \pi$, because for $m \neq n$ we obtain by integration [see (11) in App. A3.1]

$$\int_{-\pi}^{\pi} y_m(x) y_n(x)\, dx = \int_{-\pi}^{\pi} \sin mx \sin nx\, dx = \frac{1}{2}\int_{-\pi}^{\pi} \cos{(m-n)x}\, dx - \frac{1}{2}\int_{-\pi}^{\pi} \cos{(m+n)x}\, dx = 0.$$

The norm $\|y_m\|$ equals $\sqrt{\pi}$, because

$$\|y_m\|^2 = \int_{-\pi}^{\pi} \sin^2 mx\, dx = \pi \qquad (m = 1, 2, \cdots).$$

Hence the corresponding orthonormal set, obtained by division by the norm, is

$$\frac{\sin x}{\sqrt{\pi}}, \qquad \frac{\sin 2x}{\sqrt{\pi}}, \qquad \frac{\sin 3x}{\sqrt{\pi}}, \qquad \cdots$$

■

Orthogonality of Eigenfunctions

THEOREM 1

Orthogonality of Eigenfunctions

Suppose that the functions p, q, r, and p' in the Sturm–Liouville equation (1) *are real-valued and continuous and $r(x) > 0$ on the interval $a \leqq x \leqq b$. Let $y_m(x)$ and $y_n(x)$ be eigenfunctions of the Sturm–Liouville problem* (1), (2) *that correspond to different eigenvalues λ_m and λ_n, respectively. Then y_m, y_n are orthogonal on that interval with respect to the weight function r, that is,*

$$\textbf{(6)} \qquad \int_a^b r(x)y_m(x)y_n(x)\,dx = 0 \qquad (m \neq n).$$

If $p(a) = 0$, then (2a) *can be dropped from the problem. If $p(b) = 0$, then* (2b) *can be dropped.* [It is then required that y and y' remain bounded at such a point, and the problem is called **singular,** as opposed to a **regular problem** in which (2) is used.]

If $p(a) = p(b)$, then (2) *can be replaced by the* **"periodic boundary conditions"**

$$\textbf{(7)} \qquad y(a) = y(b), \qquad y'(a) = y'(b).$$

The boundary value problem consisting of the Sturm–Liouville equation (1) and the periodic boundary conditions (7) is called a **periodic Sturm–Liouville problem.**

PROOF By assumption, y_m and y_n satisfy the Sturm–Liouville equations

$$(py_m')' + (q + \lambda_m r)y_m = 0$$
$$(py_n')' + (q + \lambda_n r)y_n = 0$$

respectively. We multiply the first equation by y_n, the second by $-y_m$, and add,

$$(\lambda_m - \lambda_n)ry_my_n = y_m(py_n')' - y_n(py_m')' = \left[(py_n')y_m - (py_m')y_n\right]'$$

where the last equality can be readily verified by performing the indicated differentiation of the last expression in brackets. This expression is continuous on $a \leqq x \leqq b$ since p and p' are continuous by assumption and y_m, y_n are solutions of (1). Integrating over x from a to b, we thus obtain

$$(8) \qquad (\lambda_m - \lambda_n)\int_a^b ry_my_n\,dx = \Big[p(y_n'y_m - y_m'y_n)\Big]_a^b \qquad (a < b).$$

The expression on the right equals the sum of the subsequent Lines 1 and 2,

$$(9) \qquad \begin{aligned} &p(b)\left[y_n'(b)y_m(b) - y_m'(b)y_n(b)\right] && \text{(Line 1)} \\ &-p(a)\left[y_n'(a)y_m(a) - y_m'(a)y_n(a)\right] && \text{(Line 2).} \end{aligned}$$

Hence if (9) is zero, (8) with $\lambda_m - \lambda_n \neq 0$ implies the orthogonality (6). Accordingly, we have to show that (9) is zero, using the boundary conditions (2) as needed.

Case 1. $p(a) = p(b) = 0$. Clearly, (9) is zero, and (2) is not needed.

Case 2. $p(a) \neq 0, p(b) = 0$. Line 1 of (9) is zero. Consider Line 2. From (2a) we have

$$k_1 y_n(a) + k_2 y_n'(a) = 0,$$
$$k_1 y_m(a) + k_2 y_m'(a) = 0.$$

Let $k_2 \neq 0$. We multiply the first equation by $y_m(a)$, the last by $-y_n(a)$ and add,

$$k_2[y_n'(a)y_m(a) - y_m'(a)y_n(a)] = 0.$$

This is k_2 times Line 2 of (9), which thus is zero since $k_2 \neq 0$. If $k_2 = 0$, then $k_1 \neq 0$ by assumption, and the argument of proof is similar.

Case 3. $p(a) = 0, p(b) \neq 0$. Line 2 of (9) is zero. From (2b) it follows that Line 1 of (9) is zero; this is similar to Case 2.

Case 4. $p(a) \neq 0, p(b) \neq 0$. We use both (2a) and (2b) and proceed as in Cases 2 and 3.

Case 5. $p(a) = p(b)$. Then (9) becomes

$$p(b)\big[y_n'(b)y_m(b) - y_m'(b)y_n(b) - y_n'(a)y_m(a) + y_m'(a)y_n(a)\big].$$

The expression in brackets $[\cdots]$ is zero, either by (2) used as before, or more directly by (7). Hence in this case, (7) can be used instead of (2), as claimed. This completes the proof of Theorem 1. ∎

EXAMPLE 4 **Application of Theorem 1. Vibrating Elastic String**

The ODE in Example 2 is a Sturm–Liouville equation with $p = 1$, $q = 0$, and $r = 1$. From Theorem 1 it follows that the eigenfunctions $y_m = \sin mx$ $(m = 1, 2, \cdots)$ are orthogonal on the interval $0 \leqq x \leqq \pi$. ∎

EXAMPLE 5 **Application of Theorem 1. Orthogonality of the Legendre Polynomials**

Legendre's equation is a Sturm–Liouville equation (see Example 1)

$$\big[(1 - x^2)y'\big]' + \lambda y = 0, \qquad \lambda = n(n + 1)$$

with $p = 1 - x^2$, $q = 0$, and $r = 1$. Since $p(-1) = p(1) = 0$, we need no boundary conditions, but have a ***singular Sturm—Liouville problem*** on the interval $-1 \leqq x \leqq 1$. We know that for $n = 0, 1, \cdots$, hence $\lambda = 0, 1 \cdot 2, 2 \cdot 3, \cdots$, the Legendre polynomials $P_n(x)$ are solutions of the problem. Hence these are the eigenfunctions. From Theorem 1 it follows that they are orthogonal on that interval, that is,

$$\textbf{(10)} \qquad \int_{-1}^{1} P_m(x)\,P_n(x)\,dx = 0 \qquad (m \neq n).$$ ∎

EXAMPLE 6 **Application of Theorem 1. Orthogonality of the Bessel Functions $J_n(x)$**

The Bessel function $J_n(\tilde{x})$ with fixed integer $n \geqq 0$ satisfies Bessel's equation (Sec. 5.5)

$$\tilde{x}^2 \ddot{J}_n(\tilde{x}) + \tilde{x}\dot{J}_n(\tilde{x}) + (\tilde{x}^2 - n^2)J_n(\tilde{x}) = 0,$$

where $\dot{J}_n = dJ_n/d\tilde{x}$, $\ddot{J}_n = d^2J_n/d\tilde{x}^2$. In Example 1 we transformed this equation, by setting $\tilde{x} = kx$, into a Sturm–Liouville equation

$$[xJ_n'(kx)]' + \left(-\frac{n^2}{x} + k^2 x\right) J_n(kx) = 0$$

with $p(x) = x$, $q(x) = -n^2/x$, $r(x) = x$, and parameter $\lambda = k^2$. Since $p(0) = 0$, Theorem 1 implies orthogonality on an interval $0 \leqq x \leqq R$ (R given, fixed) of those solutions $J_n(kx)$ that are zero at $x = R$, that is,

$$(11) \qquad J_n(kR) = 0 \qquad (n \text{ fixed}).$$

[Note that $q(x) = -n^2/x$ is discontinuous at 0, but this does not affect the proof of Theorem 1.] It can be shown (see Ref. [A13]) that $J_n(\tilde{x})$ has infinitely many zeros, say, $\tilde{x} = \alpha_{n,1} < \alpha_{n,2} < \cdots$ (see Fig. 107 in Sec. 5.5 for $n = 0$ and 1). Hence we must have

$$(12) \qquad kR = \alpha_{n,m} \qquad \text{thus} \qquad k_{n,m} = \alpha_{n,m}/R \qquad (m = 1, 2, \cdots).$$

This proves the following orthogonality property.

THEOREM 2

Orthogonality of Bessel Functions

For each fixed nonnegative integer n the sequence of Bessel functions of the first kind $J_n(k_{n,1}x)$, $J_n(k_{n,2}x)$, $\cdots$ with $k_{n,m}$ as in (12) forms an orthogonal set on the interval $0 \leqq x \leqq R$ with respect to the weight function $r(x) = x$, that is,

$$\textbf{(13)} \qquad \int_0^R xJ_n(k_{n,m}x)J_n(k_{n,j}x)\,dx = 0 \qquad (j \neq m,\ n \text{ fixed}).$$

Hence we have obtained ***infinitely many orthogonal sets***, each corresponding to one of the ***fixed*** values n. This also illustrates the importance of the zeros of the Bessel functions. ■

EXAMPLE 7 **Eigenvalues from Graphs**

Solve the Sturm–Liouville problem $y'' + \lambda y = 0$, $y(0) + y'(0) = 0$, $y(\pi) - y'(\pi) = 0$.

Solution. A general solution and its derivative are

$$y = A\cos kx + B\sin kx \qquad \text{and} \qquad y' = -Ak\sin kx + Bk\cos kx, \qquad k = \sqrt{\lambda}.$$

The first boundary condition gives $y(0) + y'(0) = A + Bk = 0$, hence $A = -Bk$. The second boundary condition and substitution of $A = -Bk$ give

$$\begin{aligned} y(\pi) - y'(\pi) &= A\cos \pi k + B\sin \pi k + Ak\sin \pi k - Bk\cos \pi k \\ &= -Bk\cos \pi k + B\sin \pi k - Bk^2\sin \pi k - Bk\cos \pi k = 0. \end{aligned}$$

We must have $B \neq 0$ since otherwise $B = A = 0$, hence $y = 0$, which is not an eigenfunction. Division by $B\cos \pi k$ gives

$$-k + \tan \pi k - k^2 \tan \pi k - k = 0, \qquad \text{thus} \qquad \tan \pi k = \frac{-2k}{k^2 - 1}.$$

The graph in Fig. 110 now shows us where to look for eigenvalues. These correspond to the k-values of the points of intersection of $\tan \pi k$ and the right side $-2k/(k^2 - 1)$ of the last equation. The eigenvalues are $\lambda_m = k_m{}^2$, where $\lambda_0 = 0$ with eigenfunction $y_0 = 1$ and the other λ_m are located near $2^2, 3^2, 4^2, \cdots$, with eigenfunctions $\cos k_m x$ and $\sin k_m x$, $m = 1, 2, \cdots$. The precise numeric determination of the eigenvalues would require a root-finding method (such as those given in Sec. 19.2). ■

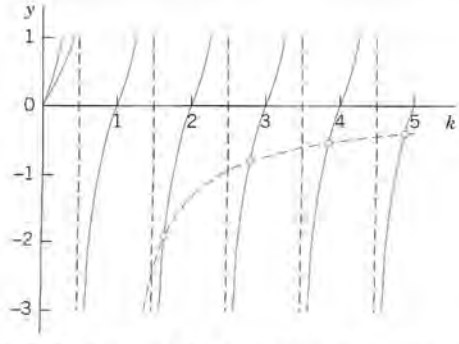

Fig. 110. Example 7. Circles mark the intersections of $\tan \pi k$ and $-2k/(k^2 - 1)$

PROBLEM SET 5.7

1. **(Proof of Theorem 1)** Carry out the details in Cases 3 and 4.
2. **Normalization of eigenfunctions** y_m of (1), (2) means that we multiply y_m by a nonzero constant c_m such that $c_m y_m$ has norm 1. Show that $z_m = cy_m$ with *any* $c \neq 0$ is an eigenfunction for the eigenvalue corresponding to y_m.
3. **(Change of x)** Show that if the functions $y_0(x)$, $y_1(x)$, $\cdots$ form an orthogonal set on an interval $a \leqq x \leqq b$ (with $r(x) = 1$), then the functions $y_0(ct + k)$, $y_1(ct + k)$, $\cdots$, $c > 0$, form an orthogonal set on the interval $(a - k)/c \leqq t \leqq (b - k)/c$.
4. **(Change of x)** Using Prob. 3, derive the orthogonality of 1, $\cos \pi x$, $\sin \pi x$, $\cos 2\pi x$, $\sin 2\pi x$, $\cdots$ on $-1 \leqq x \leqq 1$ ($r(x) = 1$) from that of 1, $\cos x$, $\sin x$, $\cos 2x$, $\sin 2x$, $\cdots$ on $-\pi \leqq x \leqq \pi$.
5. **(Legendre polynomials)** Show that the functions $P_n(\cos \theta)$, $n = 0, 1, \cdots$, form an orthogonal set on the interval $0 \leqq \theta \leqq \pi$ with respect to the weight function $\sin \theta$.
6. **(Tranformation to Sturm–Liouville form)** Show that $y'' + fy' + (g + \lambda h)y = 0$ takes the form (1) if you set $p = \exp(\int f\,dx)$, $q = pg$, $r = hp$. Why would you do such a transformation?

7–19 STURM–LIOUVILLE PROBLEMS

Write the given ODE in the form (1) if it is in a different form. (Use Prob. 6.) Find the eigenvalues and eigenfunctions. Verify orthogonality. (Show the details of your work.)

7. $y'' + \lambda y = 0, \quad y(0) = 0, \quad y(5) = 0$
8. $y'' + \lambda y = 0, \quad y'(0) = 0, \quad y'(\pi) = 0$
9. $y'' + \lambda y = 0, \quad y(0) = 0, \quad y'(L) = 0$
10. $y'' + \lambda y = 0, \quad y(0) = y(1), \quad y'(0) = y'(1)$
11. $y'' + \lambda y = 0, \quad y(0) = y(2\pi), \quad y'(0) = y'(2\pi)$
12. $y'' + \lambda y = 0, \quad y(0) + y'(0) = 0, \quad y(1) + y'(1) = 0$
13. $y'' + \lambda y = 0, \quad y(0) = 0, \quad y(1) + y'(1) = 0$
14. $(xy')' + \lambda x^{-1}y = 0, \quad y(1) = 0, \quad y'(e) = 0.$ (Set $x = e^t$.)
15. $(x^{-1}y')' + (\lambda + 1)x^{-3}y = 0, \quad y(1) = 0, \quad y(e^\pi) = 0.$ (Set $x = e^t$.)
16. $y'' - 2y' + (\lambda + 1)y = 0, \quad y(0) = 0, \quad y(1) = 0$
17. $y'' + 8y' + (\lambda + 16)y = 0, \quad y(0) = 0, \quad y(\pi) = 0$
18. $xy'' + 2y' + \lambda xy = 0, \quad y(\pi) = 0, \quad y(2\pi) = 0.$ (Use a CAS or set $y = x^{-1}u$.)
19. $y'' - 2x^{-1}y' + (k^2 + 2x^{-2})y = 0, \; y(1) = 0, \; y(2) = 0.$ (Use a CAS or set $y = xu$.)

20. **TEAM PROJECT. Special Functions. Orthogonal polynomials** play a great role in applications. For this reason, Legendre polynomials and various other orthogonal polynomials have been studied extensively; see Refs. [GR1], [GR10] in App. 1. Consider some of the most important ones as follows.

(a) Chebyshev polynomials[10] of the first and second kind are defined by

$$T_n(x) = \cos(n \arccos x)$$

$$U_n(x) = \frac{\sin[(n+1)\arccos x]}{\sqrt{1 - x^2}}$$

respectively, where $n = 0, 1, \cdots$. Show that

$$T_0 = 1, \quad T_1(x) = x, \quad T_2(x) = 2x^2 - 1, \quad T_3(x) = 4x^3 - 3x,$$

$$U_0 = 1, \quad U_1(x) = 2x, \quad U_2(x) = 4x^2 - 1, \quad U_3(x) = 8x^3 - 4x.$$

Show that the Chebyshev polynomials $T_n(x)$ are orthogonal on the interval $-1 \leqq x \leqq 1$ with respect to the weight function $r(x) = 1/\sqrt{1 - x^2}$. (*Hint.* To evaluate the integral, set $\arccos x = \theta$.) Verify that $T_n(x)$, $n = 0, 1, 2, 3$, satisfy the **Chebyshev equation**

$$(1 - x^2)y'' - xy' + n^2 y = 0.$$

(b) Orthogonality on an infinite interval: Laguerre polynomials[11] are defined by $L_0 = 1$, and

$$L_n(x) = \frac{e^x}{n!}\frac{d^n(x^n e^{-x})}{dx^n}, \qquad n = 1, 2, \cdots.$$

Show that

$$L_1(x) = 1 - x, \quad L_2(x) = 1 - 2x + x^2/2, \quad L_3(x) = 1 - 3x + 3x^2/2 - x^3/6.$$

Prove that the Laguerre polynomials are orthogonal on the positive axis $0 \leqq x < \infty$ with respect to the weight function $r(x) = e^{-x}$. *Hint.* Since the highest power in L_m is x^m, it suffices to show that $\int e^{-x}x^k L_n\,dx = 0$ for $k < n$. Do this by k integrations by parts.

[10] PAFNUTI CHEBYSHEV (1821–1894), Russian mathematician, is known for his work in approximation theory and the theory of numbers. Another transliteration of the name is TCHEBICHEF.

[11] EDMOND LAGUERRE (1834–1886), French mathematician, who did research work in geometry and in the theory of infinite series.

5.8 Orthogonal Eigenfunction Expansions

Orthogonal functions (obtained from Sturm–Liouville problems or otherwise) yield important series developments of given functions, as we shall see. This includes the famous *Fourier series* (to which we devote Chaps. 11 and 12), the daily bread of the physicist and engineer for solving problems in heat conduction, mechanical and electrical vibrations, etc. Indeed, orthogonality is one of the most useful ideas ever introduced in applied mathematics.

Standard Notation for Orthogonality and Orthonormality

The integral (4) in Sec. 5.7 defining orthogonality is denoted by (y_m, y_n). This is standard. Also, **Kronecker's delta**[12] δ_{mn} is defined by $\delta_{mn} = 0$ if $m \neq n$ and $\delta_{mn} = 1$ if $m = n$ (thus $\delta_{nn} = 1$). Hence for orthonormal functions $y_0, y_1, y_2, \cdots$ with respect to weight $r(x)$ (> 0) on $a \leqq x \leqq b$ we can now simply write $(y_m, y_n) = \delta_{mn}$, written out

$$\textbf{(1)} \qquad (y_m, y_n) = \int_a^b r(x) y_m(x) y_n(x)\, dx = \delta_{mn} = \begin{cases} 0 & \text{if } m \neq n \\ 1 & \text{if } m = n. \end{cases}$$

Also, for the norm we can now write

$$\textbf{(2)} \qquad \|y\| = \sqrt{(y_m, y_m)} = \sqrt{\int_a^b r(x) y_m^2(x)\, dx}\,.$$

Write down a few examples of your own, to get used to this practical short notation.

Orthogonal Series

Now comes the instant that shows why orthogonality is a fundamental concept. Let $y_0, y_1, y_2, \cdots$ be an orthogonal set with respect to weight $r(x)$ on an interval $a \leqq x \leqq b$. Let $f(x)$ be a function that can be represented by a convergent series

$$\textbf{(3)} \qquad f(x) = \sum_{m=0}^{\infty} a_m y_m(x) = a_0 y_0(x) + a_1 y_1(x) + \cdots.$$

This is called an **orthogonal expansion** or **generalized Fourier series.** If the y_m are eigenfunctions of a Sturm–Liouville problem, we call (3) an **eigenfunction expansion.** In (3) we use again m for summation since n will be used as a fixed order of Bessel functions.

Given $f(x)$, we have to determine the coefficients in (3), called the **Fourier constants** *of $f(x)$ with respect to $y_0, y_1, \cdots$*. Because of the orthogonality this is simple. All we have to do is to multiply both sides of (3) by $r(x)y_n(x)$ (***n* fixed**) and then integrate on both sides from a to b. We assume that term-by-term integration is permissible. (This is justified, for instance, in the case of "uniform convergence," as is shown in Sec. 15.5.) Then we obtain

$$(f, y_n) = \int_a^b r f y_n\, dx = \int_a^b r \left(\sum_{m=0}^{\infty} a_m y_m \right) y_n\, dx = \sum_{m=0}^{\infty} a_m (y_m, y_n).$$

[12] LEOPOLD KRONECKER (1823–1891). German mathematician at Berlin University, who made important contributions to algebra, group theory, and number theory.

Because of the orthogonality all the integrals on the right are zero, except when $m = n$. Hence the whole infinite series reduces to the single term

$$a_n(y_n, y_n) = a_n \|y_n\|^2.$$

Assuming that all the functions y_n have nonzero norm, we can divide by $\|y_n\|^2$; writing again m for n, to be in agreement with (3), we get the desired formula for the Fourier constants

$$\textbf{(4)} \qquad a_m = \frac{(f, y_m)}{\|y_m\|^2} = \frac{1}{\|y_m\|^2} \int_a^b r(x) f(x) y_m(x)\, dx \qquad (m = 0, 1, \cdots).$$

EXAMPLE 1 **Fourier Series**

A most important class of eigenfunction expansions is obtained from the periodic Sturm–Liouville problem

$$y'' + \lambda y = 0, \qquad y(\pi) = y(-\pi), \qquad y'(\pi) = y'(-\pi).$$

A general solution of the ODE is $y = A \cos kx + B \sin kx$, where $k = \sqrt{\lambda}$. Substituting y and its derivative into the boundary conditions, we obtain

$$A \cos k\pi + B \sin k\pi = A \cos(-k\pi) + B \sin(-k\pi)$$

$$-kA \sin k\pi + kB \cos k\pi = -kA \sin(-k\pi) + kB \cos(-k\pi).$$

Since $\cos(-\alpha) = \cos \alpha$, the cosine terms cancel, so that these equations give no condition for these terms. Since $\sin(-\alpha) = -\sin \alpha$, the equations gives the condition $\sin k\pi = 0$, hence $k\pi = m\pi$, $k = m = 0, 1, 2, \cdots$, so that the eigenfunctions are

$$\cos 0 = 1, \qquad \cos x, \qquad \sin x, \qquad \cos 2x, \qquad \sin 2x, \cdots, \qquad \cos mx, \qquad \sin mx, \cdots$$

corresponding pairwise to the eigenvalues $\lambda = k^2 = 0, 1, 4, \cdots, m^2, \cdots$. ($\sin 0 = 0$ is not an eigenfunction.)

By Theorem 1 in Sec. 5.7, any two of these belonging to different eigenvalues are orthogonal on the interval $-\pi \leqq x \leqq \pi$ (note that $r(x) = 1$ for the present ODE). The orthogonality of $\cos mx$ and $\sin mx$ for the same m follows by integration,

$$\int_{-\pi}^{\pi} \cos mx \sin mx\, dx = \frac{1}{2} \int_{-\pi}^{\pi} \sin 2mx\, dx = 0.$$

For the norms we get $\|1\| = \sqrt{2\pi}$, and $\sqrt{\pi}$ for all the others, as you may verify by integrating 1, $\cos^2 x$, $\sin^2 x$, etc., from $-\pi$ to π. This gives the series (with a slight extension of notation since we have two functions for each eigenvalue $1, 4, 9, \cdots$)

$$\textbf{(5)} \qquad f(x) = a_0 + \sum_{m=1}^{\infty} (a_m \cos mx + b_m \sin mx).$$

According to (4) the coefficients (with $m = 1, 2, \cdots$) are

$$\textbf{(6)} \qquad a_0 = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x)\, dx, \quad a_m = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos mx\, dx, \quad b_m = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin mx\, dx.$$

The series (5) is called the **Fourier series** of $f(x)$. Its coefficients are called the **Fourier coefficients** of $f(x)$, as given by the so-called **Euler formulas** (6) (not to be confused with the Euler formula (11) in Sec. 2.2).

For instance, for the **"periodic rectangular wave"** in Fig. 111, given by

$$f(x) = \begin{cases} -1 & \text{if } -\pi < x < 0 \\ 1 & \text{if } 0 < x < \pi \end{cases} \qquad \text{and} \qquad f(x + 2\pi) = f(x),$$

we get from (6) the values $a_0 = 0$ and

$$a_m = \frac{1}{\pi}\left[\int_{-\pi}^{0}(-1)\cos mx\,dx + \int_{0}^{\pi} 1\cdot\cos mx\,dx\right] = 0,$$

$$b_m = \frac{1}{\pi}\left[\int_{-\pi}^{0}(-1)\sin mx\,dx + \int_{0}^{\pi} 1\cdot\sin mx\,dx\right]$$

$$= \frac{1}{\pi}\left[\frac{\cos mx}{m}\Big|_{-\pi}^{0} - \frac{\cos mx}{m}\Big|_{0}^{\pi}\right]$$

$$= \frac{1}{\pi m}[1 - 2\cos m\pi + 1] = \begin{cases} 4/(\pi m) & \text{if } m = 1, 3, \cdots, \\ 0 & \text{if } m = 2, 4\cdots. \end{cases}$$

Hence the Fourier series of the periodic rectangular wave is

$$f(x) = \frac{4}{\pi}\left(\sin x + \frac{1}{3}\sin 3x + \frac{1}{5}\sin 5x + \cdots\right).$$

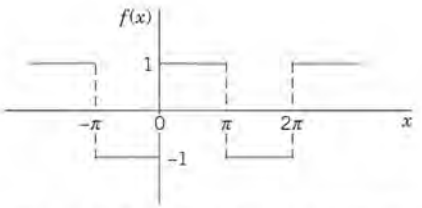

Fig. 111. Periodic rectangular wave in Example 1

Fourier series are by far the most important eigenfunction expansions, so important to the engineer that we shall devote two chapters (11 and 12) to them and their applications, and discuss numerous examples.

Did it surprise you that a series of continuous functions (sine functions) can represent a discontinuous function? More on this in Chap. 11.

EXAMPLE 2 **Fourier–Legendre Series**

A **Fourier–Legendre series** is an eigenfunction expansion

$$f(x) = \sum_{m=0}^{\infty} a_m P_m(x) = a_0 P_0 + a_1 P_1(x) + a_2 P_2(x) + \cdots = a_0 + a_1 x + a_2(\tfrac{3}{2}x^2 - \tfrac{1}{2}) + \cdots$$

in terms of Legendre polynomials (Sec. 5.3). The latter are the eigenfunctions of the Sturm–Liouville problem in Example 5 of Sec. 5.7 on the interval $-1 \leqq x \leqq 1$. We have $r(x) = 1$ for Legendre's equation, and (4) gives

$$(7) \qquad a_m = \frac{2m+1}{2}\int_{-1}^{1} f(x)P_m(x)\,dx, \qquad m = 0, 1, \cdots$$

because the norm is

$$(8) \qquad \|P_m\| = \sqrt{\int_{-1}^{1} P_m(x)^2\,dx} = \sqrt{\frac{2}{2m+1}} \qquad (m = 0, 1, \cdots)$$

as we state without proof. (The proof is tricky; it uses Rodrigues's formula in Problem Set 5.3 and a reduction of the resulting integral to a quotient of gamma functions.)

For instance, let $f(x) = \sin \pi x$. Then we obtain the coefficients

$$a_m = \frac{2m+1}{2}\int_{-1}^{1}(\sin \pi x)P_m(x)\,dx, \qquad \text{thus} \qquad a_1 = \frac{3}{2}\int_{-1}^{1} x \sin \pi x\,dx = \frac{3}{\pi} = 0.95493, \qquad \text{etc.}$$

Hence the Fourier–Legendre series of $\sin \pi x$ is

$$\sin \pi x = 0.95493P_1(x) - 1.15824P_3(x) + 0.21429P_5(x) - 0.01664P_7(x) + 0.00068P_9(x) - 0.00002P_{11}(x) + \cdots.$$

The coefficient of P_{13} is about $3 \cdot 10^{-7}$. The sum of the first three nonzero terms gives a curve that practically coincides with the sine curve. Can you see why the even-numbered coefficients are zero? Why a_3 is the absolutely biggest coefficient? ■

EXAMPLE 3 **Fourier–Bessel Series**

In Example 6 of Sec. 5.7 we obtained infinitely many orthogonal sets of Bessel functions, one for each of J_0, J_1, J_2, $\cdots$. Each set is orthogonal on an interval $0 \leqq x \leqq R$ with a fixed positive R of our choice and with respect to the weight x. The orthogonal set for J_n is $J_n(k_{n,1}x)$, $J_n(k_{n,2}x)$, $J_n(k_{n,3}x)$, $\cdots$, where n is ***fixed*** and $k_{n,m}$ is given in (12), Sec. 5.7. The corresponding Fourier–Bessel series is

$$(9) \qquad f(x) = \sum_{m=1}^{\infty} a_m J_n(k_{n,m}x) = a_1 J_n(k_{n,1}x) + a_2 J_n(k_{n,2}x) + a_3 J_n(k_{n,3}x) + \cdots \qquad (n \text{ fixed}).$$

The coefficients are (with $\alpha_{n,m} = k_{n,m}R$)

$$(10) \qquad a_m = \frac{2}{R^2 J_{n+1}^2(\alpha_{n,m})}\int_0^R x f(x) J_n(k_{n,m}x)\,dx, \qquad m = 1, 2, \cdots$$

because the square of the norm is

$$(11) \qquad \|J_n(k_{n,m}x)\|^2 = \int_0^R x J_n^2(k_{n,m}x)\,dx = \frac{R^2}{2} J_{n+1}^2(k_{n,m}R)$$

as we state without proof (which is tricky; see the discussion beginning on p. 576 of [A13]).

For instance, let us consider $f(x) = 1 - x^2$ and take $R = 1$ and $n = 0$ in the series (9), simply writing λ for $\alpha_{0,m}$. Then $k_{n,m} = \alpha_{0,m} = \lambda = 2.405$, 5.520, 8.654, 11.792, etc. (use a CAS or Table A1 in App. 5). Next we calculate the coefficients a_m by (10),

$$a_m = \frac{2}{J_1^2(\lambda)}\int_0^1 x(1 - x^2)J_0(\lambda x)\,dx.$$

This can be integrated by a CAS or by formulas as follows. First use $[xJ_1(\lambda x)]' = \lambda x J_0(\lambda x)$ from Theorem 3 in Sec. 5.5 and then integration by parts,

$$a_m = \frac{2}{J_1^2(\lambda)}\int_0^1 x(1 - x^2)J_0(\lambda x)\,dx = \frac{2}{J_1^2(\lambda)}\left[\frac{1}{\lambda}(1 - x^2)xJ_1(\lambda x)\Big|_0^1 - \frac{1}{\lambda}\int_0^1 xJ_1(\lambda x)(-2x)\,dx\right].$$

The integral-free part is zero. The remaining integral can be evaluated by $\left[x^2 J_2(\lambda x)\right]' = \lambda x^2 J_1(\lambda x)$ from Theorem 3 in Sec. 5.5. This gives

$$a_m = \frac{4J_2(\lambda)}{\lambda^2 J_1^2(\lambda)} \qquad (\lambda = \alpha_{0,m}).$$

Numeric values can be obtained from a CAS (or from the table on p. 409 of Ref. [GR1] in App. 1, together with the formula $J_2 = 2x^{-1}J_1 - J_0$ in Theorem 3 of Sec. 5.5). This gives the eigenfunction expansion of $1 - x^2$ in terms of Bessel functions J_0, that is,

$$1 - x^2 = 1.1081J_0(2.405x) - 0.1398J_0(5.520x) + 0.0455J_0(8.654x) - 0.0210J_0(11.792x) + \cdots.$$

A graph would show that the curve of $1 - x^2$ and that of the sum of the first three terms practically coincide. ■

Mean Square Convergence. Completeness of Orthonormal Sets

The remaining part of this section will give an introduction to a convergence suitable in connection with orthogonal series and quite different from the convergence used in calculus for Taylor series.

In practice, one uses only orthonormal sets that consist of "sufficiently many" functions, so that one can represent large classes of functions by a generalized Fourier series (3)—certainly all continuous functions on an interval $a \leqq x \leqq b$, but also functions that do "not have too many" discontinuities (see Example 1). Such orthonormal sets are called "complete" (in the set of functions considered; definition below). For instance, the orthonormal sets corresponding to Examples 1–3 are complete in the set of functions continuous on the intervals considered (or even in more general sets of functions; see Ref. [GR7], Secs. 3.4–3.7, listed in App. 1, where "complete sets" bear the more modern name "total sets").

In this connection, convergence is **convergence in the norm,** also called **mean-square convergence;** that is, a sequence of functions f_k is called **convergent** *with the limit* f if

$$\lim_{k\to\infty} \|f_k - f\| = 0; \tag{12*}$$

written out by (2) (where we can drop the square root, as this does not affect the limit)

$$\lim_{k\to\infty} \int_a^b r(x)[f_k(x) - f(x)]^2\,dx = 0. \tag{12}$$

Accordingly, the series (3) converges and represents f if

$$\lim_{k\to\infty} \int_a^b r(x)[s_k(x) - f(x)]^2\,dx = 0 \tag{13}$$

where s_k is the kth partial sum of (3),

$$s_k(x) = \sum_{m=0}^{k} a_m y_m(x). \tag{14}$$

By definition, an orthonormal set $y_0, y_1, \cdots$ on an interval $a \leqq x \leqq b$ is **complete** *in a set of functions* S defined on $a \leqq x \leqq b$ if we can approximate every f belonging to S arbitrarily closely by a linear combination $a_0y_0 + a_1y_1 + \cdots + a_ky_k$, that is, technically, if for every $\epsilon > 0$ we can find constants $a_0, \cdots, a_k$ (with k large enough) such that

$$\|f - (a_0y_0 + \cdots + a_ky_k)\| < \epsilon. \tag{15}$$

An interesting and basic consequence of the integral in (13) is obtained as follows. Performing the square and using (14), we first have

$$\begin{aligned}\int_a^b r(x)[s_k(x) - f(x)]^2\,dx &= \int_a^b r{s_k}^2\,dx - 2\int_a^b rfs_k\,dx + \int_a^b rf^2\,dx \\ &= \int_a^b r\left[\sum_{m=0}^{k} a_m y_m\right]^2 dx - 2\sum_{m=0}^{k} a_m \int_a^b rfy_m\,dx + \int_a^b rf^2\,dx.\end{aligned}$$

The first integral on the right equals $\Sigma\, {a_m}^2$ because $\int ry_my_l\,dx = 0$ for $m \neq l$, and $\int r{y_m}^2\,dx = 1$. In the second sum on the right, the integral equals a_m, by (4) with

$\|y_m\|^2 = 1$. Hence the first term on the right cancels half of the second term, so that the right side reduces to

$$-\sum_{m=0}^{k} a_m^2 + \int_a^b rf^2\,dx.$$

This is nonnegative because in the previous formula the integrand on the left is nonnegative (recall that the weight $r(x)$ is positive!) and so is the integral on the left. This proves the important **Bessel's inequality**

$$\sum_{m=0}^{k} a_m^2 \leqq \|f\|^2 = \int_a^b r(x)f(x)^2\,dx \qquad (k = 1, 2, \cdots). \tag{16}$$

Here we can let $k \to \infty$, because the left sides form a monotone increasing sequence that is bounded by the right side, so that we have convergence by the familiar Theorem 1 in App. A3.3. Hence

$$\sum_{m=0}^{\infty} a_m^2 \leqq \|f\|^2. \tag{17}$$

Furthermore, if $y_0, y_1, \cdots$ is complete in a set of functions S, then (13) holds for every f belonging to S. By (15) this implies equality in (16) with $k \to \infty$. Hence in the case of completeness every f in S satisfies the so-called **Parseval's equality**

$$\sum_{m=0}^{\infty} a_m^2 = \|f\|^2 = \int_a^b r(x)f(x)^2\,dx. \tag{18}$$

As a consequence of (18) we prove that in the case of *completeness* there is no function orthogonal to *every* function of the orthonormal set, with the trivial exception of a function of zero norm:

THEOREM 1

Completeness

Let $y_0, y_1, \cdots$ be a complete orthonormal set on $a \leqq x \leqq b$ in a set of functions S. Then if a function f belongs to S and is orthogonal to every y_m, it must have norm zero. In particular, if f is continuous, then f must be identically zero.

PROOF Since f is orthogonal to every y_m, the left side of (18) must be zero. If f is continuous, then $\|f\| = 0$ implies $f(x) \equiv 0$, as can be seen directly from (2) with f instead of y_m because $r(x) > 0$. ∎

EXAMPLE 4 **Fourier Series**

The orthonormal set in Example 1 is complete in the set of continuous functions on $-\pi \leqq x \leqq \pi$. Verify directly that $f(x) \equiv 0$ is the only continuous function orthogonal to all the functions of that set.

Solution. Let f be any continuous function. By the orthogonality (we can omit $\sqrt{2\pi}$ and $\sqrt{\pi}$),

$$\int_{-\pi}^{\pi} 1 \cdot f(x)\,dx = 0, \qquad \int_{-\pi}^{\pi} f(x)\cos mx\,dx = 0, \qquad \int_{-\pi}^{\pi} f(x)\sin mx\,dx = 0.$$

Hence $a_m = 0$ and $b_m = 0$ in (6) for all m, so that (3) reduces to $f(x) \equiv 0$. ∎

This is the end of Chap. 5 on the power series method and the Frobenius method, which are indispensable in solving linear ODEs with variable coefficients, some of the most important of which we have discussed and solved. We have also seen that the latter are important sources of special functions having orthogonality properties that make them suitable for orthogonal series representations of given functions.

PROBLEM SET 5.8

1–4 FOURIER–LEGENDRE SERIES

Showing the details of your calculations, develop:

1. $7x^4 - 6x^2$
2. $(x + 1)^2$
3. $x^3 - x^2 + x - 1$
4. $1, x, x^2, x^3$

5. Prove that if $f(x)$ in Example 2 is even [that is, $f(x) = f(-x)$], its series contains only $P_m(x)$ with even m.

6–16 CAS EXPERIMENTS. FOURIER–LEGENDRE SERIES

Find and graph (on common axes) the partial sums up to that S_{m_0} whose graph practically coincides with that of $f(x)$ within graphical accuracy. State what m_0 is. On what does the size of m_0 seem to depend?

6. $f(x) = \sin \pi x$
7. $f(x) = \sin 2\pi x$
8. $f(x) = \cos \pi x$
9. $f(x) = \cos 2\pi x$
10. $f(x) = \cos 3\pi x$
11. $f(x) = e^x$
12. $f(x) = e^{-x^2}$
13. $f(x) = 1/(1 + x^2)$
14. $f(x) = J_0(\alpha_{0,1}x)$, where $\alpha_{0,1}$ is the first positive zero of J_0
15. $f(x) = J_0(\alpha_{0,2}x)$, where $\alpha_{0,2}$ is the second positive zero of J_0
16. $f(x) = J_1(\alpha_{1,1}x)$, where $\alpha_{1,1}$ is the first positive zero of J_1

17. **CAS EXPERIMENT. Fourier–Bessel Series.** Use Example 3 and again take $n = 10$ and $R = 1$, so that you get the series

$$(19) \quad f(x) = a_1 J_0(\alpha_{0,1}x) + a_2 J_0(\alpha_{0,2}x) + a_3 J_0(\alpha_{0,3}x) + \cdots$$

with the zeros $\alpha_{0,1}$ $\alpha_{0,2}$, $\cdots$ from your CAS (see also Table A1 in App. 5).

(a) Graph the terms $J_0(\alpha_{0,1}x)$, $\cdots$, $J_0(\alpha_{0,10}x)$ for $0 \leqq x \leqq 1$ on common axes.

(b) Write a program for calculating partial sums of (19). Find out for what $f(x)$ your CAS can evaluate the integrals. Take two such $f(x)$ and comment empirically on the speed of convergence by observing the decrease of the coefficients.

(c) Take $f(x) = 1$ in (19) and evaluate the integrals for the coefficients analytically by (24a), Sec. 5.5, with $\nu = 1$. Graph the first few partial sums on common axes.

18. **TEAM PROJECT. Orthogonality on the Entire Real Axis. Hermite Polynomials.**[13] These orthogonal polynomials are defined by $He_0(1) = 1$ and

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} (e^{-x^2/2}), \quad n = 1, 2, \cdots.$$

REMARK. As is true for many special functions, the literature contains more than one notation, and one sometimes defines as Hermite polynomials the functions

$$H_0^* = 1, \qquad H_n^*(x) = (-1)^n e^{x^2} \frac{d^n e^{-x^2}}{dx^n}.$$

This differs from our definition, which is preferred in applications.

(a) Small Values of n. Show that

$$He_1(x) = x, \qquad He_2(x) = x^2 - 1,$$
$$He_3(x) = x^3 - 3x, \qquad He_4(x) = x^4 - 6x^2 + 3.$$

(b) Generating Function. A generating function of the Hermite polynomials is

$$(20) \quad e^{tx - t^2/2} = \sum_{n=0}^{\infty} a_n(x)t^n$$

because $He_n(x) = n!a_n(x)$. Prove this. *Hint:* Use the formula for the coefficients of a Maclaurin series and note that $tx - \frac{1}{2}t^2 = \frac{1}{2}x^2 - \frac{1}{2}(x - t)^2$.

(c) Derivative. Differentiating the generating function with respect to x, show that

$$(21) \quad He_n'(x) = nHe_{n-1}(x).$$

[13] CHARLES HERMITE (1822–1901), French mathematician, is known for his work in algebra and number theory. The great HENRI POINCARÉ (1854–1912) was one of his students.

(d) Orthogonality on the x-Axis needs a weight function that goes to zero sufficiently fast as $x \to \pm\infty$. (Why?) Show that the Hermite polynomials are orthogonal on $-\infty < x < \infty$ with respect to the weight function $r(x) = e^{-x^2/2}$. *Hint.* Use integration by parts and (21).

(e) ODEs. Show that

(22) $\quad He_n'(x) = xHe_n(x) - He_{n+1}(x).$

Using this with $n - 1$ instead of n and (21), show that $y = He_n(x)$ satisfies the ODE

(23) $\quad y'' - xy' + ny = 0.$

Show that $w = e^{-x^2/4}y$ is a solution of **Weber's equation**[14]

(24) $\quad w'' + (n + \frac{1}{2} - \frac{1}{4}x^2)w = 0 \qquad (n = 0, 1, \cdorn).$

19. WRITING PROJECT. Orthogonality. Write a short report (2–3 pages) about the most important ideas and facts related to orthogonality and orthogonal series and their applications.

CHAPTER 5 REVIEW QUESTIONS AND PROBLEMS

1. What is a power series? Can it contain negative or fractional powers? How would you test for convergence?
2. Why could we use the power series method for Legendre's equation but needed the Frobenius method for Bessel's equation?
3. Why did we introduce two kinds of Bessel functions, J and Y?
4. What is the hypergeometric equation and why did Gauss introduce it?
5. List the three cases of the Frobenius method, giving examples of your own.
6. What is the difference between an initial value problem and a boundary value problem?
7. What does orthogonality of functions mean and how is it used in series expansions? Give examples.
8. What is the Sturm–Liouville theory and its practical importance?
9. What do you remember about the orthogonality of the Legendre polynomials? Of Bessel functions?
10. What is completeness of orthogonal sets? Why is it important?

11–20 SERIES SOLUTIONS

Find a basis of solutions. Try to identify the series as expansions of known functions. (Show the details of your work.)

11. $y'' - 9y = 0$
12. $(1 - x)^2y'' + (1 - x)y' - 3y = 0$
13. $xy'' - (x + 1)y' + y = 0$
14. $x^2y'' - 3xy' + 4y = 0$
15. $y'' + 4xy' + (4x^2 + 2)y = 0$
16. $x^2y'' - 4xy' + (x^2 + 6)y = 0$
17. $xy'' + (2x + 1)y' + (x + 1)y = 0$
18. $(x^2 - 1)y'' - 2xy' + 2y = 0$
19. $(x^2 - 1)y'' + 4xy' + 2y = 0$
20. $x^2y'' + xy' + (4x^4 - 1)y = 0$

21–25 BESSEL'S EQUATION

Find a general solution in terms of Bessel functions. (Use the indicated transformations and show the details.)

21. $x^2y'' + xy' + (36x^2 - 2)y = 0 \qquad (6x = z)$
22. $x^2y'' + 5xy' + (x^2 - 12)y = 0 \qquad (y = u/x^2)$
23. $x^2y'' + xy' + 4(x^4 - 1)y = 0 \qquad (x^2 = z)$
24. $4x^2y'' - 20xy' + (4x^2 + 35)y = 0 \qquad (y = x^3u)$
25. $y'' + k^2x^2y = 0 \qquad (y = u\sqrt{x},\ \frac{1}{2}kx^2 = z)$

26–30 BOUNDARY VALUE PROBLEMS

Find the eigenvalues and eigenfunctions.

26. $y'' + \lambda y = 0, \qquad y(0) = 0, \qquad y'(\pi) = 0$
27. $y'' + \lambda y = 0, \qquad y(0) = y(1), \quad y'(0) = y'(1)$
28. $(xy')' + \lambda x^{-1}y = 0, \qquad y(1) = 0, \qquad y(e) = 0.$ (Set $x = e^t$.)
29. $x^2y'' + xy' + (\lambda x^2 - 1)y = 0, \quad y(0) = 0, \quad y(1) = 0$
30. $y'' + \lambda y = 0, \qquad y(0) + y'(0) = 0, \qquad y(2\pi) = 0$

31–35 CAS PROBLEMS

Write a program, develop in a Fourier–Legendre series, and graph the first five partial sums on common axes, together with the given function. Comment on accuracy.

31. $e^{2x} \quad (-1 \leqq x \leqq 1)$
32. $\sin(\pi x^2) \quad (-1 \leqq x \leqq 1)$
33. $1/(1 + |x|) \quad (-1 \leqq x \leqq 1)$
34. $|\cos \pi x| \quad (-1 \leqq x \leqq 1)$
35. x if $0 \leqq x \leqq 1$, 0 if $-1 \leqq x < 0$

[14]HEINRICH WEBER (1842–1913), German mathematician.

SUMMARY OF CHAPTER 5

Series Solution of ODEs. Special Functions

The **power series method** gives solutions of linear ODEs

$$y'' + p(x)y' + q(x)y = 0 \tag{1}$$

with ***variable coefficients*** p and q in the form of a power series (with any center x_0, e.g., $x_0 = 0$)

$$y(x) = \sum_{m=0}^{\infty} a_m(x - x_0)^m = a_0 + a_1(x - x_0) + a_2(x - x_0)^2 + \cdots. \tag{2}$$

Such a solution is obtained by substituting (2) and its derivatives into (1). This gives a **recurrence formula** for the coefficients. You may program this formula (or even obtain and graph the whole solution) on your CAS.

If p and q are **analytic** at x_0 (that is, representable by a power series in powers of $x - x_0$ with positive radius of convergence; Sec. 5.2), then (1) has solutions of this form (2). The same holds if $\tilde{h}$, $\tilde{p}$, $\tilde{q}$ in

$$\tilde{h}(x)y'' + \tilde{p}(x)y' + \tilde{q}(x)y = 0$$

are analytic at x_0 and $\tilde{h}(x_0) \neq 0$, so that we can divide by $\tilde{h}$ and obtain the standard form (1). **Legendre's equation** is solved by the power series method in Sec. 5.3.

The **Frobenius method** (Sec. 5.4) extends the power series method to ODEs

$$y'' + \frac{a(x)}{x - x_0}y' + \frac{b(x)}{(x - x_0)^2}y = 0 \tag{3}$$

whose coefficients are **singular** (i.e., not analytic) at x_0, but are "not too bad," namely, such that a and b are analytic at x_0. Then (3) has at least one solution of the form

$$y(x) = (x - x_0)^r \sum_{m=0}^{\infty} a_m(x - x_0)^m = a_0(x - x_0)^r + a_1(x - x_0)^{r+1} + \cdots \tag{4}$$

where r can be any real (or even complex) number and is determined by substituting (4) into (3) from the **indicial equation** (Sec. 5.4), along with the coefficients of (4). A second linearly independent solution of (3) may be of a similar form (with different r and a_m's) or may involve a logarithmic term. **Bessel's equation** is solved by the Frobenius method in Secs. 5.5 and 5.6.

"Special functions" is a common name for higher functions, as opposed to the usual functions of calculus. Most of them arise either as nonelementary integrals [see (24)–(44) in App. 3.1] or as solutions of (1) or (3). They get a name and notation and are included in the usual CASs if they are important in application or in theory.

Of this kind, and particularly useful to the engineer and physicist, are **Legendre's equation and polynomials** P_0, P_1, $\cdots$ (Sec. 5.3), **Gauss's hypergeometric equation and functions** $F(a, b, c; x)$ (Sec. 5.4), and **Bessel's equation and functions** J_ν **and** Y_ν (Secs. 5.5, 5.6).

Modeling involving ODEs usually leads to initial value problems (Chaps. 1–3) or **boundary value problems.** Many of the latter can be written in the form of **Sturm–Liouville problems** (Sec. 5.7). These are **eigenvalue problems** involving a parameter λ that is often related to frequencies, energies, or other physical quantities. Solutions of Sturm–Liouville problems, called **eigenfunctions,** have many general properties in common, notably the highly important **orthogonality** (Sec. 5.7), which is useful in **eigenfunction expansions** (Sec. 5.8) in terms of cosine and sine (*"Fourier series"*, the topic of Chap. 11), Legendre polynomials, Bessel functions (Sec. 5.8), and other eigenfunctions.

CHAPTER 6

Laplace Transforms

The Laplace transform method is a powerful method for solving linear ODEs and corresponding initial value problems, as well as systems of ODEs arising in engineering. The process of solution consists of three steps (see Fig. 112).

Step 1. The given ODE is transformed into an algebraic equation **("subsidiary equation").**

Step 2. The subsidiary equation is solved by purely algebraic manipulations.

Step 3. The solution in Step 2 is transformed back, resulting in the solution of the given problem.

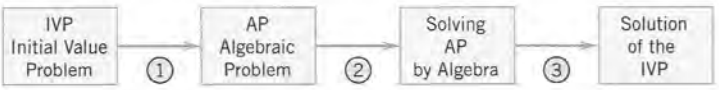

Fig. 112. Solving an IVP by Laplace transforms

Thus solving an ODE is reduced to an *algebraic* problem (plus those transformations). This switching from calculus to algebra is called **operational calculus.** The Laplace transform method is the most important operational method to the engineer. This method has two main advantages over the usual methods of Chaps. 1–4:

A. Problems are solved more directly, initial value problems without first determining a general solution, and nonhomogeneous ODEs without first solving the corresponding homogeneous ODE.

B. More importantly, the use of the **unit step function (Heaviside function** in Sec. 6.3) and **Dirac's delta** (in Sec. 6.4) make the method particularly powerful for problems with inputs (driving forces) that have discontinuities or represent short impulses or complicated periodic functions.

In this chapter we consider the Laplace transform and its application to engineering problems involving ODEs. PDEs will be solved by the Laplace transform in Sec. 12.11.

General formulas are listed in Sec. 6.8, **transforms and inverses** in Sec. 6.9. The usual **CASs** can handle most Laplace transforms.

Prerequisite: Chap. 2
Sections that may be omitted in a shorter course: 6.5, 6.7
References and Answers to Problems: App. 1 Part A, App. 2.

6.1 Laplace Transform. Inverse Transform. Linearity. s-Shifting

If $f(t)$ is a function defined for all $t \geqq 0$, its **Laplace transform**[1] is the integral of $f(t)$ times e^{-st} from $t = 0$ to ∞. It is a function of s, say, $F(s)$, and is denoted by $\mathscr{L}(f)$; thus

$$\textbf{(1)} \qquad F(s) = \mathscr{L}(f) = \int_0^\infty e^{-st} f(t)\, dt.$$

Here we must assume that $f(t)$ is such that the integral exists (that is, has some finite value). This assumption is usually satisfied in applications—we shall discuss this near the end of the section.

Not only is the result $F(s)$ called the Laplace transform, but the operation just described, which yields $F(s)$ from a given $f(t)$, is also called the **Laplace transform.** It is an **"integral transform"**

$$F(s) = \int_0^\infty k(s, t) f(t)\, dt$$

with **"kernel"** $k(s, t) = e^{-st}$.

Furthermore, the given function $f(t)$ in (1) is called the **inverse transform** of $F(s)$ and is denoted by $\mathscr{L}^{-1}(F)$; that is, we shall write

$$\textbf{(1*)} \qquad f(t) = \mathscr{L}^{-1}(F).$$

Note that (1) and (1*) together imply $\mathscr{L}^{-1}(\mathscr{L}(f)) = f$ and $\mathscr{L}(\mathscr{L}^{-1}(F)) = F$.

Notation

Original functions depend on t and their transforms on s—keep this in mind! Original functions are denoted by ***lowercase letters*** and their transforms by the same ***letters in capital,*** so that $F(s)$ denotes the transform of $f(t)$, and $Y(s)$ denotes the transform of $y(t)$, and so on.

EXAMPLE 1 **Laplace Transform**

Let $f(t) = 1$ when $t \geqq 0$. Find $F(s)$.

Solution. From (1) we obtain by integration

$$\mathscr{L}(f) = \mathscr{L}(1) = \int_0^\infty e^{-st}\, dt = -\frac{1}{s} e^{-st} \Big|_0^\infty = \frac{1}{s} \qquad (s > 0).$$

---

[1]PIERRE SIMON MARQUIS DE LAPLACE (1749–1827), great French mathematician, was a professor in Paris. He developed the foundation of potential theory and made important contributions to celestial mechanics, astronomy in general, special functions, and probability theory. Napoléon Bonaparte was his student for a year. For Laplace's interesting political involvements, see Ref. [GR2], listed in App. 1.

The powerful practical Laplace transform techniques were developed over a century later by the English electrical engineer OLIVER HEAVISIDE (1850–1925) and were often called "Heaviside calculus."

We shall drop variables when this simplifies formulas without causing confusion. For instance, in (1) we wrote $\mathscr{L}(f)$ instead of $\mathscr{L}(f)(s)$ and in (1*) $\mathscr{L}^{-1}(F)$ instead of $\mathscr{L}^{-1}(F)(t)$.

Our notation is convenient, but we should say a word about it. The interval of integration in (1) is infinite. Such an integral is called an **improper integral** and, by definition, is evaluated according to the rule

$$\int_0^\infty e^{-st} f(t)\,dt = \lim_{T\to\infty} \int_0^T e^{-st} f(t)\,dt.$$

Hence our convenient notation means

$$\int_0^\infty e^{-st}\,dt = \lim_{T\to\infty} \left[-\frac{1}{s}\, e^{-st} \right]_0^T = \lim_{T\to\infty} \left[-\frac{1}{s}\, e^{-sT} + \frac{1}{s}\, e^0 \right] = \frac{1}{s} \qquad (s > 0).$$

We shall use this notation throughout this chapter. ■

EXAMPLE 2 **Laplace Transform $\mathcal{L}(e^{at})$ of the Exponential Function e^{at}**

Let $f(t) = e^{at}$ when $t \geqq 0$, where a is a constant. Find $\mathcal{L}(f)$.

Solution. Again by (1),

$$\mathcal{L}(e^{at}) = \int_0^\infty e^{-st} e^{at}\,dt = \frac{1}{a-s}\, e^{-(s-a)t} \Big|_0^\infty;$$

hence, when $s - a > 0$,

$$\mathcal{L}(e^{at}) = \frac{1}{s-a}. \qquad ■$$

Must we go on in this fashion and obtain the transform of one function after another directly from the definition? The answer is no. And the reason is that new transforms can be found from known ones by the use of the many general properties of the Laplace transform. Above all, the Laplace transform is a "linear operation," just as differentiation and integration. By this we mean the following.

THEOREM 1 **Linearity of the Laplace Transform**

The Laplace transform is a linear operation; that is, for any functions $f(t)$ and $g(t)$ whose transforms exist and any constants a and b the transform of $af(t) + bg(t)$ exists, and

$$\mathcal{L}\{af(t) + bg(t)\} = a\mathcal{L}\{f(t)\} + b\mathcal{L}\{g(t)\}.$$

PROOF By the definition in (1),

$$\begin{aligned}\mathcal{L}\{af(t) + bg(t)\} &= \int_0^\infty e^{-st}[af(t) + bg(t)]\,dt \\ &= a\int_0^\infty e^{-st} f(t)\,dt + b\int_0^\infty e^{-st} g(t)\,dt = a\mathcal{L}\{f(t)\} + b\mathcal{L}\{g(t)\}.\end{aligned}$$ ■

EXAMPLE 3 **Application of Theorem 1: Hyperbolic Functions**

Find the transforms of $\cosh at$ and $\sinh at$.

Solution. Since $\cosh at = \frac{1}{2}(e^{at} + e^{-at})$ and $\sinh at = \frac{1}{2}(e^{at} - e^{-at})$, we obtain from Example 2 and Theorem 1

$$\mathcal{L}(\cosh at) = \frac{1}{2}(\mathcal{L}(e^{at}) + \mathcal{L}(e^{-at})) = \frac{1}{2}\left(\frac{1}{s-a} + \frac{1}{s+a}\right) = \frac{s}{s^2 - a^2}$$

$$\mathcal{L}(\sinh at) = \frac{1}{2}(\mathcal{L}(e^{at}) - \mathcal{L}(e^{-at})) = \frac{1}{2}\left(\frac{1}{s-a} - \frac{1}{s+a}\right) = \frac{a}{s^2 - a^2}. \qquad ■$$

EXAMPLE 4 Cosine and Sine

Derive the formulas

$$\mathcal{L}(\cos \omega t) = \frac{s}{s^2 + \omega^2}, \qquad \mathcal{L}(\sin \omega t) = \frac{\omega}{s^2 + \omega^2}.$$

Solution by Calculus. We write $L_c = \mathcal{L}(\cos \omega t)$ and $L_s = \mathcal{L}(\sin \omega t)$. Integrating by parts and noting that the integral-free parts give no contribution from the upper limit ∞, we obtain

$$L_c = \int_0^\infty e^{-st} \cos \omega t \, dt = \frac{e^{-st}}{-s} \cos \omega t \Big|_0^\infty - \frac{\omega}{s} \int_0^\infty e^{-st} \sin \omega t \, dt = \frac{1}{s} - \frac{\omega}{s} L_s,$$

$$L_s = \int_0^\infty e^{-st} \sin \omega t \, dt = \frac{e^{-st}}{-s} \sin \omega t \Big|_0^\infty + \frac{\omega}{s} \int_0^\infty e^{-st} \cos \omega t \, dt = \frac{\omega}{s} L_c.$$

By substituting L_s into the formula for L_c on the right and then by substituting L_c into the formula for L_s on the right, we obtain

$$L_c = \frac{1}{s} - \frac{\omega}{s}\left(\frac{\omega}{s} L_c\right), \qquad L_c\left(1 + \frac{\omega^2}{s^2}\right) = \frac{1}{s}, \qquad L_c = \frac{s}{s^2 + \omega^2},$$

$$L_s = \frac{\omega}{s}\left(\frac{1}{s} - \frac{\omega}{s} L_s\right), \qquad L_s\left(1 + \frac{\omega^2}{s^2}\right) = \frac{\omega}{s^2}, \qquad L_s = \frac{\omega}{s^2 + \omega^2}.$$

Solution by Transforms Using Derivatives. See next section.

Solution by Complex Methods. In Example 2, if we set $a = i\omega$ with $i = \sqrt{-1}$, we obtain

$$\mathcal{L}(e^{i\omega t}) = \frac{1}{s - i\omega} = \frac{s + i\omega}{(s - i\omega)(s + i\omega)} = \frac{s + i\omega}{s^2 + \omega^2} = \frac{s}{s^2 + \omega^2} + i \frac{\omega}{s^2 + \omega^2}.$$

Now by Theorem 1 and $e^{i\omega t} = \cos \omega t + i \sin \omega t$ [see (11) in Sec. 2.2 with ωt instead of t] we have

$$\mathcal{L}(e^{i\omega t}) = \mathcal{L}(\cos \omega t + i \sin \omega t) = \mathcal{L}(\cos \omega t) + i\mathcal{L}(\sin \omega t).$$

If we equate the real and imaginary parts of this and the previous equation, the result follows. (This formal calculation can be justified in the theory of complex integration.) ■

Basic transforms are listed in Table 6.1. We shall see that from these almost all the others can be obtained by the use of the general properties of the Laplace transform. Formulas 1–3 are special cases of formula 4, which is proved by induction. Indeed, it is true for $n = 0$ because of Example 1 and $0! = 1$. We make the induction hypothesis that it holds for any integer $n \geqq 0$ and then get it for $n + 1$ directly from (1). Indeed, integration by parts first gives

$$\mathcal{L}(t^{n+1}) = \int_0^\infty e^{-st} t^{n+1} \, dt = -\frac{1}{s} e^{-st} t^{n+1} \Big|_0^\infty + \frac{n + 1}{s} \int_0^\infty e^{-st} t^n \, dt.$$

Now the integral-free part is zero and the last part is $(n + 1)/s$ times $\mathcal{L}(t^n)$. From this and the induction hypothesis,

$$\mathcal{L}(t^{n+1}) = \frac{n + 1}{s} \mathcal{L}(t^n) = \frac{n + 1}{s} \cdot \frac{n!}{s^{n+1}} = \frac{(n + 1)!}{s^{n+2}}.$$

This proves formula 4.

Table 6.1 **Some Functions $f(t)$ and Their Laplace Transforms $\mathcal{L}(f)$**

	$f(t)$	$\mathcal{L}(f)$		$f(t)$	$\mathcal{L}(f)$
1	1	$1/s$	7	$\cos \omega t$	$\dfrac{s}{s^2 + \omega^2}$
2	t	$1/s^2$	8	$\sin \omega t$	$\dfrac{\omega}{s^2 + \omega^2}$
3	t^2	$2!/s^3$	9	$\cosh at$	$\dfrac{s}{s^2 - a^2}$
4	t^n $(n = 0, 1, \cdots)$	$\dfrac{n!}{s^{n+1}}$	10	$\sinh at$	$\dfrac{a}{s^2 - a^2}$
5	t^a (a positive)	$\dfrac{\Gamma(a + 1)}{s^{a+1}}$	11	$e^{at} \cos \omega t$	$\dfrac{s - a}{(s - a)^2 + \omega^2}$
6	e^{at}	$\dfrac{1}{s - a}$	12	$e^{at} \sin \omega t$	$\dfrac{\omega}{(s - a)^2 + \omega^2}$

$\Gamma(a + 1)$ in formula 5 is the so-called *gamma function* [(15) in Sec. 5.5 or (24) in App. A3.1]. We get formula 5 from (1), setting $st = x$:

$$\mathcal{L}(t^a) = \int_0^\infty e^{-st} t^a \, dt = \int_0^\infty e^{-x} \left(\frac{x}{s}\right)^a \frac{dx}{s} = \frac{1}{s^{a+1}} \int_0^\infty e^{-x} x^a \, dx$$

where $s > 0$. The last integral is precisely that defining $\Gamma(a + 1)$, so we have $\Gamma(a + 1)/s^{a+1}$, as claimed. (CAUTION! $\Gamma(a + 1)$ has x^a in the integral, not x^{a+1}.)

Note the formula 4 also follows from 5 because $\Gamma(n + 1) = n!$ for integer $n \geqq 0$.

Formulas 6–10 were proved in Examples 2–4. Formulas 11 and 12 will follow from 7 and 8 by "shifting," to which we turn next.

s-Shifting: Replacing s by $s - a$ in the Transform

The Laplace transform has the very useful property that if we know the transform of $f(t)$, we can immediately get that of $e^{at} f(t)$, as follows.

THEOREM 2

First Shifting Theorem, s-Shifting

If $f(t)$ has the transform $F(s)$ (where $s > k$ for some k), then $e^{at} f(t)$ has the transform $F(s - a)$ (where $s - a > k$). In formulas,

$$\mathcal{L}\{e^{at} f(t)\} = F(s - a)$$

or, if we take the inverse on both sides,

$$e^{at} f(t) = \mathcal{L}^{-1}\{F(s - a)\}.$$

PROOF We obtain $F(s-a)$ by replacing s with $s-a$ in the integral in (1), so that

$$F(s-a) = \int_0^\infty e^{-(s-a)t} f(t)\,dt = \int_0^\infty e^{-st}[e^{at}f(t)]\,dt = \mathscr{L}\{e^{at}f(t)\}.$$

If $F(s)$ exists (i.e., is finite) for s greater than some k, then our first integral exists for $s-a>k$. Now take the inverse on both sides of this formula to obtain the second formula in the theorem. (CAUTION! $-a$ in $F(s-a)$ but $+a$ in $e^{at}f(t)$.) ■

EXAMPLE 5 **s-Shifting: Damped Vibrations. Completing the Square**

From Example 4 and the first shifting theorem we immediately obtain formulas 11 and 12 in Table 6.1,

$$\mathscr{L}\{e^{at}\cos\omega t\} = \frac{s-a}{(s-a)^2+\omega^2}, \qquad \mathscr{L}\{e^{at}\sin\omega t\} = \frac{\omega}{(s-a)^2+\omega^2}.$$

For instance, use these formulas to find the inverse of the transform

$$\mathscr{L}(f) = \frac{3s-137}{s^2+2s+401}.$$

Solution. Applying the inverse transform, using its linearity (Prob. 28), and completing the square, we obtain

$$f = \mathscr{L}^{-1}\left\{\frac{3(s+1)-140}{(s+1)^2+400}\right\} = 3\mathscr{L}^{-1}\left\{\frac{s+1}{(s+1)^2+20^2}\right\} - 7\mathscr{L}^{-1}\left\{\frac{20}{(s+1)^2+20^2}\right\}.$$

We now see that the inverse of the right side is the damped vibration (Fig. 113)

$$f(t) = e^{-t}(3\cos 20t - 7\sin 20t).$$ ■

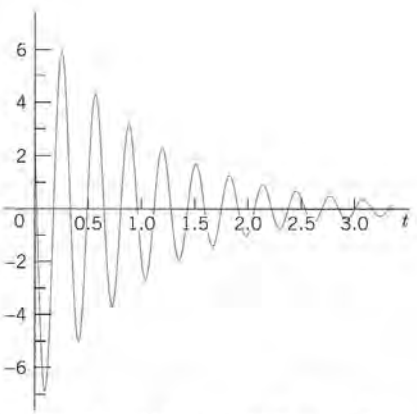

Fig. 113. Vibrations in Example 5

Existence and Uniqueness of Laplace Transforms

This is not a big *practical* problem because in most cases we can check the solution of an ODE without too much trouble. Nevertheless we should be aware of some basic facts.

A function $f(t)$ has a Laplace transform if it does not grow too fast, say, if for all $t \geqq 0$ and some constants M and k it satisfies the **"growth restriction"**

(2) $$|f(t)| \leqq Me^{kt}.$$

(The growth restriction (2) is sometimes called "growth of exponential order," which may be misleading since it hides that the exponent must be kt, not kt^2 or similar.)

$f(t)$ need not be continuous, but it should not be too bad. The technical term (generally used in mathematics) is *piecewise continuity*. $f(t)$ is **piecewise continuous** on a finite interval $a \leqq t \leqq b$ where f is defined, if this interval can be divided into *finitely many* subintervals in each of which f is continuous and has finite limits as t approaches either endpoint of such a subinterval from the interior. This then gives **finite jumps** as in Fig. 114 as the only possible discontinuities, but this suffices in most applications, and so does the following theorem.

Fig. 114. Example of a piecewise continuous function $f(t)$. (The dots mark the function values at the jumps.)

THEOREM 3

Existence Theorem for Laplace Transforms

If $f(t)$ is defined and piecewise continuous on every finite interval on the semi-axis $t \geqq 0$ and satisfies (2) for all $t \geqq 0$ and some constants M and k, then the Laplace transform $\mathcal{L}(f)$ exists for all $s > k$.

PROOF Since $f(t)$ is piecewise continuous, $e^{-st}f(t)$ is integrable over any finite interval on the t-axis. From (2), assuming that $s > k$ (to be needed for the existence of the last of the following integrals), we obtain the proof of the existence of $\mathcal{L}(f)$ from

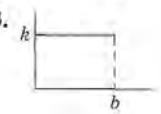
$$|\mathcal{L}(f)| = \left| \int_0^\infty e^{-st} f(t)\, dt \right| \leqq \int_0^\infty |f(t)| e^{-st}\, dt \leqq \int_0^\infty M e^{kt} e^{-st}\, dt = \frac{M}{s-k}. \qquad \blacksquare$$

Note that (2) can be readily checked. For instance, $\cosh t < e^t$, $t^n < n!e^t$ (because $t^n/n!$ is a single term of the Maclaurin series), and so on. A function that does not satisfy (2) for any M and k is e^{t^2} (take logarithms to see it). We mention that the conditions in Theorem 3 are sufficient rather than necessary (see Prob. 22).

Uniqueness. If the Laplace transform of a given function exists, it is uniquely determined. Conversely, it can be shown that if two functions (both defined on the positive real axis) have the same transform, these functions cannot differ over an interval of positive length, although they may differ at isolated points (see Ref. [A14] in App. 1). Hence we may say that the inverse of a given transform is essentially unique. In particular, if two *continuous* functions have the same transform, they are completely identical.

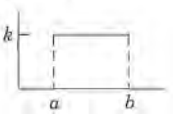
PROBLEM SET 6.1

1–20 LAPLACE TRANSFORMS



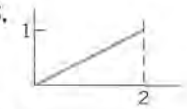
Find the Laplace transforms of the following functions. Show the details of your work. (a, b, k, ω, θ are constants.)

1. $t^2 - 2t$
2. $(t^2 - 3)^2$
3. $\cos 2\pi t$
4. $\sin^2 4t$
5. $e^{2t} \cosh t$
6. $e^{-t} \sinh 5t$
7. $\cos(\omega t + \theta)$
8. $\sin(3t - \frac{1}{2})$
9. e^{3a-2bt}
10. $-8 \sin 0.2t$

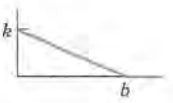


11. $\sin t \cos t$

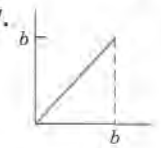
12. $(t + 1)^3$



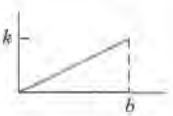
13.



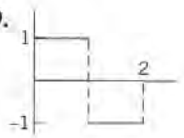
14.



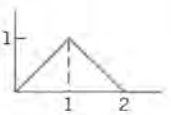
15.



16.



17.



18.

19.

20.

21. Using $\mathcal{L}(f)$ in Prob. 13, find $\mathcal{L}(f_1)$, where $f_1(t) = 0$ if $t \leqq 2$ and $f_1(t) = 1$ if $t > 2$.

22. (Existence) Show that $\mathcal{L}(1/\sqrt{t}) = \sqrt{\pi/s}$. [Use (30) $\Gamma(\frac{1}{2}) = \sqrt{\pi}$ in App. 3.1.] Conclude from this that the conditions in Theorem 3 are sufficient but not necessary for the existence of a Laplace transform.

23. (Change of scale) If $\mathcal{L}(f(t)) = F(s)$ and c is any positive constant, show that $\mathcal{L}(f(ct)) = F(s/c)/c$. (*Hint:* Use (1).) Use this to obtain $\mathcal{L}(\cos \omega t)$ from $\mathcal{L}(\cos t)$.

24. (Nonexistence) Show that e^{t^2} does not satisfy a condition of the form (2).

25. (Nonexistence) Give simple examples of functions (defined for all $x \geqq 0$) that have no Laplace transform.

26. (Table 6.1) Derive formula 6 from formulas 9 and 10.

27. (Table 6.1) Convert Table 6.1 from a table for finding transforms to a table for finding inverse transforms (with obvious changes, e.g., $\mathcal{L}^{-1}(1/s^n) = t^{n-1}/(n-1)!$, etc.).

28. (Inverse transform) Prove that $\mathcal{L}^{-1}$ is linear. *Hint.* Use the fact that $\mathcal{L}$ is linear.

29–40 INVERSE LAPLACE TRANSFORMS

Given $F(s) = \mathcal{L}(f)$, find $f(t)$. Show the details. (L, n, k, a, b are constants.)

29. $\dfrac{4s - 3\pi}{s^2 + \pi^2}$

30. $\dfrac{2s + 16}{s^2 - 16}$

31. $\dfrac{s^4 - 3s^2 + 12}{s^5}$

32. $\dfrac{10}{2s + \sqrt{2}}$

33. $\dfrac{n\pi L}{L^2 s^2 + n^2 \pi^2}$

34. $\dfrac{20}{(s - 1)(s + 4)}$

35. $\dfrac{8}{s^2 + 4s}$

36. $\displaystyle\sum_{k=1}^{4} \frac{(k + 1)^2}{s + k^2}$

37. $\dfrac{1}{(s - \sqrt{3})(s + \sqrt{5})}$

38. $\dfrac{18s - 12}{9s^2 - 1}$

39. $\dfrac{1}{s^2 + 5} - \dfrac{1}{s + 5}$

40. $\dfrac{1}{(s + a)(s + b)}$

41–54 APPLICATIONS OF THE FIRST SHIFTING THEOREM (s-SHIFTING)

In Probs. 41–46 find the transform. In Probs. 47–54 find the inverse transform. Show the details.

41. $3.8te^{2.4t}$

42. $-3t^4 e^{-0.5t}$

43. $5e^{-at} \sin \omega t$

44. $e^{-3t} \cos \pi t$

45. $e^{-kt}(a \cos t + b \sin t)$

46. $e^{-t}(a_0 + a_1 t + \cdots + a_n t^n)$

47. $\dfrac{7}{(s - 1)^3}$

48. $\dfrac{\pi}{(s + \pi)^2}$

49. $\dfrac{\sqrt{8}}{(s + \sqrt{2})^3}$

50. $\dfrac{s - 6}{(s - 1)^2 + 4}$

51. $\dfrac{15}{s^2 + 4s + 29}$

52. $\dfrac{4s - 2}{s^2 - 6s + 18}$

53. $\dfrac{\pi}{s^2 + 10\pi s + 24\pi^2}$

54. $\dfrac{2s - 56}{s^2 - 4s - 12}$

6.2 Transforms of Derivatives and Integrals. ODEs

The Laplace transform is a method of solving ODEs and initial value problems. The crucial idea is that ***operations of calculus on functions are replaced by operations of algebra on transforms.*** Roughly, *differentiation* of $f(t)$ will correspond to *multiplication* of $\mathcal{L}(f)$ by s (see Theorems 1 and 2) and *integration* of $f(t)$ to *division* of $\mathcal{L}(f)$ by s. To solve ODEs, we must first consider the Laplace transform of derivatives.

THEOREM 1

Laplace Transform of Derivatives

The transforms of the first and second derivatives of $f(t)$ satisfy

$$\mathscr{L}(f') = s\mathscr{L}(f) - f(0) \tag{1}$$

$$\mathscr{L}(f'') = s^2\mathscr{L}(f) - sf(0) - f'(0). \tag{2}$$

Formula (1) *holds if $f(t)$ is continuous for all $t \geqq 0$ and satisfies the growth restriction* (2) *in Sec.* 6.1 *and $f'(t)$ is piecewise continuous on every finite interval on the semi-axis $t \geqq 0$. Similarly,* (2) *holds if f and f' are continuous for all $t \geqq 0$ and satisfy the growth restriction and f'' is piecewise continuous on every finite interval on the semi-axis $t \geqq 0$.*

PROOF We prove (1) first under the *additional assumption* that f' is continuous. Then by the definition and integration by parts,

$$\mathscr{L}(f') = \int_0^\infty e^{-st}f'(t)\,dt = [e^{-st}f(t)]\Big|_0^\infty + s\int_0^\infty e^{-st}f(t)\,dt.$$

Since f satisfies (2) in Sec. 6.1, the integrated part on the right is zero at the upper limit when $s > k$, and at the lower limit it contributes $-f(0)$. The last integral is $\mathscr{L}(f)$. It exists for $s > k$ because of Theorem 3 in Sec. 6.1. Hence $\mathscr{L}(f')$ exists when $s > k$ and (1) holds.

If f' is merely piecewise continuous, the proof is similar. In this case the interval of integration of f' must be broken up into parts such that f' is continuous in each such part.

The proof of (2) now follows by applying (1) to f'' and then substituting (1), that is

$$\mathscr{L}(f'') = s\mathscr{L}(f') - f'(0) = s[s\mathscr{L}(f) - f(0)] = s^2\mathscr{L}(f) - sf(0) - f'(0). \qquad \blacksquare$$

Continuing by substitution as in the proof of (2) and using induction, we obtain the following extension of Theorem 1.

THEOREM 2

Laplace Transform of the Derivative $f^{(n)}$ of Any Order

Let $f, f', \cdots, f^{(n-1)}$ be continuous for all $t \geqq 0$ and satisfy the growth restriction (2) *in Sec.* 6.1. *Furthermore, let $f^{(n)}$ be piecewise continuous on every finite interval on the semi-axis $t \geqq 0$. Then the transform of $f^{(n)}$ satisfies*

$$\mathscr{L}(f^{(n)}) = s^n\mathscr{L}(f) - s^{n-1}f(0) - s^{n-2}f'(0) - \cdots - f^{(n-1)}(0). \tag{3}$$

EXAMPLE 1 **Transform of a Resonance Term (Sec. 2.8)**

Let $f(t) = t\sin\omega t$. Then $f(0) = 0$, $f'(t) = \sin\omega t + \omega t\cos\omega t$, $f'(0) = 0$, $f'' = 2\omega\cos\omega t - \omega^2 t\sin\omega t$. Hence by (2),

$$\mathscr{L}(f'') = 2\omega\frac{s}{s^2+\omega^2} - \omega^2\mathscr{L}(f) = s^2\mathscr{L}(f), \qquad \text{thus} \qquad \mathscr{L}(f) = \mathscr{L}(t\sin\omega t) = \frac{2\omega s}{(s^2+\omega^2)^2}. \qquad \blacksquare$$

EXAMPLE 2 **Formulas 7 and 8 in Table 6.1, Sec. 6.1**

This is a third derivation of $\mathscr{L}(\cos \omega t)$ and $\mathscr{L}(\sin \omega t)$; cf. Example 4 in Sec. 6.1. Let $f(t) = \cos \omega t$. Then $f(0) = 1$, $f'(0) = 0$, $f''(t) = -\omega^2 \cos \omega t$. From this and (2) we obtain

$$\mathscr{L}(f'') = s^2\mathscr{L}(f) - s = -\omega^2\mathscr{L}(f). \qquad \text{By algebra,} \qquad \mathscr{L}(\cos \omega t) = \frac{s}{s^2 + \omega^2}.$$

Similarly, let $g = \sin \omega t$. Then $g(0) = 0$, $g' = \omega \cos \omega t$. From this and (1) we obtain

$$\mathscr{L}(g') = s\mathscr{L}(g) = \omega\mathscr{L}(\cos \omega t). \qquad \text{Hence} \qquad \mathscr{L}(\sin \omega t) = \frac{\omega}{s}\mathscr{L}(\cos \omega t) = \frac{\omega}{s^2 + \omega^2}.$$ ■

Laplace Transform of the Integral of a Function

Differentiation and integration are inverse operations, and so are multiplication and division. Since differentiation of a function $f(t)$ (roughly) corresponds to multiplication of its transform $\mathscr{L}(f)$ by s, we expect integration of $f(t)$ to correspond to division of $\mathscr{L}(f)$ by s:

THEOREM 3 **Laplace Transform of Integral**

Let $F(s)$ denote the transform of a function $f(t)$ which is piecewise continuous for $t \geqq 0$ and satisfies a growth restriction (2), *Sec.* 6.1. *Then, for $s > 0$, $s > k$, and $t > 0$,*

$$\textbf{(4)} \qquad \mathscr{L}\left\{\int_0^t f(\tau)\, d\tau\right\} = \frac{1}{s}F(s), \qquad \text{thus} \qquad \int_0^t f(\tau)\, d\tau = \mathscr{L}^{-1}\left\{\frac{1}{s}F(s)\right\}.$$

PROOF Denote the integral in (4) by $g(t)$. Since $f(t)$ is piecewise continuous, $g(t)$ is continuous, and (2), Sec. 6.1, gives

$$|g(t)| = \left|\int_0^t f(\tau)\, d\tau\right| \leqq \int_0^t |f(\tau)|\, d\tau \leqq M\int_0^t e^{k\tau}\, d\tau = \frac{M}{k}(e^{kt} - 1) \leqq \frac{M}{k}e^{kt} \qquad (k > 0).$$

This shows that $g(t)$ also satisfies a growth restriction. Also, $g'(t) = f(t)$, except at points at which $f(t)$ is discontinuous. Hence $g'(t)$ is piecewise continuous on each finite interval and, by Theorem 1, since $g(0) = 0$ (the integral from 0 to 0 is zero)

$$\mathscr{L}\{f(t)\} = \mathscr{L}\{g'(t)\} = s\mathscr{L}\{g(t)\} - g(0) = s\mathscr{L}\{g(t)\}.$$

Division by s and interchange of the left and right sides gives the first formula in (4), from which the second follows by taking the inverse transform on both sides. ■

EXAMPLE 3 **Application of Theorem 3: Formulas 19 and 20 in the Table of Sec. 6.9**

Using Theorem 3, find the inverse of $\dfrac{1}{s(s^2 + \omega^2)}$ and $\dfrac{1}{s^2(s^2 + \omega^2)}$.

Solution. From Table 6.1 in Sec. 6.1 and the integration in (4) (second formula with the sides interchanged) we obtain

$$\mathscr{L}^{-1}\left\{\frac{1}{s^2 + \omega^2}\right\} = \frac{\sin \omega t}{\omega}, \qquad \mathscr{L}^{-1}\left\{\frac{1}{s(s^2 + \omega^2)}\right\} = \int_0^t \frac{\sin \omega\tau}{\omega}\, d\tau = \frac{1}{\omega^2}(1 - \cos \omega t).$$

This is formula 19 in Sec. 6.9. Integrating this result again and using (4) as before, we obtain formula 20 in Sec. 6.9:

$$\mathscr{L}^{-1}\left\{\frac{1}{s^2(s^2+\omega^2)}\right\} = \frac{1}{\omega^2}\int_0^t (1-\cos\omega\tau)\,d\tau = \left[\frac{\tau}{\omega^2} - \frac{\sin\omega\tau}{\omega^3}\right]_0^t = \frac{t}{\omega^2} - \frac{\sin\omega t}{\omega^3}.$$

It is typical that results such as these can be found in several ways. In this example, try partial fraction reduction. ■

Differential Equations, Initial Value Problems

We shall now discuss how the Laplace transform method solves ODEs and initial value problems. We consider an initial value problem

(5) $$y'' + ay' + by = r(t), \qquad y(0) = K_0, \qquad y'(0) = K_1$$

where a and b are constant. Here $r(t)$ is the given **input** (*driving force*) applied to the mechanical or electrical system and $y(t)$ is the **output** (*response to the input*) to be obtained. In Laplace's method we do three steps:

Step 1. Setting up the subsidiary equation. This is an algebraic equation for the transform $Y = \mathscr{L}(y)$ obtained by transforming (5) by means of (1) and (2), namely,

$$\big[s^2Y - sy(0) - y'(0)\big] + a[sY - y(0)] + bY = R(s)$$

where $R(s) = \mathscr{L}(r)$. Collecting the Y-terms, we have the subsidiary equation

$$(s^2 + as + b)Y = (s + a)y(0) + y'(0) + R(s).$$

Step 2. Solution of the subsidiary equation by algebra. We divide by $s^2 + as + b$ and use the so-called **transfer function**

(6) $$Q(s) = \frac{1}{s^2 + as + b} = \frac{1}{(s + \frac{1}{2}a)^2 + b - \frac{1}{4}a^2}.$$

(Q is often denoted by H, but we need H much more frequently for other purposes.) This gives the solution

(7) $$Y(s) = [(s + a)y(0) + y'(0)]Q(s) + R(s)Q(s).$$

If $y(0) = y'(0) = 0$, this is simply $Y = RQ$; hence

$$Q = \frac{Y}{R} = \frac{\mathscr{L}(\text{output})}{\mathscr{L}(\text{input})}$$

and this explains the name of Q. Note that ***Q depends neither on r(t) nor on the initial conditions*** (but only on a and b).

Step 3. Inversion of Y to obtain y = $\mathscr{L}^{-1}(Y)$. We reduce (7) (usually by ***partial fractions*** as in calculus) to a sum of terms whose inverses can be found from the tables (e.g., in Sec. 6.1 or Sec. 6.9) or by a CAS, so that we obtain the solution $y(t) = \mathscr{L}^{-1}(Y)$ *of* (5).

EXAMPLE 4 Initial Value Problem: The Basic Laplace Steps

Solve

$$y'' - y = t, \qquad y(0) = 1, \qquad y'(0) = 1.$$

Solution. ***Step 1.*** From (2) and Table 6.1 we get the subsidiary equation [with $Y = \mathcal{L}(y)$]

$$s^2Y - sy(0) - y'(0) - Y = 1/s^2, \qquad \text{thus} \qquad (s^2 - 1)Y = s + 1 + 1/s^2.$$

Step 2. The transfer function is $Q = 1/(s^2 - 1)$, and (7) becomes

$$Y = (s + 1)Q + \frac{1}{s^2}\,Q = \frac{s + 1}{s^2 - 1} + \frac{1}{s^2(s^2 - 1)}.$$

Simplification and **partial fraction expansion** gives

$$Y = \frac{1}{s - 1} + \left(\frac{1}{s^2 - 1} - \frac{1}{s^2}\right).$$

Step 3. From this expression for Y and Table 6.1 we obtain the solution

$$y(t) = \mathcal{L}^{-1}(Y) = \mathcal{L}^{-1}\left\{\frac{1}{s - 1}\right\} + \mathcal{L}^{-1}\left\{\frac{1}{s^2 - 1}\right\} - \mathcal{L}^{-1}\left\{\frac{1}{s^2}\right\} = e^t + \sinh t - t.$$

The diagram in Fig. 115 summarizes our approach. ■

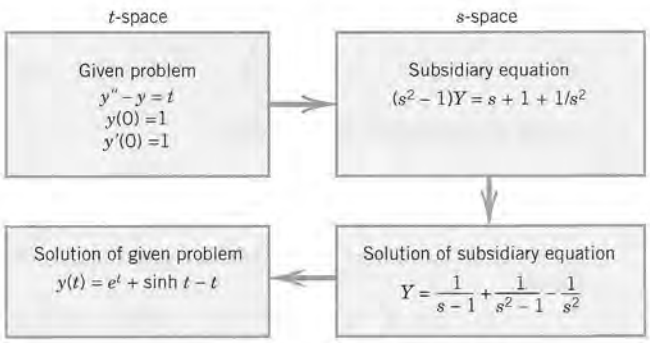


Fig. 115. Laplace transform method

EXAMPLE 5 Comparison with the Usual Method

Solve the initial value problem

$$y'' + y' + 9y = 0, \qquad y(0) = 0.16, \qquad y'(0) = 0.$$

Solution. From (1) and (2) we see that the subsidiary equation is

$$s^2Y - 0.16s + sY - 0.16 + 9Y = 0, \qquad \text{thus} \qquad (s^2 + s + 9)Y = 0.16(s + 1).$$

The solution is

$$Y = \frac{0.16(s + 1)}{s^2 + s + 9} = \frac{0.16(s + \frac{1}{2}) + 0.08}{(s + \frac{1}{2})^2 + \frac{35}{4}}.$$

Hence by the first shifting theorem and the formulas for cos and sin in Table 6.1 we obtain

$$y(t) = \mathcal{L}^{-1}(Y) = e^{-t/2}\left(0.16\cos\sqrt{\frac{35}{4}}\,t + \frac{0.08}{\frac{1}{2}\sqrt{35}}\sin\sqrt{\frac{35}{4}}\,t\right)$$

$$= e^{-0.5t}(0.16\cos 2.96t + 0.027\sin 2.96t).$$

This agrees with Example 2, Case (III) in Sec. 2.4. The work was less. ■

Advantages of the Laplace Method

1. *Solving a nonhomogeneous ODE does not require first solving the homogeneous ODE.* See Example 4.
2. *Initial values are automatically taken care of.* See Examples 4 and 5.
3. *Complicated inputs* $r(t)$ (right sides of linear ODEs) *can be handled very efficiently,* as we show in the next sections.

EXAMPLE 6 Shifted Data Problems

This means initial value problems with initial conditions given at some $t = t_0 > 0$ instead of $t = 0$. For such a problem set $t = \tilde{t} + t_0$, so that $t = t_0$ gives $\tilde{t} = 0$ and the Laplace transform can be applied. For instance, solve

$$y'' + y = 2t, \qquad y(\tfrac{1}{4}\pi) = \tfrac{1}{2}\pi, \qquad y'(\tfrac{1}{4}\pi) = 2 - \sqrt{2}.$$

Solution. We have $t_0 = \frac{1}{4}\pi$ and we set $t = \tilde{t} + \frac{1}{4}\pi$. Then the problem is

$$\tilde{y}'' + \tilde{y} = 2(\tilde{t} + \tfrac{1}{4}\pi), \qquad \tilde{y}(0) = \tfrac{1}{2}\pi, \qquad \tilde{y}'(0) = 2 - \sqrt{2}$$

where $\tilde{y}(\tilde{t}) = y(t)$. Using (2) and Table 6.1 and denoting the transform of $\tilde{y}$ by $\tilde{Y}$, we see that the subsidiary equation of the "shifted" initial value problem is

$$s^2\tilde{Y} - s \cdot \tfrac{1}{2}\pi - (2 - \sqrt{2}) + \tilde{Y} = \frac{2}{s^2} + \frac{\frac{1}{2}\pi}{s}, \quad \text{thus} \quad (s^2 + 1)\tilde{Y} = \frac{2}{s^2} + \frac{\frac{1}{2}\pi}{s} + \frac{1}{2}\pi s + 2 - \sqrt{2}.$$

Solving this algebraically for $\tilde{Y}$, we obtain

$$\tilde{Y} = \frac{2}{(s^2 + 1)s^2} + \frac{\frac{1}{2}\pi}{(s^2 + 1)s} + \frac{\frac{1}{2}\pi s}{s^2 + 1} + \frac{2 - \sqrt{2}}{s^2 + 1}.$$

The inverse of the first two terms can be seen from Example 3 (with $\omega = 1$), and the last two terms give cos and sin,

$$\tilde{y} = \mathscr{L}^{-1}(\tilde{Y}) = 2(\tilde{t} - \sin\tilde{t}) + \tfrac{1}{2}\pi(1 - \cos\tilde{t}) + \tfrac{1}{2}\pi\cos\tilde{t} + (2 - \sqrt{2})\sin\tilde{t}$$
$$= 2\tilde{t} + \tfrac{1}{2}\pi - \sqrt{2}\sin\tilde{t}.$$

Now $\tilde{t} = t - \frac{1}{4}\pi$, $\sin\tilde{t} = \dfrac{1}{\sqrt{2}}(\sin t - \cos t)$, so that the answer (the solution) is

$$y = 2t - \sin t + \cos t. \qquad \blacksquare$$

PROBLEM SET 6.2

1–8 OBTAINING TRANSFORMS BY DIFFERENTIATION

Using (1) or (2), find $\mathscr{L}(f)$ if $f(t)$ equals:

1. te^{kt}
2. $t\cos 5t$
3. $\sin^2 \omega t$
4. $\cos^2 \pi t$
5. $\sinh^2 at$
6. $\cosh^2 \frac{1}{2}t$
7. $t\sin \frac{1}{2}\pi t$
8. $\sin^4 t$ (Use Prob. 3.)

9. **(Derivation by different methods)** It is typical that various transforms can be obtained by several methods. Show this for Prob. 1. Show it for $\mathscr{L}(\cos^2 \frac{1}{2}t)$ (a) by expressing $\cos^2 \frac{1}{2}t$ in terms of $\cos t$, (b) by using Prob. 3.

10–24 INITIAL VALUE PROBLEMS

Solve the following initial value problems by the Laplace transform. (If necessary, use partial fraction expansion as in Example 4. Show all details.)

10. $y' + 4y = 0, \qquad y(0) = 2.8$
11. $y' + \frac{1}{2}y = 17\sin 2t, \qquad y(0) = -1$
12. $y'' - y' - 6y = 0, \qquad y(0) = 6, \quad y'(0) = 13$

13. $y'' - \frac{1}{4}y = 0, \quad y(0) = 4, \quad y'(0) = 0$

14. $y'' - 4y' + 4y = 0, \quad y(0) = 2.1, \quad y'(0) = 3.9$

15. $y'' + 2y' + 2y = 0, \quad y(0) = 1, \quad y'(0) = -3$

16. $y'' + ky' - 2k^2y = 0, \quad y(0) = 2, \quad y'(0) = 2k$

17. $y'' + 7y' + 12y = 21e^{3t}, \quad y(0) = 3.5, \quad y'(0) = -10$

18. $y'' + 9y = 10e^{-t}, \quad y(0) = 0, \quad y'(0) = 0$

19. $y'' + 3y' + 2.25y = 9t^3 + 64, \quad y(0) = 1, \quad y'(0) = 31.5$

20. $y'' - 6y' + 5y = 29 \cos 2t, \quad y(0) = 3.2, \quad y'(0) = 6.2$

21. (Shifted data) $y' - 6y = 0, \quad y(2) = 4$

22. $y'' - 2y' - 3y = 0, \quad y(1) = -3, \quad y'(1) = -17$

23. $y'' + 3y' - 4y = 6e^{2t-2}, \quad y(1) = 4, \quad y'(1) = 5$

24. $y'' + 2y' + 5y = 50t - 150, \quad y(3) = -4, \quad y'(3) = 14$

25. PROJECT. Comments on Sec. 6.2. (a) Give reasons why Theorems 1 and 2 are more important than Theorem 3.

(b) Extend Theorem 1 by showing that if $f(t)$ is continuous, except for an ordinary discontinuity (finite jump) at some $t = a$ (> 0), the other conditions remaining as in Theorem 1, then (see Fig. 116)

(1*) $\mathcal{L}(f') = s\mathcal{L}(f) - f(0) - [f(a + 0) - f(a - 0)]e^{-as}$.

(c) Verify (1*) for $f(t) = e^{-t}$ if $0 < t < 1$ and 0 if $t > 1$.

(d) Verify (1*) for two more complicated functions of your choice.

(e) Compare the Laplace transform of solving ODEs with the method in Chap. 2. Give examples of your own to illustrate the advantages of the present method (to the extent we have seen them so far).

26. PROJECT. Further Results by Differentiation. Proceeding as in Example 1, obtain

(a) $\mathcal{L}(t \cos \omega t) = \dfrac{s^2 - \omega^2}{(s^2 + \omega^2)^2}$

and from this and Example 1: (b) formula 21, (c) 22, (d) 23 in Sec. 6.9,

(e) $\mathcal{L}(t \cosh at) = \dfrac{s^2 + a^2}{(s^2 - a^2)^2}$,

(f) $\mathcal{L}(t \sinh at) = \dfrac{2as}{(s^2 - a^2)^2}$.

27–34 OBTAINING TRANSFORMS BY INTEGRATION

Using Theorem 3, find $f(t)$ if $\mathcal{L}(f)$ equals:

27. $\dfrac{1}{s^2 + s/2}$

28. $\dfrac{10}{s^3 - \pi s^2}$

29. $\dfrac{1}{s^3 - ks^2}$

30. $\dfrac{1}{s^4 + s^2}$

31. $\dfrac{5}{s^3 - 5s}$

32. $\dfrac{2}{s^3 + 9s}$

33. $\dfrac{1}{s^4 - 4s^2}$

34. $\dfrac{1}{s^4 + \pi^2 s^2}$

35. (Partial fractions) Solve Probs. 27, 29, and 31 by using partial fractions.

6.3 Unit Step Function. t-Shifting

This section and the next one are extremely important because we shall now reach the point where the Laplace transform method shows its real power in applications and its superiority over the classical approach of Chap. 2. The reason is that we shall introduce two auxiliary functions, the *unit step function* or *Heaviside function* $u(t - a)$ (below) and *Dirac's delta* $\delta(t - a)$ (in Sec. 6.4). These functions are suitable for solving ODEs with complicated right sides of considerable engineering interest, such as single waves, inputs (driving forces) that are discontinuous or act for some time only, periodic inputs more general than just cosine and sine, or impulsive forces acting for an instant (hammerblows, for example).

Unit Step Function (Heaviside Function) $u(t-a)$

The **unit step function** or **Heaviside function** $u(t-a)$ is 0 for $t<a$, has a jump of size 1 at $t=a$ (where we can leave it undefined), and is 1 for $t>a$, in a formula:

$$\textbf{(1)} \qquad u(t-a)=\begin{cases}0 & \text{if } t<a\\ 1 & \text{if } t>a\end{cases} \qquad (a \geqq 0).$$

Figure 117 shows the special case $u(t)$, which has its jump at zero, and Fig. 118 the general case $u(t-a)$ for an arbitrary positive a. (For Heaviside see Sec. 6.1.)

The transform of $u(t-a)$ follows directly from the defining integral in Sec. 6.1,

$$\mathcal{L}\{u(t-a)\}=\int_0^\infty e^{-st}u(t-a)\,dt=\int_a^\infty e^{-st}\cdot 1\,dt=-\frac{e^{-st}}{s}\bigg|_{t=a}^{\infty};$$

here the integration begins at $t=a$ ($\geqq 0$) because $u(t-a)$ is 0 for $t<a$. Hence

$$\textbf{(2)} \qquad \mathcal{L}\{u(t-a)\}=\frac{e^{-as}}{s} \qquad (s>0).$$

The unit step function is a typical "engineering function" made to measure for engineering applications, which often involve functions (mechanical or electrical driving forces) that are either "off" or "on." Multiplying functions $f(t)$ with $u(t-a)$, we can produce all sorts of effects. The simple basic idea is illustrated in Figs. 119 and 120. In Fig. 119 the given function is shown in (A). In (B) it is switched off between $t=0$ and $t=2$ (because $u(t-2)=0$ when $t<2$) and is switched on beginning at $t=2$. In (C) it is shifted to the right by 2 units, say, for instance, by 2 secs, so that it begins 2 secs later in the same fashion as before. More generally we have the following.

Let $f(t)=0$ for all negative t. Then $f(t-a)u(t-a)$ with $a>0$ is $f(t)$ ***shifted*** *(translated) to the right by the amount a.*

Figure 120 shows the effect of many unit step functions, three of them in (A) and infinitely many in (B) when continued periodically to the right; this is the effect of a rectifier that clips off the negative half-waves of a sinuosidal voltage. CAUTION! Make sure that you fully understand these figures, in particular the difference between parts (B) and (C) of Figure 119. Figure 119(C) will be applied next.

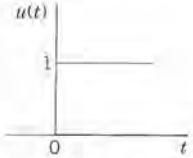

Fig. 117. Unit step function $u(t)$

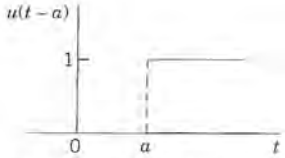

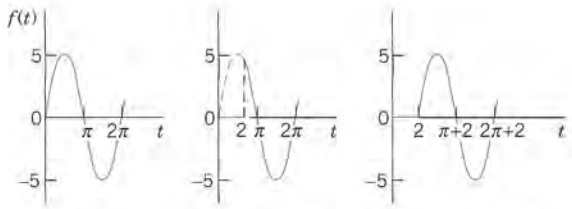

Fig. 118. Unit step function $u(t-a)$

(A) $f(t) = 5 \sin t$ (B) $f(t)u(t-2)$ (C) $f(t-2)u(t-2)$

Fig. 119. Effects of the unit step function: (A) Given function. (B) Switching off and on. (C) Shift.

(A) $k[u(t-1) - 2u(t-4) + u(t-6)]$ (B) $4 \sin(\frac{1}{2}\pi t)[u(t) - u(t-2) + u(t-4) - + \cdots]$

Fig. 120. Use of many unit step functions.

Time Shifting (t-Shifting): Replacing t by $t - a$ in $f(t)$

The first shifting theorem ("s-shifting") in Sec. 6.1 concerned transforms $F(s) = \mathcal{L}\{f(t)\}$ and $F(s - a) = \mathcal{L}\{e^{at}f(t)\}$. The second shifting theorem will concern functions $f(t)$ and $f(t - a)$. Unit step functions are just tools, and the theorem will be needed to apply them in connection with any other functions.

THEOREM 1

Second Shifting Theorem; Time Shifting

If $f(t)$ has the transform $F(s)$, then the **"shifted function"**

$$\tilde{f}(t) = f(t-a)u(t-a) = \begin{cases} 0 & \text{if } t < a \\ f(t-a) & \text{if } t > a \end{cases} \tag{3}$$

has the transform $e^{-as}F(s)$. That is, if $\mathcal{L}\{f(t)\} = F(s)$, then

$$\mathcal{L}\{f(t-a)u(t-a)\} = e^{-as}F(s). \tag{4}$$

Or, if we take the inverse on both sides, we can write

$$f(t-a)u(t-a) = \mathcal{L}^{-1}\{e^{-as}F(s)\}. \tag{4*}$$

Practically speaking, if we know $F(s)$, we can obtain the transform of (3) by multiplying $F(s)$ by e^{-as}. In Fig. 119, the transform of $5 \sin t$ is $F(s) = 5/(s^2 + 1)$, hence the shifted function $5 \sin(t - 2)\, u(t - 2)$ shown in Fig. 119(C) has the transform

$$e^{-2s}F(s) = 5e^{-2s}/(s^2 + 1).$$

PROOF We prove Theorem 1. In (4) on the right we use the definition of the Laplace transform, writing τ for t (to have t available later). Then, taking e^{-as} inside the integral, we have

$$e^{-as}F(s) = e^{-as}\int_0^\infty e^{-s\tau}f(\tau)\,d\tau = \int_0^\infty e^{-s(\tau+a)}f(\tau)\,d\tau.$$

Substituting $\tau + a = t$, thus $\tau = t - a$, $d\tau = dt$, in the integral (CAUTION, the lower limit changes!), we obtain

$$e^{-as}F(s) = \int_a^\infty e^{-st}f(t-a)\,dt.$$

To make the right side into a Laplace transform, we must have an integral from 0 to ∞, not from a to ∞. But this is easy. We multiply the integrand by $u(t-a)$. Then for t from 0 to a the integrand is 0, and we can write, with $\tilde{f}$ as in (3),

$$e^{-as}F(s) = \int_0^\infty e^{-st}f(t-a)u(t-a)\,dt = \int_0^\infty e^{-st}\tilde{f}(t)\,dt.$$

(Do you now see why $u(t-a)$ appears?) This integral is the left side of (4), the Laplace transform of $\tilde{f}(t)$ in (3). This completes the proof. ■

EXAMPLE 1 **Application of Theorem 1. Use of Unit Step Functions**

Write the following function using unit step functions and find its transform.

$$f(t) = \begin{cases} 2 & \text{if } 0 < t < 1 \\ \frac{1}{2}t^2 & \text{if } 1 < t < \frac{1}{2}\pi \\ \cos t & \text{if } t > \frac{1}{2}\pi. \end{cases} \qquad \text{(Fig. 121)}$$

Solution. ***Step 1.*** In terms of unit step functions,

$$f(t) = 2(1-u(t-1)) + \tfrac{1}{2}t^2(u(t-1) - u(t-\tfrac{1}{2}\pi)) + (\cos t)u(t-\tfrac{1}{2}\pi).$$

Indeed, $2(1-u(t-1))$ gives $f(t)$ for $0 < t < 1$, and so on.

Step 2. To apply Theorem 1, we must write each term in $f(t)$ in the form $f(t-a)u(t-a)$. Thus, $2(1-u(t-1))$ remains as it is and gives the transform $2(1-e^{-s})/s$. Then

$$\mathscr{L}\left\{\frac{1}{2}t^2u(t-1)\right\} = \mathscr{L}\left(\frac{1}{2}(t-1)^2 + (t-1) + \frac{1}{2}\right)u(t-1)\Big\} = \left(\frac{1}{s^3} + \frac{1}{s^2} + \frac{1}{2s}\right)e^{-s}$$

$$\mathscr{L}\left\{\frac{1}{2}t^2u\left(t-\frac{1}{2}\pi\right)\right\} = \mathscr{L}\left\{\frac{1}{2}\left(t-\frac{1}{2}\pi\right)^2 + \frac{\pi}{2}\left(t-\frac{1}{2}\pi\right) + \frac{\pi^2}{8}\right)u\left(t-\frac{1}{2}\pi\right)\Big\}$$

$$= \left(\frac{1}{s^3} + \frac{\pi}{2s^2} + \frac{\pi^2}{8s}\right)e^{-\pi s/2}$$

$$\mathscr{L}\left\{(\cos t)u\left(t-\frac{1}{2}\pi\right)\right\} = \mathscr{L}\left\{-\left(\sin\left(t-\frac{1}{2}\pi\right)\right)u\left(t-\frac{1}{2}\pi\right)\right\} = -\frac{1}{s^2+1}e^{-\pi s/2}.$$

Together,

$$\mathscr{L}(f) = \frac{2}{s} - \frac{2}{s}e^{-s} + \left(\frac{1}{s^3} + \frac{1}{s^2} + \frac{1}{2s}\right)e^{-s} - \left(\frac{1}{s^3} + \frac{\pi}{2s^2} + \frac{\pi^2}{8s}\right)e^{-\pi s/2} - \frac{1}{s^2+1}e^{-\pi s/2}.$$

If the conversion of $f(t)$ to $f(t-a)$ is inconvenient, replace it by

(4)** $$\mathscr{L}\{f(t)u(t-a)\} = e^{-as}\mathscr{L}\{f(t+a)\}.$$

(4**) follows from (4) by writing $f(t-a) = g(t)$, hence $f(t) = g(t+a)$ and then again writing f for g. Thus,

$$\mathscr{L}\left\{\frac{1}{2}t^2u(t-1)\right\} = e^{-s}\mathscr{L}\left\{\frac{1}{2}(t+1)^2\right\} = e^{-s}\mathscr{L}\left\{\frac{1}{2}t^2 + t + \frac{1}{2}\right\} = e^{-s}\left(\frac{1}{s^3} + \frac{1}{s^2} + \frac{1}{2s}\right)$$

as before. Similarly for $\mathscr{L}\{\frac{1}{2}t^2u(t-\frac{1}{2}\pi)\}$. Finally, by (4**),

$$\mathscr{L}\left\{\cos t\, u\left(t-\frac{1}{2}\pi\right)\right\} = e^{-\pi s/2}\mathscr{L}\left\{\cos\left(t+\frac{1}{2}\pi\right)\right\} = e^{-\pi s/2}\mathscr{L}\{-\sin t\} = -e^{-\pi s/2}\frac{1}{s^2+1}. \quad \blacksquare$$

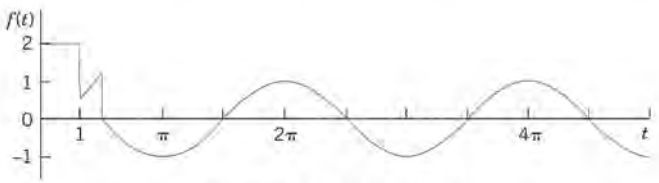

Fig. 121. $f(t)$ in Example 1

EXAMPLE 2 Application of Both Shifting Theorems. Inverse Transform

Find the inverse transform $f(t)$ of

$$F(s) = \frac{e^{-s}}{s^2+\pi^2} + \frac{e^{-2s}}{s^2+\pi^2} + \frac{e^{-3s}}{(s+2)^2}.$$

Solution. Without the exponential functions in the numerator the three terms of $F(s)$ would have the inverses $(\sin \pi t)/\pi$, $(\sin \pi t)/\pi$, and te^{-2t} because $1/s^2$ has the inverse t, so that $1/(s+2)^2$ has the inverse te^{-2t} by the first shifting theorem in Sec. 6.1. Hence by the second shifting theorem (t-shifting),

$$f(t) = \frac{1}{\pi}\sin(\pi(t-1))\,u(t-1) + \frac{1}{\pi}\sin(\pi(t-2))\,u(t-2) + (t-3)e^{-2(t-3)}\,u(t-3).$$

Now $\sin(\pi t - \pi) = -\sin \pi t$ and $\sin(\pi t - 2\pi) = \sin \pi t$, so that the second and third terms cancel each other when $t > 2$. Hence we obtain $f(t) = 0$ if $0 < t < 1$, $-(\sin \pi t)/\pi$ if $1 < t < 2$, 0 if $2 < t < 3$, and $(t-3)e^{-2(t-3)}$ if $t > 3$. See Fig. 122. $\blacksquare$

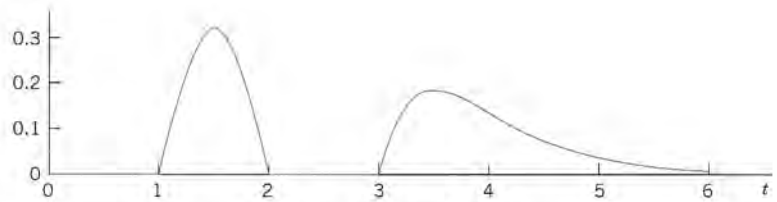

Fig. 122. $f(t)$ in Example 2

EXAMPLE 3 Response of an *RC*-Circuit to a Single Rectangular Wave

Find the current $i(t)$ in the *RC*-circuit in Fig. 123 if a single rectangular wave with voltage V_0 is applied. The circuit is assumed to be quiescent before the wave is applied.

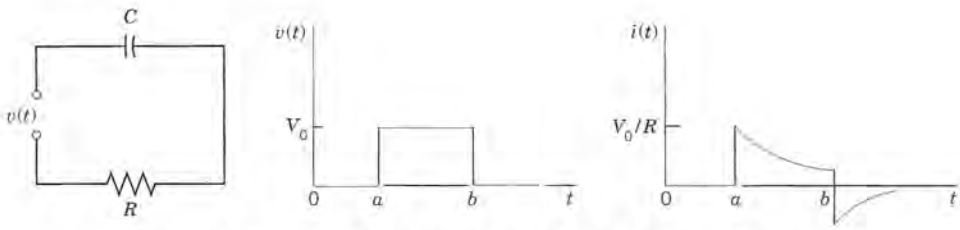

Fig. 123. *RC*-circuit, electromotive force $v(t)$, and current in Example 3

Solution. The input is $V_0[u(t-a) - u(t-b)]$. Hence the circuit is modeled by the integro-differential equation (see Sec. 2.9 and Fig. 123)

$$Ri(t) + \frac{q(t)}{C} = Ri(t) + \frac{1}{C}\int_0^t i(\tau)\,d\tau = v(t) = V_0[u(t-a) - u(t-b)].$$

Using Theorem 3 in Sec. 6.2 and formula (1) in this section, we obtain the subsidiary equation

$$RI(s) + \frac{I(s)}{sC} = \frac{V_0}{s}\,[e^{-as} - e^{-bs}].$$

Solving this equation algebraically for $I(s)$, we get

$$I(s) = F(s)(e^{-as} - e^{-bs}) \qquad \text{where} \qquad F(s) = \frac{V_0/R}{s + 1/(RC)} \qquad \text{and} \qquad \mathscr{L}^{-1}(F) = \frac{V_0}{R}\,e^{-t/(RC)},$$

the last expression being obtained from Table 6.1 in Sec. 6.1. Hence Theorem 1 yields the solution (Fig. 123)

$$i(t) = \mathscr{L}^{-1}(I) = \mathscr{L}^{-1}\{e^{-as}F(s)\} - \mathscr{L}^{-1}\{e^{-bs}F(s)\} = \frac{V_0}{R}\left[e^{-(t-a)/(RC)}u(t-a) - e^{-(t-b)/(RC)}u(t-b)\right];$$

that is, $i(t) = 0$ if $t < a$, and

$$i(t) = \begin{cases} K_1 e^{-t/(RC)} & \text{if } a < t < b \\ (K_1 - K_2)e^{-t/(RC)} & \text{if } a > b \end{cases}$$

where $K_1 = V_0 e^{a/(RC)}/R$ and $K_2 = V_0 e^{b/(RC)}/R$. ■

EXAMPLE 4 **Response of an *RLC*-Circuit to a Sinusoidal Input Acting Over a Time Interval**

Find the response (the current) of the *RLC*-circuit in Fig. 124, where $E(t)$ is sinusoidal, acting for a short time interval only, say,

$$E(t) = 100 \sin 400t \quad \text{if } 0 < t < 2\pi \qquad \text{and} \qquad E(t) = 0 \text{ if } t > 2\pi$$

and current and charge are initially zero.

Solution. The electromotive force $E(t)$ can be represented by $(100 \sin 400t)(1 - u(t - 2\pi))$. Hence the model for the current $i(t)$ in the circuit is the integro-differential equation (see Sec. 2.9)

$$0.1i' + 11i + 100\int_0^t i(\tau)\,d\tau = (100 \sin 400t)(1 - u(t - 2\pi)), \qquad i(0) = 0, \quad i'(0) = 0.$$

From Theorems 2 and 3 in Sec. 6.2 we obtain the subsidiary equation for $I(s) = \mathscr{L}(i)$

$$0.1sI + 11I + 100\,\frac{I}{s} = \frac{100 \cdot 400s}{s^2 + 400^2}\left(\frac{1}{s} - \frac{e^{-2\pi s}}{s}\right).$$

Solving it algebraically and noting that $s^2 + 110s + 1000 = (s + 10)(s + 100)$, we obtain

$$I(s) = \frac{1000 \cdot 400}{(s + 10)(s + 100)} \left(\frac{s}{s^2 + 400^2} - \frac{se^{-2\pi s}}{s^2 + 400^2} \right).$$

For the first term in the parentheses $(\cdots)$ times the factor in front of them we use the partial fraction expansion

$$\frac{400\,000s}{(s + 10)(s + 100)(s^2 + 400^2)} = \frac{A}{s + 10} + \frac{B}{s + 100} + \frac{Ds + K}{s^2 + 400^2}.$$

Now determine A, B, D, K by your favorite method or by a CAS or as follows. Multiplication by the common denominator gives

$$400\,000s = A(s + 100)(s^2 + 400^2) + B(s + 10)(s^2 + 400^2) + (Ds + K)(s + 10)(s + 100).$$

We set $s = -10$ and -100 and then equate the sums of the s^3 and s^2 terms to zero, obtaining (all values rounded)

$(s = -10)$	$-4\,000\,000 = 90(10^2 + 400^2)A,$	$A = -0.27760$
$(s = -100)$	$-40\,000\,000 = -90(100^2 + 400^2)B,$	$B = 2.6144$
(s^3-terms)	$0 = A + B + D,$	$D = -2.3368$
(s^2-terms)	$0 = 100A + 10B + 110D + K,$	$K = 258.66.$

Since $K = 258.66 = 0.6467 \cdot 400$, we thus obtain for the first term I_1 in $I = I_1 - I_2$

$$I_1 = -\frac{0.2776}{s + 10} + \frac{2.6144}{s + 100} - \frac{2.3368s}{s^2 + 400^2} + \frac{0.6467 \cdot 400}{s^2 + 400^2}.$$

From Table 6.1 in Sec. 6.1 we see that its inverse is

$$i_1(t) = -0.2776e^{-10t} + 2.6144e^{-100t} - 2.3368 \cos 400t + 0.6467 \sin 400t.$$

This is the current $i(t)$ when $0 < t < 2\pi$. It agrees for $0 < t < 2\pi$ with that in Example 1 of Sec. 2.9 (except for notation), which concerned the same *RLC*-circuit. Its graph in Fig. 62 in Sec. 2.9 shows that the exponential terms decrease very rapidly. Note that the present amount of work was substantially less.

The second term I_1 of I differs from the first term by the factor $e^{-2\pi s}$. Since $\cos 400(t - 2\pi) = \cos 400t$ and $\sin 400(t - 2\pi) = \sin 400t$, the second shifting theorem (Theorem 1) gives the inverse $i_2(t) = 0$ if $0 < t < 2\pi$, and for $> 2\pi$ it gives

$$i_2(t) = -0.2776e^{-10(t-2\pi)} + 2.6144e^{-100(t-2\pi)} - 2.3368 \cos 400t + 0.6467 \sin 400t.$$

Hence in $i(t)$ the cosine and sine terms cancel, and the current for $t > 2\pi$ is

$$i(t) = -0.2776(e^{-10t} - e^{-10(t-2\pi)}) + 2.6144(e^{-100t} - e^{-100(t-2\pi)}).$$

It goes to zero very rapidly, practically within 0.5 sec. ■

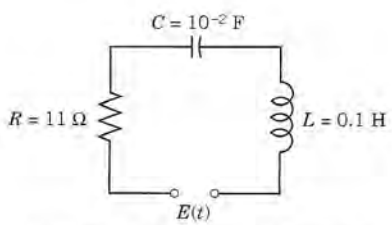

Fig. 124. *RLC*-circuit in Example 4

PROBLEM SET 6.3

1. WRITING PROJECT. Shifting Theorem. Explain and compare the different roles of the two shifting theorems, using your own formulations and examples.

2–13 UNIT STEP FUNCTION AND SECOND SHIFTING THEOREM

Sketch or graph the given function (which is assumed to be zero outside the given interval). Represent it using unit step functions. Find its transform. Show the details of your work.

2. t $(0 < t < 1)$ **3.** e^t $(0 < t < 2)$

4. $\sin 3t$ $(0 < t < \pi)$ **5.** t^2 $(1 < t < 2)$

6. t^2 $(t > 3)$ **7.** $\cos \pi t$ $(1 < t < 4)$

8. $1 - e^{-t}$ $(0 < t < \pi)$ **9.** t $(5 < t < 10)$

10. $\sin \omega t$ $(t > 6\pi/\omega)$ **11.** $20 \cos \pi t$ $(3 < t < 6)$

12. $\sinh t$ $(0 < t < 2)$ **13.** $e^{\pi t}$ $(2 < t < 4)$

14–22 INVERSE TRANSFORMS BY THE SECOND SHIFTING THEOREM

Find and sketch or graph $f(t)$ if $\mathcal{L}(f)$ equals:

14. $se^{-s}/(s^2 + \omega^2)$

15. e^{-4s}/s^2

16. $s^{-2} - (s^{-2} + s^{-1})e^{-s}$

17. $(e^{-2\pi s} - e^{-8\pi s})/(s^2 + 1)$

18. $e^{-\pi s}/(s^2 + 2s + 2)$ **19.** e^{-2s}/s^5

20. $(1 - e^{-s+k})/(s - k)$ **21.** $se^{-3s}/(s^2 - 4)$

22. $2.5(e^{-3.8s} - e^{-2.6s})/s$

23–34 INITIAL VALUE PROBLEMS, SOME WITH DISCONTINUOUS INPUTS

Using the Laplace transform and showing the details, solve:

23. $y'' + 2y' + 2y = 0$, $y(0) = 0$, $y'(0) = 1$

24. $9y'' - 6y' + y = 0$, $y(0) = 3$, $y'(0) = 1$

25. $y'' + 4y' + 13y = 145 \cos 2t$, $y(0) = 10$, $y'(0) = 14$

26. $y'' + 10y' + 24y = 144t^2$, $y(0) = \frac{19}{12}$, $y'(0) = -5$

27. $y'' + 9y = r(t)$, $r(t) = 8 \sin t$ if $0 < t < \pi$ and 0 if $t > \pi$; $y(0) = 0$, $y'(0) = 4$

28. $y'' + 3y' + 2y = r(t)$, $r(t) = 1$ if $0 < t < 1$ and 0 if $t > 1$; $y(0) = 0$, $y'(0) = 0$

29. $y'' + y = r(t)$, $r(t) = t$ if $0 < t < 1$ and 0 if $t > 1$; $y(0) = y'(0) = 0$

30. $y'' - 16y = r(t)$, $r(t) = 48e^{2t}$ if $0 < t < 4$ and 0 if $t > 4$; $y(0) = 3$, $y'(0) = -4$

31. $y'' + y' - 2y = r(t)$, $r(t) = 3 \sin t - \cos t$ if $0 < t < 2\pi$ and $3 \sin 2t - \cos 2t$ if $t > 2\pi$; $y(0) = 1$, $y'(0) = 0$

32. $y'' + 8y' + 15y = r(t)$, $r(t) = 35e^{2t}$ if $0 < t < 2$ and 0 if $t > 2$; $y(0) = 3$, $y'(0) = -8$

33. (Shifted data) $y'' + 4y = 8t^2$ if $0 < t < 5$ and 0 if $t > 5$; $y(1) = 1 + \cos 2$, $y'(1) = 4 - 2 \sin 2$

34. $y'' + 2y' + 5y = 10 \sin t$ if $0 < t < 2\pi$ and 0 if $t > 2\pi$; $y(\pi) = 1$, $y'(\pi) = 2e^{-\pi} - 2$

MODELS OF ELECTRIC CIRCUITS

35. (Discharge) Using the Laplace transform, find the charge $q(t)$ on the capacitor of capacitance C in Fig. 125 if the capacitor is charged so that its potential is V_0 and the switch is closed at $t = 0$.

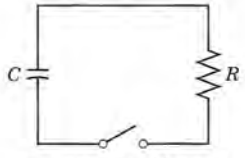

Fig. 125. Problem 35

36–38 RC-CIRCUIT

Using the Laplace transform and showing the details, find the current $i(t)$ in the circuit in Fig. 126 with $R = 10\ \Omega$ and $C = 10^{-2}$ F, where the current at $t = 0$ is assumed to be zero, and:

36. $v(t) = 100$ V if $0.5 < t < 0.6$ and 0 otherwise. Why does $i(t)$ have jumps?

37. $v = 0$ if $t < 2$ and $100(t - 2)$ V if $t > 2$

38. $v = 0$ if $t < 4$ and $14 \cdot 10^6 e^{-3t}$ V if $t > 4$

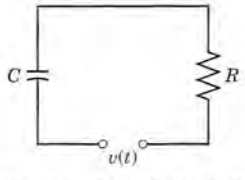

Fig. 126. Problems 36–38

39–41 RL-CIRCUIT

Using the Laplace transform and showing the details, find the current $i(t)$ in the circuit in Fig. 127, assuming $i(0) = 0$ and:

39. $R = 10\ \Omega$, $L = 0.5$ H, $v = 200t$ V if $0 < t < 2$ and 0 if $t > 2$

40. $R = 1\ \text{k}\Omega\ (= 1000\ \Omega)$, $L = 1$ H, $v = 0$ if $0 < t < \pi$, and $40 \sin t$ V if $t > \pi$

41. $R = 25\ \Omega$, $L = 0.1$ H, $v = 490e^{-5t}$ V if $0 < t < 1$ and 0 if $t > 1$

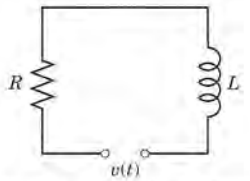

Fig. 127. Problems 39–41

42–44 LC-CIRCUIT

Using the Laplace transform and showing the details, find the current $i(t)$ in the circuit in Fig. 128, assuming zero initial current and charge on the capacitor and:

42. $L = 1$ H, $C = 0.25$ F, $v = 200(t - \frac{1}{3}t^3)$ V if $0 < t < 1$ and 0 if $t > 1$

43. $L = 1$ H, $C = 10^{-2}$ F, $v = -9900 \cos t$ V if $\pi < t < 3\pi$ and 0 otherwise

44. $L = 0.5$ H, $C = 0.05$ F, $v = 78 \sin t$ V if $0 < t < \pi$ and 0 if $t > \pi$

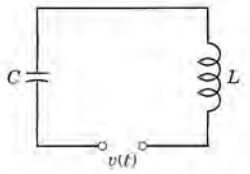

Fig. 128. Problems 42–44

45–47 RLC-CIRCUIT

Using the Laplace transform and showing the details, find the current $i(t)$ in the circuit in Fig. 129, assuming zero initial current and charge and:

45. $R = 2\ \Omega$, $L = 1$ H, $C = 0.5$ F, $v(t) = 1$ kV if $0 < t < 2$ and 0 if $t > 2$

46. $R = 4\ \Omega$, $L = 1$ H, $C = 0.05$ F, $v = 34e^{-t}$ V if $0 < t < 4$ and 0 if $t > 4$

47. $R = 2\ \Omega$, $L = 1$ H, $C = 0.1$ F, $v = 255 \sin t$ V if $0 < t < 2\pi$ and 0 if $t > 2\pi$

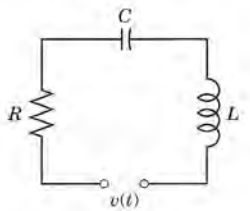

Fig. 129. Problems 45–47

6.4 Short Impulses. Dirac's Delta Function. Partial Fractions

Phenomena of an impulsive nature, such as the action of forces or voltages over short intervals of time, arise in various applications, for instance, if a mechanical system is hit by a hammerblow, an airplane makes a "hard" landing, a ship is hit by a single high wave, or we hit a tennisball by a racket, and so on. Our goal is to show how such problems are modeled by "Dirac's delta function" and can be solved very efficiently by the Laplace transform.

To model situations of that type, we consider the function

$$(1) \qquad f_k(t - a) = \begin{cases} 1/k & \text{if } a \leqq t \leqq a + k \\ 0 & \text{otherwise} \end{cases} \qquad \text{(Fig. 130)}$$

(and later its limit as $k \to 0$). This function represents, for instance, a force of magnitude $1/k$ acting from $t = a$ to $t = a + k$, where k is positive and small. In mechanics, the integral of a force acting over a time interval $a \leqq t \leqq a + k$ is called the **impulse** of the

force; similarly for electromotive forces $E(t)$ acting on circuits. Since the blue rectangle in Fig. 130 has area 1, the impulse of f_k in (1) is

$$(2) \qquad I_k = \int_0^\infty f_k(t-a)\,dt = \int_a^{a+k} \frac{1}{k}\,dt = 1.$$

To find out what will happen if k becomes smaller and smaller, we take the limit of f_k as $k \to 0$ $(k > 0)$. This limit is denoted by $\delta(t-a)$, that is,

$$\delta(t-a) = \lim_{k \to 0} f_k(t-a).$$

$\delta(t-a)$ is called the **Dirac delta function**[2] or the **unit impulse function.**

$\delta(t-a)$ is not a function in the ordinary sense as used in calculus, but a so-called *generalized function.*[2] To see this, we note that the impulse I_k of f_k is 1, so that from (1) and (2) by taking the limit as $k \to 0$ we obtain

$$(3) \qquad \delta(t-a) = \begin{cases} \infty & \text{if } t = a \\ 0 & \text{otherwise} \end{cases} \qquad \text{and} \qquad \int_0^\infty \delta(t-a)\,dt = 1,$$

but from calculus we know that a function which is everywhere 0 except at a single point must have the integral equal to 0. Nevertheless, in impulse problems it is convenient to operate on $\delta(t-a)$ as though it were an ordinary function. In particular, for a *continuous* function $g(t)$ one uses the property [often called the **sifting property** of $\delta(t-a)$, not to be confused with *shifting*]

$$(4) \qquad \int_0^\infty g(t)\,\delta(t-a)\,dt = g(a)$$

which is plausible by (2).

To obtain the Laplace transform of $\delta(t-a)$, we write

$$f_k(t-a) = \frac{1}{k}\,[u(t-a) - u(t-(a+k))]$$

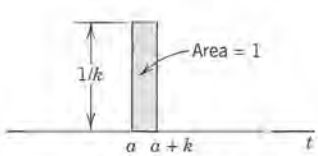

Fig. 130. The function $f_k(t-a)$ in (1)

[2]PAUL DIRAC (1902–1984), English physicist, was awarded the Nobel Prize [jointly with the Austrian ERWIN SCHRÖDINGER (1887–1961)] in 1933 for his work in quantum mechanics.

Generalized functions are also called **distributions.** Their theory was created in 1936 by the Russian mathematician SERGEI L'VOVICH SOBOLEV (1908–1989), and in 1945, under wider aspects, by the French mathematician LAURENT SCHWARTZ (1915–2002).

and take the transform [see (2)]

$$\mathcal{L}\{f_k(t-a)\} = \frac{1}{ks}\left[e^{-as} - e^{-(a+k)s}\right] = e^{-as}\,\frac{1-e^{-ks}}{ks}.$$

We now take the limit as $k \to 0$. By l'Hôpital's rule the quotient on the right has the limit 1 (differentiate the numerator and the denominator separately with respect to k, obtaining se^{-ks} and s, respectively, and use $se^{-ks}/s \to 1$ as $k \to 0$). Hence the right side has the limit e^{-as}. This suggests defining the transform of $\delta(t-a)$ by this limit, that is,

$$\mathcal{L}\{\delta(t-a)\} = e^{-as}. \tag{5}$$

The unit step and unit impulse functions can now be used on the right side of ODEs modeling mechanical or electrical systems, as we illustrate next.

EXAMPLE 1 **Mass–Spring System Under a Square Wave**

Determine the response of the damped mass–spring system (see Sec. 2.8) under a square wave, modeled by (see Fig. 131)

$$y'' + 3y' + 2y = r(t) = u(t-1) - u(t-2), \qquad y(0) = 0, \qquad y'(0) = 0.$$

Solution. From (1) and (2) in Sec. 6.2 and (2) and (4) in this section we obtain the subsidiary equation

$$s^2Y + 3sY + 2Y = \frac{1}{s}\,(e^{-s} - e^{-2s}). \qquad \text{Solution} \qquad Y(s) = \frac{1}{s(s^2+3s+2)}\,(e^{-s} - e^{-2s}).$$

Using the notation $F(s)$ and partial fractions, we obtain

$$F(s) = \frac{1}{s(s^2+3s+2)} = \frac{1}{s(s+1)(s+2)} = \frac{1/2}{s} - \frac{1}{s+1} + \frac{1/2}{s+2}.$$

From Table 6.1 in Sec. 6.1, we see that the inverse is

$$f(t) = \mathcal{L}^{-1}(F) = \tfrac{1}{2} - e^{-t} + \tfrac{1}{2}e^{-2t}.$$

Therefore, by Theorem 1 in Sec. 6.3 (t-shifting) we obtain the square-wave response shown in Fig. 131,

$$\begin{aligned} y &= \mathcal{L}^{-1}(F(s)e^{-s} - F(s)e^{-2s}) \\ &= f(t-1)u(t-1) - f(t-2)u(t-2) \\ &= \begin{cases} 0 & (0 < t < 1) \\ \frac{1}{2} - e^{-(t-1)} + \frac{1}{2}e^{-2(t-1)} & (1 < t < 2) \\ -e^{-(t-1)} + e^{-(t-2)} + \frac{1}{2}e^{-2(t-1)} - \frac{1}{2}e^{-2(t-2)} & (t > 2). \end{cases} \end{aligned}$$

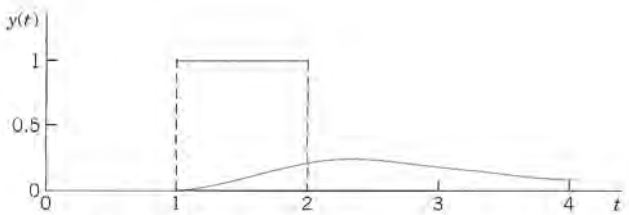

Fig. 131. Square wave and response in Example 1

EXAMPLE 2 Hammerblow Response of a Mass–Spring System

Find the response of the system in Example 1 with the square wave replaced by a unit impulse at time $t = 1$.

Solution. We now have the ODE and the subsidiary equation

$$y'' + 3y' + 2y = \delta(t - 1), \qquad \text{and} \qquad (s^2 + 3s + 2)Y = e^{-s}.$$

Solving algebraically gives

$$Y(s) = \frac{e^{-s}}{(s + 1)(s + 2)} = \left(\frac{1}{s + 1} - \frac{1}{s + 2}\right) e^{-s}.$$

By Theorem 1 the inverse is

$$y(t) = \mathcal{L}^{-1}(Y) = \begin{cases} 0 & \text{if } 0 < t < 1 \\ e^{-(t-1)} - e^{-2(t-1)} & \text{if } t > 1. \end{cases}$$

$y(t)$ is shown in Fig. 132. Can you imagine how Fig. 131 approaches Fig. 132 as the wave becomes shorter and shorter, the area of the rectangle remaining 1? ■

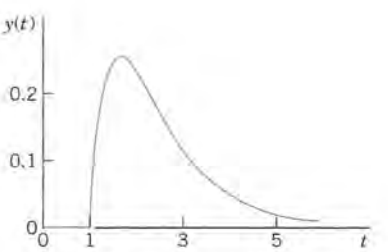

Fig. 132. Response to a hammerblow in Example 2

EXAMPLE 3 Four-Terminal *RLC*-Network

Find the output voltage response in Fig. 133 if $R = 20\ \Omega$, $L = 1$ H, $C = 10^{-4}$ F, the input is $\delta(t)$ (a unit impulse at time $t = 0$), and current and charge are zero at time $t = 0$.

Solution. To understand what is going on, note that the network is an *RLC*-circuit to which two wires at A and B are attached for recording the voltage $v(t)$ on the capacitor. Recalling from Sec. 2.9 that current $i(t)$ and charge $q(t)$ are related by $i = q' = dq/dt$, we obtain the model

$$Li' + Ri + \frac{q}{C} = Lq'' + Rq' + \frac{q}{C} = q'' + 20q' + 10\,000q = \delta(t).$$

From (1) and (2) in Sec. 6.2 and (5) in this section we obtain the subsidiary equation for $Q(s) = \mathcal{L}(q)$

$$(s^2 + 20s + 10\,000)Q = 1. \qquad \text{Solution} \qquad Q = \frac{1}{(s + 10)^2 + 9900}.$$

By the first shifting theorem in Sec. 6.1 we obtain from Q damped oscillations for q and v; rounding $9900 \approx 99.50^2$, we get (Fig. 133)

$$q = \mathcal{L}^{-1}(Q) = \frac{1}{99.50} e^{-10t} \sin 99.50t \qquad \text{and} \qquad v = \frac{q}{C} = 100.5e^{-10t} \sin 99.50t. \quad ■$$

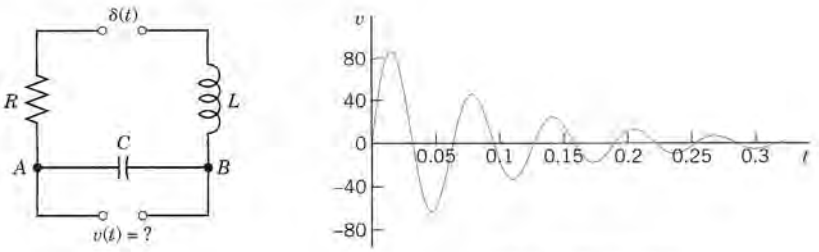

Fig. 133. Network and output voltage in Example 3

More on Partial Fractions

We have seen that the solution Y of a subsidiary equation usually appears as a quotient of polynomials $Y(s) = F(s)/G(s)$, so that a partial fraction representation leads to a sum of expressions whose inverses we can obtain from a table, aided by the first shifting theorem (Sec. 6.1). These representations are sometimes called **Heaviside expansions.**

An *unrepeated factor* $s - a$ in $G(s)$ requires a single partial fraction $A/(s - a)$. See Examples 1 and 2 on pp. 243, 244. *Repeated real factors* $(s - a)^2$, $(s - a)^3$, etc., require partial fractions

$$\frac{A_2}{(s-a)^2} + \frac{A_1}{s-a}, \qquad \frac{A_3}{(s-a)^3} + \frac{A_2}{(s-a)^2} + \frac{A_1}{s-a}, \quad \text{etc.,}$$

The inverses are $(A_2t + A_1)e^{at}$, $(\frac{1}{2}A_3t^2 + A_2t + A_1)e^{at}$, etc.

Unrepeated complex factors $(s - a)(s - \bar{a})$, $a = \alpha + i\beta$, $\bar{a} = \alpha - i\beta$, require a partial fraction $(As + B)/[(s - \alpha)^2 + \beta^2]$. For an application, see Example 4 in Sec. 6.3. A further one is the following.

EXAMPLE 4 **Unrepeated Complex Factors. Damped Forced Vibrations**

Solve the initial value problem for a damped mass–spring system acted upon by a sinusoidal force for some time interval (Fig. 134),

$$y'' + 2y' + 2y = r(t), \quad r(t) = 10 \sin 2t \text{ if } 0 < t < \pi \text{ and } 0 \text{ if } t > \pi; \qquad y(0) = 1, \quad y'(0) = -5.$$

Solution. From Table 6.1, (1), (2) in Sec. 6.2, and the second shifting theorem in Sec. 6.3, we obtain the subsidiary equation

$$(s^2Y - s + 5) + 2(sY - 1) + 2Y = 10\,\frac{2}{s^2+4}\,(1 - e^{-\pi s}).$$

We collect the Y-terms, $(s^2 + 2s + 2)Y$, take $-s + 5 - 2 = -s + 3$ to the right, and solve,

$$Y = \frac{20}{(s^2+4)(s^2+2s+2)} - \frac{20e^{-\pi s}}{(s^2+4)(s^2+2s+2)} + \frac{s-3}{s^2+2s+2}. \tag{6}$$

For the last fraction we get from Table 6.1 and the first shifting theorem

$$\mathcal{L}^{-1}\left\{\frac{s+1-4}{(s+1)^2+1}\right\} = e^{-t}(\cos t - 4 \sin t). \tag{7}$$

In the first fraction in (6) we have unrepeated complex roots, hence a partial fraction representation

$$\frac{20}{(s^2+4)(s^2+2s+2)} = \frac{As+B}{s^2+4} + \frac{Ms+N}{s^2+2s+2}.$$

Multiplication by the common denominator gives

$$20 = (As+B)(s^2+2s+2) + (Ms+N)(s^2+4).$$

We determine A, B, M, N. Equating the coefficients of each power of s on both sides gives the four equations

(a) $[s^3]$: $0 = A + M$ (b) $[s^2]$: $0 = 2A + B + N$

(c) $[s]$: $0 = 2A + 2B + 4M$ (d) $[s^0]$: $20 = 2B + 4N$.

We can solve this, for instance, obtaining $M = -A$ from (a), then $A = B$ from (c), then $N = -3A$ from (b), and finally $A = -2$ from (d). Hence $A = -2$, $B = -2$, $M = 2$, $N = 6$, and the first fraction in (6) has the representation

(8) $$\frac{-2s-2}{s^2+4} + \frac{2(s+1)+6-2}{(s+1)^2+1}.$$ Inverse transform: $-2\cos 2t - \sin 2t + e^{-t}(2\cos t + 4\sin t)$.

The sum of this and (7) is the solution of the problem for $0 < t < \pi$, namely (the sines cancel),

(9) $$y(t) = 3e^{-t}\cos t - 2\cos 2t - \sin 2t \qquad \text{if } 0 < t < \pi.$$

In the second fraction in (6) taken with the minus sign we have the factor $e^{-\pi s}$, so that from (8) and the second shifting theorem (Sec. 6.3) we get the inverse transform

$$+2\cos(2t-2\pi) + \sin(2t-2\pi) - e^{-(t-\pi)}[2\cos(t-\pi) + 4\sin(t-\pi)]$$
$$= 2\cos 2t + \sin 2t + e^{-(t-\pi)}(2\cos t + 4\sin t).$$

The sum of this and (9) is the solution for $t > \pi$,

(10) $$y(t) = e^{-t}[(3+2e^{\pi})\cos t + 4e^{\pi}\sin t] \qquad \text{if } t > \pi.$$

Figure 134 shows (9) (for $0 < t < \pi$) and (10) (for $t > \pi$), a beginning vibration, which goes to zero rapidly because of the damping and the absence of a driving force after $t = \pi$. ■

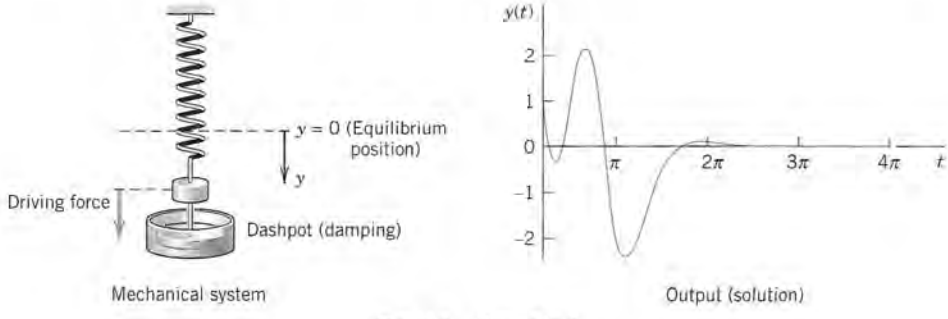

Fig. 134. Example 4

The case of repeated complex factors $[(s-a)(s-\bar{a})]^2$, which is important in connection with resonance, will be handled by "convolution" in the next section.

PROBLEM SET 6.4

1–12 EFFECT OF DELTA FUNCTION ON VIBRATING SYSTEMS

Showing the details, find, graph, and discuss the solution.

1. $y'' + y = \delta(t - 2\pi)$, $y(0) = 10$, $y'(0) = 0$
2. $y'' + 2y' + 2y = e^{-t} + 5\delta(t - 2)$, $y(0) = 0$, $y'(0) = 1$
3. $y'' - y = 10\delta(t - \frac{1}{2}) - 100\delta(t - 1)$, $y(0) = 10$, $y'(0) = 1$
4. $y'' + 3y' + 2y = 10(\sin t + \delta(t - 1))$, $y(0) = 1$, $y'(0) = -1$
5. $y'' + 4y' + 5y = [1 - u(t - 10)]e^t - e^{10}\delta(t - 10)$, $y(0) = 0$, $y'(0) = 1$
6. $y'' + 2y' - 3y = 100\delta(t - 2) + 100\delta(t - 3)$, $y(0) = 1$, $y'(0) = 0$
7. $y'' + 2y' + 10y = 10[1 - u(t - 4)] - 10\delta(t - 5)$, $y(0) = 1$, $y'(0) = 1$
8. $y'' + 5y' + 6y = \delta(t - \frac{1}{2}\pi) + u(t - \pi)\cos t$, $y(0) = 0$, $y'(0) = 0$
9. $y'' + 2y' + 5y = 25t - 100\delta(t - \pi)$, $y(0) = -2$, $y'(0) = 5$
10. $y'' + 5y = 25t - 100\delta(t - \pi)$, $y(0) = -2$, $y'(0) = 5$. (Compare with Prob. 9.)
11. $y'' + 3y' - 4y = 2e^t - 8e^2\delta(t - 2)$, $y(0) = 2$, $y'(0) = 0$
12. $y'' + y = -2\sin t + 10\delta(t - \pi)$, $y(0) = 0$, $y'(0) = 1$

13. **CAS PROJECT. Effect of Damping.** Consider a vibrating system of your choice modeled by

$$y'' + cy' + ky = r(t)$$

with $r(t)$ involving a δ-function. **(a)** Using graphs of the solution, describe the effect of continuously decreasing the damping to 0, keeping k constant.

(b) What happens if c is kept constant and k is continuously increased, starting from 0?

(c) Extend your results to a system with two δ-functions on the right, acting at different times.

14. **CAS PROJECT. Limit of a Rectangular Wave. Effects of Impulse.**

(a) In Example 1, take a rectangular wave of area 1 from 1 to $1 + k$. Graph the responses for a sequence of values of k approaching zero, illustrating that for smaller and smaller k those curves approach the curve shown in Fig. 132. *Hint:* If your CAS gives no solution for the differential equation involving k, take specific k's from the beginning.

(b) Experiment on the response of the ODE in Example 1 (or of another ODE of your choice) to an impulse $\delta(t - a)$ for various systematically chosen a (> 0); choose initial conditions $y(0) \neq 0$, $y'(0) = 0$. Also consider the solution if no impulse is applied. Is there a dependence of the response on a? On b if you choose $b\delta(t - a)$? Would $-\delta(t - \tilde{a})$ with $\tilde{a} > a$ annihilate the effect of $\delta(t - a)$? Can you think of other questions that one could consider experimentally by inspecting graphs?

15. **PROJECT. Heaviside Formulas. (a)** Show that for a simple root a and fraction $A/(s - a)$ in $F(s)/G(s)$ we have the *Heaviside formula*

$$A = \lim_{s \to a} \frac{(s - a)F(s)}{G(s)}.$$

(b) Similarly, show that for a root a of order m and fractions in

$$\frac{F(s)}{G(s)} = \frac{A_m}{(s - a)^m} + \frac{A_{m-1}}{(s - a)^{m-1}} + \cdots + \frac{A_1}{s - a} + \text{further fractions}$$

we have the *Heaviside formulas* for the first coefficient

$$A_m = \lim_{s \to a} \frac{(s - a)^m F(s)}{G(s)}$$

and for the other coefficients

$$A_k = \frac{1}{(m - k)!} \lim_{s \to a} \frac{d^{m-k}}{ds^{m-k}} \left[\frac{(s - a)^m F(s)}{G(s)} \right], \quad k = 1, \cdots, m - 1.$$

16. **TEAM PROJECT. Laplace Transform of Periodic Functions**

(a) Theorem. *The Laplace transform of a piecewise continuous function $f(t)$ with period p is*

$$\mathcal{L}(f) = \frac{1}{1 - e^{-ps}} \int_0^p e^{-st} f(t)\, dt \qquad (s > 0). \tag{11}$$

Prove this theorem. *Hint:* Write $\int_0^\infty = \int_0^p + \int_p^{2p} + \cdots$. Set $t = (n - 1)p$ in the nth integral. Take out $e^{-(n-1)ps}$ from under the integral sign. Use the sum formula for the geometric series.

(b) Half-wave rectifier. Using (11), show that the half-wave rectification of $\sin \omega t$ in Fig. 135 has the Laplace transform

$$\mathscr{L}(f) = \frac{\omega(1 + e^{-\pi s/\omega})}{(s^2 + \omega^2)(1 - e^{-2\pi s/\omega})} = \frac{\omega}{(s^2 + \omega^2)(1 - e^{-\pi s/\omega})}.$$

(A *half-wave rectifier* clips the negative portions of the curve. A *full-wave rectifier* converts them to positive; see Fig. 136.)

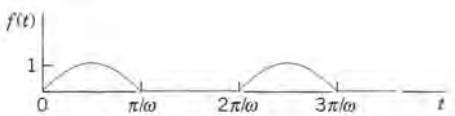

Fig. 135. Half-wave rectification

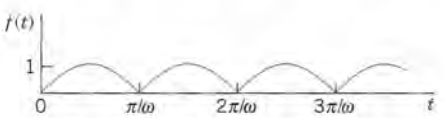

Fig. 136. Full-wave rectification

(c) Full-wave rectifier. Show that the Laplace transform of the full-wave rectification of $\sin \omega t$ is

$$\frac{\omega}{s^2 + \omega^2} \coth \frac{\pi s}{2\omega}.$$

(d) Saw-tooth wave. Find the Laplace transform of the saw-tooth wave in Fig. 137.

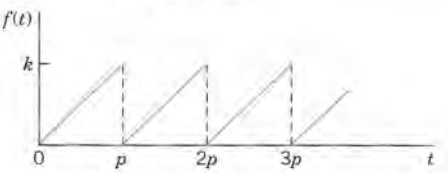

Fig. 137. Saw-tooth wave

(e) Staircase function. Find the Laplace transform of the staircase function in Fig. 138 by noting that it is the difference of kt/p and the function in (d).

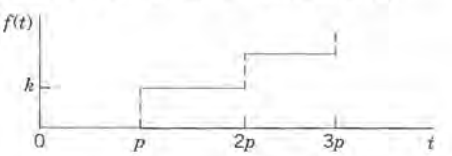

Fig. 138. Staircase function

6.5 Convolution. Integral Equations

Convolution has to do with the multiplication of transforms. The situation is as follows. *Addition* of transforms provides no problem; we know that $\mathscr{L}(f + g) = \mathscr{L}(f) + \mathscr{L}(g)$. Now **multiplication of transforms** occurs frequently in connection with ODEs, integral equations, and elsewhere. Then we usually know $\mathscr{L}(f)$ and $\mathscr{L}(g)$ and would like to know the function whose transform is the product $\mathscr{L}(f)\mathscr{L}(g)$. We might perhaps guess that it is fg, but this is false. *The transform of a product is generally different from the product of the transforms of the factors,*

$$\mathscr{L}(fg) \neq \mathscr{L}(f)\mathscr{L}(g) \qquad \text{in general.}$$

To see this take $f = e^t$ and $g = 1$. Then $fg = e^t$, $\mathscr{L}(fg) = 1/(s - 1)$, but $\mathscr{L}(f) = 1/(s - 1)$ and $\mathscr{L}(1) = 1/s$ give $\mathscr{L}(f)\mathscr{L}(g) = 1/(s^2 - s)$.

According to the next theorem, the correct answer is that $\mathscr{L}(f)\mathscr{L}(g)$ is the transform of the **convolution** of f and g, denoted by the standard notation $f * g$ and defined by the integral

$$\textbf{(1)} \qquad h(t) = (f * g)(t) = \int_0^t f(\tau)g(t - \tau)\, d\tau.$$

THEOREM 1

Convolution Theorem

If two functions f and g satisfy the assumption in the existence theorem in Sec. 6.1, so that their transforms F and G exist, the product H = FG is the transform of h given by (1). (Proof after Example 2.)

EXAMPLE 1 **Convolution**

Let $H(s) = 1/[(s - a)s]$. Find $h(t)$.

Solution. $1/(s - a)$ has the inverse $f(t) = e^{at}$, and $1/s$ has the inverse $g(t) = 1$. With $f(\tau) = e^{a\tau}$ and $g(t - \tau) \equiv 1$ we thus obtain from (1) the answer

$$h(t) = e^{at} * 1 = \int_0^t e^{a\tau} \cdot 1 \, d\tau = \frac{1}{a} (e^{at} - 1).$$

To check, calculate

$$H(s) = \mathcal{L}(h)(s) = \frac{1}{a} \left(\frac{1}{s - a} - \frac{1}{s} \right) = \frac{1}{a} \cdot \frac{a}{s^2 - as} = \frac{1}{s - a} \cdot \frac{1}{s} = \mathcal{L}(e^{at}) \, \mathcal{L}(1).$$

EXAMPLE 2 **Convolution**

Let $H(s) = 1/(s^2 + \omega^2)^2$. Find $h(t)$.

Solution. The inverse of $1/(s^2 + \omega^2)$ is $(\sin \omega t)/\omega$. Hence from (1) and the trigonometric formula (11) in App. 3.1 with $x = \frac{1}{2}(\omega t + \omega\tau)$ and $y = \frac{1}{2}(\omega t - \omega\tau)$ we obtain

$$\begin{aligned} h(t) = \frac{\sin \omega t}{\omega} * \frac{\sin \omega t}{\omega} &= \frac{1}{\omega^2} \int_0^t \sin \omega\tau \sin \omega(t - \tau) \, d\tau \\ &= \frac{1}{2\omega^2} \int_0^t [-\cos \omega t + \cos \omega\tau] \, d\tau \\ &= \frac{1}{2\omega^2} \left[-\tau \cos \omega t + \frac{\sin \omega\tau}{\omega} \right]_{\tau=0}^{t} \\ &= \frac{1}{2\omega^2} \left[-t \cos \omega t + \frac{\sin \omega t}{\omega} \right] \end{aligned}$$

in agreement with formula 21 in the table in Sec. 6.9.

PROOF We prove the Convolution Theorem 1. CAUTION! Note which ones are the variables of integration! We can denote them as we want, for instance, by τ and p, and write

$$F(s) = \int_0^\infty e^{-s\tau} f(\tau) \, d\tau \qquad \text{and} \qquad G(s) = \int_0^\infty e^{-sp} g(p) \, dp.$$

We now set $t = p + \tau$, where τ is at first constant. Then $p = t - \tau$, and t varies from τ to ∞. Thus

$$G(s) = \int_\tau^\infty e^{-s(t-\tau)} g(t - \tau) \, dt = e^{s\tau} \int_\tau^\infty e^{-st} g(t - \tau) \, dt.$$

τ in F and t in G vary independently. Hence we can insert the G-integral into the F-integral. Cancellation of $e^{-s\tau}$ and $e^{s\tau}$ then gives

$$F(s)G(s) = \int_0^\infty e^{-s\tau} f(\tau) e^{s\tau} \int_\tau^\infty e^{-st} g(t-\tau)\, dt\, d\tau = \int_0^\infty f(\tau) \int_\tau^\infty e^{-st} g(t-\tau)\, dt\, d\tau.$$

Here we integrate for fixed τ over t from τ to ∞ and then over τ from 0 to ∞. This is the blue region in Fig. 139. Under the assumption on f and g the order of integration can be reversed (see Ref. [A5] for a proof using uniform convergence). We then integrate first over τ from 0 to t and then over t from 0 to ∞, that is,

$$F(s)G(s) = \int_0^\infty e^{-st} \int_0^t f(\tau) g(t-\tau)\, d\tau\, dt = \int_0^\infty e^{-st} h(t)\, dt = \mathcal{L}(h) = H(s).$$

This completes the proof. ■

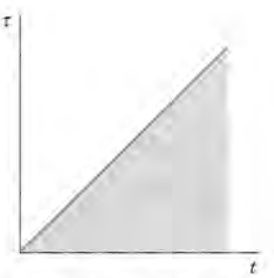

Fig. 139. Region of integration in the $t\tau$-plane in the proof of Theorem 1

From the definition it follows almost immediately that convolution has the properties

$$f * g = g * f \qquad \text{(commutative law)}$$

$$f * (g_1 + g_2) = f * g_1 + f * g_2 \qquad \text{(distributive law)}$$

$$(f * g) * v = f * (g * v) \qquad \text{(associative law)}$$

$$f * 0 = 0 * f = 0$$

similar to those of the multiplication of numbers. Unusual are the following two properties.

EXAMPLE 3 Unusual Properties of Convolution

$f * 1 \neq f$ in general. For instance,

$$t * 1 = \int_0^t \tau \cdot 1\, d\tau = \tfrac{1}{2}t^2 \neq t.$$

$(f * f)(t) \geqq 0$ may not hold. For instance, Example 2 with $\omega = 1$ gives

$$\sin t * \sin t = -\tfrac{1}{2} t \cos t + \tfrac{1}{2} \sin t \qquad \text{(Fig. 140).}$$ ■

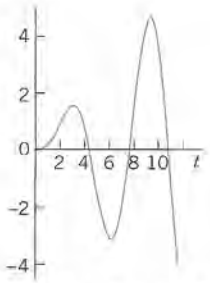

Fig. 140. Example 3

We shall now take up the case of a complex double root (left aside in the last section in connection with partial fractions) and find the solution (the inverse transform) directly by convolution.

EXAMPLE 4 **Repeated Complex Factors. Resonance**

In an undamped mass–spring system, resonance occurs if the frequency of the driving force equals the natural frequency of the system. Then the model is (see Sec. 2.8)

$$y'' + \omega_0^2 y = K \sin \omega_0 t$$

where $\omega_0^2 = k/m$, k is the spring constant, and m is the mass of the body attached to the spring. We assume $y(0) = 0$ and $y'(0) = 0$, for simplicity. Then the subsidiary equation is

$$s^2 Y + \omega_0^2 Y = \frac{K\omega_0}{s^2 + \omega_0^2}. \qquad \text{Its solution is} \qquad Y = \frac{K\omega_0}{(s^2 + \omega_0^2)^2}.$$

This is a transform as in Example 2 with $\omega = \omega_0$ and multiplied by $K\omega_0$. Hence from Example 2 we can see directly that the solution of our problem is

$$y(t) = \frac{K\omega_0}{2\omega_0^2}\left(-t\cos\omega_0 t + \frac{\sin\omega_0 t}{\omega_0}\right) = \frac{K}{2\omega_0^2}(-\omega_0 t\cos\omega_0 t + \sin\omega_0 t).$$

We see that the first term grows without bound. Clearly, in the case of resonance such a term must occur. (See also a similar kind of solution in Fig. 54 in Sec. 2.8.) ■

Application to Nonhomogeneous Linear ODEs

Nonhomogeneous linear ODEs can now be solved by a general method based on convolution by which the solution is obtained in the form of an integral. To see this, recall from Sec. 6.2 that the subsidiary equation of the ODE

$$y'' + ay' + by = r(t) \qquad (a, b \text{ constant}) \tag{2}$$

has the solution [(7) in Sec. 6.2]

$$Y(s) = \big[(s + a)y(0) + y'(0)\big]Q(s) + R(s)Q(s)$$

with $R(s) = \mathscr{L}(r)$ and $Q(s) = 1/(s^2 + as + b)$ the transfer function. Inversion of the first term $[\cdots]$ provides no difficulty; depending on whether $\frac{1}{4}a^2 - b$ is positive, zero, or negative, its inverse will be a linear combination of two exponential functions, or of the

form $(c_1 + c_2 t)e^{-at/2}$, or a damped oscillation, respectively. The interesting term is $R(s)Q(s)$ because $r(t)$ can have various forms of practical importance, as we shall see. If $y(0) = 0$ and $y'(0) = 0$, then $Y = RQ$, and the convolution theorem gives the solution

$$y(t) = \int_0^t q(t - \tau)\, r(\tau)\, d\tau. \tag{3}$$

EXAMPLE 5 **Response of a Damped Vibrating System to a Single Square Wave**

Using convolution, determine the response of the damped mass–spring system modeled by

$$y'' + 3y' + 2y = r(t), \qquad r(t) = 1 \text{ if } 1 < t < 2 \text{ and } 0 \text{ otherwise}, \qquad y(0) = y'(0) = 0.$$

This system with an **input** (a driving force) ***that acts for some time only*** (Fig. 141) has been solved by partial fraction reduction in Sec. 6.4 (Example 1).

Solution by Convolution. The transfer function and its inverse are

$$Q(s) = \frac{1}{s^2 + 3s + 2} = \frac{1}{(s + 1)(s + 2)} = \frac{1}{s + 1} - \frac{1}{s + 2}, \qquad \text{hence} \qquad q(t) = e^{-t} - e^{-2t}.$$

Hence the convolution integral (3) is (except for the limits of integration)

$$y(t) = \int q(t - \tau) \cdot 1\, d\tau = \int \left[e^{-(t-\tau)} - e^{-2(t-\tau)}\right] d\tau = e^{-(t-\tau)} - \tfrac{1}{2}e^{-2(t-\tau)}.$$

Now comes an important point in handling convolution. $r(\tau) = 1$ if $1 < \tau < 2$ only. Hence if $t < 1$, the integral is zero. If $1 < t < 2$, we have to integrate from $\tau = 1$ (not 0) to t. This gives (with the first two terms from the upper limit)

$$y(t) = e^{-0} - \tfrac{1}{2}e^{-0} - (e^{-(t-1)} - \tfrac{1}{2}e^{-2(t-1)}) = \tfrac{1}{2} - e^{-(t-1)} + \tfrac{1}{2}e^{-2(t-1)}.$$

If $t > 2$, we have to integrate from $\tau = 1$ to 2 (not to t). This gives

$$y(t) = e^{-(t-2)} - \tfrac{1}{2}e^{-2(t-2)} - (e^{-(t-1)} - \tfrac{1}{2}e^{-2(t-1)}).$$

Figure 141 shows the input (the square wave) and the interesting output, which is zero from 0 to 1, then increases, reaches a maximum (near 2.6) after the input has become zero (why?), and finally decreases to zero in a monotone fashion. ■

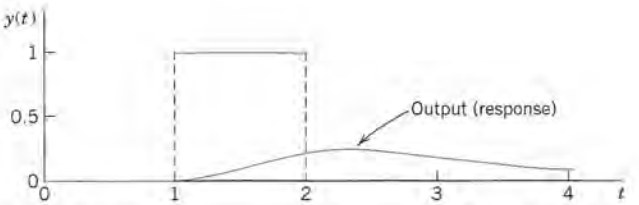

Fig. 141. Square wave and response in Example 5

Integral Equations

Convolution also helps in solving certain **integral equations,** that is, equations in which the unknown function $y(t)$ appears in an integral (and perhaps also outside of it). This concerns equations with an integral of the form of a convolution. Hence these are special and it suffices to explain the idea in terms of two examples and add a few problems in the problem set.

EXAMPLE 6 A Volterra Integral Equation of the Second Kind

Solve the Volterra integral equation of the second kind[3]

$$y(t) - \int_0^t y(\tau) \sin(t - \tau)\, d\tau = t.$$

Solution. From (1) we see that the given equation can be written as a convolution, $y - y * \sin t = t$. Writing $Y = \mathcal{L}(y)$ and applying the convolution theorem, we obtain

$$Y(s) - Y(s)\frac{1}{s^2 + 1} = Y(s)\frac{s^2}{s^2 + 1} = \frac{1}{s^2}.$$

The solution is

$$Y(s) = \frac{s^2 + 1}{s^4} = \frac{1}{s^2} + \frac{1}{s^4} \qquad \text{and gives the answer} \qquad y(t) = t + \frac{t^3}{6}.$$

Check the result by a CAS or by substitution and repeated integration by parts (which will need patience). ■

EXAMPLE 7 Another Volterra Integral Equation of the Second Kind

Solve the Volterra integral equation

$$y(t) - \int_0^t (1 + \tau)\, y(t - \tau)\, d\tau = 1 - \sinh t.$$

Solution. By (1) we can write $y - (1 + t) * y = 1 - \sinh t$. Writing $Y = \mathcal{L}(y)$, we obtain by using the convolution theorem and then taking common denominators

$$Y(s)\left[1 - \left(\frac{1}{s} + \frac{1}{s^2}\right)\right] = \frac{1}{s} - \frac{1}{s^2 - 1}, \qquad \text{hence} \qquad Y(s) \cdot \frac{s^2 - s - 1}{s^2} = \frac{s^2 - 1 - s}{s(s^2 - 1)}.$$

$(s^2 - s - 1)/s$ cancels on both sides, so that solving for Y simply gives

$$Y(s) = \frac{s}{s^2 - 1} \qquad \text{and the solution is} \qquad y(t) = \cosh t.$$ ■

PROBLEM SET 6.5

1–8 CONVOLUTIONS BY INTEGRATION

Find by integration:

1. $1 * 1$
2. $t * t$
3. $t * e^t$
4. $e^{at} * e^{bt}$ $(a \neq b)$
5. $1 * \cos \omega t$
6. $1 * f(t)$
7. $e^{kt} * e^{-kt}$
8. $\sin t * \cos t$

9–16 INVERSE TRANSFORMS BY CONVOLUTION

Find $f(t)$ if $\mathcal{L}(f)$ equals:

9. $\dfrac{1}{(s - 3)(s + 5)}$
10. $\dfrac{1}{s(s - 1)}$
11. $\dfrac{1}{s(s^2 + 4)}$
12. $\dfrac{1}{s^2(s - 2)}$
13. $\dfrac{1}{s^2(s^2 + 1)}$
14. $\dfrac{s}{(s^2 + 16)^2}$
15. $\dfrac{1}{s(s^2 - 9)}$
16. $\dfrac{5}{(s^2 + 1)(s^2 + 25)}$
17. **(Partial fractions)** Solve Probs. 9, 11, and 13 by using partial fractions. Comment on the amount of work.

18–25 SOLVING INITIAL VALUE PROBLEMS

Using the convolution theorem, solve:

18. $y'' + y = \sin t, \quad y(0) = 0, \quad y'(0) = 0$
19. $y'' + 4y = \sin 3t, \quad y(0) = 0, \quad y'(0) = 0$
20. $y'' + 5y' + 4y = 2e^{-2t}, \quad y(0) = 0, \quad y'(0) = 0$

[3] If the upper limit of integration is *variable*, the equation is named after the Italian mathematician VITO VOLTERRA (1860–1940), and if that limit is *constant*, the equation is named after the Swedish mathematician IVAR FREDHOLM (1866–1927). "Of the second kind (first kind)" indicates that y occurs (does not occur) outside of the integral.

21. $y'' + 9y = 8 \sin t$ if $0 < t < \pi$ and 0 if $t > \pi$; $y(0) = 0$, $y'(0) = 4$

22. $y'' + 3y' + 2y = 1$ if $0 < t < a$ and 0 if $t > a$; $y(0) = 0$, $y'(0) = 0$

23. $y'' + 4y = 5u(t - 1)$; $y(0) = 0$, $y'(0) = 0$

24. $y'' + 5y' + 6y = \delta(t - 3)$; $y(0) = 1$, $y'(0) = 0$

25. $y'' + 6y' + 8y = 2\delta(t - 1) + 2\delta(t - 2)$; $y(0) = 1$, $y'(0) = 0$

26. TEAM PROJECT. Properties of Convolution. Prove:

(a) Commutativity, $f * g = g * f$

(b) Associativity, $(f * g) * v = f * (g * v)$

(c) Distributivity, $f * (g_1 + g_2) = f * g_1 + f * g_2$

(d) Dirac's delta. Derive the sifting formula (4) in Sec. 6.4 by using f_k with $a = 0$ [(1), Sec. 6.4] and applying the mean value theorem for integrals.

(e) Unspecified driving force. Show that forced vibrations governed by

$$y'' + \omega^2 y = r(t), \qquad y(0) = K_1, \qquad y'(0) = K_2$$

with $\omega \neq 0$ and an unspecified driving force $r(t)$ can be written in convolution form,

$$y = \frac{1}{\omega} \sin \omega t * r(t) + K_1 \cos \omega t + \frac{K_2}{\omega} \sin \omega t.$$

27–34 INTEGRAL EQUATIONS

Using Laplace transforms and showing the details, solve:

27. $y(t) - \int_0^t y(\tau)\, d\tau = 1$

28. $y(t) + \int_0^t y(\tau) \cosh (t - \tau)\, d\tau = t + e^t$

29. $y(t) - \int_0^t y(\tau) \sin (t - \tau)\, d\tau = \cos t$

30. $y(t) + 2\int_0^t y(\tau) \cos (t - \tau)\, d\tau = \cos t$

31. $y(t) + \int_0^t (t - \tau) y(\tau)\, d\tau = 1$

32. $y(t) - \int_0^t y(\tau)(t - \tau)\, d\tau = 2 - \frac{1}{2}t^2$

33. $y(t) + 2e^t \int_0^t e^{-\tau} y(\tau)\, d\tau = te^t$

34. $y(t) + \int_0^t e^{2(t-\tau)} y(\tau)\, d\tau = t^2 - t - \frac{1}{2} + \frac{1}{2}e^{2t}$

35. CAS EXPERIMENT. Variation of a Parameter. **(a)** Replace 2 in Prob. 33 by a parameter k and investigate graphically how the solution curve changes if you vary k, in particular near $k = -2$.

(b) Make similar experiments with an integral equation of your choice whose solution is oscillating.

6.6 Differentiation and Integration of Transforms. ODEs with Variable Coefficients

The variety of methods for obtaining transforms and inverse transforms and their application in solving ODEs is surprisingly large. We have seen that they include direct integration, the use of linearity (Sec. 6.1), shifting (Secs. 6.1, 6.3), convolution (Sec. 6.5), and differentiation and integration of functions $f(t)$ (Sec. 6.2). But this is not all. In this section we shall consider operations of somewhat lesser importance, namely, differentiation and integration of *transforms* $F(s)$ and corresponding operations for functions $f(t)$, with applications to ODEs with variable coefficients.

Differentiation of Transforms

It can be shown that if a function $f(t)$ satisfies the conditions of the existence theorem in Sec. 6.1, then the derivative $F'(s) = dF/ds$ of the transform $F(s) = \mathcal{L}(f)$ can be obtained by differentiating $F(s)$ under the integral sign with respect to s (proof in Ref. [GR4] listed in App. 1). Thus, if

$$F(s) = \int_0^\infty e^{-st} f(t)\, dt, \qquad \text{then} \qquad F'(s) = -\int_0^\infty e^{-st} t f(t)\, dt.$$

Consequently, if $\mathcal{L}(f) = F(s)$, then

$$\textbf{(1)} \qquad \mathcal{L}\{tf(t)\} = -F'(s), \qquad \text{hence} \qquad \mathcal{L}^{-1}\{F'(s)\} = -tf(t)$$

where the second formula is obtained by applying $\mathcal{L}^{-1}$ on both sides of the first formula. In this way, *differentiation of the transform of a function corresponds to the multiplication of the function by* $-t$.

EXAMPLE 1 **Differentiation of Transforms. Formulas 21–23 in Sec. 6.9**

We shall derive the following three formulas.

	$\mathcal{L}(f)$	$f(t)$
(2)	$\dfrac{1}{(s^2 + \beta^2)^2}$	$\dfrac{1}{2\beta^3}(\sin \beta t - \beta t \cos \beta t)$
(3)	$\dfrac{s}{(s^2 + \beta^2)^2}$	$\dfrac{t}{2\beta} \sin \beta t$
(4)	$\dfrac{s^2}{(s^2 + \beta^2)^2}$	$\dfrac{1}{2\beta}(\sin \beta t + \beta t \cos \beta t)$

Solution. From (1) and formula 8 (with $\omega = \beta$) in Table 6.1 of Sec. 6.1 we obtain by differentiation (CAUTION! Chain rule!)

$$\mathcal{L}(t \sin \beta t) = \frac{2\beta s}{(s^2 + \beta^2)^2}.$$

Dividing by 2β and using the linearity of $\mathcal{L}$, we obtain (3).

Formulas (2) and (4) are obtained as follows. From (1) and formula 7 (with $\omega = \beta$) in Table 6.1 we find

$$\textbf{(5)} \qquad \mathcal{L}(t \cos \beta t) = -\frac{(s^2 + \beta^2) - 2s^2}{(s^2 + \beta^2)^2} = \frac{s^2 - \beta^2}{(s^2 + \beta^2)^2}.$$

From this and formula 8 (with $\omega = \beta$) in Table 6.1 we have

$$\mathcal{L}\left(t \cos \beta t \pm \frac{1}{\beta} \sin \beta t\right) = \frac{s^2 - \beta^2}{(s^2 + \beta^2)^2} \pm \frac{1}{s^2 + \beta^2}.$$

On the right we now take the common denominator. Then we see that for the plus sign the numerator becomes $s^2 - \beta^2 + s^2 + \beta^2 = 2s^2$, so that (4) follows by division by 2. Similarly, for the minus sign the numerator takes the form $s^2 - \beta^2 - s^2 - \beta^2 = -2\beta^2$, and we obtain (2). This agrees with Example 2 in Sec. 6.5. ■

Integration of Transforms

Similarly, if $f(t)$ satisfies the conditions of the existence theorem in Sec. 6.1 and the limit of $f(t)/t$, as t approaches 0 from the right, exists, then for $s > k$,

$$\textbf{(6)} \qquad \mathcal{L}\left\{\frac{f(t)}{t}\right\} = \int_s^\infty F(\tilde{s})\, d\tilde{s} \qquad \text{hence} \qquad \mathcal{L}^{-1}\left\{\int_s^\infty F(\tilde{s})\, d\tilde{s}\right\} = \frac{f(t)}{t}.$$

In this way, *integration of the transform of a function* $f(t)$ *corresponds to the division of* $f(t)$ *by* t.

We indicate how (6) is obtained. From the definition it follows that

$$\int_s^\infty F(\tilde{s})\,d\tilde{s} = \int_s^\infty \left[\int_0^\infty e^{-\tilde{s}t} f(t)\,dt\right] d\tilde{s},$$

and it can be shown (see Ref. [GR4] in App. 1) that under the above assumptions we may reverse the order of integration, that is,

$$\int_s^\infty F(\tilde{s})\,d\tilde{s} = \int_0^\infty \left[\int_s^\infty e^{-\tilde{s}t} f(t)\,d\tilde{s}\right] dt = \int_0^\infty f(t)\left[\int_s^\infty e^{-\tilde{s}t}\,d\tilde{s}\right] dt.$$

Integration of $e^{-\tilde{s}t}$ with respect to $\tilde{s}$ gives $e^{-\tilde{s}t}/(-t)$. Here the integral over $\tilde{s}$ on the right equals e^{-st}/t. Therefore,

$$\int_s^\infty F(\tilde{s})\,d\tilde{s} = \int_0^\infty e^{-st}\,\frac{f(t)}{t}\,dt = \mathcal{L}\left\{\frac{f(t)}{t}\right\} \qquad (s > k). \quad \blacksquare$$

EXAMPLE 2 Differentiation and Integration of Transforms

Find the inverse transform of $\ln\left(1 + \dfrac{\omega^2}{s^2}\right) = \ln\dfrac{s^2 + \omega^2}{s^2}$.

Solution. Denote the given transform by $F(s)$. Its derivative is

$$F'(s) = \frac{d}{ds}\left(\ln(s^2 + \omega^2) - \ln s^2\right) = \frac{2s}{s^2 + \omega^2} - \frac{2s}{s^2}.$$

Taking the inverse transform and using (1), we obtain

$$\mathcal{L}^{-1}\{F'(s)\} = \mathcal{L}^{-1}\left\{\frac{2s}{s^2 + \omega^2} - \frac{2}{s}\right\} = 2\cos\omega t - 2 = -tf(t).$$

Hence the inverse $f(t)$ of $F(s)$ is $f(t) = 2(1 - \cos\omega t)/t$. This agrees with formula 42 in Sec. 6.9.

Alternatively, if we let

$$G(s) = \frac{2s}{s^2 + \omega^2} - \frac{2}{s}, \qquad \text{then} \qquad g(t) = \mathcal{L}^{-1}(G) = 2(\cos\omega t - 1).$$

From this and (6) we get, in agreement with the answer just obtained,

$$\ln\frac{s^2 + \omega^2}{s^2} = \int_s^\infty G(s)\,ds = -\frac{g(t)}{t} = \frac{2}{t}(1 - \cos\omega t),$$

the minus occurring since s is the lower limit of integration.

In a similar way we obtain formula 43 in Sec. 6.9,

$$\mathcal{L}^{-1}\left\{\ln\left(1 - \frac{a^2}{s^2}\right)\right\} = \frac{2}{t}(1 - \cosh at). \quad \blacksquare$$

Special Linear ODEs with Variable Coefficients

Formula (1) can be used to solve certain ODEs with variable coefficients. The idea is this. Let $\mathcal{L}(y) = Y$. Then $\mathcal{L}(y') = sY - y(0)$ (see Sec. 6.2). Hence by (1),

$$\mathcal{L}(ty') = -\frac{d}{ds}\left[sY - y(0)\right] = -Y - s\,\frac{dY}{ds}. \tag{7}$$

Similarly, $\mathscr{L}(y'') = s^2Y - sy(0) - y'(0)$ and by (1)

$$(8) \qquad \mathscr{L}(ty'') = -\frac{d}{ds}\left[s^2Y - sy(0) - y'(0)\right] = -2sY - s^2\frac{dY}{ds} + y(0).$$

Hence if an ODE has coefficients such as $at + b$, the subsidiary equation is a first-order ODE for Y, which is sometimes simpler than the given second-order ODE. But if the latter has coefficients $at^2 + bt + c$, then two applications of (1) would give a second-order ODE for Y, and this shows that the present method works well only for rather special ODEs with variable coefficients. An important ODE for which the method is advantageous is the following.

EXAMPLE 3 **Laguerre's Equation. Laguerre Polynomials**

Laguerre's ODE is

$$(9) \qquad ty'' + (1 - t)y' + ny = 0.$$

We determine a solution of (9) with $n = 0, 1, 2, \cdots$. From (7)–(9) we get the subsidiary equation

$$\left[-2sY - s^2\frac{dY}{ds} + y(0)\right] + sY - y(0) - \left(-Y - s\frac{dY}{ds}\right) + nY = 0.$$

Simplification gives

$$(s - s^2)\frac{dY}{ds} + (n + 1 - s)Y = 0.$$

Separating variables, using partial fractions, integrating (with the constant of integration taken zero), and taking exponentials, we get

$$(10^*) \qquad \frac{dY}{Y} = -\frac{n + 1 - s}{s - s^2}\,ds = \left(\frac{n}{s - 1} - \frac{n + 1}{s}\right)ds \qquad \text{and} \qquad Y = \frac{(s - 1)^n}{s^{n+1}}.$$

We write $l_n = \mathscr{L}^{-1}(Y)$ and prove **Rodrigues's formula**

$$(10) \qquad l_0 = 1, \qquad l_n(t) = \frac{e^t}{n!}\frac{d^n}{dt^n}(t^ne^{-t}), \qquad n = 1, 2, \cdots.$$

These are polynomials because the exponential terms cancel if we perform the indicated differentiations. They are called **Laguerre polynomials** and are usually denoted by L_n (see Problem Set 5.7, but we continue to reserve capital letters for transforms). We prove (10). By Table 6.1 and the first shifting theorem (s-shifting),

$$\mathscr{L}(t^ne^{-t}) = \frac{n!}{(s + 1)^{n+1}}, \qquad \text{hence by (3) in Sec. 6.2} \qquad \mathscr{L}\left\{\frac{d^n}{dt^n}(t^ne^{-t})\right\} = \frac{n!s^n}{(s + 1)^{n+1}}$$

because the derivatives up to the order $n - 1$ are zero at 0. Now make another shift and divide by $n!$ to get [see (10) and then (10*)]

$$\mathscr{L}(l_n) = \frac{(s - 1)^n}{s^{n+1}} = Y.$$

PROBLEM SET 6.6

1–12 TRANSFORMS BY DIFFERENTIATION

Showing the details of your work, find $\mathscr{L}(f)$ if $f(t)$ equals:

1. $4te^t$
2. $-t\cosh 2t$
3. $t\sin \omega t$
4. $t\cos(t + k)$
5. $te^{-2t}\sin t$
6. $t^2\sin 3t$
7. $t^2\sinh 4t$
8. t^ne^{kt}
9. $t^2\sin \omega t$
10. $t\cos \omega t$
11. $t\sin(t + k)$
12. $te^{-kt}\sin t$

13–20 INVERSE TRANSFORMS

Using differentiation, integration, s-shifting, or convolution (and showing the details), find $f(t)$ if $\mathcal{L}(f)$ equals:

13. $\dfrac{6}{(s+1)^2}$

14. $\dfrac{s}{(s^2+16)^2}$

15. $\dfrac{2(s+2)}{[(s+2)^2+1]^2}$

16. $\dfrac{s}{(s^2-1)^2}$

17. $\dfrac{2}{(s-k)^3}$

18. $\ln\dfrac{s+a}{s+b}$

19. $\ln\dfrac{s}{s-1}$

20. $\operatorname{arccot}\dfrac{s}{\omega}$

21. WRITING PROJECT. Differentiation and Integration of Functions and Transforms. Make a short draft of these four operations from memory. Then compare your notes with the text and write a report of 2–3 pages on these operations and their significance in applications.

22. CAS PROJECT. Laguerre Polynomials. (a) Write a CAS program for finding $l_n(t)$ in explicit form from (10). Apply it to calculate $l_0, \cdots, l_{10}$. Verify that $l_0, \cdots, l_{10}$ satisfy Laguerre's differential equation (9).

(b) Show that

$$l_n(t) = \sum_{m=0}^{n} \frac{(-1)^m}{m!}\binom{n}{m} t^m$$

and calculate $l_0, \cdots, l_{10}$ from this formula.

(c) Calculate $l_0, \cdots, l_{10}$ recursively from $l_0 = 1$, $l_1 = 1 - t$ by

$$(n+1)l_{n+1} = (2n+1-t)l_n - nl_{n-1}.$$

(d) Experiment with the graphs of $l_0, \cdots, l_{10}$, finding out empirically how the first maximum, first minimum, $\cdots$ is moving with respect to its location as a function of n. Write a short report on this.

(e) A **generating function** (definition in Problem Set 5.3) for the Laguerre polynomials is

$$\sum_{n=0}^{\infty} l_n(t)x^n = (1-x)^{-1}e^{tx/(x-1)}.$$

Obtain $l_0, \cdots, l_{10}$ from the corresponding partial sum of this power series in x and compare the l_n with those in (a), (b), or (c).

6.7 Systems of ODEs

The Laplace transform method may also be used for solving systems of ODEs, as we shall explain in terms of typical applications. We consider a first-order linear system with constant coefficients (as discussed in Sec. 4.1)

$$\begin{aligned} y_1' &= a_{11}y_1 + a_{12}y_2 + g_1(t) \\ y_2' &= a_{21}y_1 + a_{22}y_2 + g_2(t). \end{aligned} \tag{1}$$

Writing $Y_1 = \mathcal{L}(y_1)$, $Y_2 = \mathcal{L}(y_2)$, $G_1 = \mathcal{L}(g_1)$, $G_2 = \mathcal{L}(g_2)$, we obtain from (1) in Sec. 6.2 the subsidiary system

$$\begin{aligned} sY_1 - y_1(0) &= a_{11}Y_1 + a_{12}Y_2 + G_1(s) \\ sY_2 - y_2(0) &= a_{21}Y_1 + a_{22}Y_2 + G_2(s). \end{aligned}$$

By collecting the Y_1- and Y_2-terms we have

$$\begin{aligned} (a_{11}-s)Y_1 + a_{12}Y_2 &= -y_1(0) - G_1(s) \\ a_{21}Y_1 + (a_{22}-s)Y_2 &= -y_2(0) - G_2(s). \end{aligned} \tag{2}$$

By solving this system algebraically for $Y_1(s)$, $Y_2(s)$ and taking the inverse transform we obtain the solution $y_1 = \mathcal{L}^{-1}(Y_1)$, $y_2 = \mathcal{L}^{-1}(Y_2)$ of the given system (1).

Note that (1) and (2) may be written in vector form (and similarly for the systems in the examples); thus, setting $\mathbf{y} = [y_1 \quad y_2]^T$, $\mathbf{A} = [a_{jk}]$, $\mathbf{g} = [g_1 \quad g_2]^T$, $\mathbf{Y} = [Y_1 \quad Y_2]^T$, $\mathbf{G} = [G_1 \quad G_2]^T$ we have

$$\mathbf{y}' = \mathbf{A}\mathbf{y} + \mathbf{g} \qquad \text{and} \qquad (\mathbf{A} - s\mathbf{I})\mathbf{Y} = -\mathbf{y}(0) - \mathbf{G}.$$

EXAMPLE 1 Mixing Problem Involving Two Tanks

Tank T_1 in Fig. 142 contains initially 100 gal of pure water. Tank T_2 contains initially 100 gal of water in which 150 lb of salt are dissolved. The inflow into T_1 is 2 gal/min from T_2 and 6 gal/min containing 6 lb of salt from the outside. The inflow into T_2 is 8 gal/min from T_1. The outflow from T_2 is $2 + 6 = 8$ gal/min, as shown in the figure. The mixtures are kept uniform by stirring. Find and plot the salt contents $y_1(t)$ and $y_2(t)$ in T_1 and T_2, respectively.

Solution. The model is obtained in the form of two equations

$$\text{Time rate of change} = \text{Inflow/min} - \text{Outflow/min}$$

for the two tanks (see Sec. 4.1). Thus,

$$y_1' = -\frac{8}{100}\,y_1 + \frac{2}{100}\,y_2 + 6, \qquad y_2' = \frac{8}{100}\,y_1 - \frac{8}{100}\,y_2.$$

The initial conditions are $y_1(0) = 0$, $y_2(0) = 150$. From this we see that the subsidiary system (2) is

$$\begin{aligned} (-0.08 - s)Y_1 + \quad 0.02Y_2 \quad &= -\frac{6}{s} \\ 0.08Y_1 \quad + (-0.08 - s)Y_2 &= -150. \end{aligned}$$

We solve this algebraically for Y_1 and Y_2 by elimination (or by Cramer's rule in Sec. 7.7), and we write the solutions in terms of partial fractions,

$$Y_1 = \frac{9s + 0.48}{s(s + 0.12)(s + 0.04)} = \frac{100}{s} - \frac{62.5}{s + 0.12} - \frac{37.5}{s + 0.04}$$

$$Y_2 = \frac{150s^2 + 12s + 0.48}{s(s + 0.12)(s + 0.04)} = \frac{100}{s} + \frac{125}{s + 0.12} - \frac{75}{s + 0.04}.$$

By taking the inverse transform we arrive at the solution

$$\begin{aligned} y_1 &= 100 - 62.5e^{-0.12t} - 37.5e^{-0.04t} \\ y_2 &= 100 + 125e^{-0.12t} - 75e^{-0.04t}. \end{aligned}$$

Figure 142 shows the interesting plot of these functions. Can you give physical explanations for their main features? Why do they have the limit 100? Why is y_2 not monotone, whereas y_1 is? Why is y_1 from some time on suddenly larger than y_2? Etc. ■

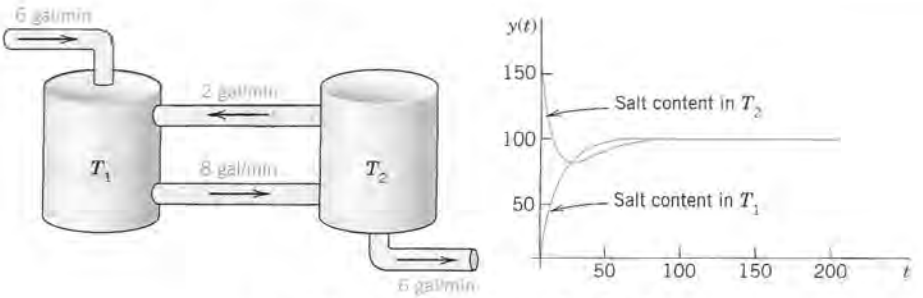

Fig. 142. Mixing problem in Example 1

Other systems of ODEs of practical importance can be solved by the Laplace transform method in a similar way, and eigenvalues and eigenvectors as we had to determine them in Chap. 4 will come out automatically, as we have seen in Example 1.

EXAMPLE 2 Electrical Network

Find the currents $i_1(t)$ and $i_2(t)$ in the network in Fig. 143 with L and R measured in terms of the usual units (see Sec. 2.9), $v(t) = 100$ volts if $0 \leqq t \leqq 0.5$ sec and 0 thereafter, and $i(0) = 0$, $i'(0) = 0$.

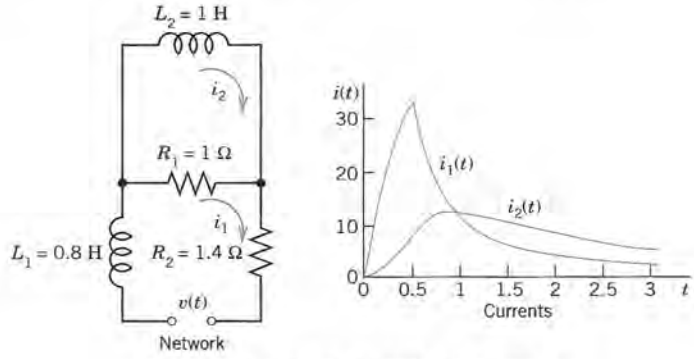

Fig. 143. Electrical network in Example 2

Solution. The model of the network is obtained from Kirchhoff's voltage law as in Sec. 2.9. For the lower circuit we obtain

$$0.8\,i_1' + 1(i_1 - i_2) + 1.4\,i_1 = 100\left[1 - u\left(t - \tfrac{1}{2}\right)\right]$$

and for the upper

$$1 \cdot i_2' + 1(i_2 - i_1) \qquad = 0.$$

Division by 0.8 and ordering gives for the lower circuit

$$i_1' + 3i_1 - 1.25\,i_2 = 125\left[1 - u\left(t - \tfrac{1}{2}\right)\right]$$

and for the upper

$$i_2' - i_1 + i_2 = 0.$$

With $i_1(0) = 0$, $i_2(0) = 0$ we obtain from (1) in Sec. 6.2 and the second shifting theorem the subsidiary system

$$\begin{aligned}(s + 3)I_1 - 1.25I_2 &= 125\left(\frac{1}{s} - \frac{e^{-s/2}}{s}\right)\\ -I_1 + (s + 1)I_2 &= 0.\end{aligned}$$

Solving algebraically for I_1 and I_2 gives

$$I_1 = \frac{125(s + 1)}{s(s + \frac{1}{2})(s + \frac{7}{2})}\,(1 - e^{-s/2}),$$

$$I_2 = \frac{125}{s(s + \frac{1}{2})(s + \frac{7}{2})}\,(1 - e^{-s/2}).$$

The right sides without the factor $1 - e^{-s/2}$ have the partial fraction expansions

$$\frac{500}{7s} - \frac{125}{3(s + \frac{1}{2})} - \frac{625}{21(s + \frac{7}{2})}$$

and

$$\frac{500}{7s} - \frac{250}{3(s+\frac{1}{2})} + \frac{250}{21(s+\frac{7}{2})},$$

respectively. The inverse transform of this gives the solution for $0 \leqq t \leqq \frac{1}{2}$,

$$\begin{aligned} i_1(t) &= -\frac{125}{3}e^{-t/2} - \frac{625}{21}e^{-7t/2} + \frac{500}{7} \\ i_2(t) &= -\frac{250}{3}e^{-t/2} + \frac{250}{21}e^{-7t/2} + \frac{500}{7} \end{aligned} \qquad (0 \leqq t \leqq \tfrac{1}{2}).$$

According to the second shifting theorem the solution for $t > \frac{1}{2}$ is $i_1(t) - i_1(t-\frac{1}{2})$ and $i_2(t) - i_2(t-\frac{1}{2})$, that is,

$$\begin{aligned} i_1(t) &= -\frac{125}{3}(1-e^{1/4})e^{-t/2} - \frac{625}{21}(1-e^{7/4})e^{-7t/2} \\ i_2(t) &= -\frac{250}{3}(1-e^{1/4})e^{-t/2} + \frac{250}{21}(1-e^{7/4})e^{-7t/2} \end{aligned} \qquad (t > \tfrac{1}{2}).$$

Can you explain physically why both currents eventually go to zero, and why $i_1(t)$ has a sharp cusp whereas $i_2(t)$ has a continuous tangent direction at $t = \frac{1}{2}$? ■

Systems of ODEs of higher order can be solved by the Laplace transform method in a similar fashion. As an important application, typical of many similar mechanical systems, we consider coupled vibrating masses on springs.

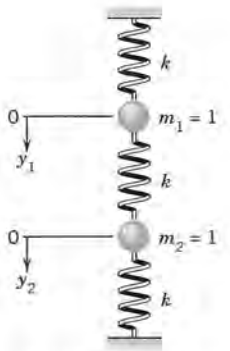

Fig. 144. Example 3

EXAMPLE 3 **Model of Two Masses on Springs (Fig. 144)**

The mechanical system in Fig. 144 consists of two bodies of mass 1 on three springs of the same spring constant k and of negligibly small masses of the springs. Also damping is assumed to be practically zero. Then the model of the physical system is the system of ODEs

$$\begin{aligned} y_1'' &= -ky_1 + k(y_2 - y_1) \\ y_2'' &= -k(y_2 - y_1) - ky_2. \end{aligned} \qquad (3)$$

Here y_1 and y_2 are the displacements of the bodies from their positions of static equilibrium. These ODEs follow from **Newton's second law,** *Mass* × *Acceleration* = *Force,* as in Sec. 2.4 for a single body. We again regard downward forces as positive and upward as negative. On the upper body, $-ky_1$ is the force of the upper spring and $k(y_2 - y_1)$ that of the middle spring, $y_2 - y_1$ being the net change in spring length—think this over before going on. On the lower body, $-k(y_2 - y_1)$ is the force of the middle spring and $-ky_2$ that of the lower spring.

We shall determine the solution corresponding to the initial conditions $y_1(0) = 1$, $y_2(0) = 1$, $y_1'(0) = \sqrt{3k}$, $y_2'(0) = -\sqrt{3k}$. Let $Y_1 = \mathcal{L}(y_1)$ and $Y_2 = \mathcal{L}(y_2)$. Then from (2) in Sec. 6.2 and the initial conditions we obtain the subsidiary system

$$s^2Y_1 - s - \sqrt{3k} = -kY_1 + k(Y_2 - Y_1)$$
$$s^2Y_2 - s + \sqrt{3k} = -k(Y_2 - Y_1) - kY_2.$$

This system of linear algebraic equations in the unknowns Y_1 and Y_2 may be written

$$(s^2 + 2k)Y_1 - kY_2 = s + \sqrt{3k}$$
$$-kY_1 + (s^2 + 2k)Y_2 = s - \sqrt{3k}.$$

Elimination (or Cramer's rule in Sec. 7.7) yields the solution, which we can expand in terms of partial fractions,

$$Y_1 = \frac{(s + \sqrt{3k})(s^2 + 2k) + k(s - \sqrt{3k})}{(s^2 + 2k)^2 - k^2} = \frac{s}{s^2 + k} + \frac{\sqrt{3k}}{s^2 + 3k}$$

$$Y_2 = \frac{(s^2 + 2k)(s - \sqrt{3k}) + k(s + \sqrt{3k})}{(s^2 + 2k)^2 - k^2} = \frac{s}{s^2 + k} - \frac{\sqrt{3k}}{s^2 + 3k}.$$

Hence the solution of our initial value problem is (Fig. 145)

$$y_1(t) = \mathcal{L}^{-1}(Y_1) = \cos\sqrt{k}t + \sin\sqrt{3k}t$$
$$y_2(t) = \mathcal{L}^{-1}(Y_2) = \cos\sqrt{k}t - \sin\sqrt{3k}t.$$

We see that the motion of each mass is harmonic (the system is undamped!), being the superposition of a "slow" oscillation and a "rapid" oscillation. ■

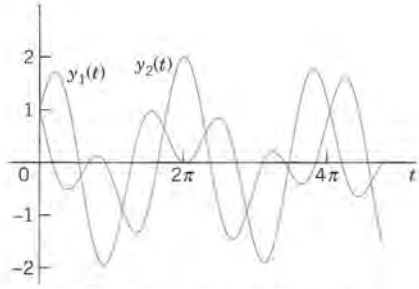

Fig. 145. Solutions in Example 3

PROBLEM SET 6.7

1–20 SYSTEMS OF ODES

Using the Laplace transform and showing the details of your work, solve the initial value problem:

1. $y_1' = -y_1 - y_2$, $y_2' = y_1 - y_2$, $y_1(0) = 0$, $y_2(0) = 1$

2. $y_1' = 5y_1 + y_2$, $y_2' = y_1 + 5y_2$, $y_1(0) = 1$, $y_2(0) = -3$

3. $y_1' = -6y_1 + 4y_2$, $y_2' = -4y_1 + 4y_2$, $y_1(0) = -2$, $y_2(0) = -7$

4. $y_1' + y_2 = 0$, $y_1 + y_2' = 2\cos t$, $y_1(0) = 1$, $y_2(0) = 0$

5. $y_1' = -4y_1 - 2y_2 + t$, $y_2' = 3y_1 + y_2 - t$, $y_1(0) = 5.75$, $y_2(0) = -6.75$

6. $y_1' = 4y_2 - 8\cos 4t$, $y_2' = -3y_1 - 9\sin 4t$, $y_1(0) = 0$, $y_2(0) = 3$

7. $y_1' = 5y_1 - 4y_2 - 9t^2 + 2t$,
$y_2' = 10y_1 - 7y_2 - 17t^2 - 2t$,
$y_1(0) = 2, \quad y_2(0) = 0$

8. $y_1' = 6y_1 + y_2, \quad y_2' = 9y_1 + 6y_2$,
$y_1(0) = -3, \quad y_2(0) = -3$

9. $y_1' = 5y_1 + 5y_2 - 15\cos t + 27\sin t$,
$y_2' = -10y_1 - 5y_2 - 150\sin t$,
$y_1(0) = 2, \quad y_2(0) = 2$

10. $y_1' = -2y_1 + 3y_2, \quad y_2' = 4y_1 - y_2$,
$y_1(0) = 4, \quad y_2(0) = 3$

11. $y_1' = y_2 + 1 - u(t-1)$,
$y_2' = -y_1 + 1 - u(t-1), \quad y_1(0) = 0$,
$y_2(0) = 0$

12. $y_1' = 2y_1 + y_2, \quad y_2' = 4y_1 + 2y_2 + 64tu(t-1)$,
$y_1(0) = 2, \quad y_2(0) = 0$

13. $y_1' = y_1 + 6u(t-2)e^{4t}, \quad y_2' = y_1 + 2y_2$,
$y_1(0) = 0, \quad y_2(0) = 1$

14. $y_1' = -y_2, \quad y_2' = -y_1 + 2[1 - u(t - 2\pi)]\cos t$,
$y_1(0) = 1, \quad y_2(0) = 0$

15. $y_1' = -3y_1 + y_2 + u(t-1)e^t$,
$y_2' = -4y_1 + 2y_2 + u(t-1)e^t$,
$y_1(0) = 0, \quad y_2(0) = 3$

16. $y_1'' = -2y_1 + 2y_2, \quad y_2'' = 2y_1 - 5y_2$,
$y_1(0) = 1, \quad y_1'(0) = 0, \quad y_2(0) = 3, \quad y_2'(0) = 0$

17. $y_1'' = 4y_1 + 8y_2, \quad y_2'' = 5y_1 + y_2$,
$y_1(0) = 8, \quad y_1'(0) = -18, \quad y_2(0) = 5$,
$y_2'(0) = -21$

18. $y_1'' + y_2 = -101\sin 10t, \quad y_2'' + y_1 = 101\sin 10t$,
$y_1(0) = 0, \quad y_1'(0) = 6, \quad y_2(0) = 8$,
$y_2'(0) = -6$

19. $y_1' + y_2' = 2e^t + e^{-t}, \quad y_2' + y_3' = 2\sinh t$,
$y_3' + y_1' = e^t$
$y_1(0) = 0, \quad y_2(0) = 1, \quad y_3(0) = 1$

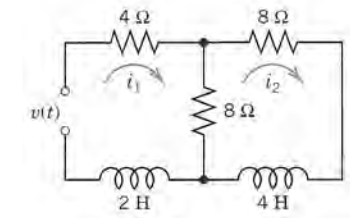
20. $4y_1' + y_2' - 2y_3' = 0, \quad -2y_1' + y_3' = 1$,
$2y_2' - 4y_3' = -16t$
$y_1(0) = 2, \quad y_2(0) = 0, \quad y_3(0) = 0$

21. TEAM PROJECT. Comparison of Methods for Linear Systems of ODEs.

(a) Models. Solve the models in Examples 1 and 2 of Sec. 4.1 by Laplace transforms and compare the amount of work with that in Sec. 4.1. (Show the details of your work.)

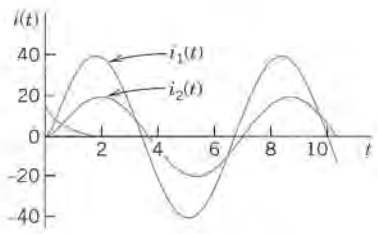
(b) Homogeneous Systems. Solve the systems (8), (11)–(13) in Sec. 4.3 by Laplace transforms. (Show the details.)

(c) Nonhomogeneous System. Solve the system (3) in Sec. 4.6 by Laplace transforms. (Show the details.)



FURTHER APPLICATIONS

22. (Forced vibrations of two masses) Solve the model in Example 3 with $k = 4$ and initial conditions $y_1(0) = 1$, $y_1'(0) = 1$, $y_2(0) = 1$, $y_2'(0) = -1$ under the assumption that the force $11\sin t$ is acting on the first body and the force $-11\sin t$ on the second. Graph the two curves on common axes and explain the motion physically.



23. CAS Experiment. Effect of Initial Conditions. In Prob. 22, vary the initial conditions systematically, describe and explain the graphs physically. The great variety of curves will surprise you. Are they always periodic? Can you find empirical laws for the changes in terms of continuous changes of those conditions?

24. (Mixing problem) What will happen in Example 1 if you double all flows (in particular, an increase to 12 gal/min containing 12 lb of salt from the outside), leaving the size of the tanks and the initial conditions as before? First guess, then calculate. Can you relate the new solution to the old one?

25. (Electrical network) Using Laplace transforms, find the currents $i_1(t)$ and $i_2(t)$ in Fig. 146, where $v(t) = 390\cos t$ and $i_1(0) = 0$, $i_2(0) = 0$. How soon will the currents practically reach their steady state?

Network

Currents

Fig. 146. Electrical network and currents in Problem 25

26. (Single cosine wave) Solve Prob. 25 when the EMF (electromotive force) is acting from 0 to 2π only. Can you do this just by looking at Prob. 25, practically without calculation?

CHAPTER 6 REVIEW QUESTIONS AND PROBLEMS

1. What do we mean by operational calculus?
2. What are the steps needed in solving an ODE by Laplace transform? What is the subsidiary equation?
3. The Laplace transform is a linear operation. What does this mean? Why is it important?
4. For what problems is the Laplace transform preferable over the usual method? Explain.
5. What are the unit step and Dirac's delta functions? Give examples.
6. What is the difference between the two shifting theorems? When do they apply?
7. Is $\mathcal{L}\{f(t)g(t)\} = \mathcal{L}\{f(t)\}\mathcal{L}\{g(t)\}$? Explain.
8. Can a discontinuous function have a Laplace transform? Does every continuous function have a Laplace transform? Give reasons.
9. State the transforms of a few simple functions from memory.
10. If two different continuous functions have transforms, the latter are different. Why is this practically important?

11–22 LAPLACE TRANSFORMS

Find the transform (showing the details of your work and indicating the method or formula you are using):

11. te^{3t}
12. $e^{-t}\sin 2t$
13. $\sin^2 t$
14. $\cos^2 4t$
15. $tu(t-\pi)$
16. $u(t-2\pi)\sin t$
17. $e^t * \cos 2t$
18. $(\sin \omega t) * (\cos \omega t)$
19. $\sin t + \sinh t$
20. $\cosh t - \cos t$
21. $e^{at} - e^{bt} \quad (a \neq b)$
22. $\cosh 2t - \cosh t$

23–34 INVERSE LAPLACE TRANSFORMS

Find the inverse transform (showing the details of your work and indicating the method or formula used):

23. $\dfrac{10s}{s^2+2}$
24. $\dfrac{15}{s^2-4}$
25. $\dfrac{12}{s^2+4s+20}$
26. $\dfrac{3s}{s^2-2s+2}$
27. $\dfrac{5s+4}{s^2}e^{-2s}$
28. $\dfrac{2s-10}{s^3}e^{-5s}$
29. $\dfrac{2s+4}{(s^2+4s+5)^2}$
30. $\dfrac{s^2-16}{(s^2+16)^2}$
31. $\left(\dfrac{2}{s^2}+\dfrac{2}{s^3}\right)e^{-s}$
32. $\dfrac{180+18s^2+3s^4}{s^7}$
33. $\dfrac{\pi}{s^2(s^2+\omega^2)}$
34. $\dfrac{2}{2s^2+2s+1}$

35–50 SINGLE ODEs AND SYSTEMS OF ODEs

Solve by Laplace transforms, showing the details and graphing the solution:

35. $y'' + y = u(t - 1), \quad y(0) = 0, \quad y'(0) = 20$

36. $y'' + 16y = 4\delta(t - \pi), \quad y(0) = -1, \quad y'(0) = 0$

37. $y'' + 4y = 8\delta(t - 5), \quad y(0) = 10, \quad y'(0) = -1$

38. $y'' + y = u(t - 2), \quad y(0) = 0, \quad y'(0) = 0$

39. $y'' + 2y' + 10y = 0, \quad y(0) = 7, \quad y'(0) = -1$

40. $y'' + 4y' + 5y = 50t, \quad y(0) = 5, \quad y'(0) = -5$

41. $y'' - y' - 2y = 12u(t - \pi) \sin t, \quad y(0) = 1, \quad y'(0) = -1$

42. $y'' - 2y' + y = t\delta(t - 1), \quad y(0) = 0, \quad y'(0) = 0$

43. $y'' - 4y' + 4y = \delta(t - 1) - \delta(t - 2), \quad y(0) = 0, \quad y'(0) = 0$

44. $y'' + 4y = \delta(t - \pi) - \delta(t - 2\pi), \quad y(0) = 1, \quad y'(0) = 0$

45. $y_1' + y_2 = \sin t, \quad y_2' + y_1 = -\sin t, \quad y_1(0) = 1, \quad y_2(0) = 0$

46. $y_1' = -3y_1 + y_2 - 12t, \quad y_2' = -4y_1 + 2y_2 + 12t, \quad y_1(0) = 0, \quad y_2(0) = 0$

47. $y_1' = y_2, \quad y_2' = -5y_1 - 2y_2, \quad y_1(0) = 0, \quad y_2(0) = 1$

48. $y_1' = y_2, \quad y_2' = -4y_1 + \delta(t - \pi), \quad y_1(0) = 0, \quad y_2(0) = 0$

49. $y_1'' = 4y_2 - 4e^t, \quad y_2'' = 3y_1 + y_2, \quad y_1(0) = 1, \quad y_1'(0) = 2, \quad y_2(0) = 2, \quad y_2'(0) = 3$

50. $y_1'' = 16y_2, \quad y_2'' = 16y_1, \quad y_1(0) = 2, \quad y_1'(0) = 12, \quad y_2(0) = 6, \quad y_2'(0) = 4$

MODELS OF CIRCUITS AND NETWORKS

51. (*RC*-circuit) Find and graph the current $i(t)$ in the *RC*-circuit in Fig. 147, where $R = 100\ \Omega$, $C = 10^{-3}$ F, $v(t) = 100t$ V if $0 < t < 2$, $v(t) = 200$ V if $t > 2$ and the initial charge on the capacitor is 0.

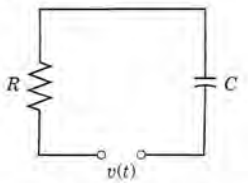

Fig. 147. *RC*-circuit

52. (*LC*-circuit) Find and graph the charge $q(t)$ and the current $i(t)$ in the *LC*-circuit in Fig. 148, where $L = 0.5$ H, $C = 0.02$ F, $v(t) = 1425 \sin 5t$ V if $0 < t < \pi$, $v(t) = 0$ if $t > \pi$, and current and charge at $t = 0$ are 0.

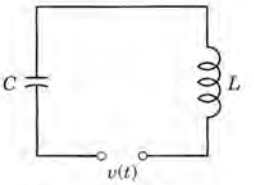

Fig. 148. *LC*-circuit

53. (*RLC*-circuit) Find and graph the current $i(t)$ in the *RLC*-circuit in Fig. 149, where $R = 1\ \Omega$, $L = 0.25$ H, $C = 0.2$ F, $v(t) = 377 \sin 20t$ V, and current and charge at $t = 0$ are 0.

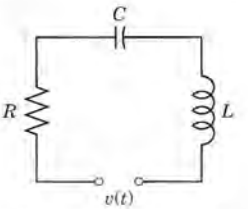

Fig. 149. *RLC*-circuit

54. (Network) Show that by Kirchhoff's voltage law (Sec. 2.9), the currents in the network in Fig. 150 are obtained from the system

$$Li_1' + R(i_1 - i_2) = v(t)$$
$$R(i_2' - i_1') + \frac{1}{C} i_2 = 0.$$

Solve this system, where $R = 1\ \Omega$, $L = 2$ H, $C = 0.5$ F, $v(t) = 90e^{-t/4}$ V, $i_1(0) = 0$, $i_2(0) = 2$ A.

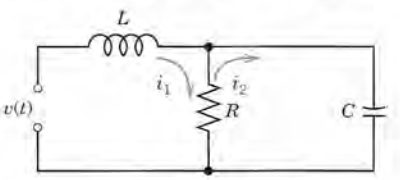

Fig. 150. Network in Problem 54

55. (Network) Set up the model of the network in Fig. 151 and find and graph the currents, assuming that the currents and the charge on the capacitor are 0 when the switch is closed at $t = 0$.

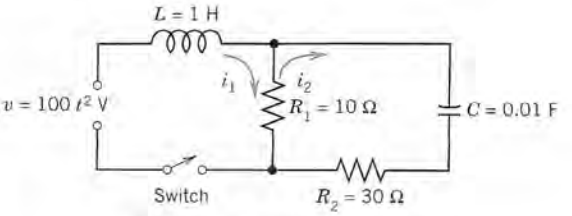

Fig. 151. Network in Problem 55

SUMMARY OF CHAPTER 6
Laplace Transforms

The main purpose of Laplace transforms is the solution of differential equations and systems of such equations, as well as corresponding initial value problems. The **Laplace transform** $F(s) = \mathcal{L}(f)$ of a function $f(t)$ is defined by

$$(1) \qquad F(s) = \mathcal{L}(f) = \int_0^\infty e^{-st} f(t)\, dt \qquad \text{(Sec. 6.1).}$$

This definition is motivated by the property that the differentiation of f with respect to t corresponds to the multiplication of the transform F by s; more precisely,

$$(2) \qquad \begin{aligned} \mathcal{L}(f') &= s\mathcal{L}(f) - f(0) \\ \mathcal{L}(f'') &= s^2\mathcal{L}(f) - sf(0) - f'(0) \end{aligned} \qquad \text{(Sec. 6.2)}$$

etc. Hence by taking the transform of a given differential equation

$$(3) \qquad y'' + ay' + by = r(t) \qquad (a, b \text{ constant})$$

and writing $\mathcal{L}(y) = Y(s)$, we obtain the **subsidiary equation**

$$(4) \qquad (s^2 + as + b)Y = \mathcal{L}(r) + sf(0) + f'(0) + af(0).$$

Here, in obtaining the transform $\mathcal{L}(r)$ we can get help from the small table in Sec. 6.1 or the larger table in Sec. 6.9. This is the first step. In the second step we solve the subsidiary equation *algebraically* for $Y(s)$. In the third step we determine the **inverse transform** $y(t) = \mathcal{L}^{-1}(Y)$, that is, the solution of the problem. This is generally the hardest step, and in it we may again use one of those two tables. $Y(s)$ will often be a rational function, so that we can obtain the inverse $\mathcal{L}^{-1}(Y)$ by partial fraction reduction (Sec. 6.4) if we see no simpler way.

The Laplace method avoids the determination of a general solution of the homogeneous ODE, and we also need not determine values of arbitrary constants in a general solution from initial conditions; instead, we can insert the latter directly into (4). Two further facts account for the practical importance of the Laplace transform. First, it has some basic properties and resulting techniques that simplify the determination of transforms and inverses. The most important of these properties are listed in Sec. 6.8, together with references to the corresponding sections. More on the use of unit step functions and Dirac's delta can be found in Secs. 6.3 and 6.4, and more on convolution in Sec. 6.5. Second, due to these properties, the present method is particularly suitable for handling right sides $r(t)$ given by different expressions over different intervals of time, for instance, when $r(t)$ is a square wave or an impulse or of a form such as $r(t) = \cos t$ if $0 \leqq t \leqq 4\pi$ and 0 elsewhere.

The application of the Laplace transform to systems of ODEs is shown in Sec. 6.7. (The application to PDEs follows in Sec. 12.11.)

PART B

Linear Algebra. Vector Calculus

CHAPTER 7 Linear Algebra: Matrices, Vectors, Determinants. Linear Systems

CHAPTER 8 Linear Algebra: Matrix Eigenvalue Problems

CHAPTER 9 Vector Differential Calculus. Grad, Div, Curl

CHAPTER 10 Vector Integral Calculus. Integral Theorems

Linear algebra in Chaps. 7 and 8 consists of the theory and application of vectors and matrices, mainly related to linear systems of equations, eigenvalue problems, and linear transformations.

Linear algebra is of growing importance in engineering research and teaching because it forms a foundation of numeric methods (see Chaps. 20–22), and its main instruments, matrices, can hold enormous amounts of data—think of a net of millions of telephone connections—in a form readily accessible by the computer.

Linear analysis in Chaps. 9 and 10, usually called **vector calculus,** extends *differentiation* of functions of one variable to functions of several variables—this includes the vector differential operations grad, div, and curl. And it generalizes *integration* to integrals over curves, surfaces, and solids, with transformations of these integrals into one another, by the basic theorems of Gauss, Green, and Stokes (Chap. 10).

Software suitable for linear algebra (Lapack, Maple, Mathematica, Matlab) can be found in the list at the opening of Part E of the book if needed.

Numeric linear algebra (Chap. 20) ***can be studied directly after Chap. 7 or 8*** because Chap. 20 is independent of the other chapters in Part E on numerics.

CHAPTER 7

Linear Algebra: Matrices, Vectors, Determinants. Linear Systems

This is the first of two chapters on **linear algebra,** which concerns mainly systems of linear equations and linear transformations (to be discussed in this chapter) and eigenvalue problems (to follow in Chap. 8).

Systems of linear equations, briefly called **linear systems,** arise in electrical networks, mechanical frameworks, economic models, optimization problems, numerics for differential equations, as we shall see in Chaps. 21–23, and so on.

As main tools, linear algebra uses **matrices** (rectangular arrays of numbers or functions) and **vectors.** Calculations with matrices handle matrices as single objects, denote them by single letters, and calculate with them in a very compact form, almost as with numbers, so that matrix calculations constitute a powerful "mathematical shorthand".

Calculations with matrices and vectors are defined and explained in Secs. 7.1–7.2. Sections 7.3–7.8 center around linear systems, with a thorough discussion of Gauss elimination, the role of rank, the existence and uniqueness problem for solutions (Sec. 7.5), and matrix inversion. This also includes determinants (Cramer's rule) in Sec. 7.6 (for quick reference) and Sec. 7.7. Applications are considered throughout this chapter. The last section (Sec. 7.9) on vector spaces, inner product spaces, and linear transformations is more abstract. Eigenvalue problems follow in Chap. 8.

COMMENT. ***Numeric linear algebra (Secs. 20.1–20.5) can be studied immediately after this chapter.***

Prerequisite: None.
Sections that may be omitted in a short course: 7.5, 7.9.
References and Answers to Problems: App. 1 Part B, and App. 2.

7.1 Matrices, Vectors: Addition and Scalar Multiplication

In this section and the next one we introduce the basic concepts and rules of matrix and vector algebra. The main application to **linear systems** (systems of linear equations) begins in Sec. 7.3.

A **matrix** is a rectangular array of numbers (or functions) enclosed in brackets. These numbers (or functions) are called the **entries** (or sometimes the *elements*) of the matrix. For example,

$$(1)\qquad \begin{bmatrix} 0.3 & 1 & -5 \\ 0 & -0.2 & 16 \end{bmatrix}, \qquad \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix},$$

$$\begin{bmatrix} e^{-x} & 2x^2 \\ e^{6x} & 4x \end{bmatrix}, \qquad [a_1 \quad a_2 \quad a_3], \qquad \begin{bmatrix} 4 \\ \frac{1}{2} \end{bmatrix}$$

are matrices. The first matrix has two **rows** (horizontal lines of entries) and three **columns** (vertical lines). The second and third matrices are **square matrices,** that is, each has as many rows as columns (3 and 2, respectively). The entries of the second matrix have two indices giving the location of the entry. The first index is the number of the row and the second is the number of the column in which the entry stands. Thus, a_{23} (read *a two three*) is in Row 2 and Column 3, etc. This notation is standard, regardless of whether a matrix is square or not.

Matrices having just a single row or column are called **vectors.** Thus the fourth matrix in (1) has just one row and is called a **row vector.** The last matrix in (1) has just one column and is called a **column vector.**

We shall see that matrices are practical in various applications for storing and processing data. As a first illustration let us consider two simple but typical examples.

EXAMPLE 1 **Linear Systems, a Major Application of Matrices**

In a system of linear equations, briefly called a **linear system,** such as

$$\begin{aligned} 4x_1 + 6x_2 + 9x_3 &= 6 \\ 6x_1 \qquad - 2x_3 &= 20 \\ 5x_1 - 8x_2 + x_3 &= 10 \end{aligned}$$

the coefficients of the **unknowns** x_1, x_2, x_3 are the entries of the **coefficient matrix,** call it **A,**

$$\mathbf{A} = \begin{bmatrix} 4 & 6 & 9 \\ 6 & 0 & -2 \\ 5 & -8 & 1 \end{bmatrix}. \qquad \text{The matrix} \qquad \tilde{\mathbf{A}} = \begin{bmatrix} 4 & 6 & 9 & 6 \\ 6 & 0 & -2 & 20 \\ 5 & -8 & 1 & 10 \end{bmatrix}$$

is obtained by augmenting **A** by the right sides of the linear system and is called the **augmented matrix** of the system. In **A** the coefficients of the system are displayed in the pattern of the equations. That is, their position in **A** corresponds to that in the system when written as shown. The same is true for $\tilde{\mathbf{A}}$.

We shall see that the augmented matrix $\tilde{\mathbf{A}}$ contains all the information about the solutions of a system, so that we can solve a system just by calculations on its augmented matrix. We shall discuss this in great detail, beginning in Sec. 7.3. Meanwhile you may verify by substitution that the solution is $x_1 = 3$, $x_2 = \frac{1}{2}$, $x_3 = -1$.

The notation x_1, x_2, x_3 for the unknowns is practical but not essential; we could choose x, y, z or some other letters. ■

EXAMPLE 2 Sales Figures in Matrix Form

Sales figures for three products I, II, III in a store on Monday (M), Tuesday (T), · · · may for each week be arranged in a matrix

$$\mathbf{A} = \begin{array}{c} \begin{matrix} \text{M} & \text{T} & \text{W} & \text{Th} & \text{F} & \text{S} \end{matrix} \\ \begin{bmatrix} 400 & 330 & 810 & 0 & 210 & 470 \\ 0 & 120 & 780 & 500 & 500 & 960 \\ 100 & 0 & 0 & 270 & 430 & 780 \end{bmatrix} \end{array} \begin{matrix} \\ \text{I} \\ \text{II} \\ \text{III} \end{matrix}$$

If the company has ten stores, we can set up ten such matrices, one for each store. Then by adding corresponding entries of these matrices we can get a matrix showing the total sales of each product on each day. Can you think of other data for which matrices are feasible? For instance, in transportation or storage problems? Or in recording phone calls, or in listing distances in a network of roads? ■

General Concepts and Notations

We shall denote matrices by capital boldface letters **A, B, C,** · · · , or by writing the general entry in brackets; thus $\mathbf{A} = [a_{jk}]$, and so on. By an $\boldsymbol{m \times n}$ **matrix** (read *m by n matrix*) we mean a matrix with m rows and n columns—rows come always first! $m \times n$ is called the **size** of the matrix. Thus an $m \times n$ matrix is of the form

$$\mathbf{A} = [a_{jk}] = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}. \tag{2}$$

The matrices in (1) are of sizes 2×3, 3×3, 2×2, 1×3, and 2×1, respectively.

Each entry in (2) has two subscripts. The first is the *row number* and the second is the *column number*. Thus a_{21} is the entry in Row 2 and Column 1.

If $m = n$, we call **A** an $n \times n$ **square matrix.** Then its diagonal containing the entries $a_{11}, a_{22}, \cdots, a_{nn}$ is called the **main diagonal** of **A.** Thus the main diagonals of the two square matrices in (1) are a_{11}, a_{22}, a_{33} and e^{-x}, $4x$, respectively.

Square matrices are particularly important, as we shall see. A matrix that is not square is called a **rectangular matrix.**

Vectors

A **vector** is a matrix with only one row or column. Its entries are called the **components** of the vector. We shall denote vectors by ***lowercase*** boldface letters **a, b,** · · · or by its general component in brackets, $\mathbf{a} = [a_j]$, and so on. Our special vectors in (1) suggest that a (general) **row vector** is of the form

$$\mathbf{a} = [a_1 \quad a_2 \quad \cdots \quad a_n]. \qquad \text{For instance,} \qquad \mathbf{a} = [-2 \quad 5 \quad 0.8 \quad 0 \quad 1].$$

A **column vector** is of the form

$$\mathbf{b} = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_m \end{bmatrix}. \qquad \text{For instance,} \qquad \mathbf{b} = \begin{bmatrix} 4 \\ 0 \\ -7 \end{bmatrix}.$$

Matrix Addition and Scalar Multiplication

What makes matrices and vectors really useful and particularly suitable for computers is the fact that we can calculate with them almost as easily as with numbers. Indeed, we now introduce rules for addition and for scalar multiplication (multiplication by numbers) that were suggested by practical applications. (Multiplication of matrices by matrices follows in the next section.) We first need the concept of equality.

DEFINITION

Equality of Matrices

Two matrices $\mathbf{A} = [a_{jk}]$ and $\mathbf{B} = [b_{jk}]$ are **equal,** written $\mathbf{A} = \mathbf{B}$, if and only if they have the same size and the corresponding entries are equal, that is, $a_{11} = b_{11}$, $a_{12} = b_{12}$, and so on. Matrices that are not equal are called **different.** Thus, matrices of different sizes are always different.

EXAMPLE 3 **Equality of Matrices**

Let

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \quad \text{and} \quad \mathbf{B} = \begin{bmatrix} 4 & 0 \\ 3 & -1 \end{bmatrix}.$$

Then

$$\mathbf{A} = \mathbf{B} \quad \text{if and only if} \quad \begin{aligned} a_{11} &= 4, \quad a_{12} = 0, \\ a_{21} &= 3, \quad a_{22} = -1. \end{aligned}$$

The following matrices are all different. Explain!

$$\begin{bmatrix} 1 & 3 \\ 4 & 2 \end{bmatrix} \quad \begin{bmatrix} 4 & 2 \\ 1 & 3 \end{bmatrix} \quad \begin{bmatrix} 4 & 1 \\ 2 & 3 \end{bmatrix} \quad \begin{bmatrix} 1 & 3 & 0 \\ 4 & 2 & 0 \end{bmatrix} \quad \begin{bmatrix} 0 & 1 & 3 \\ 0 & 4 & 2 \end{bmatrix}$$ ■

DEFINITION

Addition of Matrices

The **sum** of two matrices $\mathbf{A} = [a_{jk}]$ and $\mathbf{B} = [b_{jk}]$ ***of the same size*** is written $\mathbf{A} + \mathbf{B}$ and has the entries $a_{jk} + b_{jk}$ obtained by adding the corresponding entries of $\mathbf{A}$ and $\mathbf{B}$. Matrices of different sizes cannot be added.

As a special case, the **sum** $\mathbf{a} + \mathbf{b}$ of two row vectors or two column vectors, which must have the same number of components, is obtained by adding the corresponding components.

EXAMPLE 4 **Addition of Matrices and Vectors**

$$\text{If} \quad \mathbf{A} = \begin{bmatrix} -4 & 6 & 3 \\ 0 & 1 & 2 \end{bmatrix} \quad \text{and} \quad \mathbf{B} = \begin{bmatrix} 5 & -1 & 0 \\ 3 & 1 & 0 \end{bmatrix}, \quad \text{then} \quad \mathbf{A} + \mathbf{B} = \begin{bmatrix} 1 & 5 & 3 \\ 3 & 2 & 2 \end{bmatrix}.$$

$\mathbf{A}$ in Example 3 and our present $\mathbf{A}$ cannot be added. If $\mathbf{a} = [5 \quad 7 \quad 2]$ and $\mathbf{b} = [-6 \quad 2 \quad 0]$, then $\mathbf{a} + \mathbf{b} = [-1 \quad 9 \quad 2]$.

An application of matrix addition was suggested in Example 2. Many others will follow. ■

DEFINITION

Scalar Multiplication (Multiplication by a Number)

The **product** of any $m \times n$ matrix $\mathbf{A} = [a_{jk}]$ and any **scalar** c (number c) is written $c\mathbf{A}$ and is the $m \times n$ matrix $c\mathbf{A} = [ca_{jk}]$ obtained by multiplying each entry of $\mathbf{A}$ by c.

Here $(-1)\mathbf{A}$ is simply written $-\mathbf{A}$ and is called the **negative** of $\mathbf{A}$. Similarly, $(-k)\mathbf{A}$ is written $-k\mathbf{A}$. Also, $\mathbf{A} + (-\mathbf{B})$ is written $\mathbf{A} - \mathbf{B}$ and is called the **difference** of $\mathbf{A}$ and $\mathbf{B}$ (which must have the same size!).

EXAMPLE 5 **Scalar Multiplication**

$$\text{If} \quad \mathbf{A} = \begin{bmatrix} 2.7 & -1.8 \\ 0 & 0.9 \\ 9.0 & -4.5 \end{bmatrix}, \quad \text{then} \quad -\mathbf{A} = \begin{bmatrix} -2.7 & 1.8 \\ 0 & -0.9 \\ -9.0 & 4.5 \end{bmatrix}, \quad \frac{10}{9}\mathbf{A} = \begin{bmatrix} 3 & -2 \\ 0 & 1 \\ 10 & -5 \end{bmatrix}, \quad 0\mathbf{A} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

If a matrix $\mathbf{B}$ shows the distances between some cities in miles, $1.609\mathbf{B}$ gives these distances in kilometers. ■

Rules for Matrix Addition and Scalar Multiplication. From the familiar laws for the addition of numbers we obtain similar laws for the addition of matrices of the same size $m \times n$, namely,

(3)

$$\begin{aligned} &\text{(a)} && \mathbf{A} + \mathbf{B} = \mathbf{B} + \mathbf{A} \\ &\text{(b)} && (\mathbf{A} + \mathbf{B}) + \mathbf{C} = \mathbf{A} + (\mathbf{B} + \mathbf{C}) \qquad \text{(written } \mathbf{A} + \mathbf{B} + \mathbf{C}\text{)} \\ &\text{(c)} && \mathbf{A} + \mathbf{0} = \mathbf{A} \\ &\text{(d)} && \mathbf{A} + (-\mathbf{A}) = \mathbf{0}. \end{aligned}$$

Here $\mathbf{0}$ denotes the **zero matrix** (of size $m \times n$), that is, the $m \times n$ matrix with all entries zero. (The last matrix in Example 5 is a zero matrix.)

Hence matrix addition is *commutative* and *associative* [by (3a) and (3b)].

Similarly, for scalar multiplication we obtain the rules

(4)

$$\begin{aligned} &\text{(a)} && c(\mathbf{A} + \mathbf{B}) = c\mathbf{A} + c\mathbf{B} \\ &\text{(b)} && (c + k)\mathbf{A} = c\mathbf{A} + k\mathbf{A} \\ &\text{(c)} && c(k\mathbf{A}) = (ck)\mathbf{A} \qquad \text{(written } ck\mathbf{A}\text{)} \\ &\text{(d)} && 1\mathbf{A} = \mathbf{A}. \end{aligned}$$

PROBLEM SET 7.1

1–8 ADDITION AND SCALAR MULTIPLICATION OF MATRICES AND VECTORS

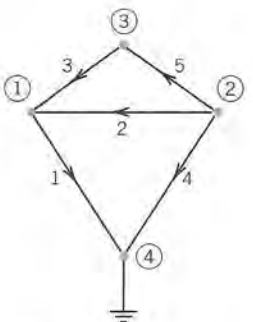
Let

$$\mathbf{A} = \begin{bmatrix} 3 & 0 & 4 \\ -1 & 2 & 2 \\ 6 & 5 & -4 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 0 & -5 & -3 \\ -5 & 2 & 4 \\ -3 & 4 & 0 \end{bmatrix},$$

$$\mathbf{C} = \begin{bmatrix} 0 & 2 \\ 2 & 4 \\ 1 & 3 \end{bmatrix}, \quad \mathbf{D} = \begin{bmatrix} 6 & 1 \\ -4 & 7 \\ -8 & 3 \end{bmatrix},$$

$$\mathbf{u} = \begin{bmatrix} 2 \\ 0 \\ -1 \end{bmatrix}, \quad \mathbf{v} = \begin{bmatrix} -4.5 \\ 0.8 \\ 1.2 \end{bmatrix}.$$

Find the following expressions or give reasons why they are undefined.



1. $\mathbf{C} + \mathbf{D}$, $\mathbf{D} + \mathbf{C}$, $6(\mathbf{D} - \mathbf{C})$, $6\mathbf{C} - 6\mathbf{D}$
2. $4\mathbf{C}$, $2\mathbf{D}$, $4\mathbf{C} + 2\mathbf{D}$, $8\mathbf{C} - 0\mathbf{D}$
3. $\mathbf{A} + \mathbf{C} - \mathbf{D}$, $\mathbf{C} - \mathbf{D}$, $\mathbf{D} - \mathbf{C}$, $\mathbf{B} + 2\mathbf{C} + 4\mathbf{D}$
4. $2(\mathbf{A} + \mathbf{B})$, $2\mathbf{A} + 2\mathbf{B}$, $5\mathbf{A} - \frac{1}{2}\mathbf{B}$, $\mathbf{A} + \mathbf{B} + \mathbf{C}$
5. $3\mathbf{C} - 8\mathbf{D}$, $4(3\mathbf{A})$, $(4 \cdot 3)\mathbf{A}$, $\mathbf{B} - \frac{1}{10}\mathbf{A}$
6. $5\mathbf{A} - 3\mathbf{C}$, $\mathbf{A} - \mathbf{B} + \mathbf{D}$, $4(\mathbf{B} - 6\mathbf{A})$, $4\mathbf{B} - 24\mathbf{A}$
7. $33\mathbf{u}$, $4\mathbf{v} + 9\mathbf{u}$, $4(\mathbf{v} + 2.25\mathbf{u})$, $\mathbf{u} - \mathbf{v}$
8. $\mathbf{A} + \mathbf{u}$, $12\mathbf{u} + 10\mathbf{v}$, $0(\mathbf{B} - \mathbf{v})$, $0\mathbf{B} + \mathbf{u}$

9. **(Linear system)** Write down a linear system (as in Example 1) whose augmented matrix is the matrix **B** in this problem set.
10. **(Scalar multiplication)** The matrix **A** in Example 2 shows the numbers of items sold. Find the matrix showing the number of units sold if a unit consists of (a) 5 items, (b) 10 items?
11. **(Double subscript notation)** Write the entries of **A** in Example 2 in the general notation shown in (2).
12. **(Sizes, diagonal)** What sizes do **A**, **B**, **C**, **D**, **u**, **v** in this problem set have? What are the main diagonals of **A** and **B**, and what about **C**?
13. **(Equality)** Give reasons why the five matrices in Example 3 are different.
14. **(Addition of vectors)** Can you add (a) row vectors whose numbers of components are different, (b) a row and a column vector with the same number of components, (c) a vector and a scalar?
15. **(General rules)** Prove (3) and (4) for general 3×2 matrices and scalars c and k.
16. **TEAM PROJECT. Matrices in Modeling Networks.** Matrices have various applications, as we shall see, in a form that these problems can be efficiently handled on the computer. For instance, they can be used to characterize connections in electrical networks, in nets of roads, in production processes, etc., as follows.

(a) Nodal incidence matrix. The network in Fig. 152 consists of 5 *branches* or *edges* (connections, numbered $1, 2, \cdots, 5$) and 4 *nodes* (points where two or more branches come together), with one node being grounded. We number the nodes and branches and give each branch a direction shown by an arrow. This we do arbitrarily. The network can now be described by a *"nodal incidence matrix"* $\mathbf{A} = [a_{jk}]$, where

$$a_{jk} = \begin{cases} +1 \text{ if branch } k \text{ leaves node } (j) \\ -1 \text{ if branch } k \text{ enters node } (j) \\ 0 \text{ if branch } k \text{ does not touch } (j). \end{cases}$$

Show that for the network in Fig. 152 the matrix **A** has the given form

Branch	1	2	3	4	5
Node ①	1	−1	−1	0	0
Node ②	0	1	0	1	1
Node ③	0	0	1	0	−1
Node ④	−1	0	0	−1	0

Fig. 152. Network and nodal incidence matrix in Team Project 16(a)

(b) Find the nodal incidence matrices of the networks in Fig. 153.

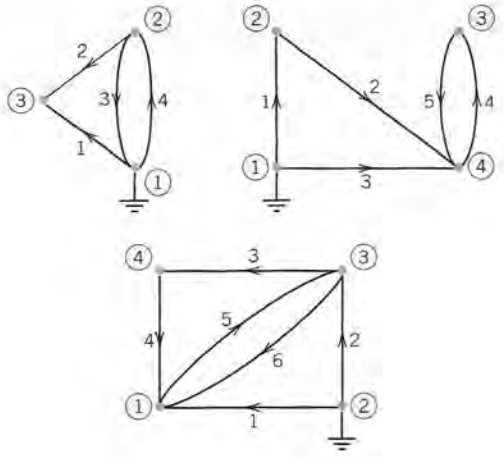


Fig. 153. Networks in Team Project 16(b)

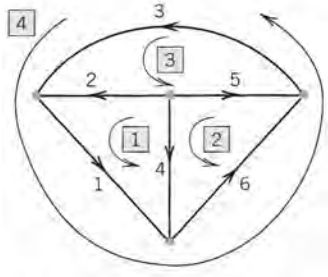
(c) Graph the three networks corresponding to the nodal incidence matrices



$$\begin{bmatrix} 1 & -1 & 1 & -1 \\ 0 & 0 & -1 & 1 \\ -1 & 1 & 0 & 0 \end{bmatrix}, \quad \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 1 \\ -1 & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix},$$

$$\begin{bmatrix} 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & -1 & 1 \\ -1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & -1 & -1 & 0 & -1 \end{bmatrix}.$$

(d) Mesh incidence matrix. A network can also be characterized by the *mesh incidence matrix* $\mathbf{M} = [m_{jk}]$, where

$$m_{jk} = \begin{cases} +1 \text{ if branch } k \text{ is in mesh } \boxed{j} \\ \text{and has the same orientation} \\ -1 \text{ if branch } k \text{ is in mesh } \boxed{j} \\ \text{and has the opposite orientation} \\ 0 \text{ if branch } k \text{ is not in mesh } \boxed{j} \end{cases}$$

and a mesh is a loop with no branch in its interior (or in its exterior). Here, the meshes are numbered and directed (oriented) in an arbitrary fashion. Show that in Fig. 154 the matrix $\mathbf{M}$ corresponds to the given figure, where Row 1 corresponds to mesh 1, etc.

$$\mathbf{M} = \begin{bmatrix} 1 & 1 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 1 & -1 & 1 \\ 0 & -1 & 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 & 0 & 1 \end{bmatrix}$$

Fig. 154. Network and matrix $\mathbf{M}$ in Team Project 16(d)

(e) Number the nodes in Fig. 154 from left to right 1, 2, 3 and the low node by 4. Find the corresponding nodal incidence matrix.

7.2 Matrix Multiplication

Matrix multiplication means multiplication of matrices by matrices. This is the last algebraic operation to be defined (except for *transposition,* which is of lesser importance). Now matrices are *added* by *adding* corresponding entries. In *multiplication,* do we *multiply* corresponding entries? The answer is no. Why not? Such an operation would not be of much use in applications. The standard definition of multiplication looks artificial, but will be fully motivated later in this section by the use of matrices in "linear transformations," by which this multiplication is suggested.

DEFINITION

Multiplication of a Matrix by a Matrix

The **product** $\mathbf{C} = \mathbf{AB}$ (in this order) of an $m \times n$ matrix $\mathbf{A} = [a_{jk}]$ times an $r \times p$ matrix $\mathbf{B} = [b_{jk}]$ is defined if and only if $r = n$ and is then the $m \times p$ matrix $\mathbf{C} = [c_{jk}]$ with entries

$$(1) \qquad c_{jk} = \sum_{l=1}^{n} a_{jl} b_{lk} = a_{j1} b_{1k} + a_{j2} b_{2k} + \cdots + a_{jn} b_{nk} \qquad \begin{matrix} j = 1, \cdots, m \\ k = 1, \cdots, p. \end{matrix}$$

The condition $r = n$ means that the second factor, **B,** must have as many rows as the first factor has columns, namely n. As a diagram of sizes (denoted as shown):

$$\begin{matrix} \mathbf{A} & \mathbf{B} & = & \mathbf{C} \\ [m \times n] & [n \times r] & = & [m \times r]. \end{matrix}$$

c_{jk} in (1) is obtained by multiplying each entry in the jth row of **A** by the corresponding entry in the kth column of **B** and then adding these n products. For instance, $c_{21} = a_{21}b_{11} + a_{22}b_{21} + \cdots + a_{2n}b_{n1}$, and so on. One calls this briefly a ***"multiplication of rows into columns."*** See the illustration in Fig. 155, where $n = 3$.

$$m = 4 \left\{ \overbrace{\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \\ a_{41} & a_{42} & a_{43} \end{bmatrix}}^{n=3} \overbrace{\begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \\ b_{31} & b_{32} \end{bmatrix}}^{p=2} = \overbrace{\begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \\ c_{31} & c_{32} \\ c_{41} & c_{42} \end{bmatrix}}^{p=2} \right\} m = 4$$

Fig. 155. Notations in a product $\mathbf{AB} = \mathbf{C}$

EXAMPLE 1 **Matrix Multiplication**

$$\mathbf{AB} = \begin{bmatrix} 3 & 5 & -1 \\ 4 & 0 & 2 \\ -6 & -3 & 2 \end{bmatrix} \begin{bmatrix} 2 & -2 & 3 & 1 \\ 5 & 0 & 7 & 8 \\ 9 & -4 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 22 & -2 & 43 & 42 \\ 26 & -16 & 14 & 6 \\ -9 & 4 & -37 & -28 \end{bmatrix}$$

Here $c_{11} = 3 \cdot 2 + 5 \cdot 5 + (-1) \cdot 9 = 22$, and so on. The entry in the box is $c_{23} = 4 \cdot 3 + 0 \cdot 7 + 2 \cdot 1 = 14$. The product **BA** is not defined. ■

EXAMPLE 2 **Multiplication of a Matrix and a Vector**

$$\begin{bmatrix} 4 & 2 \\ 1 & 8 \end{bmatrix} \begin{bmatrix} 3 \\ 5 \end{bmatrix} = \begin{bmatrix} 4 \cdot 3 + 2 \cdot 5 \\ 1 \cdot 3 + 8 \cdot 5 \end{bmatrix} = \begin{bmatrix} 22 \\ 43 \end{bmatrix} \quad \text{whereas} \quad \begin{bmatrix} 3 \\ 5 \end{bmatrix} \begin{bmatrix} 4 & 2 \\ 1 & 8 \end{bmatrix} \quad \text{is undefined.} \ ■$$

EXAMPLE 3 **Products of Row and Column Vectors**

$$\begin{bmatrix} 3 & 6 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \\ 4 \end{bmatrix} = [19], \qquad \begin{bmatrix} 1 \\ 2 \\ 4 \end{bmatrix} \begin{bmatrix} 3 & 6 & 1 \end{bmatrix} = \begin{bmatrix} 3 & 6 & 1 \\ 6 & 12 & 2 \\ 12 & 24 & 4 \end{bmatrix}. \ ■$$

EXAMPLE 4 CAUTION! Matrix Multiplication Is Not Commutative, $AB \neq BA$ in General

This is illustrated by Examples 1 and 2, where one of the two products is not even defined, and by Example 3, where the two products have different sizes. But it also holds for square matrices. For instance,

$$\begin{bmatrix} 1 & 1 \\ 100 & 100 \end{bmatrix}\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \quad \text{but} \quad \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix}\begin{bmatrix} 1 & 1 \\ 100 & 100 \end{bmatrix} = \begin{bmatrix} 99 & 99 \\ -99 & -99 \end{bmatrix}.$$

It is interesting that this also shows that $\mathbf{AB} = \mathbf{0}$ does *not* necessarily imply $\mathbf{BA} = \mathbf{0}$ or $\mathbf{A} = \mathbf{0}$ or $\mathbf{B} = \mathbf{0}$. We shall discuss this further in Sec. 7.8, along with reasons when this happens. ■

Our examples show that the ***order of factors*** in matrix products ***must always be observed very carefully.*** Otherwise matrix multiplication satisfies rules similar to those for numbers, namely.

(2)

$$\begin{aligned} &\text{(a)} \quad (k\mathbf{A})\mathbf{B} = k(\mathbf{AB}) = \mathbf{A}(k\mathbf{B}) \quad \textit{written } k\mathbf{AB} \textit{ or } \mathbf{A}k\mathbf{B} \\ &\text{(b)} \quad \mathbf{A}(\mathbf{BC}) = (\mathbf{AB})\mathbf{C} \quad \textit{written } \mathbf{ABC} \\ &\text{(c)} \quad (\mathbf{A} + \mathbf{B})\mathbf{C} = \mathbf{AC} + \mathbf{BC} \\ &\text{(d)} \quad \mathbf{C}(\mathbf{A} + \mathbf{B}) = \mathbf{CA} + \mathbf{CB} \end{aligned}$$

provided **A, B,** and **C** are such that the expressions on the left are defined; here, k is any scalar. (2b) is called the **associative law.** (2c) and (2d) are called the **distributive laws.**

Since matrix multiplication is a multiplication of rows into columns, we can write the defining formula (1) more compactly as

(3)
$$c_{jk} = \mathbf{a}_j\mathbf{b}_k, \qquad j = 1, \cdots, m; \quad k = 1, \cdots, p,$$

where $\mathbf{a}_j$ is the jth row vector of **A** and $\mathbf{b}_k$ is the kth column vector of **B,** so that in agreement with (1),

$$\mathbf{a}_j\mathbf{b}_k = [a_{j1} \quad a_{j2} \quad \cdots \quad a_{jn}]\begin{bmatrix} b_{1k} \\ \vdots \\ b_{nk} \end{bmatrix} = a_{j1}b_{1k} + a_{j2}b_{2k} + \cdots + a_{jn}b_{nk}.$$

EXAMPLE 5 Product in Terms of Row and Column Vectors

If $\mathbf{A} = [a_{jk}]$ is of size 3×3 and $\mathbf{B} = [b_{jk}]$ is of size 3×4, then

(4)
$$\mathbf{AB} = \begin{bmatrix} \mathbf{a}_1\mathbf{b}_1 & \mathbf{a}_1\mathbf{b}_2 & \mathbf{a}_1\mathbf{b}_3 & \mathbf{a}_1\mathbf{b}_4 \\ \mathbf{a}_2\mathbf{b}_1 & \mathbf{a}_2\mathbf{b}_2 & \mathbf{a}_2\mathbf{b}_3 & \mathbf{a}_2\mathbf{b}_4 \\ \mathbf{a}_3\mathbf{b}_1 & \mathbf{a}_3\mathbf{b}_2 & \mathbf{a}_3\mathbf{b}_3 & \mathbf{a}_3\mathbf{b}_4 \end{bmatrix}.$$

Taking $\mathbf{a}_1 = [3 \quad 5 \quad -1]$, $\mathbf{a}_2 = [4 \quad 0 \quad 2]$, etc., verify (4) for the product in Example 1. ■

Parallel processing of products on the computer is facilitated by a variant of (3) for computing $\mathbf{C} = \mathbf{AB}$, which is used by standard algorithms (such as in Lapack). In this method, **A** is used as given, **B** is taken in terms of its column vectors, and the product is computed columnwise; thus,

(5)
$$\mathbf{AB} = \mathbf{A}[\mathbf{b}_1 \quad \mathbf{b}_2 \quad \cdots \quad \mathbf{b}_p] = [\mathbf{Ab}_1 \quad \mathbf{Ab}_2 \quad \cdots \quad \mathbf{Ab}_p].$$

Columns of **B** are then assigned to different processors (individually or several to each processor), which simultaneously compute the columns of the product matrix $\mathbf{Ab}_1$, $\mathbf{Ab}_2$, etc.

EXAMPLE 6 Computing Products Columnwise by (5)

To obtain

$$\mathbf{AB} = \begin{bmatrix} 4 & 1 \\ -5 & 2 \end{bmatrix} \begin{bmatrix} 3 & 0 & 7 \\ -1 & 4 & 6 \end{bmatrix} = \begin{bmatrix} 11 & 4 & 34 \\ -17 & 8 & -23 \end{bmatrix}$$

from (5), calculate the columns

$$\begin{bmatrix} 4 & 1 \\ -5 & 2 \end{bmatrix} \begin{bmatrix} 3 \\ -1 \end{bmatrix} = \begin{bmatrix} 11 \\ -17 \end{bmatrix}, \quad \begin{bmatrix} 4 & 1 \\ -5 & 2 \end{bmatrix} \begin{bmatrix} 0 \\ 4 \end{bmatrix} = \begin{bmatrix} 4 \\ 8 \end{bmatrix}, \quad \begin{bmatrix} 4 & 1 \\ -5 & 2 \end{bmatrix} \begin{bmatrix} 7 \\ 6 \end{bmatrix} = \begin{bmatrix} 34 \\ -23 \end{bmatrix}$$

of **AB** and then write them as a single matrix, as shown in the first formula on the right. ■

Motivation of Multiplication by Linear Transformations

Let us now motivate the "unnatural" matrix multiplication by its use in **linear transformations.** For $n = 2$ variables these transformations are of the form

$$\begin{aligned} y_1 &= a_{11}x_1 + a_{12}x_2 \\ y_2 &= a_{21}x_1 + a_{22}x_2 \end{aligned} \tag{6*}$$

and suffice to explain the idea. (For general n they will be discussed in Sec. 7.9.) For instance, (6*) may relate an x_1x_2-coordinate system to a y_1y_2-coordinate system in the plane. In vectorial form we can write (6*) as

$$\mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \mathbf{Ax} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} a_{11}x_1 + a_{12}x_2 \\ a_{21}x_1 + a_{22}x_2 \end{bmatrix}. \tag{6}$$

Now suppose further that the x_1x_2-system is related to a w_1w_2-system by another linear transformation, say,

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \mathbf{Bw} = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} b_{11}w_1 + b_{12}w_2 \\ b_{21}w_1 + b_{22}w_2 \end{bmatrix}. \tag{7}$$

Then the y_1y_2-system is related to the w_1w_2-system indirectly via the x_1x_2-system, and we wish to express this relation directly. Substitution will show that this direct relation is a linear transformation, too, say,

$$\mathbf{y} = \mathbf{Cw} = \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} c_{11}w_1 + c_{12}w_2 \\ c_{21}w_1 + c_{22}w_2 \end{bmatrix}. \tag{8}$$

Indeed, substituting (7) into (6), we obtain

$$\begin{aligned} y_1 &= a_{11}(b_{11}w_1 + b_{12}w_2) + a_{12}(b_{21}w_1 + b_{22}w_2) \\ &= (a_{11}b_{11} + a_{12}b_{21})w_1 + (a_{11}b_{12} + a_{12}b_{22})w_2 \\ y_2 &= a_{21}(b_{11}w_1 + b_{12}w_2) + a_{22}(b_{21}w_1 + b_{22}w_2) \\ &= (a_{21}b_{11} + a_{22}b_{21})w_1 + (a_{21}b_{12} + a_{22}b_{22})w_2. \end{aligned}$$

Comparing this with (8), we see that

$$c_{11} = a_{11}b_{11} + a_{12}b_{21} \qquad c_{12} = a_{11}b_{12} + a_{12}b_{22}$$
$$c_{21} = a_{21}b_{11} + a_{22}b_{21} \qquad c_{22} = a_{21}b_{12} + a_{22}b_{22}.$$

This proves that $\mathbf{C} = \mathbf{AB}$ with the product defined as in (1). For larger matrix sizes the idea and result are exactly the same. Only the number of variables changes. We then have m variables y and n variables x and p variables w. The matrices **A, B,** and $\mathbf{C} = \mathbf{AB}$ then have sizes $m \times n$, $n \times p$, and $m \times p$, respectively. And the requirement that **C** be the product **AB** leads to formula (1) in its general form. *This motivates matrix multiplication completely.*

Transposition

Transposition provides a transition from row vectors to column vectors and conversely. More generally, it gives us a choice to work either with a matrix or with its transpose, whatever will be more practical in a specific situation.

DEFINITION

Transposition of Matrices and Vectors

The transpose of an $m \times n$ matrix $\mathbf{A} = [a_{jk}]$ is the $n \times m$ matrix $\mathbf{A}^T$ (read *A transpose*) that has the first *row* of **A** as its first *column*, the second *row* of **A** as its second *column*, and so on. Thus the transpose of **A** in (2) is $\mathbf{A}^T = [a_{kj}]$, written out

$$\mathbf{A}^T = [a_{kj}] = \begin{bmatrix} a_{11} & a_{21} & \cdots & a_{m1} \\ a_{12} & a_{22} & \cdots & a_{m2} \\ \cdot & \cdot & \cdots & \cdot \\ a_{1n} & a_{2n} & \cdots & a_{mn} \end{bmatrix}. \tag{9}$$

As a special case, transposition converts row vectors to column vectors and conversely.

EXAMPLE 7 **Transposition of Matrices and Vectors**

$$\text{If} \quad \mathbf{A} = \begin{bmatrix} 5 & -8 & 1 \\ 4 & 0 & 0 \end{bmatrix}, \quad \text{then} \quad \mathbf{A}^T = \begin{bmatrix} 5 & 4 \\ -8 & 0 \\ 1 & 0 \end{bmatrix}.$$

A little more compactly, we can write

$$\begin{bmatrix} 5 & -8 & 1 \\ 4 & 0 & 0 \end{bmatrix}^T = \begin{bmatrix} 5 & 4 \\ -8 & 0 \\ 1 & 0 \end{bmatrix}, \quad \begin{bmatrix} 3 & 0 \\ 8 & -1 \end{bmatrix}^T = \begin{bmatrix} 3 & 8 \\ 0 & -1 \end{bmatrix}$$

$$[6 \quad 2 \quad 3]^T = \begin{bmatrix} 6 \\ 2 \\ 3 \end{bmatrix}, \quad \begin{bmatrix} 6 \\ 2 \\ 3 \end{bmatrix}^T = [6 \quad 2 \quad 3].$$

Note that for a square matrix, the transpose is obtained by interchanging entries that are symmetrically positioned with respect to the main diagonal, e.g., a_{12} and a_{21}, and so on. ■

Rules for transposition are

$$\textbf{(10)} \qquad \begin{aligned} &\text{(a)} && (\mathbf{A}^T)^T = \mathbf{A} \\ &\text{(b)} && (\mathbf{A} + \mathbf{B})^T = \mathbf{A}^T + \mathbf{B}^T \\ &\text{(c)} && (c\mathbf{A})^T = c\mathbf{A}^T \\ &\text{(d)} && (\mathbf{AB})^T = \mathbf{B}^T\mathbf{A}^T. \end{aligned}$$

CAUTION! Note that in (10d) the transposed matrices are ***in reversed order.*** We leave the proofs to the student. (See Prob. 22.)

Special Matrices

Certain kinds of matrices will occur quite frequently in our work, and we now list the most important ones of them.

Symmetric and Skew-Symmetric Matrices. Transposition gives rise to two useful classes of matrices, as follows. *Symmetric matrices* and *skew-symmetric matrices* are ***square*** matrices whose transpose equals the matrix itself or minus the matrix, respectively:

$$\textbf{(11)} \qquad \underset{\text{Symmetric Matrix}}{\mathbf{A}^T = \mathbf{A}} \quad (\text{thus } a_{kj} = a_{jk}), \qquad \underset{\text{Skew-Symmetric Matrix}}{\mathbf{A}^T = -\mathbf{A}} \quad (\text{thus } a_{kj} = -a_{jk}, \text{ hence } a_{jj} = 0).$$

EXAMPLE 8 Symmetric and Skew-Symmetric Matrices

$$\mathbf{A} = \begin{bmatrix} 20 & 120 & 200 \\ 120 & 10 & 150 \\ 200 & 150 & 30 \end{bmatrix} \text{ is symmetric, and } \quad \mathbf{B} = \begin{bmatrix} 0 & 1 & -3 \\ -1 & 0 & -2 \\ 3 & 2 & 0 \end{bmatrix} \text{ is skew-symmetric.}$$

For instance, if a company has three building supply centers C_1, C_2, C_3, then $\mathbf{A}$ could show costs, say, a_{jj} for handling 1000 bags of cement on center C_j, and a_{jk} $(j \neq k)$ the cost of shipping 1000 bags from C_j to C_k. Clearly, $a_{jk} = a_{kj}$ because shipping in the opposite direction will usually cost the same.

Symmetric matrices have several general properties which make them important. This will be seen as we proceed. ■

Triangular Matrices. **Upper triangular matrices** are square matrices that can have nonzero entries only on and ***above*** the main diagonal, whereas any entry below the diagonal must be zero. Similarly, **lower triangular matrices** can have nonzero entries only on and ***below*** the main diagonal. Any entry on the main diagonal of a triangular matrix may be zero or not.

EXAMPLE 9 Upper and Lower Triangular Matrices

$$\underset{\text{Upper triangular}}{\begin{bmatrix} 1 & 3 \\ 0 & 2 \end{bmatrix}, \quad \begin{bmatrix} 1 & 4 & 2 \\ 0 & 3 & 2 \\ 0 & 0 & 6 \end{bmatrix}}, \qquad \underset{\text{Lower triangular}}{\begin{bmatrix} 2 & 0 & 0 \\ 8 & -1 & 0 \\ 7 & 6 & 8 \end{bmatrix}, \quad \begin{bmatrix} 3 & 0 & 0 & 0 \\ 9 & -3 & 0 & 0 \\ 1 & 0 & 2 & 0 \\ 1 & 9 & 3 & 6 \end{bmatrix}}. \quad ■$$

Diagonal Matrices. These are square matrices that can have nonzero entries only on the main diagonal. Any entry above or below the main diagonal must be zero.

If all the diagonal entries of a diagonal matrix **S** are equal, say, c, we call **S** a **scalar matrix** because multiplication of any square matrix **A** of the same size by **S** has the same effect as the multiplication by a scalar, that is,

$$\mathbf{AS} = \mathbf{SA} = c\mathbf{A}. \tag{12}$$

In particular, a scalar matrix whose entries on the main diagonal are all 1 is called a **unit matrix** (or **identity matrix**) and is denoted by $\mathbf{I}_n$ or simply by **I.** For **I,** formula (12) becomes

$$\mathbf{AI} = \mathbf{IA} = \mathbf{A}. \tag{13}$$

EXAMPLE 10 Diagonal Matrix D. Scalar Matrix S. Unit Matrix I

$$\mathbf{D} = \begin{bmatrix} 2 & 0 & 0 \\ 0 & -3 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad \mathbf{S} = \begin{bmatrix} c & 0 & 0 \\ 0 & c & 0 \\ 0 & 0 & c \end{bmatrix}, \quad \mathbf{I} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Applications of Matrix Multiplication

Matrix multiplication will play a crucial role in connection with linear systems of equations, beginning in the next section. For the time being we mention some other simple applications that need no lengthy explanations.

EXAMPLE 11 Computer Production. Matrix Times Matrix

Supercomp Ltd produces two computer models PC1086 and PC1186. The matrix **A** shows the cost per computer (in thousands of dollars) and **B** the production figures for the year 2005 (in multiples of 10000 units.) Find a matrix **C** that shows the shareholders the cost per quarter (in millions of dollars) for raw material, labor, and miscellaneous.

$$\mathbf{A} = \begin{array}{c} \\ \\ \\ \end{array} \begin{array}{c} \begin{array}{cc} \text{PC1086} & \text{PC1186} \end{array} \\ \begin{bmatrix} 1.2 & 1.6 \\ 0.3 & 0.4 \\ 0.5 & 0.6 \end{bmatrix} \end{array} \begin{array}{l} \\ \text{Raw Components} \\ \text{Labor} \\ \text{Miscellaneous} \end{array}$$

$$\mathbf{B} = \begin{array}{c} \\ \end{array} \begin{array}{c} \begin{array}{cccc} \multicolumn{4}{c}{\text{Quarter}} \\ 1 & 2 & 3 & 4 \end{array} \\ \begin{bmatrix} 3 & 8 & 6 & 9 \\ 6 & 2 & 4 & 3 \end{bmatrix} \end{array} \begin{array}{l} \\ \text{PC1086} \\ \text{PC1186} \end{array}$$

Solution.

$$\mathbf{C} = \mathbf{AB} = \begin{array}{c} \\ \\ \\ \end{array} \begin{array}{c} \begin{array}{cccc} \multicolumn{4}{c}{\text{Quarter}} \\ 1 & 2 & 3 & 4 \end{array} \\ \begin{bmatrix} 13.2 & 12.8 & 13.6 & 15.6 \\ 3.3 & 3.2 & 3.4 & 3.9 \\ 5.1 & 5.2 & 5.4 & 6.3 \end{bmatrix} \end{array} \begin{array}{l} \\ \text{Raw Components} \\ \text{Labor} \\ \text{Miscellaneous} \end{array}$$

Since cost is given in multiples of \$1000 and production in multiples of 10 000 units, the entries of **C** are multiples of \$10 millions: thus $c_{11} = 13.2$ means \$132 million, etc.

EXAMPLE 12 Weight Watching. Matrix Times Vector

Suppose that in a weight-watching program, a person of 185 lb burns 350 cal/hr in walking (3 mph), 500 in bycycling (13 mph) and 950 in jogging (5.5 mph). Bill, weighing 185 lb, plans to exercise according to the matrix shown. Verify the calculations (W = Walking, B = Bicycling, J = Jogging).

$$\begin{array}{c} \\ \text{MON} \\ \text{WED} \\ \text{FRI} \\ \text{SAT} \end{array} \begin{array}{c} \begin{array}{ccc} \text{W} & \text{B} & \text{J} \end{array} \\ \begin{bmatrix} 1.0 & 0 & 0.5 \\ 1.0 & 1.0 & 0.5 \\ 1.5 & 0 & 0.5 \\ 2.0 & 1.5 & 1.0 \end{bmatrix} \end{array} \begin{bmatrix} 350 \\ 500 \\ 950 \end{bmatrix} = \begin{bmatrix} 825 \\ 1325 \\ 1000 \\ 2400 \end{bmatrix} \begin{array}{c} \\ \text{MON} \\ \text{WED} \\ \text{FRI} \\ \text{SAT} \end{array}$$

■

EXAMPLE 13 Markov Process. Powers of a Matrix. Stochastic Matrix

Suppose that the 2004 state of land use in a city of 60 mi^2 of built-up area is

C: Commercially Used 25% I: Industrially Used 20% R: Residentially Used 55%.

Find the states in 2009, 2014, and 2019, assuming that the transition probabilities for 5-year intervals are given by the matrix **A** and remain practically the same over the time considered.

$$\mathbf{A} = \begin{array}{c} \begin{array}{ccc} \text{From C} & \text{From I} & \text{From R} \end{array} \\ \begin{bmatrix} 0.7 & 0.1 & 0 \\ 0.2 & 0.9 & 0.2 \\ 0.1 & 0 & 0.8 \end{bmatrix} \end{array} \begin{array}{c} \\ \text{To C} \\ \text{To I} \\ \text{To R} \end{array}$$

A is a **stochastic matrix,** that is, a square matrix with all entries nonnegative and all column sums equal to 1. Our example concerns a **Markov process**[1], that is, a process for which the probability of entering a certain state depends only on the last state occupied (and the matrix **A**), not on any earlier state.

Solution. From the matrix **A** and the 2004 state we can compute the 2009 state,

$$\begin{array}{c} \text{C} \\ \text{I} \\ \text{R} \end{array} \begin{bmatrix} 0.7 \cdot 25 + 0.1 \cdot 20 + 0 \cdot 55 \\ 0.2 \cdot 25 + 0.9 \cdot 20 + 0.2 \cdot 55 \\ 0.1 \cdot 25 + 0 \cdot 20 + 0.8 \cdot 55 \end{bmatrix} = \begin{bmatrix} 0.7 & 0.1 & 0 \\ 0.2 & 0.9 & 0.2 \\ 0.1 & 0 & 0.8 \end{bmatrix} \begin{bmatrix} 25 \\ 20 \\ 55 \end{bmatrix} = \begin{bmatrix} 19.5 \\ 34.0 \\ 46.5 \end{bmatrix}.$$

To explain: The 2009 figure for C equals 25% times the probability 0.7 that C goes into C, plus 20% times the probability 0.1 that I goes into C, plus 55% times the probability 0 that R goes into C. Together,

$$25 \cdot 0.7 + 20 \cdot 0.1 + 55 \cdot 0 = 19.5 \text{ [\%]}. \qquad \text{Also} \qquad 25 \cdot 0.2 + 20 \cdot 0.9 + 55 \cdot 0.2 = 34 \text{ [\%]}.$$

Similarly, the new R is 46.5%. We see that the 2009 state vector is the column vector

$$\mathbf{y} = [19.5 \quad 34.0 \quad 46.5]^T = \mathbf{Ax} = \mathbf{A}\,[25 \quad 20 \quad 55]^T$$

where the column vector $\mathbf{x} = [25 \quad 20 \quad 55]^T$ is the given 2004 state vector. Note that the sum of the entries of **y** is 100 [%]. Similarly, you may verify that for 2014 and 2019 we get the state vectors

$$\mathbf{z} = \mathbf{Ay} = \mathbf{A}(\mathbf{Ax}) = \mathbf{A}^2\mathbf{x} = [17.05 \quad 43.80 \quad 39.15]^T$$

$$\mathbf{u} = \mathbf{Az} = \mathbf{A}^2\mathbf{y} = \mathbf{A}^3\mathbf{x} = [16.315 \quad 50.660 \quad 33.025]^T.$$

---

[1]ANDREI ANDREJEVITCH MARKOV (1856–1922), Russian mathematician, known for his work in probability theory.

Answer. In 2009 the commercial area will be 19.5% (11.7 mi^2), the industrial 34% (20.4 mi^2) and the residential 46.5% (27.9 mi^2). For 2014 the corresponding figures are 17.05%, 43.80%, 39.15%. For 2019 they are 16.315%, 50.660%, 33.025%. (In Sec. 8.2 we shall see what happens in the limit, assuming that those probabilities remain the same. In the meantime, can you experiment or guess?) ■

PROBLEM SET 7.2

1–14 MULTIPLICATION, ADDITION, AND TRANSPOSITION OF MATRICES AND VECTORS

Let

$$\mathbf{A} = \begin{bmatrix} 6 & -2 & -2 \\ 10 & -3 & 1 \\ -10 & 5 & 1 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 9 & 4 & -4 \\ 4 & 7 & 0 \\ -4 & 0 & 11 \end{bmatrix},$$

$$\mathbf{C} = \begin{bmatrix} 3 & 1 \\ 0 & -2 \\ 4 & 0 \end{bmatrix}, \quad \mathbf{a} = \begin{bmatrix} 5 \\ 1 \\ 2 \end{bmatrix}, \quad \mathbf{b} = [3 \quad 0 \quad 8].$$

Calculate the following products and sums or give reasons why they are not defined. (Show all intermediate results.)

1. $\mathbf{Aa}$, $\mathbf{Ab}$, $\mathbf{Ab}^T$, $\mathbf{AB}$
2. $\mathbf{Ab}^T + \mathbf{Bb}^T$, $(\mathbf{A} + \mathbf{B})\mathbf{b}^T$, $\mathbf{bA}$, $\mathbf{B} - \mathbf{B}^T$
3. $\mathbf{AB}$, $\mathbf{BA}$, $\mathbf{AA}^T$, $\mathbf{A}^T\mathbf{A}$
4. $\mathbf{A}^2$, $\mathbf{B}^2$, $(\mathbf{A}^T)^2$, $(\mathbf{A}^2)^T$
5. $\mathbf{a}^T\mathbf{A}$, $\mathbf{bA}$, $5\mathbf{B}(3\mathbf{a} + 2\mathbf{b}^T)$, $15\mathbf{Ba} + 10\mathbf{Bb}^T$
6. $\mathbf{A}^T\mathbf{b}$, $\mathbf{b}^T\mathbf{B}$, $(3\mathbf{A} - 2\mathbf{B})^T\mathbf{a}$, $\mathbf{a}^T(3\mathbf{A} - 2\mathbf{B})$
7. $\mathbf{ab}$, $\mathbf{ba}$, $(\mathbf{ab})\mathbf{A}$, $\mathbf{a}(\mathbf{bA})$
8. $\mathbf{ab} - \mathbf{ba}$, $-(4\mathbf{b})(7\mathbf{a})$, $-28\mathbf{ba}$, $5\mathbf{abB}$
9. $(\mathbf{A} + \mathbf{B})^2$, $\mathbf{A}^2 + \mathbf{AB} + \mathbf{BA} + \mathbf{B}^2$, $\mathbf{A}^2 + 2\mathbf{AB} + \mathbf{B}^2$
10. $(\mathbf{A} + \mathbf{B})(\mathbf{A} - \mathbf{B})$, $\mathbf{A}^2 - \mathbf{AB} + \mathbf{BA} - \mathbf{B}^2$, $\mathbf{A}^2 - \mathbf{B}^2$
11. $\mathbf{A}^2\mathbf{B}$, $\mathbf{A}^3$, $(\mathbf{AB})^2$, $\mathbf{A}^2\mathbf{B}^2$
12. $\mathbf{B}^3$, $\mathbf{BC}$, $(\mathbf{BC})^2$, $(\mathbf{BC})(\mathbf{BC})^T$
13. $\mathbf{a}^T\mathbf{Aa}$, $\mathbf{a}^T(\mathbf{A} + \mathbf{A}^T)\mathbf{a}$, $\mathbf{bBb}^T$, $\mathbf{b}(\mathbf{B} - \mathbf{B}^T)\mathbf{b}^T$
14. $\mathbf{a}^T\mathbf{CC}^T\mathbf{a}$, $\mathbf{a}^T\mathbf{C}^2\mathbf{a}$, $\mathbf{bC}^T\mathbf{Cb}^T$, $\mathbf{bCC}^T\mathbf{b}^T$

15. **(General rules)** Prove (2) for 2×2 matrices $\mathbf{A} = [a_{jk}]$, $\mathbf{B} = [b_{jk}]$, $\mathbf{C} = [c_{jk}]$ and a general scalar.
16. **(Commutativity)** Find all 2×2 matrices $\mathbf{A} = [a_{jk}]$ that commute with $\mathbf{B} = [b_{jk}]$, where $b_{jk} = j + k$.
17. **(Product)** Write $\mathbf{AB}$ in Probs. 1–14 in terms of row and column vectors.
18. **(Product)** Calculate $\mathbf{AB}$ in Prob. 1 columnwise. (See Example 6.)
19. **TEAM PROJECT. Symmetric and Skew-Symmetric Matrices.** These matrices occur quite frequently in applications, so it is worthwhile to study some of their most important properties.

    (a) Verify the claims in (11) that $a_{kj} = a_{jk}$ for a symmetric matrix, and $a_{kj} = -a_{jk}$ for a skew-symmetric matrix. Give examples.

    (b) Show that for every square matrix $\mathbf{C}$ the matrix $\mathbf{C} + \mathbf{C}^T$ is symmetric and $\mathbf{C} - \mathbf{C}^T$ is skew-symmetric. Write $\mathbf{C}$ in the form $\mathbf{C} = \mathbf{S} + \mathbf{T}$, where $\mathbf{S}$ is symmetric and $\mathbf{T}$ is skew-symmetric and find $\mathbf{S}$ and $\mathbf{T}$ in terms of $\mathbf{C}$. Represent $\mathbf{A}$ and $\mathbf{B}$ in Probs. 1–14 in this form.

    (c) A **linear combination** of matrices $\mathbf{A}, \mathbf{B}, \mathbf{C}, \cdots, \mathbf{M}$ of the same size is an expression of the form

    $$(14) \qquad a\mathbf{A} + b\mathbf{B} + c\mathbf{C} + \cdots + m\mathbf{M},$$

    where $a, \cdots, m$ are any scalars. Show that if these matrices are square and symmetric, so is (14); similarly, if they are skew-symmetric, so is (14).

    (d) Show that $\mathbf{AB}$ with symmetric $\mathbf{A}$ and $\mathbf{B}$ is symmetric if and only if $\mathbf{A}$ and $\mathbf{B}$ **commute,** that is, $\mathbf{AB} = \mathbf{BA}$.

    (e) Under what condition is the product of skew-symmetric matrices skew-symmetric?
20. **(Idempotent and nilpotent matrices)** By definition, $\mathbf{A}$ is **idempotent** if $\mathbf{A}^2 = \mathbf{A}$, and $\mathbf{B}$ is **nilpotent** if $\mathbf{B}^m = \mathbf{0}$ for some positive integer m. Give examples (different from $\mathbf{0}$ or $\mathbf{I}$). Also give examples such that $\mathbf{A}^2 = \mathbf{I}$ (the unit matrix).
21. **(Triangular matrices)** Let $\mathbf{U}_1$, $\mathbf{U}_2$ be upper triangular and $\mathbf{L}_1$, $\mathbf{L}_2$ lower triangular. Which of the following are triangular? Give examples. How can you save half of your work by transposition?

    $$\mathbf{U}_1 + \mathbf{U}_2, \mathbf{U}_1\mathbf{U}_2, \mathbf{U}_1^2, \mathbf{U}_1 + \mathbf{L}_1, \mathbf{U}_1\mathbf{L}_1, \mathbf{L}_1 + \mathbf{L}_2,$$

    $$\mathbf{L}_1\mathbf{L}_2, \mathbf{L}_1^2$$
22. **(Transposition of products)** Prove (10a)–(10c). Illustrate the basic formula (10d) by examples of your own. Then prove it.

APPLICATIONS

23. **(Markov process)** If the transition matrix $\mathbf{A}$ has the entries $a_{11} = 0.5$, $a_{12} = 0.3$, $a_{21} = 0.5$, $a_{22} = 0.7$ and the initial state is $[1 \quad 1]^T$, what will the next three states be?
24. **(Concert subscription)** In a community of 300 000 adults, subscribers to a concert series tend to renew their subscription with probability 90% and persons presently not subscribing will subscribe for the next season with probability 0.1%. If the present number of subscribers is 2000, can one predict an increase, decrease, or no change over each of the next three seasons?

25. **CAS Experiment. Markov Process.** Write a program for a Markov process. Use it to calculate further steps in Example 13 of the text. Experiment with other stochastic 3×3 matrices, also using different starting values.

26. **(Production)** In a production process, let N mean "no trouble" and T "trouble." Let the transition probabilities from one day to the next be 0.9 for $N \to N$, hence 0.1 for $N \to T$, and 0.5 for $T \to N$, hence 0.5 for $T \to T$. If today there is no trouble, what is the probability of N two days after today? Three days after today?

27. **(Profit vector)** Two factory outlets F_1 and F_2 in New York and Los Angeles sell sofas (S), chairs (C), and tables (T) with a profit of \$110, \$45, and \$80, respectively. Let the sales in a certain week be given by the matrix

$$\begin{matrix} & S & C & T & \\ \mathbf{A} = & \begin{bmatrix} 600 & 400 & 100 \\ 300 & 820 & 205 \end{bmatrix} & \begin{matrix} F_1 \\ F_2 \end{matrix} \end{matrix}$$

Introduce a "profit vector" $\mathbf{p}$ such that the components of $\mathbf{v} = \mathbf{Ap}$ give the total profits of F_1 and F_2.

28. **TEAM PROJECT. Special Linear Transformations. Rotations** have various applications. We show in this project how they can be handled by matrices.

(a) Rotation in the plane. Show that the linear transformation $\mathbf{y} = \mathbf{Ax}$ with matrix

$$\mathbf{A} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \quad \text{and} \quad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad \mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$$

is a counterclockwise rotation of the Cartesian x_1x_2-coordinate system in the plane about the origin, where θ is the angle of rotation.

(b) Rotation through $n\theta$. Show that in (a)

$$\mathbf{A}^n = \begin{bmatrix} \cos n\theta & -\sin n\theta \\ \sin n\theta & \cos n\theta \end{bmatrix}.$$

Is this plausible? Explain this in words.

(c) Addition formulas for cosine and sine. By geometry we should have

$$\begin{bmatrix} \cos\alpha & -\sin\alpha \\ \sin\alpha & \cos\alpha \end{bmatrix} \begin{bmatrix} \cos\beta & -\sin\beta \\ \sin\beta & \cos\beta \end{bmatrix} = \begin{bmatrix} \cos(\alpha+\beta) & -\sin(\alpha+\beta) \\ \sin(\alpha+\beta) & \cos(\alpha+\beta) \end{bmatrix}.$$

Derive from this the addition formulas (6) in App. A3.1.

(d) Computer graphics. To visualize a three-dimensional object with plane faces (e.g., a cube), we may store the position vectors of the vertices with respect to a suitable $x_1x_2x_3$-coordinate system (and a list of the connecting edges) and then obtain a two-dimensional image on a video screen by projecting the object onto a coordinate plane, for instance, onto the x_1x_2-plane by setting $x_3 = 0$. To change the appearance of the image, we can impose a linear transformation on the position vectors stored. Show that a diagonal matrix $\mathbf{D}$ with main diagonal entries 3, 1, $\frac{1}{2}$ gives from an $\mathbf{x} = [x_j]$ the new position vector $\mathbf{y} = \mathbf{Dx}$, where $y_1 = 3x_1$ (stretch in the x_1-direction by a factor 3), $y_2 = x_2$ (unchanged), $y_3 = \frac{1}{2}x_3$ (contraction in the x_3-direction). What effect would a scalar matrix have?

(e) Rotations in space. Explain $\mathbf{y} = \mathbf{Ax}$ geometrically when $\mathbf{A}$ is one of the three matrices

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & -\sin\theta \\ 0 & \sin\theta & \cos\theta \end{bmatrix},$$

$$\begin{bmatrix} \cos\varphi & 0 & -\sin\varphi \\ 0 & 1 & 0 \\ \sin\varphi & 0 & \cos\varphi \end{bmatrix}, \quad \begin{bmatrix} \cos\psi & -\sin\psi & 0 \\ \sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

What effect would these transformations have in situations such as that described in (d)?

7.3 Linear Systems of Equations. Gauss Elimination

The most important use of matrices occurs in the solution of *systems of linear equations*, briefly called **linear systems.** Such systems model various problems, for instance, in frameworks, electrical networks, traffic flow, economics, statistics, and many others. In this section we show an important solution method, the *Gauss elimination*. General properties of solutions will be discussed in the next sections.

Linear System, Coefficient Matrix, Augmented Matrix

A **linear system of m equations in n unknowns** $x_1, \cdots, x_n$ is a set of equations of the form

$$\begin{aligned} a_{11}x_1 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + \cdots + a_{2n}x_n &= b_2 \\ \cdots\cdots\cdots\cdots\cdots\cdots & \\ a_{m1}x_1 + \cdots + a_{mn}x_n &= b_m \end{aligned} \tag{1}$$

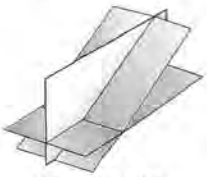
The system is called *linear* because each variable x_j appears in the first power only, just as in the equation of a straight line. $a_{11}, \cdots, a_{mn}$ are given numbers, called the **coefficients** of the system. $b_1, \cdots, b_m$ on the right are also given numbers. If all the b_j are zero, then (1) is called a **homogeneous system.** If at least one b_j is not zero, then (1) is called a **nonhomogeneous system.**

A **solution** of (1) is a set of numbers $x_1, \cdots, x_n$ that satisfies all the m equations. A **solution vector** of (1) is a vector $\mathbf{x}$ whose components form a solution of (1). If the system (1) is homogeneous, it has at least the **trivial solution** $x_1 = 0, \cdots, x_n = 0$.

Matrix Form of the Linear System (1). From the definition of matrix multiplication we see that the m equations of (1) may be written as a single vector equation

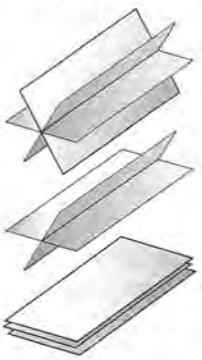
$$\mathbf{Ax} = \mathbf{b} \tag{2}$$

where the **coefficient matrix** $\mathbf{A} = [a_{jk}]$ is the $m \times n$ matrix



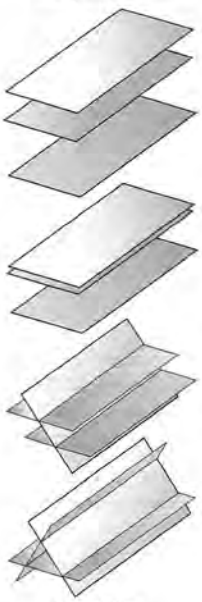
$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}, \quad \text{and} \quad \mathbf{x} = \begin{bmatrix} x_1 \\ \cdot \\ \cdot \\ \cdot \\ x_n \end{bmatrix} \quad \text{and} \quad \mathbf{b} = \begin{bmatrix} b_1 \\ \cdot \\ \cdot \\ \cdot \\ b_m \end{bmatrix}$$

are column vectors. We assume that the coefficients a_{jk} are not all zero, so that $\mathbf{A}$ is not a zero matrix. Note that $\mathbf{x}$ has n components, whereas $\mathbf{b}$ has m components. The matrix



$$\widetilde{\mathbf{A}} = \left[\begin{array}{ccc|c} a_{11} & \cdots & a_{1n} & b_1 \\ \cdot & \cdots & \cdot & \cdot \\ \cdot & \cdots & \cdot & \cdot \\ a_{m1} & \cdots & a_{mn} & b_m \end{array}\right]$$

is called the **augmented matrix** of the system (1). The dashed vertical line could be omitted (as we shall do later); it is merely a reminder that the last column of $\widetilde{\mathbf{A}}$ does not belong to $\mathbf{A}$.



The augmented matrix $\widetilde{\mathbf{A}}$ determines the system* (1) *completely because it contains all the given numbers appearing in (1).

Unique solution

Infinitely many solutions

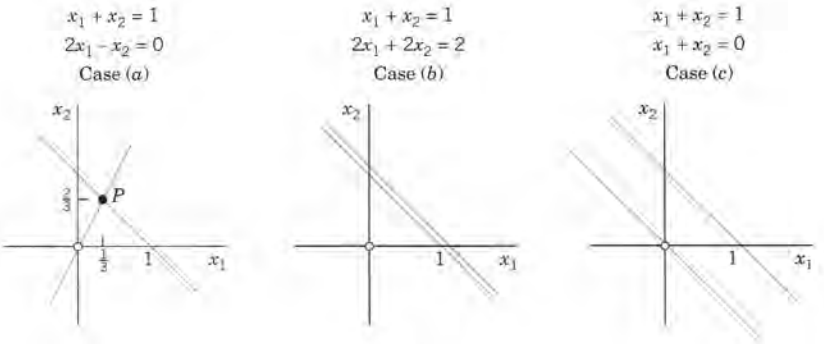
No solution

Fig. 156. Three equations in three unknowns interpreted as planes in space

EXAMPLE 1 Geometric Interpretation. Existence and Uniqueness of Solutions

If $m = n = 2$, we have two equations in two unknowns x_1, x_2

$$a_{11}x_1 + a_{12}x_2 = b_1$$
$$a_{21}x_1 + a_{22}x_2 = b_2.$$



If we interpret x_1, x_2 as coordinates in the x_1x_2-plane, then each of the two equations represents a straight line, and (x_1, x_2) is a solution if and only if the point P with coordinates x_1, x_2 lies on both lines. Hence there are three possible cases:

(a) Precisely one solution if the lines intersect.

(b) Infinitely many solutions if the lines coincide.

(c) No solution if the lines are parallel

For instance,

If the system is homogenous, Case (c) cannot happen, because then those two straight lines pass through the origin, whose coordinates 0, 0 constitute the trivial solution. If you wish, consider three equations in three unknowns as representations of three planes in space and discuss the various possible cases in a similar fashion. See Fig. 156. ■

Our simple example illustrates that a system (1) may perhaps have no solution. This poses the following problem. Does a given system (1) have a solution? Under what conditions does it have precisely one solution? If it has more than one solution, how can we characterize the set of all solutions? How can we actually obtain the solutions? Perhaps the last question is the most immediate one from a practical viewpoint. We shall answer it first and discuss the other questions in Sec. 7.5.

Gauss Elimination and Back Substitution

This is a standard elimination method for solving linear systems that proceeds systematically irrespective of particular features of the coefficients. It is a method of great practical importance and is reasonable with respect to computing time and storage demand (two aspects we shall consider in Sec. 20.1 in the chapter on numeric linear algebra). We begin by motivating the method. If a system is in **"triangular form,"** say,

$$2x_1 + 5x_2 = 2$$
$$13x_2 = -26$$

we can solve it by **"back substitution,"** that is, solve the last equation for the variable, $x_2 = -26/13 = -2$, and then work backward, substituting $x_2 = -2$ into the first equation

and solve it for x_1, obtaining $x_1 = \frac{1}{2}(2 - 5x_2) = \frac{1}{2}(2 - 5 \cdot (-2)) = 6$. This gives us the idea of first reducing a general system to triangular form. For instance, let the given system be

$$\begin{aligned} 2x_1 + 5x_2 &= 2 \\ -4x_1 + 3x_2 &= -30. \end{aligned} \qquad \text{Its augmented matrix is} \qquad \begin{bmatrix} 2 & 5 & 2 \\ -4 & 3 & -30 \end{bmatrix}.$$

We leave the first equation as it is. We eliminate x_1 from the second equation, to get a triangular system. For this we add twice the first equation to the second, and we do the same operation on the ***rows*** of the augmented matrix. This gives $-4x_1 + 4x_1 + 3x_2 + 10x_2 = -30 + 2 \cdot 2$, that is,

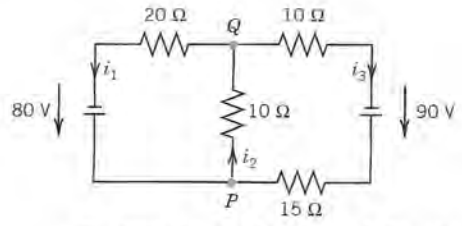
$$\begin{aligned} 2x_1 + 5x_2 &= 2 \\ 13x_2 &= -26 \end{aligned} \qquad \text{Row 2 + 2 Row 1} \qquad \begin{bmatrix} 2 & 5 & 2 \\ 0 & 13 & -26 \end{bmatrix}$$

where Row 2 + 2 Row 1 means "Add twice Row 1 to Row 2" in the original matrix. This is the **Gauss elimination** (for 2 equations in 2 unknowns) giving the triangular form, from which back substitution now yields $x_2 = -2$ and $x_1 = 6$, as before.

Since a linear system is completely determined by its augmented matrix, ***Gauss elimination can be done by merely considering the matrices,*** as we have just indicated. We do this again in the next example, emphasizing the matrices by writing them first and the equations behind them, just as a help in order not to lose track.

EXAMPLE 2 Gauss Elimination. Electrical Network

Solve the linear system



$$\begin{aligned} x_1 - x_2 + x_3 &= 0 \\ -x_1 + x_2 - x_3 &= 0 \\ 10x_2 + 25x_3 &= 90 \\ 20x_1 + 10x_2 &= 80. \end{aligned}$$

Derivation from the circuit in Fig. 157 (Optional). This is the system for the unknown currents $x_1 = i_1$, $x_2 = i_2$, $x_3 = i_3$ in the electrical network in Fig. 157. To obtain it, we label the currents as shown, choosing directions arbitrarily; if a current will come out negative, this will simply mean that the current flows against the direction of our arrow. The current entering each battery will be the same as the current leaving it. The equations for the currents result from Kirchhoff's laws:

Kirchhoff's current law (KCL). *At any point of a circuit, the sum of the inflowing currents equals the sum of the outflowing currents.*

Kirchhoff's voltage law (KVL). *In any closed loop, the sum of all voltage drops equals the impressed electromotive force.*

Node P gives the first equation, node Q the second, the right loop the third, and the left loop the fourth, as indicated in the figure.

Node P: $i_1 - i_2 + i_3 = 0$

Node Q: $-i_1 + i_2 - i_3 = 0$

Right loop: $10i_2 + 25i_3 = 90$

Left loop: $20i_1 + 10i_2 = 80$

Fig. 157. Network in Example 2 and equations relating the currents

Solution by Gauss Elimination. This system could be solved rather quickly by noticing its particular form. But this is not the point. The point is that the Gauss elimination is systematic and will work in general, also for large systems. We apply it to our system and then do back substitution. As indicated let us write the augmented matrix of the system first and then the system itself:

Augmented Matrix $\tilde{\mathbf{A}}$ | Equations

Pivot 1 → $\left[\begin{array}{rrr|r} \textcircled{1} & -1 & 1 & 0 \\ -1 & 1 & -1 & 0 \\ 0 & 10 & 25 & 90 \\ 20 & 10 & 0 & 80 \end{array}\right]$ ← Eliminate

Pivot 1 → $\begin{array}{rrrr} \textcircled{x_1} & - x_2 + & x_3 = & 0 \\ -x_1 & + x_2 - & x_3 = & 0 \\ & 10x_2 + & 25x_3 = & 90 \\ 20x_1 & + 10x_2 & = & 80. \end{array}$ ← Eliminate

Step 1. Elimination of x_1

Call the first row of **A** the **pivot row** and the first equation the **pivot equation.** Call the coefficient 1 of its x_1-term the **pivot** in this step. Use this equation to eliminate x_1 (get rid of x_1) in the other equations. For this, do:

Add 1 times the pivot equation to the second equation.

Add −20 times the pivot equation to the fourth equation.

This corresponds to **row operations** on the augmented matrix as indicated in BLUE behind the ***new matrix*** in (3). So the operations are performed on the ***preceding matrix.*** The result is

$$(3)\qquad \left[\begin{array}{rrr|r} 1 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 10 & 25 & 90 \\ 0 & 30 & -20 & 80 \end{array}\right] \begin{array}{l} \\ \text{Row 2} + \text{Row 1} \\ \\ \text{Row 4} - 20\ \text{Row 1} \end{array} \qquad \begin{array}{rrrr} x_1 - & x_2 + & x_3 = & 0 \\ & & 0 = & 0 \\ & 10x_2 + & 25x_3 = & 90 \\ & 30x_2 - & 20x_3 = & 80. \end{array}$$

Step 2. Elimination of x_2

The first equation remains as it is. We want the new second equation to serve as the next pivot equation. But since it has no x_2-term (in fact, it is $0 = 0$), we must first change the order of the equations and the corresponding rows of the new matrix. We put $0 = 0$ at the end and move the third equation and the fourth equation one place up. This is called **partial pivoting** (as opposed to the rarely used *total pivoting*, in which also the order of the unknowns is changed). It gives

Pivot 10 → $\left[\begin{array}{rrr|r} 1 & -1 & 1 & 0 \\ 0 & \textcircled{10} & 25 & 90 \\ 0 & \boxed{30} & -20 & 80 \\ 0 & 0 & 0 & 0 \end{array}\right]$ ← Eliminate 30

$\begin{array}{rrrr} x_1 - & x_2 + & x_3 = & 0 \\ \text{Pivot 10} \longrightarrow & \textcircled{$10x_2$} + & 25x_3 = & 90 \\ \text{Eliminate } 30x_2 \longrightarrow & \boxed{30x_2} - & 20x_3 = & 80 \\ & & 0 = & 0 \end{array}$

To eliminate x_2, do:

Add −3 times the pivot equation to the third equation.

The result is

$$(4)\qquad \left[\begin{array}{rrr|r} 1 & -1 & 1 & 0 \\ 0 & 10 & 25 & 90 \\ 0 & 0 & -95 & -190 \\ 0 & 0 & 0 & 0 \end{array}\right] \begin{array}{l} \\ \\ \text{Row 3} - 3\ \text{Row 2} \\ \\ \end{array} \qquad \begin{array}{rrrr} x_1 - & x_2 + & x_3 = & 0 \\ & 10x_2 + & 25x_3 = & 90 \\ & & -95x_3 = & -190 \\ & & 0 = & 0 \end{array}$$

Back Substitution. ***Determination of x_3, x_2, x_1 (in this order)***

Working backward from the last to the first equation of this "triangular" system (4), we can now readily find x_3, then x_2, and then x_1:

$$\begin{array}{rrrr} & & -95x_3 = & -190 \\ & 10x_2 + & 25x_3 = & 90 \\ x_1 - & x_2 + & x_3 = & 0 \end{array} \qquad \begin{array}{l} x_3 = i_3 = 2\ [\text{A}] \\ x_2 = \frac{1}{10}(90 - 25x_3) = i_2 = 4\ [\text{A}] \\ x_1 = x_2 - x_3 = i_1 = 2\ [\text{A}] \end{array}$$

where A stands for "amperes." This is the answer to our problem. The solution is unique. ■

Elementary Row Operations. Row-Equivalent Systems

Example 2 illustrates the operations of the Gauss elimination. These are the first two of three operations, which are called

Elementary Row Operations for Matrices:

Interchange of two rows

Addition of a constant multiple of one row to another row

Multiplication of a row by a ***nonzero*** *constant c.*

CAUTION! These operations are for rows, ***not for columns!*** They correspond to the following

Elementary Operations for Equations:

Interchange of two equations

Addition of a constant multiple of one equation to another equation

Multiplication of an equation by a ***nonzero*** *constant c.*

Clearly, the interchange of two equations does not alter the solution set. Neither does that addition because we can undo it by a corresponding subtraction. Similarly for that multiplication, which we can undo by multiplying the new equation by $1/c$ (since $c \neq 0$), producing the original equation.

We now call a linear system S_1 **row-equivalent** to a linear system S_2 if S_1 can be obtained from S_2 by (finitely many!) row operations. Thus we have proved the following result, which also justifies the Gauss elimination.

THEOREM 1

Row-Equivalent Systems

Row-equivalent linear systems have the same set of solutions.

Because of this theorem, systems having the same solution sets are often called *equivalent systems*. But note well that we are dealing with ***row operations.*** No column operations on the augmented matrix are permitted in this context because they would generally alter the solution set.

A linear system (1) is called **overdetermined** if it has more equations than unknowns, as in Example 2, **determined** if $m = n$, as in Example 1, and **underdetermined** if it has fewer equations than unknowns.

Furthermore, a system (1) is called **consistent** if it has at least one solution (thus, one solution or infinitely many solutions), but **inconsistent** if it has no solutions at all, as $x_1 + x_2 = 1$, $x_1 + x_2 = 0$ in Example 1.

Gauss Elimination: The Three Possible Cases of Systems

The Gauss elimination can take care of linear systems with a unique solution (see Example 2), with infinitely many solutions (Example 3, below), and without solutions (inconsistent systems; see Example 4).

EXAMPLE 3 Gauss Elimination if Infinitely Many Solutions Exist

Solve the following linear systems of three equations in four unknowns whose augmented matrix is

$$(5)\quad \left[\begin{array}{cccc|c} 3.0 & 2.0 & 2.0 & -5.0 & 8.0 \\ 0.6 & 1.5 & 1.5 & -5.4 & 2.7 \\ 1.2 & -0.3 & -0.3 & 2.4 & 2.1 \end{array}\right].$$

Thus,

$$\begin{aligned} \textcircled{3.0x_1} + 2.0x_2 + 2.0x_3 - 5.0x_4 &= 8.0 \\ \boxed{0.6x_1} + 1.5x_2 + 1.5x_3 - 5.4x_4 &= 2.7 \\ \boxed{1.2x_1} - 0.3x_2 - 0.3x_3 + 2.4x_4 &= 2.1. \end{aligned}$$

Solution. As in the previous example, we circle pivots and box terms of equations and corresponding entries to be eliminated. We indicate the operations in terms of equations and operate on both equations and matrices.

Step 1. Elimination of x_1 from the second and third equations by adding

$$-0.6/3.0 = -0.2 \text{ times the first equation to the second equation,}$$

$$-1.2/3.0 = -0.4 \text{ times the first equation to the third equation.}$$

This gives the following, in which the pivot of the next step is circled.

$$(6)\quad \left[\begin{array}{cccc|c} 3.0 & 2.0 & 2.0 & -5.0 & 8.0 \\ 0 & 1.1 & 1.1 & -4.4 & 1.1 \\ 0 & -1.1 & -1.1 & 4.4 & -1.1 \end{array}\right] \begin{array}{l} \\ \text{Row 2} - 0.2\ \text{Row 1} \\ \text{Row 3} - 0.4\ \text{Row 1} \end{array}$$

$$\begin{aligned} 3.0x_1 + 2.0x_2 + 2.0x_3 - 5.0x_4 &= 8.0 \\ \textcircled{1.1x_2} + 1.1x_3 - 4.4x_4 &= 1.1 \\ \boxed{-1.1x_2} - 1.1x_3 + 4.4x_4 &= -1.1 \end{aligned}$$

Step 2. Elimination of x_2 from the third equation of (6) by adding

$$1.1/1.1 = 1 \text{ times the second equation to the third equation.}$$

This gives

$$(7)\quad \left[\begin{array}{cccc|c} 3.0 & 2.0 & 2.0 & -5.0 & 8.0 \\ 0 & 1.1 & 1.1 & -4.4 & 1.1 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right] \begin{array}{l} \\ \\ \text{Row 3} + \text{Row 2} \end{array}$$

$$\begin{aligned} 3.0x_1 + 2.0x_2 + 2.0x_3 - 5.0x_4 &= 8.0 \\ 1.1x_2 + 1.1x_3 - 4.4x_4 &= 1.1 \\ 0 &= 0\ . \end{aligned}$$

Back Substitution. From the second equation, $x_2 = 1 - x_3 + 4x_4$. From this and the first equation, $x_1 = 2 - x_4$. Since x_3 and x_4 remain arbitrary, we have infinitely many solutions. If we choose a value of x_3 and a value of x_4, then the corresponding values of x_1 and x_2 are uniquely determined.

On Notation. If unknowns remain arbitrary, it is also customary to denote them by other letters $t_1, t_2, \cdots$. In this example we may thus write $x_1 = 2 - x_4 = 2 - t_2$, $x_2 = 1 - x_3 + 4x_4 = 1 - t_1 + 4t_2$, $x_3 = t_1$ (first arbitrary unknown), $x_4 = t_2$ (second arbitrary unknown). ■

EXAMPLE 4 Gauss Elimination if no Solution Exists

What will happen if we apply the Gauss elimination to a linear system that has no solution? The answer is that in this case the method will show this fact by producing a contradiction. For instance, consider

$$\left[\begin{array}{ccc|c} 3 & 2 & 1 & 3 \\ 2 & 1 & 1 & 0 \\ 6 & 2 & 4 & 6 \end{array}\right]$$

$$\begin{aligned} \textcircled{3x_1} + 2x_2 + x_3 &= 3 \\ \boxed{2x_1} + x_2 + x_3 &= 0 \\ \boxed{6x_1} + 2x_2 + 4x_3 &= 6. \end{aligned}$$

Step 1. Elimination of x_1 from the second and third equations by adding

$$-\tfrac{2}{3} \text{ times the first equation to the second equation,}$$

$$-\tfrac{6}{3} = -2 \text{ times the first equation to the third equation.}$$

This gives

$$\left[\begin{array}{ccc|c} 3 & 2 & 1 & 3 \\ 0 & -\frac{1}{3} & \frac{1}{3} & -2 \\ 0 & -2 & 2 & 0 \end{array}\right] \begin{array}{l} \\ \text{Row 2} - \frac{2}{3}\ \text{Row 1} \\ \text{Row 3} - 2\ \text{Row 1} \end{array}$$

$$\begin{aligned} 3x_1 + 2x_2 + x_3 &= 3 \\ \textcircled{-\tfrac{1}{3}x_2} + \tfrac{1}{3}x_3 &= -2 \\ \boxed{-2x_2} + 2x_3 &= 0. \end{aligned}$$

Step 2. Elimination of x_2 from the third equation gives

$$\left[\begin{array}{ccc|c} 3 & 2 & 1 & 3 \\ 0 & -\frac{1}{3} & \frac{1}{3} & -2 \\ 0 & 0 & 0 & 12 \end{array}\right] \quad \text{Row 3} - 0 \text{ Row 2} \qquad \begin{aligned} 3x_1 + 2x_2 + x_3 &= 3 \\ -\tfrac{1}{3}x_2 + \tfrac{1}{3}x_3 &= -2 \\ 0 &= 12. \end{aligned}$$

The false statement $0 = 12$ shows that the system has no solution. ■

Row Echelon Form and Information From It

At the end of the Gauss elimination the form of the coefficient matrix, the augmented matrix, and the system itself are called the **row echelon form.** In it, rows of zeros, if present, are the last rows, and in each nonzero row the leftmost nonzero entry is farther to the right than in the previous row. For instance, in Example 4 the coefficient matrix and its augmented in row echelon form are

$$\begin{bmatrix} 3 & 2 & 1 \\ 0 & -\frac{1}{3} & \frac{1}{3} \\ 0 & 0 & 0 \end{bmatrix} \quad \text{and} \quad \left[\begin{array}{ccc|c} 3 & 2 & 1 & 3 \\ 0 & -\frac{1}{3} & \frac{1}{3} & -2 \\ 0 & 0 & 0 & 12 \end{array}\right].$$

Note that we do not require that the leftmost nonzero entries be 1 since this would have no theoretic or numeric advantage. (The so-called *reduced echelon form*, in which those entries *are* 1, will be discussed in Sec. 7.8.)

At the end of the Gauss elimination (before the back substitution) the row echelon form of the augmented matrix will be

(8)

$$\left[\begin{array}{cccc|c} a_{11} & a_{12} & \cdots\cdots & a_{1n} & b_1 \\ & c_{22} & \cdots\cdots & c_{2n} & \tilde{b}_2 \\ & & \ddots & \vdots & \vdots \\ & & k_{rr} \cdots & k_{rn} & \tilde{b}_r \\ & & & & \tilde{b}_{r+1} \\ & & & & \vdots \\ & & & & \tilde{b}_m \end{array}\right].$$

Here, $r \leqq m$ and $a_{11} \neq 0$, $c_{22} \neq 0, \cdots, k_{rr} \neq 0$, and all the entries in the blue triangle as well as in the blue rectangle are zero. From this we see that with respect to solutions of the system with augmented matrix (8) (and thus with respect to the originally given system) there are three possible cases:

(a) ***Exactly one solution*** if $r = n$ and $\tilde{b}_{r+1}, \cdots, \tilde{b}_m$, if present, are zero. To get the solution, solve the nth equation corresponding to (8) (which is $k_{nn}x_n = \tilde{b}_n$) for x_n, then the $(n-1)$st equation for x_{n-1}, and so on up the line. See Example 2, where $r = n = 3$ and $m = 4$.

(b) ***Infinitely many solutions*** if $r < n$ and $\tilde{b}_{r+1}, \cdots, \tilde{b}_m$, if present, are zero. To obtain any of these solutions, choose values of $x_{r+1}, \cdots, x_n$ arbitrarily. Then solve the rth equation for x_r, then the $(r-1)$st equation for x_{r-1}, and so on up the line. See Example 3.

(c) ***No solution*** if $r < m$ and one of the entries $\tilde{b}_{r+1}, \cdots, \tilde{b}_m$ is not zero. See Example 4, where $r = 2 < m = 3$ and $\tilde{b}_{r+1} = \tilde{b}_3 = 12$.

PROBLEM SET 7.3

1–16 GAUSS ELIMINATION AND BACK SUBSTITUTION

Solve the following systems or indicate the nonexistence of solutions. (Show the details of your work.)

1.
$$5x - 2y = 20.9$$
$$-x + 4y = -19.3$$

2.
$$3.0x + 6.2y = 0.2$$
$$2.1x + 8.5y = 4.3$$

3.
$$0.5x + 3.5y = 5.7$$
$$-x + 5.0y = 7.8$$

4.
$$4y - 2z = 2$$
$$6x - 2y + z = 29$$
$$4x + 8y - 4z = 24$$

5.
$$0.8x + 1.2y - 0.6z = -7.8$$
$$2.6x + 1.7z = 15.3$$
$$4.0x - 7.3y - 1.5z = 1.1$$

6.
$$14x - 2y - 4z = 0$$
$$18x - 2y - 6z = 0$$
$$4x + 8y - 14z = 0$$

7.
$$y + z = -2$$
$$4y + 6z = -12$$
$$x + y + z = 2$$

8.
$$2x + y - 3z = 8$$
$$5x + 2z = 3$$
$$8x - y + 7z = 0$$

9.
$$4y + 4z = 24$$
$$3x - 11y - 2z = -6$$
$$6x - 17y + z = 18$$

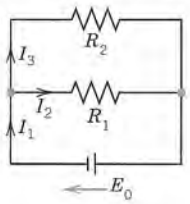
10.
$$0.6x + 0.3y - 0.4z = -1.9$$
$$-4.6x + 0.5y + 1.2z = -1.3$$

11.
$$2x - y + 3z = -1$$
$$-4x + 2y - 6z = 2$$

12.
$$-2y - 2z = -8$$
$$3x + 4y - 5z = 13$$

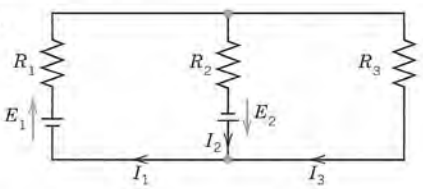
13.
$$x + y - 2z = 0$$
$$-4w - x - y + 2z = -4$$
$$-2w + 3x + 3y - 6z = -2$$

14.
$$w - 2x + 5y - 3z = 0$$
$$-3w + 6x + y + z = 0$$
$$2w - 4x + 3y - z = 3$$



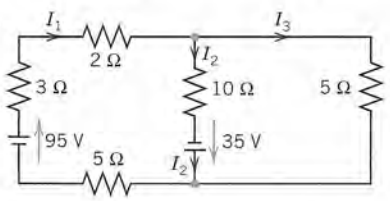
15.
$$3x + 7y - 4z = -46$$
$$5w + 4x + 8y + z = 7$$
$$8w + 4y - 2z = 0$$
$$-w + 6x + 2z = 13$$

16.
$$-2w - 17x + 4y + 3z = 0$$
$$7w + 3y - 2z = 0$$
$$2x + 8y - 6z = -20$$
$$5w - 13x - y + 5z = 16$$

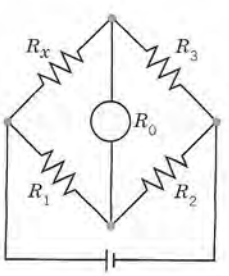


17–19 MODELS OF ELECTRICAL NETWORKS

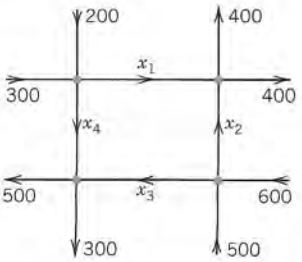
Using Kirchhoff's laws (see Example 2), find the currents. (Show the details of your work.)



17.



18.



19.

Wheatstone bridge

(Prob. 20, next page)

Net of one-way streets

(Prob. 21, next page)

20. (Wheatstone bridge) Show that if $R_x/R_3 = R_1/R_2$ in the figure, then $I = 0$. (R_0 is the resistance of the instrument by which I is measured.) This bridge is a method for determining R_x. R_1, R_2, R_3 are known. R_3 is variable. To get R_x, make $I = 0$ by varing R_3. Then calculate $R_x = R_3R_1/R_2$.

21. (Traffic flow) Methods of electrical circuit analysis have applications to other fields. For instance, applying the analog of Kirchhoff's current law, find the traffic flow (cars per hour) in the net of one-way streets (in the directions indicated by the arrows) shown in the figure. Is the solution unique?

22. (Models of markets) Determine the equilibrium solution ($D_1 = S_1$, $D_2 = S_2$) of the two-commodity market with linear model (D, S, P = demand, supply, price; index 1 = first commodity, index 2 = second commodity)

$$D_1 = 60 - 2P_1 - P_2, \quad S_1 = 4P_1 - 2P_2 + 14$$
$$D_2 = 4P_1 - P_2 + 10, \quad S_2 = 5P_2 - 2.$$

23. (Equivalence relation) By definition, an *equivalence relation* on a set is a relation satisfying three conditions (named as indicated):

(i) Each element A of the set is equivalent to itself (*"Reflexivity"*).

(ii) If A is equivalent to B, then B is equivalent to A (*"Symmetry"*).

(iii) If A is equivalent to B and B is equivalent to C, then A is equivalent to C (*"Transitivity"*).

Show that row equivalence of matrices satisfies these three conditions. *Hint.* Show that for each of the three elementary row operations these conditions hold.

24. PROJECT. Elementary Matrices. The idea is that elementary operations can be accomplished by matrix multiplication. If $\mathbf{A}$ is an $m \times n$ matrix on which we want to do an elementary operation, then there is a matrix $\mathbf{E}$ such that $\mathbf{EA}$ is the new matrix after the operation. Such an $\mathbf{E}$ is called an **elementary matrix.** This idea can be helpful, for instance, in the design of algorithms. (*Computationally*, it is generally preferable to do row operations *directly*, rather than by multiplication by $\mathbf{E}$.)

(a) Show that the following are elementary matrices, for interchanging Rows 2 and 3, for adding -5 times the first row to the third, and for multiplying the fourth row by 8.

$$\mathbf{E}_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{E}_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ -5 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{E}_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 8 \end{bmatrix}.$$

Apply $\mathbf{E}_1$, $\mathbf{E}_2$, $\mathbf{E}_3$ to a vector and to a 4×3 matrix of your choice. Find $\mathbf{B} = \mathbf{E}_3\mathbf{E}_2\mathbf{E}_1\mathbf{A}$, where $\mathbf{A} = [a_{jk}]$ is the general 4×2 matrix. Is $\mathbf{B}$ equal to $\mathbf{C} = \mathbf{E}_1\mathbf{E}_2\mathbf{E}_3\mathbf{A}$?

(b) Conclude that $\mathbf{E}_1$, $\mathbf{E}_2$, $\mathbf{E}_3$ are obtained by doing the corresponding elementary operations on the 4×4 unit matrix. Prove that *if* $\mathbf{M}$ *is obtained from* $\mathbf{A}$ *by an elementary row operation, then*

$$\mathbf{M} = \mathbf{EA},$$

where $\mathbf{E}$ *is obtained from the* $n \times n$ *unit matrix* $\mathbf{I}_n$ *by the same row operation.*

25. CAS PROJECT. Gauss Elimination and Back Substitution. Write a program for Gauss elimination and back substitution (a) that does not include pivoting, (b) that does include pivoting. Apply the programs to Probs. 13–16 and to some larger systems of your choice.

7.4 Linear Independence. Rank of a Matrix. Vector Space

In the last section we explained the Gauss elimination with back substitution, the most important numeric solution method for linear systems of equations. It appeared that such a system may have a unique solution or infinitely many solutions, or it may be inconsistent, that is, have no solution at all. Hence we are confronted with the questions of **existence and uniqueness of solutions.** We shall answer these questions in the next section. As the

key concept for this (and other questions) we introduce the ***rank of a matrix.*** To define rank, we first need the following concepts, which are of general importance.

Linear Independence and Dependence of Vectors

Given any set of m vectors $\mathbf{a}_{(1)}, \cdots, \mathbf{a}_{(m)}$ (with the same number of components), a **linear combination** of these vectors is an expression of the form

$$c_1\mathbf{a}_{(1)} + c_2\mathbf{a}_{(2)} + \cdots + c_m\mathbf{a}_{(m)}$$

where $c_1, c_2, \cdots, c_m$ are any scalars. Now consider the equation

$$\textbf{(1)} \qquad c_1\mathbf{a}_{(1)} + c_2\mathbf{a}_{(2)} + \cdots + c_m\mathbf{a}_{(m)} = \mathbf{0}.$$

Clearly, this vector equation (1) holds if we choose all c_j's zero, because then it becomes $\mathbf{0} = \mathbf{0}$. If this is the only m-tuple of scalars for which (1) holds, then our vectors $\mathbf{a}_{(1)}, \cdots, \mathbf{a}_{(m)}$ are said to form a *linearly independent set* or, more briefly, we call them **linearly independent.** Otherwise, if (1) also holds with scalars not all zero, we call these vectors **linearly dependent,** because then we can express (at least) one of them as a linear combination of the others. For instance, if (1) holds with, say, $c_1 \neq 0$, we can solve (1) for $\mathbf{a}_{(1)}$:

$$\mathbf{a}_{(1)} = k_2\mathbf{a}_{(2)} + \cdots + k_m\mathbf{a}_{(m)} \qquad \text{where } k_j = -c_j/c_1.$$

(Some k_j's may be zero. Or even all of them, namely, if $\mathbf{a}_{(1)} = \mathbf{0}$.)

Why is this important? Well, in the case of linear dependence we can get rid of some of the vectors until we arrive at a linearly independent set that is optimal to work with because it is smallest possible in the sense that it consists only of the "really essential" vectors, which can no longer be expressed linearly in terms of each other. This motivates the idea of a "basis" used in various contexts, notably later in our present section.

EXAMPLE 1 **Linear Independence and Dependence**

The three vectors

$$\mathbf{a}_{(1)} = [\,3 \quad 0 \quad 2 \quad 2\,]$$
$$\mathbf{a}_{(2)} = [\,-6 \quad 42 \quad 24 \quad 54\,]$$
$$\mathbf{a}_{(3)} = [\,21 \quad -21 \quad 0 \quad -15\,]$$

are linearly dependent because

$$6\mathbf{a}_{(1)} - \tfrac{1}{2}\mathbf{a}_{(2)} - \mathbf{a}_{(3)} = \mathbf{0}.$$

Although this is easily checked (do it!), it is not so easy to discover. However, a systematic method for finding out about linear independence and dependence follows below.

The first two of the three vectors are linearly independent because $c_1\mathbf{a}_{(1)} + c_2\mathbf{a}_{(2)} = \mathbf{0}$ implies $c_2 = 0$ (from the second components) and then $c_1 = 0$ (from any other component of $\mathbf{a}_{(1)}$). ■

Rank of a Matrix

DEFINITION

The **rank** of a matrix $\mathbf{A}$ is the maximum number of linearly independent row vectors of $\mathbf{A}$. It is denoted by rank $\mathbf{A}$.

Our further discussion will show that the rank of a matrix is an important key concept for understanding general properties of matrices and linear systems of equations.

EXAMPLE 2 Rank

The matrix

$$\mathbf{A} = \begin{bmatrix} 3 & 0 & 2 & 2 \\ -6 & 42 & 24 & 54 \\ 21 & -21 & 0 & -15 \end{bmatrix} \tag{2}$$

has rank 2, because Example 1 shows that the first two row vectors are linearly independent, whereas all three row vectors are linearly dependent.

Note further that rank $\mathbf{A} = 0$ if and only if $\mathbf{A} = \mathbf{0}$. This follows directly from the definition. ■

We call a matrix $\mathbf{A}_1$ **row-equivalent** to a matrix $\mathbf{A}_2$ if $\mathbf{A}_1$ can be obtained from $\mathbf{A}_2$ by (finitely many!) elementary row operations.

Now the maximum number of linearly independent row vectors of a matrix does not change if we change the order of rows or multiply a row by an nonzero c or take a linear combination by adding a multiple of a row to another row. This proves that rank is **invariant** under elementary row operations:

THEOREM 1 Row-Equivalent Matrices

Row-equivalent matrices have the same rank.

Hence we can determine the rank of a matrix by reduction to row-echelon form (Sec. 7.3) and then see the rank directly.

EXAMPLE 3 Determination of Rank

For the matrix in Example 2 we obtain successively

$$\mathbf{A} = \begin{bmatrix} 3 & 0 & 2 & 2 \\ -6 & 42 & 24 & 54 \\ 21 & -21 & 0 & -15 \end{bmatrix} \quad \text{(given)}$$

$$\begin{bmatrix} 3 & 0 & 2 & 2 \\ 0 & 42 & 28 & 58 \\ 0 & -21 & -14 & -29 \end{bmatrix} \quad \begin{matrix} \text{Row 2} + 2\ \text{Row 1} \\ \text{Row 3} - 7\ \text{Row 1} \end{matrix}$$

$$\begin{bmatrix} 3 & 0 & 2 & 2 \\ 0 & 42 & 28 & 58 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad \text{Row 3} + \tfrac{1}{2}\ \text{Row 2}$$

■

Since rank is defined in terms of two vectors, we immediately have the useful

THEOREM 2 Linear Independence and Dependence of Vectors

p vectors with n components each are linearly independent if the matrix with these vectors as row vectors has rank p, but they are linearly dependent if that rank is less than p.

Further important properties will result from the basic

THEOREM 3

Rank in Terms of Column Vectors

The rank r of a matrix $\mathbf{A}$ equals the maximum number of linearly independent ***column*** *vectors of* $\mathbf{A}$.

Hence $\mathbf{A}$ *and its transpose* $\mathbf{A}^T$ *have the same rank.*

PROOF In this proof we write simply "rows" and "columns" for row and column vectors. Let $\mathbf{A}$ be an $m \times n$ matrix of rank $\mathbf{A} = r$. Then by definition of rank, $\mathbf{A}$ has r linearly independent rows which we denote by $\mathbf{v}_{(1)}, \cdots, \mathbf{v}_{(r)}$ (regardless of their position in $\mathbf{A}$), and all the rows $\mathbf{a}_{(1)}, \cdots, \mathbf{a}_{(m)}$ of $\mathbf{A}$ are linear combinations of those, say,

$$
\begin{aligned}
\mathbf{a}_{(1)} &= c_{11}\mathbf{v}_{(1)} + c_{12}\mathbf{v}_{(2)} + \cdots + c_{1r}\mathbf{v}_{(r)} \\
\mathbf{a}_{(2)} &= c_{21}\mathbf{v}_{(1)} + c_{22}\mathbf{v}_{(2)} + \cdots + c_{2r}\mathbf{v}_{(r)} \\
&\cdots \\
\mathbf{a}_{(m)} &= c_{m1}\mathbf{v}_{(1)} + c_{m2}\mathbf{v}_{(2)} + \cdots + c_{mr}\mathbf{v}_{(r)}.
\end{aligned} \tag{3}
$$

These are vector equations for rows. To switch to columns, we write (3) in terms of components as n such systems, with $k = 1, \cdots, n$,

$$
\begin{aligned}
a_{1k} &= c_{11}v_{1k} + c_{12}v_{2k} + \cdots + c_{1r}v_{rk} \\
a_{2k} &= c_{21}v_{1k} + c_{22}v_{2k} + \cdots + c_{2r}v_{rk} \\
&\cdots \\
a_{mk} &= c_{m1}v_{1k} + c_{m2}v_{2k} + \cdots + c_{mr}v_{rk}
\end{aligned} \tag{4}
$$

and collect components in columns. Indeed, we can write (4) as

$$
\begin{bmatrix} a_{1k} \\ a_{2k} \\ \cdot \\ \cdot \\ a_{mk} \end{bmatrix} = v_{1k} \begin{bmatrix} c_{11} \\ c_{21} \\ \cdot \\ \cdot \\ c_{m1} \end{bmatrix} + v_{2k} \begin{bmatrix} c_{12} \\ c_{22} \\ \cdot \\ \cdot \\ c_{m2} \end{bmatrix} + \cdots + v_{rk} \begin{bmatrix} c_{1r} \\ c_{2r} \\ \cdot \\ \cdot \\ c_{mr} \end{bmatrix} \tag{5}
$$

where $k = 1, \cdots, n$. Now the vector on the left is the kth column vector of $\mathbf{A}$. We see that each of these n columns is a linear combination of the same r columns on the right. Hence $\mathbf{A}$ cannot have more linearly independent columns than rows, whose number is rank $\mathbf{A} = r$. Now rows of $\mathbf{A}$ are columns of the transpose $\mathbf{A}^T$. For $\mathbf{A}^T$ our conclusion is that $\mathbf{A}^T$ cannot have more linearly independent columns than rows, so that $\mathbf{A}$ cannot have more linearly independent rows than columns. Together, the number of linearly independent columns of $\mathbf{A}$ must be r, the rank of $\mathbf{A}$. This completes the proof. ■

EXAMPLE 4 **Illustration of Theorem 3**

The matrix in (2) has rank 2. From Example 3 we see that the first two row vectors are linearly independent and by "working backward" we can verify that Row 3 = 6 Row 1 $-\frac{1}{2}$ Row 2. Similarly, the first two columns are linearly independent, and by reducing the last matrix in Example 3 by columns we find that

$$\text{Column 3} = \tfrac{2}{3}\,\text{Column 1} + \tfrac{2}{3}\,\text{Column 2} \qquad \text{and} \qquad \text{Column 4} = \tfrac{2}{3}\,\text{Column 1} + \tfrac{29}{21}\,\text{Column 2}.$$ ■

Combining Theorems 2 and 3 we obtain

THEOREM 4

Linear Dependence of Vectors

p vectors with $n < p$ components are always linearly dependent.

PROOF The matrix $\mathbf{A}$ with those p vectors as row vectors has p rows and $n < p$ columns; hence by Theorem 3 it has rank $\mathbf{A} \leqq n < p$, which implies linear dependence by Theorem 2. ■

Vector Space

The following related concepts are of general interest in linear algebra. In the present context they provide a clarification of essential properties of matrices and their role in connection with linear systems.

A **vector space** is a (nonempty) set V of vectors such that with any two vectors $\mathbf{a}$ and $\mathbf{b}$ in V all their linear combinations $\alpha\mathbf{a} + \beta\mathbf{b}$ (α, β any real numbers) are elements of V, and these vectors satisfy the laws (3) and (4) in Sec. 7.1 (written in lowercase letters **a, b, u,** $\cdots$, which is our notation for vectors). (This definition is presently sufficient. General vector spaces will be discussed in Sec. 7.9.)

The maximum number of linearly independent vectors in V is called the **dimension** of V and is denoted by dim V. Here we assume the dimension to be finite; infinite dimension will be defined in Sec. 7.9.

A linearly independent set in V consisting of a maximum possible number of vectors in V is called a **basis** for V. Thus the number of vectors of a basis for V equals dim V.

The set of all linear combinations of given vectors $\mathbf{a}_{(1)}, \cdots, \mathbf{a}_{(p)}$ with the same number of components is called the **span** of these vectors. Obviously, a span is a vector space.

By a **subspace** of a vector space V we mean a nonempty subset of V (including V itself) that forms itself a vector space with respect to the two algebraic operations (addition and scalar multiplication) defined for the vectors of V.

EXAMPLE 5 **Vector Space, Dimension, Basis**

The span of the three vectors in Example 1 is a vector space of dimension 2, and a basis is $\mathbf{a}_{(1)}$, $\mathbf{a}_{(2)}$, for instance, or $\mathbf{a}_{(1)}$, $\mathbf{a}_{(3)}$, etc. ■

We further note the simple

THEOREM 5

Vector Space R^n

The vector space R^n consisting of all vectors with n components (n real numbers) has dimension n.

PROOF A basis of n vectors is $\mathbf{a}_{(1)} = [1 \quad 0 \quad \cdots \quad 0]$, $\mathbf{a}_{(2)} = [0 \quad 1 \quad 0 \quad \cdots \quad 0], \cdots,$ $\mathbf{a}_{(n)} = [0 \quad \cdots \quad 0 \quad 1]$. ■

In the case of a matrix $\mathbf{A}$ we call the span of the row vectors the **row space** of $\mathbf{A}$ and the span of the column vectors the **column space** of $\mathbf{A}$.

Now, Theorem 3 shows that a matrix **A** has as many linearly independent rows as columns. By the definition of dimension, their number is the dimension of the row space or the column space of **A.** This proves

THEOREM 6

Row Space and Column Space

The row space and the column space of a matrix **A** *have the same dimension, equal to rank* **A.**

Finally, for a given matrix **A** the solution set of the homogeneous system $\mathbf{Ax} = \mathbf{0}$ is a vector space, called the **null space** of **A,** and its dimension is called the **nullity** of **A.** In the next section we motivate and prove the basic relation

(6) rank **A** + nullity **A** = Number of columns of **A.**

PROBLEM SET 7.4

1–12 RANK, ROW SPACE, COLUMN SPACE

Find the rank and a basis for the row space and for the column space. *Hint.* Row-reduce the matrix and its transpose. (You may omit obvious factors from the vectors of these bases.)

1. $\begin{bmatrix} 1 & -2 \\ 0 & 0 \\ -3 & 6 \end{bmatrix}$

2. $\begin{bmatrix} 8 & 2 & 5 \\ 16 & 6 & 29 \\ 4 & 0 & -7 \end{bmatrix}$

3. $\begin{bmatrix} 0 & -2 & 1 & 3 \\ 1 & 4 & 0 & 7 \\ 5 & 5 & 5 & 5 \end{bmatrix}$

4. $\begin{bmatrix} a & b & c \\ b & a & c \end{bmatrix}$

5. $\begin{bmatrix} 0 & 3 & 4 \\ -3 & 0 & -5 \\ -4 & 5 & 0 \end{bmatrix}$

6. $\begin{bmatrix} 1 & 1 & a \\ 1 & a & 1 \\ a & 1 & 1 \end{bmatrix}$

7. $\begin{bmatrix} 8 & 0 & 4 \\ 0 & 2 & 0 \\ 4 & 0 & 2 \\ 0 & 4 & 0 \end{bmatrix}$

8. $\begin{bmatrix} 1 & -2 & 3 & -4 \\ 2 & -3 & 4 & -1 \\ 3 & -4 & 1 & -2 \\ 4 & -1 & 2 & -3 \end{bmatrix}$

9. $\begin{bmatrix} 1 & 0 & 3 & 0 \\ 0 & 5 & 8 & -37 \\ 3 & 8 & 7 & 0 \\ 0 & -37 & 0 & 37 \end{bmatrix}$

10. $\begin{bmatrix} 1 & 2 & 3 & 4 \\ 2 & 3 & 4 & 5 \\ 3 & 4 & 5 & 6 \\ 4 & 5 & 6 & 7 \end{bmatrix}$

11. $\begin{bmatrix} 2 & 4 & 8 & 16 \\ 16 & 8 & 4 & 2 \\ 4 & 8 & 16 & 2 \\ 2 & 16 & 8 & 4 \end{bmatrix}$

12. $\begin{bmatrix} 0 & 0 & -7 & 1 \\ 0 & 0 & 5 & 0 \\ -7 & 5 & 0 & 2 \\ 1 & 0 & 2 & 0 \end{bmatrix}$

13–20 LINEAR INDEPENDENCE

Are the following sets of vectors linearly independent? (Show the details.)

13. [3 −2 0 4], [5 0 0 1], [−6 1 0 1], [2 0 0 3]

14. [1 1 0], [1 0 0], [1 1 1]

15. [6 0 3 1 4 2], [0 −1 2 7 0 5], [12 3 0 −19 8 −11]

16. [3 4 7], [2 0 3], [8 2 3], [5 5 6]

17. [0.2 1.2 5.3 2.8 1.6], [4.3 3.4 0.9 2.0 −4.3]

18. [3 2 1], [0 0 0], [4 3 6]

19. $[1\ \frac{1}{2}\ \frac{1}{3}\ \frac{1}{4}]$, $[\frac{1}{2}\ \frac{1}{3}\ \frac{1}{4}\ \frac{1}{5}]$, $[\frac{1}{3}\ \frac{1}{4}\ \frac{1}{5}\ \frac{1}{6}]$, $[\frac{1}{4}\ \frac{1}{5}\ \frac{1}{6}\ \frac{1}{7}]$

20. [1 2 3 4], [2 3 4 5], [3 4 5 6], [4 5 6 7]

21. CAS Experiment. Rank. **(a)** Show experimentally that the $n \times n$ matrix $\mathbf{A} = [a_{jk}]$ with $a_{jk} = j + k - 1$ has rank 2 for any n. (Problem 20 shows $n = 4$.) Try to prove it.

(b) Do the same when $a_{jk} = j + k + c$, where c is any positive integer.

(c) What is rank $\mathbf{A}$ if $a_{jk} = 2^{j+k-2}$? Try to find other large matrices of low rank independent of n.

22–26 PROPERTIES OF RANK AND CONSEQUENCES

Show the following.

22. rank $\mathbf{B}^T\mathbf{A}^T$ = rank $\mathbf{AB}$. (Note the order!)

23. rank $\mathbf{A}$ = rank $\mathbf{B}$ does *not* imply rank $\mathbf{A}^2$ = rank $\mathbf{B}^2$. (Give a counterexample.)

24. If $\mathbf{A}$ is not square, either the row vectors or the column vectors of $\mathbf{A}$ are linearly dependent.

25. If the row vectors of a square matrix are linearly independent, so are the column vectors, and conversely.

26. Give examples showing that the rank of a product of matrices cannot exceed the rank of either factor.

27–36 VECTOR SPACES

Is the given set of vectors a vector space? (Give reason.) If your answer is yes, determine the dimension and find a basis. ($v_1, v_2, \cdots$ denote components.)

27. All vectors in R^3 such that $v_1 + v_2 = 0$

28. All vectors in R^4 such that $2v_2 - 3v_4 = k$

29. All vectors in R^3 with $v_1 \geqq 0$, $v_2 = -4v_3$

30. All vectors in R^2 with $v_1 \leqq v_2$

31. All vectors in R^3 with $4v_1 + v_3 = 0$, $3v_2 = v_3$

32. All vectors in R^4 with $v_1 - v_2 = 0$, $v_3 = 5v_1$, $v_4 = 0$

33. All vectors in R^n with $|v_j| \leqq 1$ for $j = 1, \cdots, n$

34. All ordered quadruples of positive real numbers

35. All vectors in R^5 with $v_1 = 2v_2 = 3v_3 = 4v_4 = 5v_5$

36. All vectors in R^4 with $3v_1 - v_3 = 0$, $2v_1 + 3v_2 - 4v_4 = 0$

7.5 Solutions of Linear Systems: Existence, Uniqueness

Rank as just defined gives complete information about existence, uniqueness, and general structure of the solution set of linear systems as follows.

A linear system of equations in n unknowns has a unique solution if the coefficient matrix and the augmented matrix have the same rank n, and infinitely many solution if that common rank is less than n. The system has no solution if those two matrices have different rank.

To state this precisely and prove it, we shall use the (generally important) concept of a **submatrix** of $\mathbf{A}$. By this we mean any matrix obtained from $\mathbf{A}$ by omitting some rows or columns (or both). By definition this includes $\mathbf{A}$ itself (as the matrix obtained by omitting no rows or columns); this is practical.

THEOREM 1

Fundamental Theorem for Linear Systems

(a) Existence. *A linear system of m equations in n unknowns $x_1, \cdots, x_n$*

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots & \\ a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n &= b_m \end{aligned} \tag{1}$$

is **consistent,** *that is, has solutions, if and only if the coefficient matrix* $\mathbf{A}$ *and the augmented matrix* $\widetilde{\mathbf{A}}$ *have the same rank. Here,*

$$\mathbf{A} = \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \cdot & \cdots & \cdot \\ \cdot & \cdots & \cdot \\ a_{m1} & \cdots & a_{mn} \end{bmatrix} \quad \text{and} \quad \widetilde{\mathbf{A}} = \left[\begin{array}{ccc|c} a_{11} & \cdots & a_{1n} & b_1 \\ \cdot & \cdots & \cdot & \cdot \\ \cdot & \cdots & \cdot & \cdot \\ a_{m1} & \cdots & a_{mn} & b_m \end{array}\right]$$

(b) Uniqueness. *The system* (1) *has precisely one solution if and only if this common rank* r *of* $\mathbf{A}$ *and* $\widetilde{\mathbf{A}}$ *equals* n.

(c) Infinitely many solutions. *If this common rank* r *is less than* n, *the system* (1) *has infinitely many solutions. All of these solutions are obtained by determining* r *suitable unknowns (whose submatrix of coefficients must have rank* r*) in terms of the remaining* $n - r$ *unknowns, to which arbitrary values can be assigned.* (See Example 3 in Sec. 7.3.)

(d) Gauss elimination (Sec. 7.3). *If solutions exist, they can all be obtained by the Gauss elimination.* (This method will automatically reveal whether or not solutions exist; see Sec. 7.3.)

PROOF **(a)** We can write the system (1) in vector form $\mathbf{Ax} = \mathbf{b}$ or in terms of column vectors $\mathbf{c}_{(1)}, \cdots, \mathbf{c}_{(n)}$ of $\mathbf{A}$:

$$\mathbf{c}_{(1)}x_1 + \mathbf{c}_{(2)}x_2 + \cdots + \mathbf{c}_{(n)}x_n = \mathbf{b}. \tag{2}$$

$\widetilde{\mathbf{A}}$ is obtained by augmenting $\mathbf{A}$ by a single column $\mathbf{b}$. Hence, by Theorem 3 in Sec. 7.4, rank $\widetilde{\mathbf{A}}$ equals rank $\mathbf{A}$ or rank $\mathbf{A} + 1$. Now if (1) has a solution $\mathbf{x}$, then (2) shows that $\mathbf{b}$ must be a linear combination of those column vectors, so that $\widetilde{\mathbf{A}}$ and $\mathbf{A}$ have the same maximum number of linearly independent column vectors and thus the same rank.

Conversely, if rank $\widetilde{\mathbf{A}}$ = rank $\mathbf{A}$, then $\mathbf{b}$ must be a linear combination of the column vectors of $\mathbf{A}$, say,

$$\mathbf{b} = \alpha_1\mathbf{c}_{(1)} + \cdots + \alpha_n\mathbf{c}_{(n)} \tag{2*}$$

since otherwise rank $\widetilde{\mathbf{A}}$ = rank $\mathbf{A} + 1$. But (2*) means that (1) has a solution, namely, $x_1 = \alpha_1, \cdots, x_n = \alpha_n$, as can be seen by comparing (2*) and (2).

(b) If rank $\mathbf{A} = n$, the n column vectors in (2) are linearly independent by Theorem 3 in Sec. 7.4. We claim that then the representation (2) of $\mathbf{b}$ is unique because otherwise

$$\mathbf{c}_{(1)}x_1 + \cdots + \mathbf{c}_{(n)}x_n = \mathbf{c}_{(1)}\tilde{x}_1 + \cdots + \mathbf{c}_{(n)}\tilde{x}_n.$$

This would imply (take all terms to the left, with a minus sign)

$$(x_1 - \tilde{x}_1)\mathbf{c}_{(1)} + \cdots + (x_n - \tilde{x}_n)\mathbf{c}_{(n)} = \mathbf{0}$$

and $x_1 - \tilde{x}_1 = 0, \cdots, x_n - \tilde{x}_n = 0$ by linear independence. But this means that the scalars $x_1, \cdots, x_n$ in (2) are uniquely determined, that is, the solution of (1) is unique.

(c) If rank $\mathbf{A}$ = rank $\widetilde{\mathbf{A}} = r < n$, then by Theorem 3 in Sec. 7.4 there is a linearly independent set K of r column vectors of $\mathbf{A}$ such that the other $n - r$ column vectors of $\mathbf{A}$ are linear combinations of those vectors. We renumber the columns and unknowns, denoting the renumbered quantities by $\hat{}$, so that $\{\hat{\mathbf{c}}_{(1)}, \cdots, \hat{\mathbf{c}}_{(r)}\}$ is that linearly independent set K. Then (2) becomes

$$\hat{\mathbf{c}}_{(1)}\hat{x}_1 + \cdots + \hat{\mathbf{c}}_{(r)}\hat{x}_r + \hat{\mathbf{c}}_{(r+1)}\hat{x}_{r+1} + \cdots + \hat{\mathbf{c}}_{(n)}\hat{x}_n = \mathbf{b},$$

$\hat{\mathbf{c}}_{(r+1)}, \cdots, \hat{\mathbf{c}}_{(n)}$ are linear combinations of the vectors of K, and so are the vectors $\hat{x}_{r+1}\hat{\mathbf{c}}_{(r+1)}, \cdots, \hat{x}_n\hat{\mathbf{c}}_{(n)}$. Expressing these vectors in terms of the vectors of K and collecting terms, we can thus write the system in the form

$$\hat{\mathbf{c}}_{(1)}y_1 + \cdots + \hat{\mathbf{c}}_{(r)}y_r = \mathbf{b} \tag{3}$$

with $y_j = \hat{x}_j + \beta_j$, where β_j results from the $n - r$ terms $\hat{\mathbf{c}}_{(r+1)}\hat{x}_{r+1}, \cdots, \hat{\mathbf{c}}_{(n)}\hat{x}_n$; here, $j = 1, \cdots, r$. Since the system has a solution, there are $y_1, \cdots, y_r$ satisfying (3). These scalars are unique since K is linearly independent. Choosing $\hat{x}_{r+1}, \cdots, \hat{x}_n$ fixes the β_j and corresponding $\hat{x}_j = y_j - \beta_j$, where $j = 1, \cdots, r$.

(d) This was discussed in Sec. 7.3 and is restated here as a reminder. ■

The theorem is illustrated in Sec. 7.3. In Example 2 there is a unique solution since rank $\widetilde{\mathbf{A}}$ = rank $\mathbf{A} = n = 3$ (as can be seen from the last matrix in the example). In Example 3 we have rank $\widetilde{\mathbf{A}}$ = rank $\mathbf{A} = 2 < n = 4$ and can choose x_3 and x_4 arbitrarily. In Example 4 there is no solution because rank $\mathbf{A} = 2 <$ rank $\widetilde{\mathbf{A}} = 3$.

Homogeneous Linear System

Recall from Sec. 7.3 that a linear system (1) is called **homogeneous** if all the b_j's are zero, and **nonhomogeneous** if one or several b_j's are not zero. For the homogeneous system we obtain from the Fundamental Theorem the following results.

THEOREM 2

Homogeneous Linear System

A homogeneous linear system

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= 0 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= 0 \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots & \\ a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n &= 0 \end{aligned} \tag{4}$$

always has the **trivial solution** $x_1 = 0, \cdots, x_n = 0$. *Nontrivial solutions exist if and only if rank* $\mathbf{A} < n$. *If* rank $\mathbf{A} = r < n$, *these solutions, together with* $\mathbf{x} = \mathbf{0}$, *form a vector space* (see Sec. 7.4) *of dimension* $n - r$, called the **solution space** of (4).

In particular, if $\mathbf{x}_{(1)}$ *and* $\mathbf{x}_{(2)}$ *are solution vectors of* (4), *then* $\mathbf{x} = \mathbf{c}_1\mathbf{x}_{(1)} + \mathbf{c}_2\mathbf{x}_{(2)}$ *with any scalars* c_1 *and* c_2 *is a solution vector of* (4). (This ***does not hold*** for nonhomogeneous systems. Also, the term *solution space* is used for *homogeneous* systems only.)

PROOF The first proposition can be seen directly from the system. It agrees with the fact that $\mathbf{b} = \mathbf{0}$ implies that rank $\widetilde{\mathbf{A}}$ = rank $\mathbf{A}$, so that a homogeneous system is always ***consistent.*** If rank $\mathbf{A} = n$, the trivial solution is the unique solution according to (b) in Theorem 1. If rank $\mathbf{A} < n$, there are nontrivial solutions according to (c) in Theorem 1. The solutions form a vector space because if $\mathbf{x}_{(1)}$ and $\mathbf{x}_{(2)}$ are any of them, then $\mathbf{A}\mathbf{x}_{(1)} = \mathbf{0}$, $\mathbf{A}\mathbf{x}_{(2)} = \mathbf{0}$, and this implies $\mathbf{A}(\mathbf{x}_{(1)} + \mathbf{x}_{(2)}) = \mathbf{A}\mathbf{x}_{(1)} + \mathbf{A}\mathbf{x}_{(2)} = \mathbf{0}$ as well as $\mathbf{A}(c\mathbf{x}_{(1)}) = c\mathbf{A}\mathbf{x}_{(1)} = \mathbf{0}$, where c is arbitrary. If rank $\mathbf{A} = r < n$, Theorem 1 (c) implies that we can choose $n - r$ suitable unknowns, call them $x_{r+1}, \cdots, x_n$, in an arbitrary fashion, and every solution is obtained in this way. Hence a basis for the solution space, briefly called a **basis of solutions** of (4), is $\mathbf{y}_{(1)}, \cdots, \mathbf{y}_{(n-r)}$, where the basis vector $\mathbf{y}_{(j)}$ is obtained by choosing $x_{r+j} = 1$ and the other $x_{r+1}, \cdots, x_n$ zero; the corresponding first r components of this solution vector are then determined. Thus the solution space of (4) has dimension $n - r$. This proves Theorem 2. ∎

The solution space of (4) is also called the **null space** of $\mathbf{A}$ because $\mathbf{A}\mathbf{x} = \mathbf{0}$ for every $\mathbf{x}$ in the solution space of (4). Its dimension is called the **nullity** of $\mathbf{A}$. Hence Theorem 2 states that

$$\text{rank } \mathbf{A} + \text{nullity } \mathbf{A} = n \tag{5}$$

where n is the number of unknowns (number of columns of $\mathbf{A}$).

Furthermore, by the definition of rank we have rank $\mathbf{A} \leqq m$ in (4). Hence if $m < n$, then rank $\mathbf{A} < n$. By Theorem 2 this gives the practically important

THEOREM 3

Homogeneous Linear System with Fewer Equations Than Unknowns

A homogeneous linear system with fewer equations than unknowns has always nontrivial solutions.

Nonhomogeneous Linear Systems

The characterization of all solutions of the linear system (1) is now quite simple, as follows.

THEOREM 4

Nonhomogeneous Linear System

If a nonhomogeneous linear system (1) *is consistent, then all of its solutions are obtained as*

$$\mathbf{x} = \mathbf{x}_0 + \mathbf{x}_h \tag{6}$$

where $\mathbf{x}_0$ *is any* (fixed) *solution of* (1) *and* $\mathbf{x}_h$ *runs through all the solutions of the corresponding homogeneous system* (4).

PROOF The difference $\mathbf{x}_h = \mathbf{x} - \mathbf{x}_0$ of any two solutions of (1) is a solution of (4) because $\mathbf{A}\mathbf{x}_h = \mathbf{A}(\mathbf{x} - \mathbf{x}_0) = \mathbf{A}\mathbf{x} - \mathbf{A}\mathbf{x}_0 = \mathbf{b} - \mathbf{b} = \mathbf{0}$. Since $\mathbf{x}$ is any solution of (1), we get all the solutions of (1) if in (6) we take any solution $\mathbf{x}_0$ of (1) and let $\mathbf{x}_h$ vary throughout the solution space of (4). ∎

7.6 For Reference: Second- and Third-Order Determinants

We explain these determinants separately from the general theory in Sec. 7.7 because they will be sufficient for many of our examples and problems. Since this section is for reference, ***go on to the next section, consulting this material only when needed.***

A **determinant of second order** is denoted and defined by

$$D = \det \mathbf{A} = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{12}a_{21}. \tag{1}$$

So here we have ***bars*** (whereas a matrix has ***brackets***).

Cramer's rule for solving linear systems of two equations in two unknowns

$$\begin{aligned} &\text{(a)} \quad a_{11}x_1 + a_{12}x_2 = b_1 \\ &\text{(b)} \quad a_{21}x_1 + a_{22}x_2 = b_2 \end{aligned} \tag{2}$$

is

$$x_1 = \frac{\begin{vmatrix} b_1 & a_{12} \\ b_2 & a_{22} \end{vmatrix}}{D} = \frac{b_1a_{22} - a_{12}b_2}{D}, \tag{3}$$

$$x_2 = \frac{\begin{vmatrix} a_{11} & b_1 \\ a_{21} & b_2 \end{vmatrix}}{D} = \frac{a_{11}b_2 - b_1a_{21}}{D}.$$

with D as in (1), provided

$$D \neq 0.$$

The value $D = 0$ appears for inconsistent nonhomogeneous systems and for homogeneous systems with nontrivial solutions.

PROOF We prove (3). To eliminate x_2, multiply (2a) by a_{22} and (2b) by $-a_{12}$ and add,

$$(a_{11}a_{22} - a_{12}a_{21})x_1 = b_1a_{22} - a_{12}b_2.$$

Similarly, to eliminate x_1, multiply (2a) by $-a_{21}$ and (2b) by a_{11} and add,

$$(a_{11}a_{22} - a_{12}a_{21})x_2 = a_{11}b_2 - b_1a_{21}.$$

Assuming that $D = a_{11}a_{22} - a_{12}a_{21} \neq 0$, dividing, and writing the right sides of these two equations as determinants, we obtain (3). ∎

EXAMPLE 1 Cramer's Rule for Two Equations

$$\text{If} \quad \begin{aligned} 4x_1 + 3x_2 &= 12 \\ 2x_1 + 5x_2 &= -8 \end{aligned} \quad \text{then} \quad x_1 = \frac{\begin{vmatrix} 12 & 3 \\ -8 & 5 \end{vmatrix}}{\begin{vmatrix} 4 & 3 \\ 2 & 5 \end{vmatrix}} = \frac{84}{14} = 6, \quad x_2 = \frac{\begin{vmatrix} 4 & 12 \\ 2 & -8 \end{vmatrix}}{\begin{vmatrix} 4 & 3 \\ 2 & 5 \end{vmatrix}} = \frac{-56}{14} = -4. \quad \blacksquare$$

Third-Order Determinants

A **determinant of third order** can be defined by

$$\textbf{(4)} \qquad D = \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = a_{11} \begin{vmatrix} a_{22} & a_{23} \\ a_{32} & a_{33} \end{vmatrix} - a_{21} \begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix} + a_{31} \begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix}.$$

Note the following. The signs on the right are $+ \; - \; +$. Each of the three terms on the right is an entry in the first column of D times its **minor,** that is, the second-order determinant obtained from D by deleting the row and column of that entry; thus, for a_{11} delete the first row and first column, and so on.

If we write out the minors in (4), we obtain

$$(4^*) \quad D = a_{11}a_{22}a_{33} - a_{11}a_{23}a_{32} + a_{21}a_{13}a_{32} - a_{21}a_{12}a_{33} + a_{31}a_{12}a_{23} - a_{31}a_{13}a_{22}.$$

Cramer's Rule for Linear Systems of Three Equations

$$\textbf{(5)} \qquad \begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 &= b_2 \\ a_{31}x_1 + a_{32}x_2 + a_{33}x_3 &= b_3 \end{aligned}$$

is

$$\textbf{(6)} \qquad x_1 = \frac{D_1}{D}, \quad x_2 = \frac{D_2}{D}, \quad x_3 = \frac{D_3}{D} \qquad (D \neq 0)$$

with the *determinant D of the system* given by (4) and

$$D_1 = \begin{vmatrix} b_1 & a_{12} & a_{13} \\ b_2 & a_{22} & a_{23} \\ b_3 & a_{32} & a_{33} \end{vmatrix}, \quad D_2 = \begin{vmatrix} a_{11} & b_1 & a_{13} \\ a_{21} & b_2 & a_{23} \\ a_{31} & b_3 & a_{33} \end{vmatrix}, \quad D_3 = \begin{vmatrix} a_{11} & a_{12} & b_1 \\ a_{21} & a_{22} & b_2 \\ a_{31} & a_{32} & b_3 \end{vmatrix}.$$

Note that D_1, D_2, D_3 are obtained by replacing Columns 1, 2, 3, respectively, by the column of the right sides of (5).

Cramer's rule (6) can be derived by eliminations similar to those for (3), but it also follows from the general case (Theorem 4) in the next section.

7.7 Determinants. Cramer's Rule

Determinants were originally introduced for solving linear systems. Although ***impractical in computations,*** they have important engineering applications in eigenvalue problems (Sec. 8.1), differential equations, vector algebra (Sec. 9.3), and so on. They can be introduced in several equivalent ways. Our definition is particularly practical in connection with linear systems.

A **determinant of order** n is a scalar associated with an $n \times n$ (hence ***square!***) matrix $\mathbf{A} = [a_{jk}]$, which is written

$$\textbf{(1)} \qquad D = \det \mathbf{A} = \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix}$$

and is defined for $n = 1$ by

$$\textbf{(2)} \qquad D = a_{11}$$

and for $n \geqq 2$ by

$$\textbf{(3a)} \qquad D = a_{j1}C_{j1} + a_{j2}C_{j2} + \cdots + a_{jn}C_{jn} \qquad (j = 1, 2, \cdots, \text{or } n)$$

or

$$\textbf{(3b)} \qquad D = a_{1k}C_{1k} + a_{2k}C_{2k} + \cdots + a_{nk}C_{nk} \qquad (k = 1, 2, \cdots, \text{or } n)$$

Here,

$$C_{jk} = (-1)^{j+k}M_{jk}$$

and M_{jk} is a determinant of order $n - 1$, namely, the determinant of the submatrix of $\mathbf{A}$ obtained from $\mathbf{A}$ by omitting the row and column of the entry a_{jk}, that is, the jth row and the kth column.

In this way, D is defined in terms of n determinants of order $n - 1$, each of which is, in turn, defined in terms of $n - 1$ determinants of order $n - 2$, and so on; we finally arrive at second-order determinants, in which those submatrices consist of single entries whose determinant is defined to be the entry itself.

From the definition it follows that *we may* ***expand*** *D by any row or column,* that is, choose in (3) the entries in any row or column, similarly when expanding the C_{jk}'s in (3), and so on.

This definition is unambiguous, that is, yields the same value for D no matter which columns or rows we choose in expanding. A proof is given in App. 4.

Terms used in connection with determinants are taken from matrices. In D we have n^2 **entries** a_{jk}, also n **rows** and n **columns,** and a **main diagonal** on which $a_{11}, a_{22}, \cdots, a_{nn}$ stand. Two terms are new:

M_{jk} is called the **minor** *of* a_{jk} *in* D, and C_{jk} the **cofactor** *of* a_{jk} *in* D.

For later use we note that (3) may also be written in terms of minors

(4a)
$$D = \sum_{k=1}^{n} (-1)^{j+k} a_{jk} M_{jk} \qquad (j = 1, 2, \cdots, \text{or } n)$$

(4b)
$$D = \sum_{j=1}^{n} (-1)^{j+k} a_{jk} M_{jk} \qquad (k = 1, 2, \cdots, \text{or } n).$$

EXAMPLE 1 Minors and Cofactors of a Third-Order Determinant

In (4) of the previous section the minors and cofactors of the entries in the first column can be seen directly. For the entries in the second row the minors are

$$M_{21} = \begin{vmatrix} a_{12} & a_{13} \\ a_{32} & a_{33} \end{vmatrix}, \qquad M_{22} = \begin{vmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{vmatrix}, \qquad M_{23} = \begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix}$$

and the cofactors are $C_{21} = -M_{21}$, $C_{22} = +M_{22}$, and $C_{23} = -M_{23}$. Similarly for the third row—write these down yourself. And verify that the signs in C_{jk} form a **checkerboard pattern**

$$\begin{matrix} + & - & + \\ - & + & - \\ + & - & + \end{matrix}$$

EXAMPLE 2 Expansions of a Third-Order Determinant

$$D = \begin{vmatrix} 1 & 3 & 0 \\ 2 & 6 & 4 \\ -1 & 0 & 2 \end{vmatrix} = 1 \begin{vmatrix} 6 & 4 \\ 0 & 2 \end{vmatrix} - 3 \begin{vmatrix} 2 & 4 \\ -1 & 2 \end{vmatrix} + 0 \begin{vmatrix} 2 & 6 \\ -1 & 0 \end{vmatrix}$$

$$= 1(12 - 0) - 3(4 + 4) + 0(0 + 6) = -12.$$

This is the expansion by the first row. The expansion by the third column is

$$D = 0 \begin{vmatrix} 2 & 6 \\ -1 & 0 \end{vmatrix} - 4 \begin{vmatrix} 1 & 3 \\ -1 & 0 \end{vmatrix} + 2 \begin{vmatrix} 1 & 3 \\ 2 & 6 \end{vmatrix} = 0 - 12 + 0 = -12,$$

Verify that the other four expansions also give the value -12.

EXAMPLE 3 Determinant of a Triangular Matrix

$$\begin{vmatrix} -3 & 0 & 0 \\ 6 & 4 & 0 \\ -1 & 2 & 5 \end{vmatrix} = -3 \begin{vmatrix} 4 & 0 \\ 2 & 5 \end{vmatrix} = -3 \cdot 4 \cdot 5 = -60.$$

Inspired by this, can you formulate a little theorem on determinants of triangular matrices? Of diagonal matrices?

General Properties of Determinants

To obtain the value of a determinant (1), we can first simplify it systematically by elementary row operations, similar to those for matrices in Sec. 7.3, as follows.

THEOREM 1

Behavior of an *n*th-Order Determinant under Elementary Row Operations

(a) *Interchange of two rows multiplies the value of the determinant by* -1.

(b) *Addition of a multiple of a row to another row does not alter the value of the determinant.*

(c) *Multiplication of a row by a nonzero constant c multiplies the value of the determinant by c.* (This holds also when $c = 0$, but gives no longer an elementary row operation.)

PROOF **(a)** By induction. The statement holds for $n = 2$ because

$$\begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc, \qquad \text{but} \qquad \begin{vmatrix} c & d \\ a & b \end{vmatrix} = bc - ad.$$

We now make the induction hypothesis that (a) holds for determinants of order $n - 1 \geqq 2$ and show that it then holds for determinants of order n. Let D be of order n. Let E be obtained from D by the interchange of two rows. Expand D and E by a row that is ***not*** one of those interchanged, call it the jth row. Then by (4a),

$$(5) \qquad D = \sum_{k=1}^{n} (-1)^{j+k} a_{jk} M_{jk}, \qquad E = \sum_{k=1}^{n} (-1)^{j+k} a_{jk} N_{jk}$$

where N_{jk} is obtained from the minor M_{jk} of a_{jk} in D by the interchange of those two rows which have been interchanged in D (and which N_{jk} must both contain because we expand by another row!). Now these minors are of order $n - 1$. Hence the induction hypothesis applies and gives $N_{jk} = -M_{jk}$. Thus $E = -D$ by (5).

(b) Add c times Row i to Row j. Let $\tilde{D}$ be the new determinant. Its entries in Row j are $a_{jk} + ca_{ik}$. If we expand $\tilde{D}$ by this Row j, we see that we can write it as $\tilde{D} = D_1 + cD_2$, where $D_1 = D$ has in Row j the a_{jk}, whereas D_2 has in that Row j the a_{ik} from the addition. Hence D_2 has a_{ik} in both Row i and Row j. Interchanging these two rows gives D_2 back, but on the other hand it gives $-D_2$ by (a). Together $D_2 = -D_2 = 0$, so that $\tilde{D} = D_1 = D$.

(c) Expand the determinant by the row that has been multiplied.

CAUTION! $\det(c\mathbf{A}) = c^n \det \mathbf{A}$ (not $c \det \mathbf{A}$). Explain why. ■

EXAMPLE 4 **Evaluation of Determinants by Reduction to Triangular Form**

Because of Theorem 1 we may evaluate determinants by reduction to triangular form, as in the Gauss elimination for a matrix. For instance (with the blue explanations always referring to the ***preceding determinant***)

$$D = \begin{vmatrix} 2 & 0 & -4 & 6 \\ 4 & 5 & 1 & 0 \\ 0 & 2 & 6 & -1 \\ -3 & 8 & 9 & 1 \end{vmatrix}$$

$$= \begin{vmatrix} 2 & 0 & -4 & 6 \\ 0 & 5 & 9 & -12 \\ 0 & 2 & 6 & -1 \\ 0 & 8 & 3 & 10 \end{vmatrix} \quad \text{Row 2} - 2 \text{ Row 1}$$

$$\quad \text{Row 4} + 1.5 \text{ Row 1}$$

$$= \begin{vmatrix} 2 & 0 & -4 & 6 \\ 0 & 5 & 9 & -12 \\ 0 & 0 & 2.4 & 3.8 \\ 0 & 0 & -11.4 & 29.2 \end{vmatrix} \quad \text{Row 3} - 0.4 \text{ Row 2}$$

$$\quad \text{Row 4} - 1.6 \text{ Row 2}$$

$$= \begin{vmatrix} 2 & 0 & -4 & 6 \\ 0 & 5 & 9 & -12 \\ 0 & 0 & 2.4 & 3.8 \\ 0 & 0 & -0 & 47.25 \end{vmatrix} \quad \text{Row 4} + 4.75 \text{ Row 3}$$

$$= 2 \cdot 5 \cdot 2.4 \cdot 47.25 = 1134. \qquad \blacksquare$$

THEOREM 2

Further Properties of *n*th-Order Determinants

(a)–(c) *in Theorem* 1 *hold also for columns.*

(d) ***Transposition*** *leaves the value of a determinant unaltered.*

(e) ***A zero row or column*** *renders the value of a determinant zero.*

(f) ***Proportional rows or columns*** *render the value of a determinant zero. In particular, a determinant with two identical rows or columns has the value zero.*

PROOF **(a)–(e)** follow directly from the fact that a determinant can be expanded by any row column. In **(d),** transposition is defined as for matrices, that is, the jth row becomes the jth column of the transpose.

(f) If Row j = c times Row i, then $D = cD_1$, where D_1 has Row j = Row i. Hence an interchange of these rows reproduces D_1, but it also gives $-D_1$ by Theorem 1(a). Hence $D_1 = 0$ and $D = cD_1 = 0$. Similarly for columns. ■

It is quite remarkable that the important concept of the rank of a matrix **A,** which is the maximum number of linearly independent row or column vectors of **A** (see Sec. 7.4), can be related to determinants. Here we may assume that rank $\mathbf{A} > 0$ because the only matrices with rank 0 are the zero matrices (see Sec. 7.4).

THEOREM 3

Rank in Terms of Determinants

An $m \times n$ matrix $\mathbf{A} = [a_{jk}]$ has rank $r \geqq 1$ if and only if **A** *has an $r \times r$ submatrix with nonzero determinant, whereas every square submatrix with more than r rows that* **A** *has (or does not have!) has determinant equal to zero.*

In particular, if **A** *is square, $n \times n$, it has rank n if and only if*

$$\det \mathbf{A} \neq 0.$$

PROOF The key idea is that elementary row operations (Sec. 7.3) alter neither rank (by Theorem 1 in Sec. 7.4) nor the property of a determinant being nonzero (by Theorem 1 in this section). The echelon form $\hat{\mathbf{A}}$ of $\mathbf{A}$ (see Sec. 7.3) has r nonzero row vectors (which are the first r row vectors) if and only if rank $\mathbf{A} = r$. Let $\hat{\mathbf{R}}$ be the $r \times r$ submatrix in the left upper corner of $\hat{\mathbf{A}}$ (so that the entries of $\hat{\mathbf{R}}$ are in both the first r rows and r columns of $\hat{\mathbf{A}}$). Now $\hat{\mathbf{R}}$ is triangular, with all diagonal entries r_{jj} nonzero. Thus, $\det \hat{\mathbf{R}} = r_{11} \cdots r_{rr} \neq 0$. Also $\det \mathbf{R} \neq 0$ for the corresponding $r \times r$ submatrix $\mathbf{R}$ of $\mathbf{A}$ because $\hat{\mathbf{R}}$ results from $\mathbf{R}$ by elementary row operations. Similarly, $\det \mathbf{S} = 0$ for any square submatrix $\mathbf{S}$ of $r + 1$ or more rows perhaps contained in $\mathbf{A}$ because the corresponding submatrix $\hat{\mathbf{S}}$ of $\hat{\mathbf{A}}$ must contain a row of zeros (otherwise we would have rank $\mathbf{A} \geqq r + 1$), so that $\det \hat{\mathbf{S}} = 0$ by Theorem 2. This proves the theorem for an $m \times n$ matrix.

In particular, if $\mathbf{A}$ is square, $n \times n$, then rank $\mathbf{A} = n$ if and only if $\mathbf{A}$ contains an $n \times n$ submatrix with nonzero determinant. But the only such submatrix can be $\mathbf{A}$ itself, hence $\det \mathbf{A} \neq 0$. ∎

Cramer's Rule

Theorem 3 opens the way to the classical solution formula for linear systems known as **Cramer's rule**[2], which gives solutions as quotients of determinants. ***Cramer's rule is not practical in computations*** (for which the methods in Secs. 7.3 and 20.1–20.3 are suitable), but is of ***theoretical interest*** in differential equations (Secs. 2.10, 3.3) and other theories that have engineering applications.

THEOREM 4

Cramer's Theorem (Solution of Linear Systems by Determinants)

(a) *If a linear system of n equations in the same number of unknowns* $x_1, \cdots, x_n$

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots & \\ a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n &= b_n \end{aligned} \tag{6}$$

has a nonzero coefficient determinant $D = \det \mathbf{A}$, *the system has precisely one solution. This solution is given by the formulas*

$$x_1 = \frac{D_1}{D}, \quad x_2 = \frac{D_2}{D}, \cdots, \quad x_n = \frac{D_n}{D} \tag{7}$$ **(Cramer's rule)**

where D_k *is the determinant obtained from D by replacing in D the kth column by the column with the entries* $b_1, \cdots, b_n$.

(b) *Hence if the system* (6) *is* ***homogeneous*** *and* $D \neq 0$, *it has only the trivial solution* $x_1 = 0, x_2 = 0, \cdots, x_n = 0$. *If* $D = 0$, *the homogeneous system also has nontrivial solutions.*

[2]GABRIEL CRAMER (1704–1752), Swiss mathematician.

PROOF The augmented matrix $\widetilde{\mathbf{A}}$ of the system (6) is of size $n \times (n + 1)$. Hence its rank can be at most n. Now if

$$D = \det \mathbf{A} = \begin{vmatrix} a_{11} & \cdots & a_{1n} \\ \cdot & \cdots & \cdot \\ \cdot & \cdots & \cdot \\ a_{n1} & \cdots & a_{nn} \end{vmatrix} \neq 0, \tag{8}$$

then rank $\mathbf{A} = n$ by Theorem 3. Thus rank $\widetilde{\mathbf{A}}$ = rank $\mathbf{A}$. Hence, by the Fundamental Theorem in Sec. 7.5, the system (6) has a unique solution.

Let us now prove (7). Expanding D by its kth column, we obtain

$$D = a_{1k}C_{1k} + a_{2k}C_{2k} + \cdots + a_{nk}C_{nk}, \tag{9}$$

where C_{ik} is the cofactor of entry a_{ik} in D. If we replace the entries in the kth column of D by any other numbers, we obtain a new determinant, say, $\hat{D}$. Clearly, its expansion by the kth column will be of the form (9), with $a_{1k}, \cdots, a_{nk}$ replaced by those new numbers and the cofactors C_{ik} as before. In particular, if we choose as new numbers the entries $a_{1l}, \cdots, a_{nl}$ of the lth column of D (where $l \neq k$), we have a new determinant $\hat{D}$ which has twice the column $[a_{1l} \quad \cdots \quad a_{nl}]^T$, once as its lth column, and once as its kth because of the replacement. Hence $\hat{D} = 0$ by Theorem 2(f). If we now expand $\hat{D}$ by the column that has been replaced (the kth column), we thus obtain

$$a_{1l}C_{1k} + a_{2l}C_{2k} + \cdots + a_{nl}C_{nk} = 0 \qquad (l \neq k). \tag{10}$$

We now multiply the first equation in (6) by C_{1k} on both sides, the second by $C_{2k}, \cdots$, the last by C_{nk}, and add the resulting equations. This gives

$$\begin{aligned} C_{1k}(a_{11}x_1 + \cdots + a_{1n}x_n) + \cdots + C_{nk}(a_{n1}x_1 + \cdots + a_{nn}x_n) \\ = b_1C_{1k} + \cdots + b_nC_{nk}. \end{aligned} \tag{11}$$

Collecting terms with the same x_j, we can write the left side as

$$x_1(a_{11}C_{1k} + a_{21}C_{2k} + \cdots + a_{n1}C_{nk}) + \cdots + x_n(a_{1n}C_{1k} + a_{2n}C_{2k} + \cdots + a_{nn}C_{nk}).$$

From this we see that x_k is multiplied by

$$a_{1k}C_{1k} + a_{2k}C_{2k} + \cdots + a_{nk}C_{nk}.$$

Equation (9) shows that this equals D. Similarly, x_l is multiplied by

$$a_{1l}C_{1k} + a_{2l}C_{2k} + \cdots + a_{nl}C_{nk}.$$

Equation (10) shows that this is zero when $l \neq k$. Accordingly, the left side of (11) equals simply x_kD, so that (11) becomes

$$x_kD = b_1C_{1k} + b_2C_{2k} + \cdots + b_nC_{nk}.$$

Now the right side of this is D_k as defined in the theorem, expanded by its kth column, so that division by D gives (7). This proves Cramer's rule.

If (6) is homogeneous and $D \neq 0$, then each D_k has a column of zeros, so that $D_k = 0$ by Theorem 2(e), and (7) gives the trivial solution.

Finally, if (6) is homogeneous and $D = 0$, then rank $\mathbf{A} < n$ by Theorem 3, so that nontrivial solutions exist by Theorem 2 in Sec. 7.5. ∎

Illustrations of Theorem 4 for $n = 2$ and 3 are given in Sec. 7.6, and an important application of the present formulas will follow in the next section.

PROBLEM SET 7.7

1. **(Second-order determinant)** Expand a general second-order determinant in four possible ways and show that the results agree.
2. **(Minors, cofactors)** Complete the list of minors and cofactors in Example 1.
3. **(Third-order determinant)** Do the task indicated in Example 2. Also evaluate D by reduction to triangular form.
4. **(Scalar multiplication)** Show that $\det(k\mathbf{A}) = k^n \det \mathbf{A}$ (not $k \det \mathbf{A}$), where $\mathbf{A}$ is any $n \times n$ matrix. Give an example.

5–16 EVALUATION OF DETERMINANTS

Evaluate, showing the details of your work.

5. $\begin{vmatrix} 13 & 8 \\ -2 & 7 \end{vmatrix}$

6. $\begin{vmatrix} \cos n\theta & \sin n\theta \\ -\sin n\theta & \cos n\theta \end{vmatrix}$

7. $\begin{vmatrix} \cos\alpha & \sin\alpha \\ \sin\beta & \cos\beta \end{vmatrix}$

8. $\begin{vmatrix} 14 & 2 & 5 \\ 2 & 0 & 8 \\ 5 & 8 & -2 \end{vmatrix}$

9. $\begin{vmatrix} 70.4 & 0.3 & 0.8 \\ 0 & 0.5 & 2.6 \\ 0 & 0 & -1.9 \end{vmatrix}$

10. $\begin{vmatrix} 2 & 1 & 2 \\ -2 & 2 & 1 \\ 1 & 2 & -2 \end{vmatrix}$

11. $\begin{vmatrix} 0 & 3 & -1 \\ -3 & 0 & -4 \\ 1 & 4 & 0 \end{vmatrix}$

12. $\begin{vmatrix} 0 & a & b \\ -a & 0 & c \\ -b & -c & 0 \end{vmatrix}$

13. $\begin{vmatrix} u & v & w \\ w & u & v \\ v & w & u \end{vmatrix}$

14. $\begin{vmatrix} 1 & -2 & 0 & 0 \\ 4 & 3 & 5 & 0 \\ 0 & 2 & 7 & 5 \\ 0 & 0 & 2 & 4 \end{vmatrix}$

15. $\begin{vmatrix} 1 & 2 & 0 & 0 \\ 3 & 4 & 0 & 0 \\ 0 & 0 & 5 & 6 \\ 0 & 0 & 7 & 8 \end{vmatrix}$

16. $\begin{vmatrix} 0 & -2 & 1 & 0 \\ 2 & 0 & -2 & 4 \\ -1 & 2 & 0 & 1 \\ 0 & -4 & -1 & 0 \end{vmatrix}$

17. (Expansion numerically impractical) Show that the computation of an nth-order determinant by expansion involves $n!$ multiplications, which if a multiplication takes 10^{-9} sec would take these times:

n	10	15	20	25
Time	0.004 sec	22 min	77 years	$0.5 \cdot 10^9$ years

18–20 CRAMER'S RULE

Solve by Cramer's rule and check by Gauss elimination and back substitution. (Show details.)

18.
$$2x - 5y = 23$$
$$4x + 6y = -2$$

19.
$$3y + 4z = 14.8$$
$$4x + 2y - z = -6.3$$
$$x - y + 5z = 13.5$$

20.
$$w + 2x - 3z = 30$$
$$4x - 5y + 2z = 13$$
$$2w + 8x - 4y + z = 42$$
$$3w + y - 5z = 35$$

21–23 RANK BY DETERMINANTS

Find the rank by Theorem 3 (which is not a very practical way) and check by row reduction. (Show details.)

21. $\begin{bmatrix} 8 & 4 \\ -2 & -1 \\ 6 & 3 \end{bmatrix}$

22. $\begin{bmatrix} 2 & 1 & 0 \\ 13 & -13 & 12 \\ -3 & 5 & -4 \end{bmatrix}$

23. $\begin{bmatrix} 0.4 & 0 & -2.4 & 3.0 \\ 1.2 & 0.6 & 0 & 0.3 \\ 0 & 1.2 & 1.2 & 0 \end{bmatrix}$

24. **TEAM PROJECT. Geometrical Applications: Curves and Surfaces Through Given Points.** The idea is to get an equation from the vanishing of the determinant of a homogeneous linear system as the condition for a nontrivial solution in Cramer's theorem. We explain the trick for obtaining such a system for the case of a line L through two given points P_1: (x_1, y_1) and P_2: (x_2, y_2). The unknown line is $ax + by = -c$, say. We write it as $ax + by + c \cdot 1 = 0$. To get a nontrivial solution a, b, c, the determinant of the "coefficients" x, y, 1 must be zero. The system is

$$\begin{aligned} ax + by \quad + c \cdot 1 &= 0 \quad (\text{Line } L) \\ (12) \qquad ax_1 + by_1 + c \cdot 1 &= 0 \quad (P_1 \text{ on } L) \\ ax_2 + by_2 + c \cdot 1 &= 0 \quad (P_2 \text{ on } L). \end{aligned}$$

(a) Line through two points. Derive from $D = 0$ in (12) the familiar formula

$$\frac{x - x_1}{x_1 - x_2} = \frac{y - y_1}{y_1 - y_2}.$$

(b) Plane. Find the analog of (12) for a plane through three given points. Apply it when the points are (1, 1, 1), (3, 2, 6), (5, 0, 5).

(c) Circle. Find a similar formula for a circle in the plane through three given points. Find and sketch the circle through (2, 6), (6, 4), (7, 1).

(d) Sphere. Find the analog of the formula in (c) for a sphere through four given points. Find the sphere through (0, 0, 5), (4, 0, 1), (0, 4, 1), (0, 0, −3) by this formula or by inspection.

(e) General conic section. Find a formula for a general conic section (the vanishing of a determinant of 6th order). Try it out for a quadratic parabola and for a more general conic section of your own choice.

25. **WRITING PROJECT. General Properties of Determinants.** Illustrate each statement in Theorems 1 and 2 with an example of your choice.

26. **CAS EXPERIMENT. Determinant of Zeros and Ones.** Find the value of the determinant of the $n \times n$ matrix $\mathbf{A}_n$ with main diagonal entries all 0 and all others 1. Try to find a formula for this. Try to prove it by induction. Interpret $\mathbf{A}_3$ and $\mathbf{A}_4$ as *"incidence matrices"* (as in Problem Set 7.1 but without the minuses) of a triangle and a tetrahedron, respectively; similarly for an *"n-simplex"*, having n vertices and $n(n-1)/2$ edges (and spanning R^{n-1}, $n = 5, 6, \cdots$).

7.8 Inverse of a Matrix. Gauss–Jordan Elimination

In this section we consider* square *matrices exclusively.

The **inverse** of an $n \times n$ matrix $\mathbf{A} = [a_{jk}]$ is denoted by $\mathbf{A}^{-1}$ and is an $n \times n$ matrix such that

$$(1) \qquad \mathbf{A}\mathbf{A}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$$

where $\mathbf{I}$ is the $n \times n$ unit matrix (see Sec. 7.2).

If $\mathbf{A}$ has an inverse, then $\mathbf{A}$ is called a **nonsingular matrix.** If $\mathbf{A}$ has no inverse, then $\mathbf{A}$ is called a **singular matrix.**

If $\mathbf{A}$ *has an inverse, the inverse is unique.*

Indeed, if both $\mathbf{B}$ and $\mathbf{C}$ are inverses of $\mathbf{A}$, then $\mathbf{AB} = \mathbf{I}$ and $\mathbf{CA} = \mathbf{I}$, so that we obtain the uniqueness from

$$\mathbf{B} = \mathbf{IB} = (\mathbf{CA})\mathbf{B} = \mathbf{C}(\mathbf{AB}) = \mathbf{CI} = \mathbf{C}.$$

We prove next that $\mathbf{A}$ has an inverse (is nonsingular) if and only if it has maximum possible rank n. The proof will also show that $\mathbf{Ax} = \mathbf{b}$ implies $\mathbf{x} = \mathbf{A}^{-1}\mathbf{b}$ provided $\mathbf{A}^{-1}$ exists, and will thus give a motivation for the inverse as well as a relation to linear systems. (But this will ***not*** give a good method of solving $\mathbf{Ax} = \mathbf{b}$ ***numerically*** because the Gauss elimination in Sec. 7.3 requires fewer computations.)

THEOREM 1

Existence of the Inverse

The inverse $\mathbf{A}^{-1}$ *of an* $n \times n$ *matrix* $\mathbf{A}$ *exists if and only if* rank $\mathbf{A} = n$, *thus* (by Theorem 3, Sec. 7.7) *if and only if* $\det \mathbf{A} \neq 0$. *Hence* $\mathbf{A}$ *is nonsingular if* rank $\mathbf{A} = n$, *and is singular if* rank $\mathbf{A} < n$.

PROOF Let $\mathbf{A}$ be a given $n \times n$ matrix and consider the linear system

$$\mathbf{Ax} = \mathbf{b}. \tag{2}$$

If the inverse $\mathbf{A}^{-1}$ exists, then multiplication from the left on both sides and use of (1) gives

$$\mathbf{A}^{-1}\mathbf{Ax} = \mathbf{x} = \mathbf{A}^{-1}\mathbf{b}.$$

This shows that (2) has a unique solution $\mathbf{x}$. Hence $\mathbf{A}$ must have rank n by the Fundamental Theorem in Sec. 7.5.

Conversely, let rank $\mathbf{A} = n$. Then by the same theorem, the system (2) has a unique solution $\mathbf{x}$ for any $\mathbf{b}$. Now the back substitution following the Gauss elimination (Sec. 7.3) shows that the components x_j of $\mathbf{x}$ are linear combinations of those of $\mathbf{b}$. Hence we can write

$$\mathbf{x} = \mathbf{Bb} \tag{3}$$

with $\mathbf{B}$ to be determined. Substitution into (2) gives

$$\mathbf{Ax} = \mathbf{A}(\mathbf{Bb}) = (\mathbf{AB})\mathbf{b} = \mathbf{Cb} = \mathbf{b} \qquad (\mathbf{C} = \mathbf{AB})$$

for any $\mathbf{b}$. Hence $\mathbf{C} = \mathbf{AB} = \mathbf{I}$, the unit matrix. Similarly, if we substitute (2) into (3) we get

$$\mathbf{x} = \mathbf{Bb} = \mathbf{B}(\mathbf{Ax}) = (\mathbf{BA})\mathbf{x}$$

for any $\mathbf{x}$ (and $\mathbf{b} = \mathbf{Ax}$). Hence $\mathbf{BA} = \mathbf{I}$. Together, $\mathbf{B} = \mathbf{A}^{-1}$ exists. ■

---

[3]WILHELM JORDAN (1842–1899), German mathematician and geodesist. [See *American Mathematical Monthly* **94** (1987), 130–142.]

We do ***not recommend*** it as a method for solving systems of linear equations, since the number of operations in addition to those of the Gauss elimination is larger than that for back substitution, which the Gauss–Jordan elimination avoids. See also Sec. 20.1.

Determination of the Inverse by the Gauss–Jordan Method

For the practical determination of the inverse $\mathbf{A}^{-1}$ of a nonsingular $n \times n$ matrix $\mathbf{A}$ we can use the Gauss elimination (Sec. 7.3), actually a variant of it, called the **Gauss-Jordan elimination**[3] (footnote of p. 316). The idea of the method is as follows.

Using $\mathbf{A}$, we form n linear systems

$$\mathbf{A}\mathbf{x}_{(1)} = \mathbf{e}_{(1)}, \qquad \cdots, \qquad \mathbf{A}\mathbf{x}_{(n)} = \mathbf{e}_{(n)}$$

where $\mathbf{e}_{(1)}, \cdots, \mathbf{e}_{(n)}$ are the columns of the $n \times n$ unit matrix $\mathbf{I}$; thus, $\mathbf{e}_{(1)} = [1 \quad 0 \quad \cdots \quad 0]^T$, $\mathbf{e}_{(2)} = [0 \quad 1 \quad 0 \quad \cdots \quad 0]^T$, etc. These are n vector equations in the unknown vectors $\mathbf{x}_{(1)}, \cdots, \mathbf{x}_{(n)}$. We combine them into a single matrix equation $\mathbf{AX} = \mathbf{I}$, with the unknown matrix $\mathbf{X}$ having the columns $\mathbf{x}_{(1)}, \cdots, \mathbf{x}_{(n)}$. Correspondingly, we combine the n augmented matrices $[\mathbf{A} \quad \mathbf{e}_{(1)}], \cdots, [\mathbf{A} \quad \mathbf{e}_{(n)}]$ into one $n \times 2n$ "augmented matrix" $\widetilde{\mathbf{A}} = [\mathbf{A} \quad \mathbf{I}]$. Now multiplication of $\mathbf{AX} = \mathbf{I}$ by $\mathbf{A}^{-1}$ from the left gives $\mathbf{X} = \mathbf{A}^{-1}\mathbf{I} = \mathbf{A}^{-1}$. Hence, to solve $\mathbf{AX} = \mathbf{I}$ for $\mathbf{X}$, we can apply the Gauss elimination to $\widetilde{\mathbf{A}} = [\mathbf{A} \quad \mathbf{I}]$. This gives a matrix of the form $[\mathbf{U} \quad \mathbf{H}]$ with upper triangular $\mathbf{U}$ because the Gauss elimination triangularizes systems. The Gauss–Jordan method reduces $\mathbf{U}$ by further elementary row operations to diagonal form, in fact to the unit matrix $\mathbf{I}$. This is done by eliminating the entries of $\mathbf{U}$ above the main diagonal and making the diagonal entries all 1 by multiplication (see the example below). Of course, the method operates on the entire matrix $[\mathbf{U} \quad \mathbf{H}]$, transforming $\mathbf{H}$ into some matrix $\mathbf{K}$, hence the entire $[\mathbf{U} \quad \mathbf{H}]$ to $[\mathbf{I} \quad \mathbf{K}]$. This is the "augmented matrix" of $\mathbf{IX} = \mathbf{K}$. Now $\mathbf{IX} = \mathbf{X} = \mathbf{A}^{-1}$, as shown before. By comparison, $\mathbf{K} = \mathbf{A}^{-1}$, so that we can read $\mathbf{A}^{-1}$ directly from $[\mathbf{I} \quad \mathbf{K}]$.

The following example illustrates the practical details of the method.

EXAMPLE 1 **Inverse of a Matrix. Gauss–Jordan Elimination**

Determine the inverse $\mathbf{A}^{-1}$ of

$$\mathbf{A} = \begin{bmatrix} -1 & 1 & 2 \\ 3 & -1 & 1 \\ -1 & 3 & 4 \end{bmatrix}.$$

Solution. We apply the Gauss elimination (Sec. 7.3) to the following $n \times 2n = 3 \times 6$ matrix, where BLUE always refers to the previous matrix.

$$[\mathbf{A} \quad \mathbf{I}] = \left[\begin{array}{ccc|ccc} -1 & 1 & 2 & 1 & 0 & 0 \\ 3 & -1 & 1 & 0 & 1 & 0 \\ -1 & 3 & 4 & 0 & 0 & 1 \end{array}\right]$$

$$\left[\begin{array}{ccc|ccc} -1 & 1 & 2 & 1 & 0 & 0 \\ 0 & 2 & 7 & 3 & 1 & 0 \\ 0 & 2 & 2 & -1 & 0 & 1 \end{array}\right] \quad \begin{array}{l} \\ \text{Row 2} + 3\,\text{Row 1} \\ \text{Row 3} - \text{Row 1} \end{array}$$

$$\left[\begin{array}{ccc|ccc} -1 & 1 & 2 & 1 & 0 & 0 \\ 0 & 2 & 7 & 3 & 1 & 0 \\ 0 & 0 & -5 & -4 & -1 & 1 \end{array}\right] \quad \begin{array}{l} \\ \\ \text{Row 3} - \text{Row 2} \end{array}$$

This is [**U** **H**] as produced by the Gauss elimination. Now follow the additional Gauss–Jordan steps, reducing **U** to **I**, that is, to diagonal form with entries 1 on the main diagonal.

$$\left[\begin{array}{ccc|ccc} 1 & -1 & -2 & -1 & 0 & 0 \\ 0 & 1 & 3.5 & 1.5 & 0.5 & 0 \\ 0 & 0 & 1 & 0.8 & 0.2 & -0.2 \end{array}\right] \quad -\text{Row } 1$$

$$\left[\begin{array}{ccc|ccc} 1 & -1 & -2 & -1 & 0 & 0 \\ 0 & 1 & 3.5 & 1.5 & 0.5 & 0 \\ 0 & 0 & 1 & 0.8 & 0.2 & -0.2 \end{array}\right] \quad 0.5\,\text{Row } 2$$

$$\left[\begin{array}{ccc|ccc} 1 & -1 & -2 & -1 & 0 & 0 \\ 0 & 1 & 3.5 & 1.5 & 0.5 & 0 \\ 0 & 0 & 1 & 0.8 & 0.2 & -0.2 \end{array}\right] \quad -0.2\,\text{Row } 3$$

$$\left[\begin{array}{ccc|ccc} 1 & -1 & 0 & 0.6 & 0.4 & -0.4 \\ 0 & 1 & 3.5 & 1.5 & 0.5 & 0 \\ 0 & 0 & 1 & 0.8 & 0.2 & -0.2 \end{array}\right] \quad \text{Row } 1 + 2\,\text{Row } 3$$

$$\left[\begin{array}{ccc|ccc} 1 & -1 & 0 & 0.6 & 0.4 & -0.4 \\ 0 & 1 & 0 & -1.3 & -0.2 & 0.7 \\ 0 & 0 & 1 & 0.8 & 0.2 & -0.2 \end{array}\right] \quad \text{Row } 2 - 3.5\,\text{Row } 3$$

$$\left[\begin{array}{ccc|ccc} 1 & 0 & 0 & -0.7 & 0.2 & 0.3 \\ 0 & 1 & 0 & -1.3 & -0.2 & 0.7 \\ 0 & 0 & 1 & 0.8 & 0.2 & -0.2 \end{array}\right] \quad \text{Row } 1 + \text{Row } 2$$

The last three columns constitute $\mathbf{A}^{-1}$. Check:

$$\begin{bmatrix} -1 & 1 & 2 \\ 3 & -1 & 1 \\ -1 & 3 & 4 \end{bmatrix} \begin{bmatrix} -0.7 & 0.2 & 0.3 \\ -1.3 & -0.2 & 0.7 \\ 0.8 & 0.2 & -0.2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

Hence $\mathbf{A}\mathbf{A}^{-1} = \mathbf{I}$. Similarly, $\mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$. ■

Useful Formulas for Inverses

The explicit formula (4) in the following theorem is often useful in theoretical studies (as opposed to *computing* inverses). In fact, the special case $n = 2$ occurs quite frequently in geometrical and other applications.

THEOREM 2

Inverse of a Matrix

The inverse of a nonsingular $n \times n$ matrix $\mathbf{A} = [a_{jk}]$ is given by

$$\textbf{(4)} \qquad \mathbf{A}^{-1} = \frac{1}{\det \mathbf{A}} [C_{jk}]^{\mathsf{T}} = \frac{1}{\det \mathbf{A}} \begin{bmatrix} C_{11} & C_{21} & \cdots & C_{n1} \\ C_{12} & C_{22} & \cdots & C_{n2} \\ \cdot & \cdot & \cdots & \cdot \\ C_{1n} & C_{2n} & \cdots & C_{nn} \end{bmatrix},$$

where C_{jk} is the cofactor of a_{jk} in det **A** (see Sec. 7.7). (CAUTION! Note well that in $\mathbf{A}^{-1}$, the cofactor C_{jk} occupies the same place as a_{kj} (not a_{jk}) does in **A**.)

In particular, the inverse of

$$\textbf{(4*)} \quad \mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \quad \textit{is} \quad \mathbf{A}^{-1} = \frac{1}{\det \mathbf{A}} \begin{bmatrix} a_{22} & -a_{12} \\ -a_{21} & a_{11} \end{bmatrix}.$$

PROOF We denote the right side of (4) by **B** and show that $\mathbf{BA} = \mathbf{I}$. We first write

$$\mathbf{BA} = \mathbf{G} = [g_{kl}] \tag{5}$$

and then show that $\mathbf{G} = \mathbf{I}$. Now by the definition of matrix multiplication and because of the form of **B** in (4), we obtain (CAUTION! C_{sk}, not C_{ks})

$$g_{kl} = \sum_{s=1}^{n} \frac{C_{sk}}{\det \mathbf{A}}\, a_{sl} = \frac{1}{\det \mathbf{A}}\,(a_{1l}C_{1k} + \cdots + a_{nl}C_{nk}). \tag{6}$$

Now (9) and (10) in Sec. 7.7 show that the sum $(\cdots)$ on the right is $D = \det \mathbf{A}$ when $l = k$, and is zero when $l \neq k$. Hence

$$g_{kk} = \frac{1}{\det \mathbf{A}} \det \mathbf{A} = 1,$$

$$g_{kl} = 0 \quad (l \neq k),$$

In particular, for $n = 2$ we have in (4) in the first row $C_{11} = a_{22}$, $C_{21} = -a_{12}$ and in the second row $C_{12} = -a_{21}$, $C_{22} = a_{11}$. This gives (4*). ∎

EXAMPLE 2 **Inverse of a 2 × 2 Matrix**

$$\mathbf{A} = \begin{bmatrix} 3 & 1 \\ 2 & 4 \end{bmatrix}, \qquad \mathbf{A}^{-1} = \frac{1}{10}\begin{bmatrix} 4 & -1 \\ -2 & 3 \end{bmatrix} = \begin{bmatrix} 0.4 & -0.1 \\ -0.2 & 0.3 \end{bmatrix}$$ ∎

EXAMPLE 3 **Further Illustration of Theorem 2**

Using (4), find the inverse of

$$\mathbf{A} = \begin{bmatrix} -1 & 1 & 2 \\ 3 & -1 & 1 \\ -1 & 3 & 4 \end{bmatrix}.$$

Solution. We obtain $\det \mathbf{A} = -1(-7) - 1 \cdot 13 + 2 \cdot 8 = 10$, and in (4),

$$C_{11} = \begin{vmatrix} -1 & 1 \\ 3 & 4 \end{vmatrix} = -7, \qquad C_{21} = -\begin{vmatrix} 1 & 2 \\ 3 & 4 \end{vmatrix} = 2, \qquad C_{31} = \begin{vmatrix} 1 & 2 \\ -1 & 1 \end{vmatrix} = 3,$$

$$C_{12} = -\begin{vmatrix} 3 & 1 \\ -1 & 4 \end{vmatrix} = -13, \qquad C_{22} = \begin{vmatrix} -1 & 2 \\ -1 & 4 \end{vmatrix} = -2, \qquad C_{32} = -\begin{vmatrix} -1 & 2 \\ 3 & 1 \end{vmatrix} = 7,$$

$$C_{13} = \begin{vmatrix} 3 & -1 \\ -1 & 3 \end{vmatrix} = 8, \qquad C_{23} = -\begin{vmatrix} -1 & 1 \\ -1 & 3 \end{vmatrix} = 2, \qquad C_{33} = \begin{vmatrix} -1 & 1 \\ 3 & -1 \end{vmatrix} = -2,$$

so that by (4), in agreement with Example 1,

$$\mathbf{A}^{-1} = \begin{bmatrix} -0.7 & 0.2 & 0.3 \\ -1.3 & -0.2 & 0.7 \\ 0.8 & 0.2 & -0.2 \end{bmatrix}.$$ ∎

Diagonal matrices $\mathbf{A} = [a_{jk}]$, $a_{jk} = 0$ when $j \neq k$, have an inverse if and only if all $a_{jj} \neq 0$. Then $\mathbf{A}^{-1}$ is diagonal, too, with entries $1/a_{11}, \cdots, 1/a_{nn}$.

PROOF For a diagonal matrix we have in (4)

$$\frac{C_{11}}{D} = \frac{a_{22} \cdots a_{nn}}{a_{11}a_{22} \cdots a_{nn}} = \frac{1}{a_{11}}, \qquad \text{etc.}$$

EXAMPLE 4 **Inverse of a Diagonal Matrix**

Let

$$\mathbf{A} = \begin{bmatrix} -0.5 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

Then the inverse is

$$\mathbf{A}^{-1} = \begin{bmatrix} -2 & 0 & 0 \\ 0 & 0.25 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Products can be inverted by taking the inverse of each factor and multiplying these inverses ***in reverse order,***

$$(\mathbf{AC})^{-1} = \mathbf{C}^{-1}\mathbf{A}^{-1}. \tag{7}$$

Hence for more than two factors,

$$(\mathbf{AC} \cdots \mathbf{PQ})^{-1} = \mathbf{Q}^{-1}\mathbf{P}^{-1} \cdots \mathbf{C}^{-1}\mathbf{A}^{-1}. \tag{8}$$

PROOF The idea is to start from (1) for $\mathbf{AC}$ instead of $\mathbf{A}$, that is, $\mathbf{AC}(\mathbf{AC})^{-1} = \mathbf{I}$, and multiply it on both sides from the left, first by $\mathbf{A}^{-1}$, which because of $\mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$ gives

$$\begin{aligned} \mathbf{A}^{-1}\mathbf{AC}(\mathbf{AC})^{-1} &= \mathbf{C}(\mathbf{AC})^{-1} \\ &= \mathbf{A}^{-1}\mathbf{I} = \mathbf{A}^{-1}, \end{aligned}$$

and then multiplying this on both sides from the left, this time by $\mathbf{C}^{-1}$ and by using $\mathbf{C}^{-1}\mathbf{C} = \mathbf{I}$,

$$\mathbf{C}^{-1}\mathbf{C}(\mathbf{AC})^{-1} = (\mathbf{AC})^{-1} = \mathbf{C}^{-1}\mathbf{A}^{-1}.$$

This proves (7), and from it, (8) follows by induction.

We also note that *the inverse of the inverse is the given matrix,* as you may prove.

$$(\mathbf{A}^{-1})^{-1} = \mathbf{A}. \tag{9}$$

Unusual Properties of Matrix Multiplication. Cancellation Laws

Section 7.2 contains warnings that some properties of matrix multiplication deviate from those for numbers, and we are now able to explain the restricted validity of the so-called **cancellation laws** [2.] and [3.] below, using rank and inverse, concepts that were not yet available in Sec. 7.2. The deviations from the usual are of great practical importance and must be carefully observed. They are as follows.

[1.] Matrix multiplication is not commutative, that is, in general we have

$$\mathbf{AB} \neq \mathbf{BA}.$$

[2.] $\mathbf{AB} = \mathbf{0}$ does not generally imply $\mathbf{A} = \mathbf{0}$ or $\mathbf{B} = \mathbf{0}$ (or $\mathbf{BA} = \mathbf{0}$); for example,

$$\begin{bmatrix} 1 & 1 \\ 2 & 2 \end{bmatrix} \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

[3.] $\mathbf{AC} = \mathbf{AD}$ does not generally imply $\mathbf{C} = \mathbf{D}$ (even when $\mathbf{A} \neq \mathbf{0}$).

Complete answers to [2.] and [3.] are contained in the following theorem.

THEOREM 3

Cancellation Laws

Let $\mathbf{A}, \mathbf{B}, \mathbf{C}$ *be* $n \times n$ *matrices. Then:*

(a) *If* rank $\mathbf{A} = n$ *and* $\mathbf{AB} = \mathbf{AC}$, *then* $\mathbf{B} = \mathbf{C}$.

(b) *If* rank $\mathbf{A} = n$, *then* $\mathbf{AB} = \mathbf{0}$ *implies* $\mathbf{B} = \mathbf{0}$. *Hence if* $\mathbf{AB} = \mathbf{0}$, *but* $\mathbf{A} \neq \mathbf{0}$ *as well as* $\mathbf{B} \neq \mathbf{0}$, *then* rank $\mathbf{A} < n$ *and* rank $\mathbf{B} < n$.

(c) *If* $\mathbf{A}$ *is singular, so are* $\mathbf{BA}$ *and* $\mathbf{AB}$.

PROOF **(a)** The inverse of $\mathbf{A}$ exists by Theorem 1. Multiplication by $\mathbf{A}^{-1}$ from the left gives $\mathbf{A}^{-1}\mathbf{AB} = \mathbf{A}^{-1}\mathbf{AC}$, hence $\mathbf{B} = \mathbf{C}$.

(b) Let rank $\mathbf{A} = n$. Then $\mathbf{A}^{-1}$ exists, and $\mathbf{AB} = \mathbf{0}$ implies $\mathbf{A}^{-1}\mathbf{AB} = \mathbf{B} = \mathbf{0}$. Similarly when rank $\mathbf{B} = n$. This implies the second statement in (b).

(c_1) Rank $\mathbf{A} < n$ by Theorem 1. Hence $\mathbf{Ax} = \mathbf{0}$ has nontrivial solutions by Theorem 2 in Sec. 7.5. Multiplication by $\mathbf{B}$ shows that these solutions are also solutions of $\mathbf{BAx} = \mathbf{0}$, so that rank $(\mathbf{BA}) < n$ by Theorem 2 in Sec. 7.5 and $\mathbf{BA}$ is singular by Theorem 1.

(c_2) $\mathbf{A}^\mathsf{T}$ is singular by Theorem 2(d) in Sec. 7.7. Hence $\mathbf{B}^\mathsf{T}\mathbf{A}^\mathsf{T}$ is singular by part (c_1), and is equal to $(\mathbf{AB})^\mathsf{T}$ by (10d) in Sec. 7.2. Hence $\mathbf{AB}$ is singular by Theorem 2(d) in Sec. 7.7. ∎

Determinants of Matrix Products

The determinant of a matrix product $\mathbf{AB}$ or $\mathbf{BA}$ can be written as the product of the determinants of the factors, and it is interesting that $\det \mathbf{AB} = \det \mathbf{BA}$, although $\mathbf{AB} \neq \mathbf{BA}$ in general. The corresponding formula (10) is needed occasionally and can be obtained by Gauss-Jordan elimination (see Example 1) and from the theorem just proved.

THEOREM 4

Determinant of a Product of Matrices

For any $n \times n$ matrices **A** *and* **B,**

$$\det(\mathbf{AB}) = \det(\mathbf{BA}) = \det \mathbf{A} \det \mathbf{B}. \tag{10}$$

PROOF If **A** or **B** is singular, so are **AB** and **BA** by Theorem 3(c), and (10) reduces to $0 = 0$ by Theorem 3 in Sec. 7.7.

Now let **A** and **B** be nonsingular. Then we can reduce **A** to a diagonal matrix $\hat{\mathbf{A}} = [a_{jk}]$ by Gauss–Jordan steps. Under these operations, det **A** retains its value, by Theorem 1 in Sec. 7.7, (a) and (b) [not (c)] except perhaps for a sign reversal in row interchanging when pivoting. But the same operations reduce **AB** to $\hat{\mathbf{A}}\mathbf{B}$ with the same effect on det (**AB**). Hence it remains to prove (10) for $\hat{\mathbf{A}}\mathbf{B}$; written out,

$$\hat{\mathbf{A}}\mathbf{B} = \begin{bmatrix} \hat{a}_{11} & 0 & \cdots & 0 \\ 0 & \hat{a}_{22} & \cdots & 0 \\ & & \ddots & \\ 0 & 0 & \cdots & \hat{a}_{nn} \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1n} \\ b_{21} & b_{22} & \cdots & b_{2n} \\ & & & \vdots \\ b_{n1} & b_{n2} & \cdots & b_{nn} \end{bmatrix}$$

$$= \begin{bmatrix} \hat{a}_{11}b_{11} & \hat{a}_{11}b_{12} & \cdots & \hat{a}_{11}b_{1n} \\ \hat{a}_{22}b_{21} & \hat{a}_{22}b_{22} & \cdots & \hat{a}_{22}b_{2n} \\ & & \vdots & \\ \hat{a}_{nn}b_{n1} & \hat{a}_{nn}b_{n2} & \cdots & \hat{a}_{nn}b_{nn} \end{bmatrix}.$$

We now take the determinant det ($\hat{\mathbf{A}}\mathbf{B}$). On the right we can take out a factor $\hat{a}_{11}$ from the first row, $\hat{a}_{22}$ from the second, $\cdots$, $\hat{a}_{nn}$ from the nth. But this product $\hat{a}_{11}\hat{a}_{22}\cdots\hat{a}_{nn}$ equals det $\hat{\mathbf{A}}$ because $\hat{\mathbf{A}}$ is diagonal. The remaining determinant is det **B.** This proves (10) for det (**AB**), and the proof for det (**BA**) follows by the same idea. ∎

This completes our discussion of linear systems (Secs. 7.3–7.8). Section 7.9 on vector spaces and linear transformations is optional. ***Numeric methods*** are discussed in Secs. 20.1–20.4, which are independent of other sections on numerics.

PROBLEM SET 7.8

1–12 INVERSE

Find the inverse by Gauss–Jordan [or by (4*) if $n = 2$] or state that it does not exist. Check by using (1).

1. $\begin{bmatrix} 1.20 & 4.64 \\ 0.50 & 3.60 \end{bmatrix}$

2. $\begin{bmatrix} 0.6 & 0.8 \\ 0.8 & -0.6 \end{bmatrix}$

3. $\begin{bmatrix} \cos 2\theta & \sin 2\theta \\ -\sin 2\theta & \cos 2\theta \end{bmatrix}$

4. $\begin{bmatrix} \frac{2}{3} & \frac{1}{3} & \frac{2}{3} \\ -\frac{2}{3} & \frac{2}{3} & \frac{1}{3} \\ \frac{1}{3} & \frac{2}{3} & -\frac{2}{3} \end{bmatrix}$

5. $\begin{bmatrix} 3 & -1 & 1 \\ -15 & 6 & -5 \\ 5 & -2 & 2 \end{bmatrix}$ **6.** $\begin{bmatrix} 29 & -11 & 10 \\ -160 & 61 & -55 \\ 55 & -21 & 19 \end{bmatrix}$

7. $\begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 5 & 4 & 1 \end{bmatrix}$ **8.** $\begin{bmatrix} 1 & 2 & 5 \\ 0 & -1 & 2 \\ 2 & 4 & 11 \end{bmatrix}$

9. $\begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ **10.** $\begin{bmatrix} 0 & 8 & 0 \\ 0 & 0 & 4 \\ 2 & 0 & 0 \end{bmatrix}$

11. $\begin{bmatrix} 1 & 2 & 5 \\ 0 & -1 & 2 \\ 2 & 4 & 10 \end{bmatrix}$ **12.** $\begin{bmatrix} 1 & 2 & -9 \\ -2 & -4 & 19 \\ 0 & -1 & 2 \end{bmatrix}$

13. (Triangular matrix) Is the inverse of a triangular matrix always triangular (as in Prob. 7)? Give reason.

14. (Rotation) Give an application of the matrix in Prob. 3 that makes the form of its inverse obvious.

15. (Inverse of the square) Verify $(\mathbf{A}^2)^{-1} = (\mathbf{A}^{-1})^2$ for $\mathbf{A}$ in Prob. 5.

16. Prove the formula in Prob. 15.

17. (Inverse of the transpose) Verify $(\mathbf{A}^\mathrm{T})^{-1} = (\mathbf{A}^{-1})^\mathrm{T}$ for $\mathbf{A}$ in Prob. 5.

18. Prove the formula in Prob. 17.

19. (Inverse of the inverse) Prove that $(\mathbf{A}^{-1})^{-1} = \mathbf{A}$.

20. (Row interchange) Same question as in Prob. 14 for the matrix in Prob. 9.

21–23 EXPLICIT FORMULA (4) FOR THE INVERSE

Formula (4) is generally not very practical. To understand its use, apply it:

21. To Prob. 9. **22.** To Prob. 4. **23.** To Prob. 7.

7.9 Vector Spaces, Inner Product Spaces, Linear Transformations *Optional*

In Sec. 7.4 we have seen that ***special vector spaces*** arise quite naturally in connection with matrices and linear systems, that their elements, called *vectors*, satisfy rules quite similar to those for numbers [(3) and (4) in Sec. 7.1], and that they are often obtained as *spans* (sets of linear combinations) of finitely many given vectors. Each such vector has n real numbers as its *components*. Look this up before going on.

Now if we take *all* vectors with n real numbers as components (*"real vectors"*), we obtain the very important **real n-dimensional vector space** R^n. This is a standard name and notation. Thus, each vector in R^n is an ordered n-tuple of real numbers.

Particular cases are R^2, the space of all ordered pairs (**"vectors in the plane"**) and R^3, the space of all ordered triples (**"vectors in 3-space"**). These vectors have wide applications in mechanics, geometry, and calculus that are basic to the engineer and physicist.

Similarly, if we take all ordered n-tuples of *complex numbers* as vectors and complex numbers as scalars, we obtain the **complex vector space** C^n, which we shall consider in Sec. 8.5.

This is not all. There are other sets of practical interest (sets of matrices, functions, transformations, etc.) for which addition and scalar multiplication can be defined in a natural way so that they form a "vector space". This suggests to create from the ***"concrete model"*** R^n the ***"abstract concept"*** of a ***"real vector space"*** V by taking the basic properties (3) and (4) in Sec. 7.1 as axioms. These axioms guarantee that one obtains a useful and applicable theory of those more general situations. Note that each axiom expresses a simple property of R^n or, as a matter of fact, of R^3. Selecting good axioms needs experience and is a process of trial and error that often extends over a long period of time.

DEFINITION

Real Vector Space

A nonempty set V of elements **a, b,** $\cdots$ is called a **real vector space** (or *real linear space*), and these elements are called **vectors** (regardless of their nature, which will come out from the context or will be left arbitrary) if in V there are defined two algebraic operations (called *vector addition* and *scalar multiplication*) as follows.

I. Vector addition associates with every pair of vectors **a** and **b** of V a unique vector of V, called the *sum* of **a** and **b** and denoted by $\mathbf{a} + \mathbf{b}$, such that the following axioms are satisfied.

I.1 *Commutativity.* For any two vectors **a** and **b** of V,

$$\mathbf{a} + \mathbf{b} = \mathbf{b} + \mathbf{a}.$$

I.2 *Associativity.* For any three vectors **u, v, w** of V,

$$(\mathbf{u} + \mathbf{v}) + \mathbf{w} = \mathbf{u} + (\mathbf{v} + \mathbf{w}) \quad \text{(written } \mathbf{u} + \mathbf{v} + \mathbf{w}\text{)}.$$

I.3 There is a unique vector in V, called the *zero vector* and denoted by **0**, such that for every **a** in V,

$$\mathbf{a} + \mathbf{0} = \mathbf{a}.$$

I.4 For every **a** in V there is a unique vector in V that is denoted by $-\mathbf{a}$ and is such that

$$\mathbf{a} + (-\mathbf{a}) = \mathbf{0}.$$

II. Scalar multiplication. The real numbers are called **scalars.** Scalar multiplication associates with every **a** in V and every scalar c a unique vector of V, called the *product* of c and **a** and denoted by $c\mathbf{a}$ (or $\mathbf{a}c$) such that the following axioms are satisfied.

II.1 *Distributivity.* For every scalar c and vectors **a** and **b** in V,

$$c(\mathbf{a} + \mathbf{b}) = c\mathbf{a} + c\mathbf{b}.$$

II.2 *Distributivity.* For all scalars c and k and every **a** in V,

$$(c + k)\mathbf{a} = c\mathbf{a} + k\mathbf{a}.$$

II.3 *Associativity.* For all scalars c and k and every **a** in V,

$$c(k\mathbf{a}) = (ck)\mathbf{a} \quad \text{(written } ck\mathbf{a}\text{)}.$$

II.4 For every **a** in V,

$$1\mathbf{a} = \mathbf{a}.$$

A **complex vector space** is obtained if, instead of real numbers, we take complex numbers as scalars.

Basic concepts related to the concept of a vector space are defined as in Sec. 7.4.

A **linear combination** of vectors $\mathbf{a}_{(1)}, \cdots, \mathbf{a}_{(m)}$ in a vector space V is an expression

$$c_1\mathbf{a}_{(1)} + \cdots + c_m\mathbf{a}_{(m)} \qquad (c_1, \cdots, c_m \text{ any scalars}).$$

These vectors form a **linearly independent set** (briefly, they are called **linearly independent**) if

$$c_1\mathbf{a}_{(1)} + \cdots + c_m\mathbf{a}_{(m)} = \mathbf{0} \tag{1}$$

implies that $c_1 = 0, \cdots, c_m = 0$. Otherwise, if (1) also holds with scalars not all zero, the vectors are called **linearly dependent.**

Note that (1) with $m = 1$ is $c\mathbf{a} = \mathbf{0}$ and shows that a single vector $\mathbf{a}$ is linearly independent if and only if $\mathbf{a} \neq \mathbf{0}$.

V has **dimension n,** or is **n-dimensional,** if it contains a linearly independent set of n vectors, whereas any set of more than n vectors in V is linearly dependent. That set of n linearly independent vectors is called a **basis** for V. Then every vector in V can be written as a linear combination of the basis vectors; for a given basis, this representation is unique (see Prob. 14).

EXAMPLE 1 Vector Space of Matrices

The real 2×2 matrices form a four-dimensional real vector space. A basis is

$$\mathbf{B}_{11} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad \mathbf{B}_{12} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad \mathbf{B}_{21} = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \quad \mathbf{B}_{22} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}$$

because any 2×2 matrix $\mathbf{A} = [a_{jk}]$ has a unique representation $\mathbf{A} = a_{11}\mathbf{B}_{11} + a_{12}\mathbf{B}_{12} + a_{21}\mathbf{B}_{21} + a_{22}\mathbf{B}_{22}$. Similarly, the real $m \times n$ matrices with fixed m and n form an mn-dimensional vector space. What is the dimension of the vector space of all 3×3 skew-symmetric matrices? Can you find a basis? ■

EXAMPLE 2 Vector Space of Polynomials

The set of all constant, linear, and quadratic polynomials in x together is a vector space of dimension 3 with basis $\{1, x, x^2\}$ under the usual addition and multiplication by real numbers because these two operations give polynomials not exceeding degree 2. What is the dimension of the vector space of all polynomials of degree not exceeding a given fixed n? Can you find a basis? ■

If a vector space V contains a linearly independent set of n vectors for every n, no matter how large, then V is called **infinite dimensional,** as opposed to a *finite dimensional* (n-dimensional) vector space just defined. An example of an infinite dimensional vector space is the space of all continuous functions on some interval $[a, b]$ of the x-axis, as we mention without proof.

Inner Product Spaces

If $\mathbf{a}$ and $\mathbf{b}$ are vectors in R^n, regarded as column vectors, we can form the product $\mathbf{a}^\mathsf{T}\mathbf{b}$. This is a 1×1 matrix, which we can identify with its single entry, that is, with a number. This product is called the **inner product** or **dot product** of $\mathbf{a}$ and $\mathbf{b}$. Other notations for it are $(\mathbf{a}, \mathbf{b})$ and $\mathbf{a} \cdot \mathbf{b}$. Thus

$$\mathbf{a}^\mathsf{T}\mathbf{b} = (\mathbf{a}, \mathbf{b}) = \mathbf{a} \cdot \mathbf{b} = [a_1 \cdots a_n] \begin{bmatrix} b_1 \\ \vdots \\ b_n \end{bmatrix} = \sum_{l=1}^{n} a_l b_l = a_1 b_1 + \cdots + a_n b_n.$$

We now extend this concept to general real vector spaces by taking basic properties of $(\mathbf{a}, \mathbf{b})$ as axioms for an "abstract inner product" $(\mathbf{a}, \mathbf{b})$ as follows.

DEFINITION

Real Inner Product Space

A real vector space V is called a **real inner product space** (or *real pre-Hilbert*[4] *space*) if it has the following property. With every pair of vectors $\mathbf{a}$ and $\mathbf{b}$ in V there is associated a real number, which is denoted by $(\mathbf{a}, \mathbf{b})$ and is called the **inner product** of $\mathbf{a}$ and $\mathbf{b}$, such that the following axioms are satisfied.

I. For all scalars q_1 and q_2 and all vectors $\mathbf{a}, \mathbf{b}, \mathbf{c}$ in V,

$$(q_1\mathbf{a} + q_2\mathbf{b}, \mathbf{c}) = q_1(\mathbf{a}, \mathbf{c}) + q_2(\mathbf{b}, \mathbf{c}) \qquad (\textit{Linearity}).$$

II. For all vectors $\mathbf{a}$ and $\mathbf{b}$ in V,

$$(\mathbf{a}, \mathbf{b}) = (\mathbf{b}, \mathbf{a}) \qquad (\textit{Symmetry}).$$

III. For every $\mathbf{a}$ in V,

$$\left.\begin{aligned} &(\mathbf{a}, \mathbf{a}) \geqq 0, \\ &(\mathbf{a}, \mathbf{a}) = 0 \quad \text{if and only if} \quad \mathbf{a} = \mathbf{0} \end{aligned}\right\} \quad (\textit{Positive-definiteness}).$$

Vectors whose inner product is zero are called **orthogonal.**

The *length* or **norm** of a vector in V is defined by

$$\|\mathbf{a}\| = \sqrt{(\mathbf{a}, \mathbf{a})} \qquad (\geqq 0). \tag{2}$$

A vector of norm 1 is called a **unit vector.**

From these axioms and from (2) one can derive the basic inequality

$$|(\mathbf{a}, \mathbf{b})| \leqq \|\mathbf{a}\| \, \|\mathbf{b}\| \qquad (\textit{Cauchy–Schwarz}[5] \textit{ inequality}). \tag{3}$$

From this follows

$$\|\mathbf{a} + \mathbf{b}\| \leqq \|\mathbf{a}\| + \|\mathbf{b}\| \qquad (\textit{Triangle inequality}). \tag{4}$$

A simple direct calculation gives

$$\|\mathbf{a} + \mathbf{b}\|^2 + \|\mathbf{a} - \mathbf{b}\|^2 = 2(\|\mathbf{a}\|^2 + \|\mathbf{b}\|^2) \qquad (\textit{Parallelogram equality}). \tag{5}$$

---

[4]DAVID HILBERT (1862–1943), great German mathematician, taught at Königsberg and Göttingen and was the creator of the famous Göttingen mathematical school. He is known for his basic work in algebra, the calculus of variations, integral equations, functional analysis, and mathematical logic. His "Foundations of Geometry" helped the axiomatic method to gain general recognition. His famous 23 problems (presented in 1900 at the International Congress of Mathematicians in Paris) considerably influenced the development of modern mathematics.

If V is finite dimensional, it is actually a so-called *Hilbert space;* see Ref. [GR7], p. 73, listed in App. I.

[5]HERMANN AMANDUS SCHWARZ (1843–1921), German mathematician, known by his work in complex analysis (conformal mapping) and differential geometry. For Cauchy see Sec. 2.5.

EXAMPLE 3 ***n*-Dimensional Euclidean Space**

R^n with the inner product

$$(\mathbf{a}, \mathbf{b}) = \mathbf{a}^T\mathbf{b} = a_1b_1 + \cdots + a_nb_n \tag{6}$$

(where both $\mathbf{a}$ and $\mathbf{b}$ are *column* vectors) is called the ***n*-dimensional Euclidean space** and is denoted by E^n or again simply by R^n. Axioms I–III hold, as direct calculation shows. Equation (2) gives the **"Euclidean norm"**

$$\|\mathbf{a}\| = \sqrt{(\mathbf{a}, \mathbf{a})} = \sqrt{\mathbf{a}^T\mathbf{a}} = \sqrt{a_1^2 + \cdots + a_n^2}. \tag{7}$$

■

EXAMPLE 4 **An Inner Product for Functions. Function Space**

The set of all real-valued continuous functions $f(x)$, $g(x)$, $\cdots$ on a given interval $\alpha \leqq x \leqq \beta$ is a real vector space under the usual addition of functions and multiplication by scalars (real numbers). On this **"function space"** we can define an inner product by the integral

$$(f, g) = \int_\alpha^\beta f(x)\, g(x)\, dx. \tag{8}$$

Axioms I–III can be verified by direct calculation. Equation (2) gives the norm

$$\|f\| = \sqrt{(f, f)} = \sqrt{\int_\alpha^\beta f(x)^2\, dx}. \tag{9}$$

■

Our examples give a first impression of the great generality of the abstract concepts of vector spaces and inner product spaces. Further details belong to more advanced courses (on functional analysis, meaning abstract modern analysis; see Ref. [GR7] listed in App. 1) and cannot be discussed here. Instead we now take up a related topic where matrices play a central role.

Linear Transformations

Let X and Y be any vector spaces. To each vector $\mathbf{x}$ in X we assign a unique vector $\mathbf{y}$ in Y. Then we say that a **mapping** (or **transformation** or **operator**) of X into Y is given. Such a mapping is denoted by a capital letter, say F. The vector $\mathbf{y}$ in Y assigned to a vector $\mathbf{x}$ in X is called the **image** of $\mathbf{x}$ under F and is denoted by $F(\mathbf{x})$ [or $F\mathbf{x}$, without parentheses].

F is called a **linear mapping** or **linear transformation** if for all vectors $\mathbf{v}$ and $\mathbf{x}$ in X and scalars c,

$$\begin{aligned} F(\mathbf{v} + \mathbf{x}) &= F(\mathbf{v}) + F(\mathbf{x}) \\ F(c\mathbf{x}) &= cF(\mathbf{x}). \end{aligned} \tag{10}$$

Linear Transformation of Space R^n into Space R^m

From now on we let $X = R^n$ and $Y = R^m$. Then any real $m \times n$ matrix $\mathbf{A} = [a_{jk}]$ gives a transformation of R^n into R^m,

$$\mathbf{y} = \mathbf{A}\mathbf{x}. \tag{11}$$

Since $\mathbf{A}(\mathbf{u} + \mathbf{x}) = \mathbf{A}\mathbf{u} + \mathbf{A}\mathbf{x}$ and $\mathbf{A}(c\mathbf{x}) = c\mathbf{A}\mathbf{x}$, this transformation is linear.

We show that, conversely, every linear transformation F of R^n into R^m can be given in terms of an $m \times n$ matrix $\mathbf{A}$, after a basis for R^n and a basis for R^m have been chosen. This can be proved as follows.

Let $\mathbf{e}_{(1)}, \cdots, \mathbf{e}_{(n)}$ be any basis for R^n. Then every $\mathbf{x}$ in R^n has a unique representation

$$\mathbf{x} = x_1\mathbf{e}_{(1)} + \cdots + x_n\mathbf{e}_{(n)}.$$

Since F is linear, this representation implies for the image $F(\mathbf{x})$:

$$F(\mathbf{x}) = F(x_1\mathbf{e}_{(1)} + \cdots + x_n\mathbf{e}_{(n)}) = x_1F(\mathbf{e}_{(1)}) + \cdots + x_nF(\mathbf{e}_{(n)}).$$

Hence F is uniquely determined by the images of the vectors of a basis for R^n. We now choose for R^n the **"standard basis"**

$$\mathbf{(12)} \qquad \mathbf{e}_{(1)} = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \quad \mathbf{e}_{(2)} = \begin{bmatrix} 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \quad \cdots, \quad \mathbf{e}_{(n)} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ \vdots \\ 1 \end{bmatrix}$$

where $\mathbf{e}_{(j)}$ has its jth component equal to 1 and all others 0. We show that we can now determine an $m \times n$ matrix $\mathbf{A} = [a_{jk}]$ such that for every $\mathbf{x}$ in R^n and image $\mathbf{y} = F(\mathbf{x})$ in R^m,

$$\mathbf{y} = F(\mathbf{x}) = \mathbf{Ax}.$$

Indeed, from the image $\mathbf{y}^{(1)} = F(\mathbf{e}_{(1)})$ of $\mathbf{e}_{(1)}$ we get the condition

$$\mathbf{y}^{(1)} = \begin{bmatrix} y_1^{(1)} \\ y_2^{(1)} \\ \vdots \\ y_m^{(1)} \end{bmatrix} = \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ a_{21} & \cdots & a_{2n} \\ \vdots & & \vdots \\ a_{m1} & \cdots & a_{mn} \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

from which we can determine the first column of $\mathbf{A}$, namely $a_{11} = y_1^{(1)}$, $a_{21} = y_2^{(1)}, \cdots,$ $a_{m1} = y_m^{(1)}$. Similarly, from the image of $\mathbf{e}_{(2)}$ we get the second column of $\mathbf{A}$, and so on. This completes the proof. ■

We say that $\mathbf{A}$ **represents** F, or *is a representation of* F, with respect to the bases for R^n and R^m. Quite generally, the purpose of a **"representation"** is the replacement of one object of study by another object whose properties are more readily apparent.

In three-dimensional Euclidean space E^3 the standard basis is usually written $\mathbf{e}_{(1)} = \mathbf{i}$, $\mathbf{e}_{(2)} = \mathbf{j}$, $\mathbf{e}_{(3)} = \mathbf{k}$. Thus,

$$\mathbf{(13)} \qquad \mathbf{i} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \quad \mathbf{j} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \quad \mathbf{k} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}.$$

These are the three unit vectors in the positive directions of the axes of the **Cartesian coordinate system in space,** that is, the usual coordinate system with the same scale of measurement on the three mutually perpendicular coordinate axes.

EXAMPLE 5 Linear Transformations

Interpreted as transformations of Cartesian coordinates in the plane, the matrices

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}, \quad \begin{bmatrix} a & 0 \\ 0 & 1 \end{bmatrix}$$

represent a reflection in the line $x_2 = x_1$, a reflection in the x_1-axis, a reflection in the origin, and a stretch (when $a > 1$, or a contraction when $0 < a < 1$) in the x_1-direction, respectively. ■

EXAMPLE 6 Linear Transformations

Our discussion preceding Example 5 is simpler than it may look at first sight. To see this, find **A** representing the linear transformation that maps (x_1, x_2) onto $(2x_1 - 5x_2, 3x_1 + 4x_2)$.

Solution. Obviously, the transformation is

$$y_1 = 2x_1 - 5x_2$$
$$y_2 = 3x_1 + 4x_2.$$

From this we can directly see that the matrix is

$$\mathbf{A} = \begin{bmatrix} 2 & -5 \\ 3 & 4 \end{bmatrix}. \qquad \text{Check:} \quad \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} 2 & -5 \\ 3 & 4 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 2x_1 - 5x_2 \\ 3x_1 + 4x_2 \end{bmatrix}.$$ ■

If **A** in (11) is square, $n \times n$, then (11) maps R^n into R^n. If this **A** is nonsingular, so that $\mathbf{A}^{-1}$ exists (see Sec. 7.8), then multiplication of (11) by $\mathbf{A}^{-1}$ from the left and use of $\mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$ gives the **inverse transformation**

$$\mathbf{x} = \mathbf{A}^{-1}\mathbf{y}. \tag{14}$$

It maps every $\mathbf{y} = \mathbf{y}_0$ onto that **x,** which by (11) is mapped onto $\mathbf{y}_0$. *The inverse of a linear transformation is itself linear,* because it is given by a matrix, as (14) shows.

PROBLEM SET 7.9

1–12 VECTOR SPACES

(Additional problems in Problem Set 7.4.)

Is the given set (taken with the usual addition and scalar multiplication) a vector space? (Give a reason.) If your answer is yes, find the dimension and a basis.

1. All vectors in R^3 satisfying $5v_1 - 3v_2 + 2v_3 = 0$
2. All vectors in R^3 satisfying $2v_1 + 3v_2 - v_3 = 0$, $v_1 - 4v_2 + v_3 = 0$
3. All 2×3 matrices with all entries nonnegative
4. All symmetric 3×3 matrices
5. All vectors in R^5 with the first three components 0
6. All vectors in R^4 with $v_1 + v_2 = 0$, $v_3 - v_4 = 1$
7. All skew-symmetric 2×2 matrices
8. All $n \times n$ matrices **A** with fixed n and $\det \mathbf{A} = 0$
9. All polynomials with positive coefficients and degree 3 or less
10. All functions $f(x) = a \cos x + b \sin x$ with any constants a and b
11. All functions $f(x) = (ax + b)e^{-x}$ with any constants a and b
12. All 2×3 matrices with the second row any multiple of $[4 \quad 0 \quad -9]$

13. (Different bases) Find three bases for R^2.

14. (Uniqueness) Show that the representation $\mathbf{v} = c_1\mathbf{a}_{(1)} + \cdots + c_n\mathbf{a}_{(n)}$ of any given vector in an n-dimensional vector space V in terms of a given basis $\mathbf{a}_{(1)}, \cdots, \mathbf{a}_{(n)}$ for V is unique.

15–20 LINEAR TRANSFORMATIONS

Find the inverse transformation. (Show the details of your work.)

15.
$$y_1 = x_1 - 2x_2$$
$$y_2 = 4x_1 - 3x_2$$

16.
$$y_1 = 5x_1 - x_2$$
$$y_2 = 3x_1 - x_2$$

17.
$$y_1 = 3x_1 - x_2$$
$$y_2 = -5x_1 + 2x_2$$

18.
$$y_1 = 0.25x_1 - 0.1x_3$$
$$y_2 = x_2 - 0.8x_3$$
$$y_3 = 0.2x_3$$

19.
$$y_1 = 2x_1 - 3x_2$$
$$y_2 = -10x_1 + 16x_2 + x_3$$
$$y_3 = -7x_1 + 11x_2 + x_3$$

20.
$$y_1 = x_1 + x_2 - 2x_3$$
$$y_2 = x_1 + x_2 + 2x_3$$
$$y_3 = -2x_1 + 2x_2 + 4x_3$$

21–26 INNER PRODUCT. ORTHOGONALITY

Find the Euclidean norm of the vectors

21. $[4 \quad 2 \quad -6]^T$

22. $[0 \quad -3 \quad 3 \quad 0 \quad 5 \quad 1]^T$

23. $[16 \quad -32 \quad 0]^T$

24. $[\frac{1}{4} \quad \frac{3}{8} \quad \frac{1}{2} \quad 2]^T$

25. $[0 \quad 1 \quad 0 \quad 0 \quad -1 \quad 1 \quad -1]^T$

26. $[\frac{2}{3} \quad -\frac{2}{3} \quad \frac{1}{3}]^T$

27. (Orthogonality) Show that the vectors in Probs. 21 and 23 are orthogonal.

28. Find all vectors $\mathbf{v}$ in R^3 orthogonal to $[2 \quad 0 \quad 1]^T$.

29. (Unit vectors) Find all unit vectors orthogonal to $[4 \quad -3]^T$. Make a sketch.

30. (Triangle inequality) Verify (4) for the vectors in Probs. 21 and 23.

CHAPTER 7 REVIEW QUESTIONS AND PROBLEMS

1. What properties of matrix multiplication differ from those of the multiplication of numbers? What about division of matrices?
2. Let $\mathbf{A}$ be a 50×50 matrix and $\mathbf{B}$ a 50×20 matrix. Are the following expressions defined or not? $\mathbf{A} + \mathbf{B}$, $\mathbf{A}^2$, $\mathbf{B}^2$, $\mathbf{AB}$, $\mathbf{BA}$, $\mathbf{AA}^T$, $\mathbf{B}^T\mathbf{A}$, $\mathbf{B}^T\mathbf{B}$, $\mathbf{BB}^T$, $\mathbf{B}^T\mathbf{AB}$. (Give reasons.)
3. How is matrix multiplication motivated?
4. Are there any linear systems without solutions? With one solution? With more than one solution? Give simple examples.
5. How can you give the rank of a matrix in terms of row vectors? Of column vectors? Of determinants?
6. What is the role of rank in connection with solving linear systems?
7. What is the row space of a matrix? The column space? The null space?
8. What is the idea of Gauss elimination and back substitution?
9. What is the inverse of a matrix? When does it exist? How would you determine it?
10. What is Cramer's rule? When would you apply it?

11–19 LINEAR SYSTEMS

Find all solutions or indicate that no solution exists. (Show the details of your work.)

11.
$$9x - 3y = 15$$
$$5x + 4y = 48$$

12.
$$-2x - 4y + 7z = -6$$
$$x + 2y + 16z = 3$$

13.
$$3x + 5y - 8z = 18$$
$$x + 2y - 3z = 6$$

14.
$$5x - 10y = 2$$
$$3x + y = 13$$
$$-x + 6y = 6$$

15.
$$-8x + 2z = 1$$
$$6y + 4z = 3$$
$$12x + 2y = 2$$

16.
$$2y + z = -1$$
$$2x + 3y - z = -12$$
$$5x - 4y + 3z = 32$$

17.
$$3x + 7y = 0$$
$$5x - 4y = 47$$
$$6x + 9y = 15$$

18.
$$-x + 4y - 2z = 1$$
$$3x + 4y + 6z = 1$$
$$x - 2y + 2z = -\frac{1}{2}$$

19.
$$7x + 9y - 14z = 36$$
$$-x - 3y + 2z = -12$$
$$2x + y - 4z = 4$$

20–30 CALCULATIONS WITH MATRICES AND VECTORS

Calculate the following expressions (showing the details of your work) or indicate why they do not exist, when

$$\mathbf{A} = \begin{bmatrix} 9 & 2 & 8 \\ 2 & 18 & 10 \\ 8 & 10 & 15 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 0 & 2 & 6 \\ -2 & 0 & -3 \\ -6 & 3 & 0 \end{bmatrix},$$

$$\mathbf{a} = \begin{bmatrix} 3 \\ 7 \\ 1 \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} 4 \\ 0 \\ 2 \end{bmatrix}.$$

20. $\mathbf{AB}$, $\mathbf{BA}$

21. $\mathbf{A} - \mathbf{A}^T$

22. $\mathbf{A}^2 + \mathbf{B}^2$

23. det $\mathbf{A}$, det $\mathbf{B}$, det $\mathbf{AB}$

24. $\mathbf{AA}^T$, $\mathbf{A}^T\mathbf{A}$

25. $0.2\mathbf{BB}^T$

26. $\mathbf{Aa}$, $\mathbf{a}^T\mathbf{A}$, $\mathbf{a}^T\mathbf{Aa}$

27. $\mathbf{a}^T\mathbf{b}$, $\mathbf{b}^T\mathbf{a}$, $\mathbf{ab}^T$

28. $\mathbf{b}^T\mathbf{Bb}$

29. $\mathbf{a}^T\mathbf{B}$, $\mathbf{B}^T\mathbf{a}$

30. $0.1(\mathbf{A} + \mathbf{A}^T)(\mathbf{B} - \mathbf{B}^T)$

31–36 RANK

Determine the ranks of the coefficient matrix and the augmented matrix and state how many solutions the linear system will have.

31. In Prob. 13

32. In Prob. 12

33. In Prob. 17

34. In Prob. 14

35. In Prob. 19

36. In Prob. 18

37–42 INVERSE

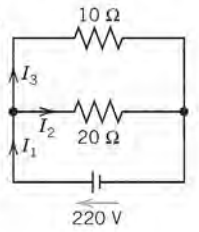
Find the inverse or state why it does not exist. (Show details.)

37. Of the coefficient matrix in Prob. 11

38. Of the coefficient matrix in Prob. 15

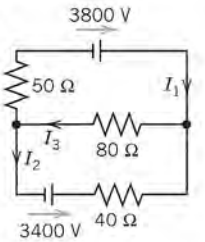
39. Of the coefficient matrix in Prob. 16

40. Of the coefficient matrix in Prob. 18



41. Of the augmented matrix in Prob. 14

42. Of the diagonal matrix with entries 3, −1, 5



43–45 NETWORKS

Find the currents in the following networks.

SUMMARY OF CHAPTER 7

Linear Algebra: Matrices, Vectors, Determinants Linear Systems of Equations

An $m \times n$ **matrix** $\mathbf{A} = [a_{jk}]$ is a rectangular array of numbers or functions ("entries", "elements") arranged in m horizontal **rows** and n vertical **columns.** If $m = n$, the matrix is called **square.** A $1 \times n$ matrix is called a **row vector** and an $m \times 1$ matrix a **column vector** (Sec. 7.1).

The **sum** $\mathbf{A} + \mathbf{B}$ of matrices of the same **size** (i.e., both $m \times n$) is obtained by adding corresponding entries. The **product** of $\mathbf{A}$ by a scalar c is obtained by multiplying each a_{jk} by c (Sec. 7.1).

The **product** $\mathbf{C} = \mathbf{AB}$ of an $m \times n$ matrix $\mathbf{A}$ by an $r \times p$ matrix $\mathbf{B} = [b_{jk}]$ is defined only when $r = n$, and is the $m \times p$ matrix $\mathbf{C} = [c_{jk}]$ with entries

$$(1) \qquad c_{jk} = a_{j1}b_{1k} + a_{j2}b_{2k} + \cdots + a_{jn}b_{nk} \qquad \begin{matrix} (\text{row } j \text{ of } \mathbf{A} \text{ times} \\ \text{column } k \text{ of } \mathbf{B}). \end{matrix}$$

This multiplication is motivated by the composition of **linear transformations** (Secs. 7.2, 7.9). It is associative, but is ***not commutative:*** if **AB** is defined, **BA** may not be defined, but even if **BA** is defined, $\mathbf{AB} \neq \mathbf{BA}$ in general. Also $\mathbf{AB} = \mathbf{0}$ may not imply $\mathbf{A} = \mathbf{0}$ or $\mathbf{B} = \mathbf{0}$ or $\mathbf{BA} = \mathbf{0}$ (Secs. 7.2, 7.8). Illustrations:

$$\begin{bmatrix} 1 & 1 \\ 2 & 2 \end{bmatrix}\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix}\begin{bmatrix} 1 & 1 \\ 2 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -1 & -1 \end{bmatrix}$$

$$[1 \quad 2]\begin{bmatrix} 3 \\ 4 \end{bmatrix} = [11], \qquad \begin{bmatrix} 3 \\ 4 \end{bmatrix}[1 \quad 2] = \begin{bmatrix} 3 & 6 \\ 4 & 8 \end{bmatrix}.$$

The **transpose** $\mathbf{A}^T$ of a matrix $\mathbf{A} = [a_{jk}]$ is $\mathbf{A}^T = [a_{kj}]$; rows become columns and conversely (Sec. 7.2). Here, **A** need not be square. If it is and $\mathbf{A} = \mathbf{A}^T$, then **A** is called **symmetric;** if $\mathbf{A} = -\mathbf{A}^T$, it is called **skew-symmetric.** For a product, $(\mathbf{AB})^T = \mathbf{B}^T\mathbf{A}^T$ (Sec. 7.2).

A main application of matrices concerns **linear systems of equations**

$$\mathbf{Ax} = \mathbf{b} \tag{2}$$ (Sec. 7.3)

(m equations in n unknowns $x_1, \cdots, x_n$; **A** and **b** given). The most important method of solution is the **Gauss elimination** (Sec. 7.3), which reduces the system to "triangular" form by *elementary row operations,* which leave the set of solutions unchanged. (Numeric aspects and variants, such as *Doolittle's* and *Cholesky's methods,* are discussed in Secs. 20.1 and 20.2)

Cramer's rule (Secs. 7.6, 7.7) represents the unknowns in a system (2) of n equations in n unknowns as quotients of determinants; for numeric work it is impractical. **Determinants** (Sec. 7.7) have decreased in importance, but will retain their place in eigenvalue problems, elementary geometry, etc.

The **inverse** $\mathbf{A}^{-1}$ of a square matrix satisfies $\mathbf{AA}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$. It exists if and only if $\det \mathbf{A} \neq 0$. It can be computed by the *Gauss–Jordan elimination* (Sec. 7.8).

The **rank** r of a matrix **A** is the maximum number of linearly independent rows or columns of **A** or, equivalently, the number of rows of the largest square submatrix of **A** with nonzero determinant (Secs. 7.4, 7.7).

The system (2) has solutions if and only if rank **A** = rank [**A** **b**], where [**A** **b**] is the **augmented matrix** (Fundamental Theorem, Sec. 7.5).

The **homogeneous system**

$$\mathbf{Ax} = \mathbf{0} \tag{3}$$

has solutions $\mathbf{x} \neq \mathbf{0}$ ("nontrivial solutions") if and only if rank $\mathbf{A} < n$, in the case $m = n$ equivalently if and only if $\det \mathbf{A} = 0$ (Secs. 7.6, 7.7).

Vector spaces, inner product spaces, and linear transformations are discussed in Sec. 7.9. See also Sec. 7.4.

CHAPTER 8

Linear Algebra: Matrix Eigenvalue Problems

Matrix eigenvalue problems concern the solutions of vector equations

$$\mathbf{Ax} = \lambda\mathbf{x} \tag{1}$$

where $\mathbf{A}$ is a given ***square*** matrix and vector $\mathbf{x}$ and scalar λ are unknown. Clearly, $\mathbf{x} = \mathbf{0}$ is a solution of (1), giving $\mathbf{0} = \mathbf{0}$. But this of no interest, and we want to find solution vectors $\mathbf{x} \neq \mathbf{0}$ of (1), called **eigenvectors** of $\mathbf{A}$. We shall see that eigenvectors can be found only for certain values of the scalar λ; these values λ for which an eigenvector exists are called the **eigenvalues** of $\mathbf{A}$. Geometrically, solving (1) in this way means that we are looking for vectors $\mathbf{x}$ for which the multiplication of $\mathbf{x}$ by the matrix $\mathbf{A}$ has the same effect as the multiplication of $\mathbf{x}$ by a scalar λ, giving a vector $\lambda\mathbf{x}$ with components proportional to those of $\mathbf{x}$, and λ as the factor of proportionality.

Eigenvalue problems are of greatest practical interest to the engineer, physicist, and mathematician, and we shall see that their theory makes up a beautiful chapter in linear algebra that has found numerous applications.

We shall explain how to solve that vector equation (1) in Sec. 8.1, show a few typical applications in Sec. 8.2, and then discuss eigenvalue problems for symmetric, skew-symmetric, and orthogonal matrices in Sec. 8.3. In Sec. 8.4 we show how to obtain eigenvalues by diagonalization of a matrix. We also consider the complex counterparts of those matrices (Hermitian, skew-Hermitian, and unitary matrices, Sec. 8.5), which play a role in modern physics.

COMMENT. ***Numerics for eigenvalues* (Secs. 20.6–20.9) *can be studied immediately after this chapter.***

8.1 Eigenvalues, Eigenvectors

From the viewpoint of engineering applications, eigenvalue problems are among the most important problems in connection with matrices, and the student should follow the present discussion with particular attention. We begin by defining the basic concepts and show how to solve these problems, by examples as well as in general. Then we shall turn to applications.

Let $\mathbf{A} = [a_{jk}]$ be a given $n \times n$ matrix and consider the vector equation

$$\mathbf{Ax} = \lambda \mathbf{x}. \tag{1}$$

Here $\mathbf{x}$ is an unknown vector and λ an unknown scalar. Our task is to determine $\mathbf{x}$'s and λ's that satisfy (1). Geometrically, we are looking for vectors $\mathbf{x}$ for which the multiplication by $\mathbf{A}$ has the same effect as the multiplication by a scalar λ; in other words, $\mathbf{Ax}$ should be proportional to $\mathbf{x}$.

Clearly, the zero vector $\mathbf{x} = \mathbf{0}$ is a solution of (1) for any value of λ, because $\mathbf{A0} = \mathbf{0}$. This is of no interest. A value of λ for which (1) has a solution $\mathbf{x} \neq \mathbf{0}$ is called an **eigenvalue** or *characteristic value* (or *latent root*) of the matrix $\mathbf{A}$. ("Eigen" is German and means "proper" or "characteristic.") The corresponding solutions $\mathbf{x} \neq \mathbf{0}$ of (1) are called the **eigenvectors** or *characteristic vectors* of $\mathbf{A}$ corresponding to that eigenvalue λ. The set of all the eigenvalues of $\mathbf{A}$ is called the **spectrum** of $\mathbf{A}$. We shall see that the spectrum consists of at least one eigenvalue and at most of n numerically different eigenvalues. The largest of the absolute values of the eigenvalues of $\mathbf{A}$ is called the *spectral radius* of $\mathbf{A}$, a name to be motivated later.

How to Find Eigenvalues and Eigenvectors

The problem of determining the eigenvalues and eigenvectors of a matrix is called an **eigenvalue problem.** (More precisely: an *algebraic* eigenvalue problem, as opposed to an eigenvalue problem involving an ODE, PDE (see Secs. 5.7 and 12.3) or integral equation.) Such problems occur in physical, technical, geometric, and other applications, as we shall see. We show how to solve them, first by an example and then in general. Some typical applications will follow afterwards.

EXAMPLE 1 **Determination of Eigenvalues and Eigenvectors**

We illustrate all the steps in terms of the matrix

$$\mathbf{A} = \begin{bmatrix} -5 & 2 \\ 2 & -2 \end{bmatrix}.$$

Solution. **(a) *Eigenvalues.*** These must be determined *first.* Equation (1) is

$$\mathbf{Ax} = \begin{bmatrix} -5 & 2 \\ 2 & -2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \lambda \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}; \qquad \text{in components,} \qquad \begin{aligned} -5x_1 + 2x_2 &= \lambda x_1 \\ 2x_1 - 2x_2 &= \lambda x_2. \end{aligned}$$

Transferring the terms on the right to the left, we get

$$\begin{aligned} (-5 - \lambda)x_1 + \quad 2x_2 \quad &= 0 \\ 2x_1 \quad + (-2 - \lambda)x_2 &= 0. \end{aligned} \tag{2*}$$

This can be written in matrix notation

$$(3^*) \qquad (\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}$$

because (1) is $\mathbf{Ax} - \lambda\mathbf{x} = \mathbf{Ax} - \lambda\mathbf{Ix} = (\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}$, which gives (3*). We see that this is a ***homogeneous*** linear system. By Cramer's theorem in Sec. 7.7 it has a nontrivial solution $\mathbf{x} \neq \mathbf{0}$ (an eigenvector of $\mathbf{A}$ we are looking for) if and only if its coefficient determinant is zero, that is,

$$(4^*) \quad D(\lambda) = \det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} -5 - \lambda & 2 \\ 2 & -2 - \lambda \end{vmatrix} = (-5 - \lambda)(-2 - \lambda) - 4 = \lambda^2 + 7\lambda + 6 = 0.$$

We call $D(\lambda)$ the **characteristic determinant** or, if expanded, the **characteristic polynomial,** and $D(\lambda) = 0$ the **characteristic equation** of $\mathbf{A}$. The solutions of this quadratic equation are $\lambda_1 = -1$ and $\lambda_2 = -6$. These are the eigenvalues of $\mathbf{A}$.

($\mathbf{b_1}$) *Eigenvector of* $\mathbf{A}$ *corresponding to* $\boldsymbol{\lambda_1}$. This vector is obtained from (2*) with $\lambda = \lambda_1 = -1$, that is,

$$\begin{aligned} -4x_1 + 2x_2 &= 0 \\ 2x_1 - x_2 &= 0. \end{aligned}$$

A solution is $x_2 = 2x_1$, as we see from either of the two equations, so that we need only one of them. This determines an eigenvector corresponding to $\lambda_1 = -1$ up to a scalar multiple. If we choose $x_1 = 1$, we obtain the eigenvector

$$\mathbf{x}_1 = \begin{bmatrix} 1 \\ 2 \end{bmatrix}. \qquad \text{Check:} \qquad \mathbf{Ax}_1 = \begin{bmatrix} -5 & 2 \\ 2 & -2 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \end{bmatrix} = \begin{bmatrix} -1 \\ -2 \end{bmatrix} = (-1)\mathbf{x}_1 = \lambda_1\mathbf{x}_1.$$

($\mathbf{b_2}$) *Eigenvector of* $\mathbf{A}$ *corresponding to* $\boldsymbol{\lambda_2}$. For $\lambda = \lambda_2 = -6$, equation (2*) becomes

$$\begin{aligned} x_1 + 2x_2 &= 0 \\ 2x_1 + 4x_2 &= 0. \end{aligned}$$

A solution is $x_2 = -x_1/2$ with arbitrary x_1. If we choose $x_1 = 2$, we get $x_2 = -1$. Thus an eigenvector of $\mathbf{A}$ corresponding to $\lambda_2 = -6$ is

$$\mathbf{x}_2 = \begin{bmatrix} 2 \\ -1 \end{bmatrix}. \qquad \text{Check:} \qquad \mathbf{Ax}_2 = \begin{bmatrix} -5 & 2 \\ 2 & -2 \end{bmatrix} \begin{bmatrix} 2 \\ -1 \end{bmatrix} = \begin{bmatrix} -12 \\ 6 \end{bmatrix} = (-6)\mathbf{x}_2 = \lambda_2\mathbf{x}_2. \quad \blacksquare$$

This example illustrates the general case as follows. Equation (1) written in components is

$$\begin{aligned} a_{11}x_1 + \cdots + a_{1n}x_n &= \lambda x_1 \\ a_{21}x_1 + \cdots + a_{2n}x_n &= \lambda x_2 \\ \cdots\cdots\cdots\cdots\cdots\cdots & \\ a_{n1}x_1 + \cdots + a_{nn}x_n &= \lambda x_n. \end{aligned}$$

Transferring the terms on the right side to the left side, we have

$$(2) \qquad \begin{aligned} (a_{11} - \lambda)x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= 0 \\ a_{21}x_1 + (a_{22} - \lambda)x_2 + \cdots + a_{2n}x_n &= 0 \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots & \\ a_{n1}x_1 + a_{n2}x_2 + \cdots + (a_{nn} - \lambda)x_n &= 0. \end{aligned}$$

In matrix notation,

$$(3) \qquad (\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}.$$

By Cramer's theorem in Sec. 7.7, this homogeneous linear system of equations has a nontrivial solution if and only if the corresponding determinant of the coefficients is zero:

$$\textbf{(4)} \quad D(\lambda) = \det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} a_{11} - \lambda & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} - \lambda & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ a_{n1} & a_{n2} & \cdots & a_{nn} - \lambda \end{vmatrix} = 0.$$

$\mathbf{A} - \lambda\mathbf{I}$ is called the **characteristic matrix** and $D(\lambda)$ the **characteristic determinant** of **A.** Equation (4) is called the **characteristic equation** of **A.** By developing $D(\lambda)$ we obtain a polynomial of nth degree in λ. This is called the **characteristic polynomial** of **A.**

This proves the following important theorem.

THEOREM 1

Eigenvalues

The eigenvalues of a square matrix **A** *are the roots of the characteristic equation* (4) *of* **A.**

Hence an $n \times n$ *matrix has at least one eigenvalue and at most* n *numerically different eigenvalues.*

For larger n, the actual computation of eigenvalues will in general require the use of Newton's method (Sec. 19.2) or another numeric approximation method in Secs. 20.7–20.9.

The eigenvalues must be determined first. Once these are known, corresponding eigen*vectors* are obtained from the system (2), for instance, by the Gauss elimination, where λ is the eigenvalue for which an eigenvector is wanted. This is what we did in Example 1 and shall do again in the examples below. (To prevent misunderstandings: *numeric approximation methods* (Sec. 20.8) may determine eigen*vectors first.*)

Eigenvectors have the following properties.

THEOREM 2

Eigenvectors, Eigenspace

If $\mathbf{w}$ *and* $\mathbf{x}$ *are eigenvectors of a matrix* $\mathbf{A}$ *corresponding to* ***the same*** *eigenvalue* λ, *so are* $\mathbf{w} + \mathbf{x}$ (provided $\mathbf{x} \neq -\mathbf{w}$) *and* $k\mathbf{x}$ *for any* $k \neq 0$.

Hence the eigenvectors corresponding to one and the same eigenvalue λ *of* **A,** *together with* **0,** *form a vector space* (cf. Sec. 7.4), *called the* **eigenspace** *of* **A** *corresponding to that* λ.

PROOF $\mathbf{Aw} = \lambda\mathbf{w}$ and $\mathbf{Ax} = \lambda\mathbf{x}$ *imply* $\mathbf{A}(\mathbf{w} + \mathbf{x}) = \mathbf{Aw} + \mathbf{Ax} = \lambda\mathbf{w} + \lambda\mathbf{x} = \lambda(\mathbf{w} + \mathbf{x})$ and $\mathbf{A}(k\mathbf{w}) = k(\mathbf{Aw}) = k(\lambda\mathbf{w}) = \lambda(k\mathbf{w})$; hence $\mathbf{A}(k\mathbf{w} + \ell\mathbf{x}) = \lambda(k\mathbf{w} + \ell\mathbf{x})$. ■

In particular, *an eigenvector* $\mathbf{x}$ *is determined only up to a constant factor.* Hence we can **normalize x,** that is, multiply it by a scalar to get a unit vector (see Sec. 7.9). For instance, $\mathbf{x}_1 = [1 \quad 2]^\mathsf{T}$ in Example 1 has the length $\|\mathbf{x}_1\| = \sqrt{1^2 + 2^2} = \sqrt{5}$; hence $[1/\sqrt{5} \quad 2/\sqrt{5}]^\mathsf{T}$ is a normalized eigenvector (a unit eigenvector).

Examples 2 and 3 will illustrate that an $n \times n$ matrix may have n linearly independent eigenvectors, or it may have fewer than n. In Example 4 we shall see that a *real* matrix may have *complex* eigenvalues and eigenvectors.

EXAMPLE 2 Multiple Eigenvalues

Find the eigenvalues and eigenvectors of

$$\mathbf{A} = \begin{bmatrix} -2 & 2 & -3 \\ 2 & 1 & -6 \\ -1 & -2 & 0 \end{bmatrix}.$$

Solution. For our matrix, the characteristic determinant gives the characteristic equation

$$-\lambda^3 - \lambda^2 + 21\lambda + 45 = 0.$$

The roots (eigenvalues of $\mathbf{A}$) are $\lambda_1 = 5$, $\lambda_2 = \lambda_3 = -3$. To find eigenvectors, we apply the Gauss elimination (Sec. 7.3) to the system $(\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}$, first with $\lambda = 5$ and then with $\lambda = -3$. For $\lambda = 5$ the characteristic matrix is

$$\mathbf{A} - \lambda\mathbf{I} = \mathbf{A} - 5\mathbf{I} = \begin{bmatrix} -7 & 2 & -3 \\ 2 & -4 & -6 \\ -1 & -2 & -5 \end{bmatrix} \quad \text{It row-reduces to} \quad \begin{bmatrix} -7 & 2 & -3 \\ 0 & -\frac{24}{7} & -\frac{48}{7} \\ 0 & 0 & 0 \end{bmatrix}.$$

Hence it has rank 2. Choosing $x_3 = -1$ we have $x_2 = 2$ from $-\frac{24}{7}x_2 - \frac{48}{7}x_3 = 0$ and then $x_1 = 1$ from $-7x_1 + 2x_2 - 3x_3 = 0$. Hence an eigenvector of $\mathbf{A}$ coresponding to $\lambda = 5$ is $\mathbf{x}_1 = [1 \quad 2 \quad -1]^\mathsf{T}$.

For $\lambda = -3$ the characteristic matrix

$$\mathbf{A} - \lambda\mathbf{I} = \mathbf{A} + 3\mathbf{I} = \begin{bmatrix} 1 & 2 & -3 \\ 2 & 4 & -6 \\ -1 & -2 & 3 \end{bmatrix} \quad \text{row-reduces to} \quad \begin{bmatrix} 1 & 2 & -3 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

Hence it has rank 1. From $x_1 + 2x_2 - 3x_3 = 0$ we have $x_1 = -2x_2 + 3x_3$. Choosing $x_2 = 1$, $x_3 = 0$ and $x_2 = 0$, $x_3 = 1$, we obtain two linearly independent eigenvectors of $\mathbf{A}$ corresponding to $\lambda = -3$ [as they must exist by (5), Sec. 7.5, with rank = 1 and $n = 3$],

$$\mathbf{x}_2 = \begin{bmatrix} -2 \\ 1 \\ 0 \end{bmatrix}$$

and

$$\mathbf{x}_3 = \begin{bmatrix} 3 \\ 0 \\ 1 \end{bmatrix}. \qquad \blacksquare$$

The order M_λ of an eigenvalue λ as a root of the characteristic polynomial is called the **algebraic multiplicity** of λ. The number m_λ of linearly independent eigenvectors corresponding to λ is called the **geometric multiplicity** of λ. Thus m_λ is the dimension of the eigenspace corresponding to this λ. Since the characteristic polynomial has degree n, the sum of all the algebraic multiplicities must equal n. In Example 2 for $\lambda = -3$ we have $m_\lambda = M_\lambda = 2$. In general, $m_\lambda \leqq M_\lambda$, as can be shown. The difference $\Delta_\lambda = M_\lambda - m_\lambda$ is called the **defect** of λ. Thus $\Delta_{-3} = 0$ in Example 2, but positive defects Δ_λ can easily occur:

EXAMPLE 3 **Algebraic Multiplicity, Geometric Multiplicity. Positive Defect**

The characteristic equation of the matrix

$$\mathbf{A} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \quad \text{is} \quad \det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} -\lambda & 1 \\ 0 & -\lambda \end{vmatrix} = \lambda^2 = 0.$$

Hence $\lambda = 0$ is an eigenvalue of algebraic multiplicity $M_0 = 2$. But its geometric multiplicity is only $m_0 = 1$, since eigenvectors result from $-0x_1 + x_2 = 0$, hence $x_2 = 0$, in the form $[x_1 \quad 0]^\mathsf{T}$. Hence for $\lambda = 0$ the defect is $\Delta_0 = 1$.

Similarly, the characteristic equation of the matrix

$$\mathbf{A} = \begin{bmatrix} 3 & 2 \\ 0 & 3 \end{bmatrix} \quad \text{is} \quad \det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} 3 - \lambda & 2 \\ 0 & 3 - \lambda \end{vmatrix} = (3 - \lambda)^2 = 0.$$

Hence $\lambda = 3$ is an eigenvalue of algebraic multiplicity $M_3 = 2$, but its geometric multiplicity is only $m_3 = 1$, since eigenvectors result from $0x_1 + 2x_2 = 0$ in the form $[x_1 \quad 0]^\mathsf{T}$. ■

EXAMPLE 4 **Real Matrices with Complex Eigenvalues and Eigenvectors**

Since real polynomials may have complex roots (which then occur in conjugate pairs), a real matrix may have complex eigenvalues and eigenvectors. For instance, the characteristic equation of the skew-symmetric matrix

$$\mathbf{A} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \quad \text{is} \quad \det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} -\lambda & 1 \\ -1 & -\lambda \end{vmatrix} = \lambda^2 + 1 = 0.$$

It gives the eigenvalues $\lambda_1 = i$ $(= \sqrt{-1})$, $\lambda_2 = -i$. Eigenvectors are obtained from $-ix_1 + x_2 = 0$ and $ix_1 + x_2 = 0$, respectively, and we can choose $x_1 = 1$ to get

$$\begin{bmatrix} 1 \\ i \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 1 \\ -i \end{bmatrix}.$$

■

In the next section we shall need the following simple theorem.

THEOREM 3

Eigenvalues of the Transpose

The transpose $\mathbf{A}^\mathsf{T}$ *of a square matrix* $\mathbf{A}$ *has the same eigenvalues as* $\mathbf{A}$.

PROOF Transposition does not change the value of the characteristic determinant, as follows from Theorem 2d in Sec. 7.7. ■

Having gained a first impression of matrix eigenvalue problems, in the next section we illustrate their importance with some typical applications.

PROBLEM SET 8.1

1–25 EIGENVALUES AND EIGENVECTORS

Find the eigenvalues and eigenvectors of the following matrices. (Use the given λ or factors.)

1. $\begin{bmatrix} -2 & 0 \\ 0 & 0.4 \end{bmatrix}$

2. $\begin{bmatrix} a & b \\ 0 & c \end{bmatrix}$

3. $\begin{bmatrix} 4 & 0 \\ 2 & -4 \end{bmatrix}$

4. $\begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$

5. $\begin{bmatrix} 5 & -2 \\ 9 & -6 \end{bmatrix}$

6. $\begin{bmatrix} a & b \\ -b & a \end{bmatrix}$

7. $\begin{bmatrix} 0.8 & -0.6 \\ 0.6 & 0.8 \end{bmatrix}$

8. $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

9. $\begin{bmatrix} 1 & 2 \\ 2 & 4 \end{bmatrix}$

10. $\begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}$

11. $\begin{bmatrix} 4 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{bmatrix}$

12. $\begin{bmatrix} 85 & -28 & -28 \\ -10 & -11 & -11 \\ -46 & -2 & -2 \end{bmatrix}$

13. $\begin{bmatrix} 6 & 2 & -2 \\ 2 & 5 & 0 \\ -2 & 0 & 7 \end{bmatrix}$, $\lambda = 3$

14. $\begin{bmatrix} 2 & 0 & -2 \\ 0 & 0 & -2 \\ -2 & -2 & 1 \end{bmatrix}$, $\lambda = 1$

15. $\begin{bmatrix} 1 & 0 & 0 \\ 2 & 4 & 0 \\ 6 & 4 & 2 \end{bmatrix}$

16. $\begin{bmatrix} 0.5 & 0.2 & 0.1 \\ 0 & 1.0 & 1.5 \\ 0 & 0 & 3.5 \end{bmatrix}$

17. $\begin{bmatrix} 4 & -2 & 3 \\ -2 & 1 & 6 \\ 1 & 2 & 2 \end{bmatrix}$, $\lambda = -3$

18. $\begin{bmatrix} 3 & 0 & 12 \\ -6 & 3 & 0 \\ 9 & 6 & 3 \end{bmatrix}$, $\lambda = 9$

19. $\begin{bmatrix} 13 & 5 & 2 \\ 2 & 7 & -8 \\ 5 & 4 & 7 \end{bmatrix}$

20. $\begin{bmatrix} 0 & 0 & -5 & 7 \\ 0 & 0 & 7 & -5 \\ 0 & 0 & 19 & -1 \\ 0 & 0 & -1 & 19 \end{bmatrix}$

21. $\begin{bmatrix} 0 & -2 & 2 & 0 \\ -4 & 2 & -2 & 4 \\ 0 & 2 & 2 & -4 \\ 0 & 2 & -6 & 4 \end{bmatrix}$, $\lambda = 4$

22. $\begin{bmatrix} -3 & 0 & 4 & 2 \\ 0 & 1 & -2 & 4 \\ 2 & 4 & -1 & -2 \\ 0 & 2 & -2 & 3 \end{bmatrix}$, $(\lambda - 3)^2$

23. $\begin{bmatrix} 2 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 2 & 0 & 3 & 0 \\ 1 & 4 & 2 & -6 \end{bmatrix}$

24. $\begin{bmatrix} -3 & 0 & -2 & 8 \\ 0 & 1 & 4 & -2 \\ -4 & 10 & -1 & -2 \\ 6 & -4 & -2 & 3 \end{bmatrix}$, $\lambda = 3$, $\lambda = -5$

25. $\begin{bmatrix} -1 & 0 & 12 & 0 \\ 0 & -1 & 0 & 12 \\ 0 & 0 & -1 & -4 \\ 0 & 0 & -4 & -1 \end{bmatrix}$, $(\lambda + 1)^2$

26. (Multiple eigenvalues) Find further 2×2 and 3×3 matrices with multiple eigenvalues. (See Example 2.)

27. (Nonzero defect) Find further 2×2 and 3×3 matrices with positive defect. (See Example 3.)

28. (Transpose) Illustrate Theorem 3 with examples of your own.

29. (Complex eigenvalues) Show that the eigenvalues of a real matrix are real or complex conjugate in pairs.

30. (Inverse) Show that the inverse $\mathbf{A}^{-1}$ exists if and only if none of the eigenvalues $\lambda_1, \cdots, \lambda_n$ of $\mathbf{A}$ is zero, and then $\mathbf{A}^{-1}$ has the eigenvalues $1/\lambda_1, \cdots, 1/\lambda_n$.

8.2 Some Applications of Eigenvalue Problems

In this section we discuss a few typical examples from the range of applications of matrix eigenvalue problems, which is incredibly large. Chapter 4 shows matrix eigenvalue problems related to ODEs governing mechanical systems and electrical networks. To keep our present discussion independent of Chap. 4, we include a typical application of that kind as our last example.

EXAMPLE 1 **Stretching of an Elastic Membrane**

An elastic membrane in the x_1x_2-plane with boundary circle $x_1^2 + x_2^2 = 1$ (Fig. 158) is stretched so that a point P: (x_1, x_2) goes over into the point Q: (y_1, y_2) given by

$$(1) \qquad \mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \mathbf{A}\mathbf{x} = \begin{bmatrix} 5 & 3 \\ 3 & 5 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}; \qquad \text{in components,} \qquad \begin{aligned} y_1 &= 5x_1 + 3x_2 \\ y_2 &= 3x_1 + 5x_2. \end{aligned}$$

Find the **principal directions,** that is, the directions of the position vector $\mathbf{x}$ of P for which the direction of the position vector $\mathbf{y}$ of Q is the same or exactly opposite. What shape does the boundary circle take under this deformation?

Solution. We are looking for vectors $\mathbf{x}$ such that $\mathbf{y} = \lambda\mathbf{x}$. Since $\mathbf{y} = \mathbf{A}\mathbf{x}$, this gives $\mathbf{A}\mathbf{x} = \lambda\mathbf{x}$, the equation of an eigenvalue problem. In components, $\mathbf{A}\mathbf{x} = \lambda\mathbf{x}$ is

$$(2) \qquad \begin{aligned} 5x_1 + 3x_2 &= \lambda x_1 \\ 3x_1 + 5x_2 &= \lambda x_2 \end{aligned} \qquad \text{or} \qquad \begin{aligned} (5 - \lambda)x_1 + \quad 3x_2 \quad &= 0 \\ 3x_1 \quad + (5 - \lambda)x_2 &= 0. \end{aligned}$$

The characteristic equation is

$$(3) \qquad \begin{vmatrix} 5 - \lambda & 3 \\ 3 & 5 - \lambda \end{vmatrix} = (5 - \lambda)^2 - 9 = 0.$$

Its solutions are $\lambda_1 = 8$ and $\lambda_2 = 2$. These are the eigenvalues of our problem. For $\lambda = \lambda_1 = 8$, our system (2) becomes

$$\begin{aligned} -3x_1 + 3x_2 &= 0, \\ 3x_1 - 3x_2 &= 0. \end{aligned} \quad \Big| \quad \text{Solution } x_2 = x_1, \quad x_1 \text{ arbitrary,} \quad \text{for instance, } x_1 = x_2 = 1.$$

For $\lambda_2 = 2$, our system (2) becomes

$$\begin{aligned} 3x_1 + 3x_2 &= 0, \\ 3x_1 + 3x_2 &= 0. \end{aligned} \quad \Big| \quad \text{Solution } x_2 = -x_1, \quad x_1 \text{ arbitrary,} \quad \text{for instance, } x_1 = 1, x_2 = -1.$$

We thus obtain as eigenvectors of $\mathbf{A}$, for instance, $[1 \;\; 1]^T$ corresponding to λ_1 and $[1 \;\; -1]^T$ corresponding to λ_2 (or a nonzero scalar multiple of these). These vectors make 45° and 135° angles with the positive x_1-direction. They give the principal directions, the answer to our problem. The eigenvalues show that in the principal directions the membrane is stretched by factors 8 and 2, respectively; see Fig. 158.

Accordingly, if we choose the principal directions as directions of a new Cartesian u_1u_2-coordinate system, say, with the positive u_1-semi-axis in the first quadrant and the positive u_2-semi-axis in the second quadrant of the x_1x_2-system, and if we set $u_1 = r\cos\phi$, $u_2 = r\sin\phi$, then a boundary point of the unstretched circular membrane has coordinates $\cos\phi$, $\sin\phi$. Hence, after the stretch we have

$$z_1 = 8\cos\phi, \qquad z_2 = 2\sin\phi.$$

Since $\cos^2\phi + \sin^2\phi = 1$, this shows that the deformed boundary is an ellipse (Fig. 158)

$$(4) \qquad \frac{z_1^2}{8^2} + \frac{z_2^2}{2^2} = 1. \qquad \blacksquare$$

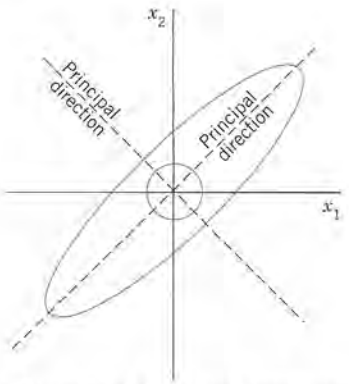

Fig. 158. Undeformed and deformed membrane in Example 1

EXAMPLE 2 Eigenvalue Problems Arising from Markov Processes

Markov processes as considered in Example 13 of Sec. 7.2 lead to eigenvalue problems if we ask for the limit state of the process in which the state vector $\mathbf{x}$ is reproduced under the multiplication by the stochastic matrix $\mathbf{A}$ governing the process, that is, $\mathbf{Ax} = \mathbf{x}$. Hence $\mathbf{A}$ should have the eigenvalue 1, and $\mathbf{x}$ should be a corresponding eigenvector. This is of practical interest because it shows the long-term tendency of the development modeled by the process.

In that example,

$$\mathbf{A} = \begin{bmatrix} 0.7 & 0.1 & 0 \\ 0.2 & 0.9 & 0.2 \\ 0.1 & 0 & 0.8 \end{bmatrix}. \qquad \text{For the transpose,} \qquad \begin{bmatrix} 0.7 & 0.2 & 0.1 \\ 0.1 & 0.9 & 0 \\ 0 & 0.2 & 0.8 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}.$$

Hence $\mathbf{A}^T$ has the eigenvalue 1, and the same is true for $\mathbf{A}$ by Theorem 3 in Sec. 8.1. An eigenvector $\mathbf{x}$ of $\mathbf{A}$ for $\lambda = 1$ is obtained from

$$\mathbf{A} - \mathbf{I} = \begin{bmatrix} -0.3 & 0.1 & 0 \\ 0.2 & -0.1 & 0.2 \\ 0.1 & 0 & -0.2 \end{bmatrix}, \qquad \text{row-reduced to} \qquad \begin{bmatrix} -3/10 & 1/10 & 0 \\ 0 & -1/30 & 1/5 \\ 0 & 0 & 0 \end{bmatrix}.$$

Taking $x_3 = 1$, we get $x_2 = 6$ from $-x_2/30 + x_3/5 = 0$ and then $x_1 = 2$ from $-3x_1/10 + x_2/10 = 0$. This gives $\mathbf{x} = [2 \quad 6 \quad 1]^T$. It means that in the long run, the ratio Commercial : Industrial : Residential will approach 2 : 6 : 1, provided that the probabilities given by $\mathbf{A}$ remain (about) the same. (We switched to ordinary fractions to avoid rounding errors.) ■

EXAMPLE 3 Eigenvalue Problems Arising from Population Models. Leslie Model

The Leslie model describes age-specified population growth, as follows. Let the oldest age attained by the females in some animal population be 9 years. Divide the population into three age classes of 3 years each. Let the *"Leslie matrix"* be

$$\mathbf{L} = [l_{jk}] = \begin{bmatrix} 0 & 2.3 & 0.4 \\ 0.6 & 0 & 0 \\ 0 & 0.3 & 0 \end{bmatrix} \tag{5}$$

where l_{1k} is the average number of daughters born to a single female during the time she is in age class k, and $l_{j,j-1}$ $(j = 2, 3)$ is the fraction of females in age class $j - 1$ that will survive and pass into class j. (a) What is the number of females in each class after 3, 6, 9 years if each class initially consists of 400 females? (b) For what initial distribution will the number of females in each class change by the same proportion? What is this rate of change?

Solution. **(a)** Initially, $\mathbf{x}_{(0)}^{\mathsf{T}} = [400 \quad 400 \quad 400]$. After 3 years,

$$\mathbf{x}_{(3)} = \mathbf{L}\mathbf{x}_{(0)} = \begin{bmatrix} 0 & 2.3 & 0.4 \\ 0.6 & 0 & 0 \\ 0 & 0.3 & 0 \end{bmatrix} \begin{bmatrix} 400 \\ 400 \\ 400 \end{bmatrix} = \begin{bmatrix} 1080 \\ 240 \\ 120 \end{bmatrix}.$$

Similarly, after 6 years the number of females in each class is given by $\mathbf{x}_{(6)}^{\mathsf{T}} = (\mathbf{L}\mathbf{x}_{(3)})^{\mathsf{T}} = [600 \quad 648 \quad 72]$, and after 9 years we have $\mathbf{x}_{(9)}^{\mathsf{T}} = (\mathbf{L}\mathbf{x}_{(6)})^{\mathsf{T}} = [1519.2 \quad 360 \quad 194.4]$.

(b) Proportional change means that we are looking for a distribution vector $\mathbf{x}$ such that $\mathbf{L}\mathbf{x} = \lambda\mathbf{x}$, where λ is the rate of change (growth if $\lambda > 1$, decrease if $\lambda < 1$). The characteristic equation is (develop the characteristic determinant by the first column)

$$\det(\mathbf{L} - \lambda\mathbf{I}) = -\lambda^3 - 0.6(-2.3\lambda - 0.3 \cdot 0.4) = -\lambda^3 + 1.38\lambda + 0.072 = 0.$$

A positive root is found to be (for instance, by Newton's method, Sec. 19.2) $\lambda = 1.2$. A corresponding eigenvector $\mathbf{x}$ can be determined from the characteristic matrix

$$\mathbf{A} - 1.2\mathbf{I} = \begin{bmatrix} -1.2 & 2.3 & 0.4 \\ 0.6 & -1.2 & 0 \\ 0 & 0.3 & -1.2 \end{bmatrix}, \qquad \text{say,} \qquad \mathbf{x} = \begin{bmatrix} 1 \\ 0.5 \\ 0.125 \end{bmatrix}$$

where $x_3 = 0.125$ is chosen, $x_2 = 0.5$ then follows from $0.3x_2 - 1.2x_3 = 0$, and $x_1 = 1$ from $-1.2x_1 + 2.3x_2 + 0.4x_3 = 0$. To get an initial population of 1200 as before, we multiply $\mathbf{x}$ by $1200/(1 + 0.5 + 0.125) = 738$. *Answer:* Proportional growth of the numbers of females in the three classes will occur if the initial values are 738, 369, 92 in classes 1, 2, 3, respectively. The growth rate will be 1.2 per 3 years. ■

EXAMPLE 4 Vibrating System of Two Masses on Two Springs (Fig. 159)

Mass–spring systems involving several masses and springs can be treated as eigenvalue problems. For instance, the mechanical system in Fig. 159 is governed by the system of ODEs

$$\begin{aligned} y_1'' &= -5y_1 + 2y_2 \\ y_2'' &= 2y_1 - 2y_2 \end{aligned} \tag{6}$$

where y_1 and y_2 are the displacements of the masses from rest, as shown in the figure, and primes denote derivatives with respect to time t. In vector form, this becomes

$$\mathbf{y}'' = \begin{bmatrix} y_1'' \\ y_2'' \end{bmatrix} = \mathbf{A}\mathbf{y} = \begin{bmatrix} -5 & 2 \\ 2 & -2 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}. \tag{7}$$

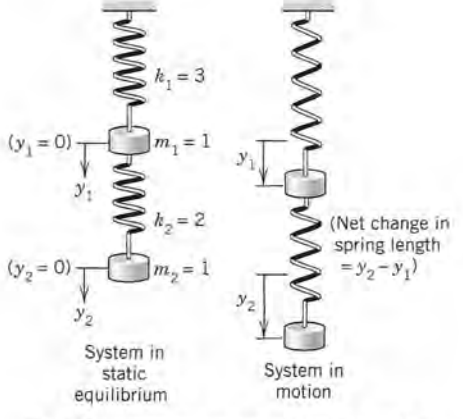

Fig. 159. Masses on springs in Example 4

We try a vector solution of the form

$$\mathbf{y} = \mathbf{x}e^{\omega t}. \tag{8}$$

This is suggested by a mechanical system of a single mass on a spring (Sec. 2.4), whose motion is given by exponential functions (and sines and cosines). Substitution into (7) gives

$$\omega^2 \mathbf{x}e^{\omega t} = \mathbf{A}\mathbf{x}e^{\omega t}.$$

Dividing by $e^{\omega t}$ and writing $\omega^2 = \lambda$, we see that our mechanical system leads to the eigenvalue problem

$$\mathbf{A}\mathbf{x} = \lambda \mathbf{x} \qquad \text{where } \lambda = \omega^2. \tag{9}$$

From Example 1 in Sec. 8.1 we see that $\mathbf{A}$ has the eigenvalues $\lambda_1 = -1$ and $\lambda_2 = -6$. Consequently, $\omega = \sqrt{-1} = \pm i$ and $\sqrt{-6} = \pm i\sqrt{6}$, respectively. Corresponding eigenvectors are

$$\mathbf{x}_1 = \begin{bmatrix} 1 \\ 2 \end{bmatrix} \quad \text{and} \quad \mathbf{x}_2 = \begin{bmatrix} 2 \\ -1 \end{bmatrix}. \tag{10}$$

From (8) we thus obtain the four complex solutions [see (10), Sec. 2.2]

$$\mathbf{x}_1 e^{\pm it} = \mathbf{x}_1(\cos t \pm i \sin t),$$
$$\mathbf{x}_2 e^{\pm i\sqrt{6}t} = \mathbf{x}_2(\cos \sqrt{6}\, t \pm i \sin \sqrt{6}\, t).$$

By addition and subtraction (see Sec. 2.2) we get the four real solutions

$$\mathbf{x}_1 \cos t, \quad \mathbf{x}_1 \sin t, \quad \mathbf{x}_2 \cos \sqrt{6}\, t, \quad \mathbf{x}_2 \sin \sqrt{6}\, t.$$

A general solution is obtained by taking a linear combination of these,

$$\mathbf{y} = \mathbf{x}_1(a_1 \cos t + b_1 \sin t) + \mathbf{x}_2(a_2 \cos \sqrt{6}\, t + b_2 \sin \sqrt{6}\, t)$$

with arbitrary constants a_1, b_1, a_2, b_2 (to which values can be assigned by prescribing initial displacement and initial velocity of each of the two masses). By (10), the components of $\mathbf{y}$ are

$$y_1 = a_1 \cos t + b_1 \sin t + 2a_2 \cos \sqrt{6}\, t + 2b_2 \sin \sqrt{6}\, t$$
$$y_2 = 2a_1 \cos t + 2b_1 \sin t - a_2 \cos \sqrt{6}\, t - b_2 \sin \sqrt{6}\, t.$$

These functions describe harmonic oscillations of the two masses. Physically, this had to be expected because we have neglected damping. ■

PROBLEM SET 8.2

1–6 LINEAR TRANSFORMATIONS

Find the matrix $\mathbf{A}$ in the indicated linear transformation $\mathbf{y} = \mathbf{A}\mathbf{x}$. Explain the geometric significance of the eigenvalues and eigenvectors of $\mathbf{A}$. Show the details.

1. Reflection about the y-axis in R^2
2. Reflection about the xy-plane in R^3
3. Orthogonal projection (perpendicular projection) of R^2 onto the x-axis
4. Orthogonal projection of R^3 onto the plane $y = x$
5. Dilatation (uniform stretching) in R^2 by a factor 5
6. Counterclockwise rotation through the angle $\pi/2$ about the origin in R^2

7–14 ELASTIC DEFORMATIONS

Given $\mathbf{A}$ in a deformation $\mathbf{y} = \mathbf{A}\mathbf{x}$, find the principal directions and corresponding factors of extension or contraction. Show the details.

7. $\begin{bmatrix} 3 & 5 \\ 5 & 3 \end{bmatrix}$

8. $\begin{bmatrix} 0.4 & 0.8 \\ 0.8 & 0.4 \end{bmatrix}$

9. $\begin{bmatrix} 2.5 & 1.5 \\ 1.5 & 6.5 \end{bmatrix}$

10. $\begin{bmatrix} 5 & 4 \\ 4 & 11 \end{bmatrix}$

11. $\begin{bmatrix} 7 & \sqrt{6} \\ \sqrt{6} & 2 \end{bmatrix}$

12. $\begin{bmatrix} 5 & 2 \\ 2 & 13 \end{bmatrix}$

13. $\begin{bmatrix} -2 & 3 \\ 3 & -2 \end{bmatrix}$

14. $\begin{bmatrix} 10.5 & 1/\sqrt{2} \\ 1/\sqrt{2} & 10.0 \end{bmatrix}$

15. (Leontief[1] input–output model) Suppose that three industries are interrelated so that their outputs are used as inputs by themselves, according to the 3×3 **consumption matrix**

$$\mathbf{A} = [a_{jk}] = \begin{bmatrix} 0.2 & 0.5 & 0 \\ 0.6 & 0 & 0.3 \\ 0.2 & 0.5 & 0.7 \end{bmatrix}$$

where a_{jk} is the fraction of the output of industry k consumed (purchased) by industry j. Let p_j be the price charged by industry j for its total output. A problem is to find prices so that for each industry, total expenditures equal total income. Show that this leads to $\mathbf{Ap} = \mathbf{p}$, where $\mathbf{p} = [p_1 \quad p_2 \quad p_3]^T$, and find a solution $\mathbf{p}$ with nonnegative p_1, p_2, p_3.

16. Show that a consumption matrix as considered in Prob. 15 must have column sums 1 and always has the eigenvalue 1.

17. (Open Leontief input–output model) If not the whole output but only a portion of it is consumed by the industries themselves, then instead of $\mathbf{Ax} = \mathbf{x}$ (as in Prob. 15), we have $\mathbf{x} - \mathbf{Ax} = \mathbf{y}$, where $\mathbf{x} = [x_1 \quad x_2 \quad x_3]^T$ is produced, $\mathbf{Ax}$ is consumed by the industries, and, thus, $\mathbf{y}$ is the net production available for other consumers. Find for what production $\mathbf{x}$ a given **demand vector** $\mathbf{y} = [0.136 \quad 0.272 \quad 0.136]^T$ can be achieved if the consumption matrix is

$$\mathbf{A} = \begin{bmatrix} 0.2 & 0.4 & 0.2 \\ 0.3 & 0 & 0.1 \\ 0.2 & 0.4 & 0.5 \end{bmatrix}.$$

18–20 MARKOV PROCESSES

Find limit states of the Markov processes modeled by the following matrices. (Show the details.)

18. $\begin{bmatrix} 0.1 & 0.4 \\ 0.9 & 0.6 \end{bmatrix}$

19. $\begin{bmatrix} 0.5 & 0.3 & 0.2 \\ 0.3 & 0.5 & 0.2 \\ 0.2 & 0.2 & 0.6 \end{bmatrix}$

20. $\begin{bmatrix} 0.6 & 0.1 & 0.2 \\ 0.4 & 0.1 & 0.4 \\ 0 & 0.8 & 0.4 \end{bmatrix}$

21–23 POPULATION MODEL WITH AGE SPECIFICATION

Find the growth rate in the Leslie model (see Example 3) with the matrix as given. (Show details.)

21. $\begin{bmatrix} 0 & 3.45 & 0.60 \\ 0.90 & 0 & 0 \\ 0 & 0.45 & 0 \end{bmatrix}$

22. $\begin{bmatrix} 0 & 12.0 & 0 \\ 0.75 & 0 & 0 \\ 0 & 0.30 & 0 \end{bmatrix}$

23. $\begin{bmatrix} 0 & 7.280 & 2.975 \\ 0.560 & 0 & 0 \\ 0 & 0.420 & 0 \end{bmatrix}$

24. TEAM PROJECT. General Properties of Eigenvalues and Eigenvectors. Prove the following statements and illustrate them with examples of your own choice. Here, $\lambda_1, \cdots, \lambda_n$ are the (not necessarily distinct) eigenvalues of a given $n \times n$ matrix $\mathbf{A} = [a_{jk}]$.

(a) Trace. The sum of the main diagonal entries is called the **trace** of $\mathbf{A}$. It equals the sum of the eigenvalues.

(b) "Spectral shift." $\mathbf{A} - k\mathbf{I}$ has the eigenvalues $\lambda_1 - k, \cdots, \lambda_n - k$ and the same eigenvectors as $\mathbf{A}$.

(c) Scalar multiples, powers. $k\mathbf{A}$ has the eigenvalues $k\lambda_1, \cdots, k\lambda_n$. $\mathbf{A}^m$ $(m = 1, 2, \cdots)$ has the eigenvalues $\lambda_1^m, \cdots, \lambda_n^m$. The eigenvectors are those of $\mathbf{A}$.

(d) Spectral mapping theorem. The **"polynomial matrix"**

$$p(\mathbf{A}) = k_m\mathbf{A}^m + k_{m-1}\mathbf{A}^{m-1} + \cdots + k_1\mathbf{A} + k_0\mathbf{I}$$

has the eigenvalues

$$p(\lambda_j) = k_m\lambda_j^m + k_{m-1}\lambda_j^{m-1} + \cdots + k_1\lambda_j + k_0$$

where $j = 1, \cdots, n$, and the same eigenvectors as $\mathbf{A}$.

(e) Perron's theorem. Show that a Leslie matrix $\mathbf{L}$ with positive $l_{12}, l_{13}, l_{21}, l_{32}$ has a positive eigenvalue. (This is a special case of the famous Perron–Frobenius theorem in Sec. 20.7, which is difficult to prove in its general form.)

8.3 Symmetric, Skew-Symmetric, and Orthogonal Matrices

We consider three classes of real square matrices that occur quite frequently in applications because they have several remarkable properties which we shall now discuss. The first two of these classes have already been mentioned in Sec. 7.2.

DEFINITIONS

Symmetric, Skew-Symmetric, and Orthogonal Matrices

A ***real*** square matrix $\mathbf{A} = [a_{jk}]$ is called

symmetric if transposition leaves it unchanged,

$$\mathbf{A}^T = \mathbf{A}, \qquad \text{thus} \qquad a_{kj} = a_{jk}, \tag{1}$$

skew-symmetric if transposition gives the negative of $\mathbf{A}$,

$$\mathbf{A}^T = -\mathbf{A}, \qquad \text{thus} \qquad a_{kj} = -a_{jk}, \tag{2}$$

orthogonal if transposition gives the inverse of $\mathbf{A}$,

$$\mathbf{A}^T = \mathbf{A}^{-1}. \tag{3}$$

EXAMPLE 1 **Symmetric, Skew-Symmetric, and Orthogonal Matrices**

The matrices

$$\begin{bmatrix} -3 & 1 & 5 \\ 1 & 0 & -2 \\ 5 & -2 & 4 \end{bmatrix}, \quad \begin{bmatrix} 0 & 9 & -12 \\ -9 & 0 & 20 \\ 12 & -20 & 0 \end{bmatrix}, \quad \begin{bmatrix} \frac{2}{3} & \frac{1}{3} & \frac{2}{3} \\ -\frac{2}{3} & \frac{2}{3} & \frac{1}{3} \\ \frac{1}{3} & \frac{2}{3} & -\frac{2}{3} \end{bmatrix}$$

are symmetric, skew-symmetric, and orthogonal, respectively, as you should verify. Every skew-symmetric matrix has all main diagonal entries zero. (Can you prove this?) ■

Any real square matrix $\mathbf{A}$ may be written as the sum of a symmetric matrix $\mathbf{R}$ and a skew-symmetric matrix $\mathbf{S}$, where

$$\mathbf{R} = \tfrac{1}{2}(\mathbf{A} + \mathbf{A}^T) \qquad \text{and} \qquad \mathbf{S} = \tfrac{1}{2}(\mathbf{A} - \mathbf{A}^T). \tag{4}$$

EXAMPLE 2 **Illustration of Formula (4)**

$$\mathbf{A} = \begin{bmatrix} 9 & 5 & 2 \\ 2 & 3 & -8 \\ 5 & 4 & 3 \end{bmatrix} = \mathbf{R} + \mathbf{S} = \begin{bmatrix} 9.0 & 3.5 & 3.5 \\ 3.5 & 3.0 & -2.0 \\ 3.5 & -2.0 & 3.0 \end{bmatrix} + \begin{bmatrix} 0 & 1.5 & -1.5 \\ -1.5 & 0 & -6.0 \\ 1.5 & 6.0 & 0 \end{bmatrix}$$ ■

THEOREM 1

Eigenvalues of Symmetric and Skew-Symmetric Matrices

(a) *The eigenvalues of a symmetric matrix are real.*

(b) *The eigenvalues of a skew-symmetric matrix are pure imaginary or zero.*

This basic theorem (and an extension of it) will be proved in Sec. 8.5.

EXAMPLE 3 **Eigenvalues of Symmetric and Skew-Symmetric Matrices**

The matrices in (1) and (7) of Sec. 8.2 are symmetric and have real eigenvalues. The skew-symmetric matrix in Example 1 has the eigenvalues 0, $-25i$, and $25i$. (Verify this.) The following matrix has the real eigenvalues 1 and 5 but is not symmetric. Does this contradict Theorem 1?

$$\begin{bmatrix} 3 & 4 \\ 1 & 3 \end{bmatrix}$$

■

Orthogonal Transformations and Orthogonal Matrices

Orthogonal transformations are transformations

(5) $$\mathbf{y} = \mathbf{A}\mathbf{x} \qquad \text{where } \mathbf{A} \text{ is an orthogonal matrix.}$$

With each vector $\mathbf{x}$ in R^n such a transformation assigns a vector $\mathbf{y}$ in R^n. For instance, the plane rotation through an angle θ

(6) $$\mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

is an orthogonal transformation. It can be shown that any orthogonal transformation in the plane or in three-dimensional space is a **rotation** (possibly combined with a reflection in a straight line or a plane, respectively).

The main reason for the importance of orthogonal matrices is as follows.

THEOREM 2

Invariance of Inner Product

An orthogonal transformation preserves the value of the **inner product** *of vectors* $\mathbf{a}$ *and* $\mathbf{b}$ *in* R^n*, defined by*

(7) $$\mathbf{a} \cdot \mathbf{b} = \mathbf{a}^T\mathbf{b} = [a_1 \quad \cdots \quad a_n] \begin{bmatrix} b_1 \\ \vdots \\ b_n \end{bmatrix}.$$

That is, for any $\mathbf{a}$ *and* $\mathbf{b}$ *in* R^n*, orthogonal* $n \times n$ *matrix* $\mathbf{A}$*, and* $\mathbf{u} = \mathbf{A}\mathbf{a}$, $\mathbf{v} = \mathbf{A}\mathbf{b}$ *we have* $\mathbf{u} \cdot \mathbf{v} = \mathbf{a} \cdot \mathbf{b}$.

Hence the transformation also preserves the **length** *or* **norm** *of any vector* $\mathbf{a}$ *in* R^n *given by*

(8) $$\| \mathbf{a} \| = \sqrt{\mathbf{a} \cdot \mathbf{a}} = \sqrt{\mathbf{a}^T\mathbf{a}}.$$

PROOF Let $\mathbf{A}$ be orthogonal. Let $\mathbf{u} = \mathbf{Aa}$ and $\mathbf{v} = \mathbf{Ab}$. We must show that $\mathbf{u} \cdot \mathbf{v} = \mathbf{a} \cdot \mathbf{b}$. Now $(\mathbf{Aa})^T = \mathbf{a}^T\mathbf{A}^T$ by (10d) in Sec. 7.2 and $\mathbf{A}^T\mathbf{A} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$ by (3). Hence

$$\mathbf{u} \cdot \mathbf{v} = \mathbf{u}^T\mathbf{v} = (\mathbf{Aa})^T\mathbf{Ab} = \mathbf{a}^T\mathbf{A}^T\mathbf{Ab} = \mathbf{a}^T\mathbf{I}\,\mathbf{b} = \mathbf{a}^T\mathbf{b} = \mathbf{a} \cdot \mathbf{b}. \tag{9}$$

From this the invariance of $\|\mathbf{a}\|$ follows if we set $\mathbf{b} = \mathbf{a}$. ∎

Orthogonal matrices have further interesting properties as follows.

THEOREM 3

Orthonormality of Column and Row Vectors

A real square matrix is orthogonal if and only if its column vectors $\mathbf{a}_1, \cdots, \mathbf{a}_n$ *(and also its row vectors) form an* **orthonormal system,** *that is,*

$$\mathbf{a}_j \cdot \mathbf{a}_k = \mathbf{a}_j^T\mathbf{a}_k = \begin{cases} 0 & \text{if } j \neq k \\ 1 & \text{if } j = k. \end{cases} \tag{10}$$

PROOF **(a)** Let $\mathbf{A}$ be orthogonal. Then $\mathbf{A}^{-1}\mathbf{A} = \mathbf{A}^T\mathbf{A} = \mathbf{I}$, in terms of column vectors $\mathbf{a}_1, \cdots, \mathbf{a}_n$.

$$\mathbf{I} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{A}^T\mathbf{A} = \begin{bmatrix} \mathbf{a}_1^T \\ \vdots \\ \mathbf{a}_n^T \end{bmatrix} [\mathbf{a}_1 \cdots \mathbf{a}_n] = \begin{bmatrix} \mathbf{a}_1^T\mathbf{a}_1 & \mathbf{a}_1^T\mathbf{a}_2 \cdots \mathbf{a}_1^T\mathbf{a}_n \\ \cdot & \cdot \quad \cdots \quad \cdot \\ \mathbf{a}_n^T\mathbf{a}_1 & \mathbf{a}_n^T\mathbf{a}_2 \cdots \mathbf{a}_n^T\mathbf{a}_n \end{bmatrix}. \tag{11}$$

The last equality implies (10), by the definition of the $n \times n$ unit matrix $\mathbf{I}$. From (3) it follows that the inverse of an orthogonal matrix is orthogonal (see CAS Experiment 20). Now the column vectors of $\mathbf{A}^{-1}$ $(= \mathbf{A}^T)$ are the row vectors of $\mathbf{A}$. Hence the row vectors of $\mathbf{A}$ also form an orthonormal system.

(b) Conversely, if the column vectors of $\mathbf{A}$ satisfy (10), the off-diagonal entries in (11) must be 0 and the diagonal entries 1. Hence $\mathbf{A}^T\mathbf{A} = \mathbf{I}$, as (11) shows. Similarly, $\mathbf{AA}^T = \mathbf{I}$. This implies $\mathbf{A}^T = \mathbf{A}^{-1}$ because also $\mathbf{A}^{-1}\mathbf{A} = \mathbf{AA}^{-1} = \mathbf{I}$ and the inverse is unique. Hence $\mathbf{A}$ is orthogonal. Similarly when the row vectors of $\mathbf{A}$ form an orthonormal system, by what has been said at the end of part **(a)**. ∎

THEOREM 4

Determinant of an Orthogonal Matrix

The determinant of an orthogonal matrix has the value $+1$ *or* -1.

PROOF From $\det \mathbf{AB} = \det \mathbf{A} \det \mathbf{B}$ (Sec. 7.8, Theorem 4) and $\det \mathbf{A}^T = \det \mathbf{A}$ (Sec. 7.7, Theorem 2d), we get for an orthogonal matrix

$$1 = \det \mathbf{I} = \det (\mathbf{AA}^{-1}) = \det (\mathbf{AA}^T) = \det \mathbf{A} \det \mathbf{A}^T = (\det \mathbf{A})^2. \qquad ∎$$

EXAMPLE 4 **Illustration of Theorems 3 and 4**

The last matrix in Example 1 and the matrix in (6) illustrate Theorems 3 and 4 because their determinants are -1 and $+1$, as you should verify. ∎

THEOREM 5

Eigenvalues of an Orthogonal Matrix

The eigenvalues of an orthogonal matrix **A** *are real or complex conjugates in pairs and have absolute value* 1.

PROOF The first part of the statement holds for any real matrix **A** because its characteristic polynomial has real coefficients, so that its zeros (the eigenvalues of **A**) must be as indicated. The claim that $|\lambda| = 1$ will be proved in Sec. 8.5. ∎

EXAMPLE 5 **Eigenvalues of an Orthogonal Matrix**

The orthogonal matrix in Example 1 has the characteristic equation

$$-\lambda^3 + \tfrac{2}{3}\lambda^2 + \tfrac{2}{3}\lambda - 1 = 0.$$

Now one of the eigenvalues must be real (why?), hence $+1$ or -1. Trying, we find -1. Division by $\lambda + 1$ gives $-(\lambda^2 - 5\lambda/3 + 1) = 0$ and the two eigenvalues $(5 + i\sqrt{11})/6$ and $(5 - i\sqrt{11})/6$, which have absolute value 1. Verify all of this. ∎

Looking back at this section, you will find that the numerous basic results it contains have relatively short, straightforward proofs. This is typical of large portions of matrix eigenvalue theory.

PROBLEM SET 8.3

1. **(Verification)** Verify the statements in Example 1.
2. Verify the statements in Examples 3 and 4.
3. Are the eigenvalues of $\mathbf{A} + \mathbf{B}$ of the form $\lambda_j + \mu_j$, where λ_j and μ_j are the eigenvalues of **A** and **B**, respectively?
4. **(Orthogonality)** Prove that eigenvectors of a symmetric matrix corresponding to different eigenvalues are orthogonal. Give an example.
5. **(Skew-symmetric matrix)** Show that the inverse of a skew-symmetric matrix is skew-symmetric.
6. Do there exist nonsingular skew-symmetric $n \times n$ matrices with odd n?
7. **(Orthogonal matrix)** Do there exist skew-symmetric orthogonal 3×3 matrices?
8. **(Symmetric matrix)** Do there exist nondiagonal symmetric 3×3 matrices that are orthogonal?

9–17 EIGENVALUES OF SYMMETRIC, SKEW-SYMMETRIC, AND ORTHOGONAL MATRICES

Are the following matrices symmetric, skew-symmetric, or orthogonal? Find their spectrum (thereby illustrating Theorems 1 and 5). (Show the details of your work.)

9. $\begin{bmatrix} 0.96 & -0.28 \\ 0.28 & 0.96 \end{bmatrix}$

10. $\begin{bmatrix} a & b \\ -b & a \end{bmatrix}$

11. $\begin{bmatrix} 3 & 1 \\ -1 & 1 \end{bmatrix}$

12. $\begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$

13. $\begin{bmatrix} 14 & 4 & -2 \\ 4 & 14 & 2 \\ -2 & 2 & 17 \end{bmatrix}$

14. $\begin{bmatrix} 0 & -6 & -12 \\ 6 & 0 & -12 \\ 12 & 12 & 0 \end{bmatrix}$

15. $\begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ -1 & 0 & 0 \end{bmatrix}$

16. $\begin{bmatrix} \frac{4}{9} & \frac{8}{9} & \frac{1}{9} \\ -\frac{7}{9} & \frac{4}{9} & -\frac{4}{9} \\ -\frac{4}{9} & \frac{1}{9} & \frac{8}{9} \end{bmatrix}$

17. $\begin{bmatrix} a & b & b \\ b & a & b \\ b & b & a \end{bmatrix}$

18. **(Rotation in space)** Give a geometric interpretation of the transformation $\mathbf{y} = \mathbf{A}\mathbf{x}$ with **A** as in Prob. 12 and **x** and **y** referred to a Cartesian coordinate system.
19. **WRITING PROJECT. Section Summary.** Summarize the main concepts and facts in this section, with illustrative examples of your own.

20. CAS EXPERIMENT. Orthogonal Matrices.

(a) Products. Inverse. Prove that the product of two orthogonal matrices is orthogonal, and so is the inverse of an orthogonal matrix. What does this mean in terms of rotations?

(b) Rotation. Show that (6) is an orthogonal transformation. Verify that it satisfies Theorem 3. Find the inverse transformation.

(c) Powers. Write a program for computing powers $\mathbf{A}^m$ $(m = 1, 2, \cdots)$ of a 2×2 matrix $\mathbf{A}$ and their spectra. Apply it to the matrix in Prob. 9 (call it $\mathbf{A}$). To what rotation does $\mathbf{A}$ correspond? Do the eigenvalues of $\mathbf{A}^m$ have a limit as $m \to \infty$?

(d) Compute the eigenvalues of $(0.9\mathbf{A})^m$, where $\mathbf{A}$ is the matrix in Prob. 9. Plot them as points. What is their limit? Along what kind of curve do these points approach the limit?

(e) Find $\mathbf{A}$ such that $\mathbf{y} = \mathbf{Ax}$ is a counterclockwise rotation through 30° in the plane.

8.4 Eigenbases. Diagonalization. Quadratic Forms

So far we have emphasized properties of eigen*values*. We now turn to general properties of eigen*vectors*. Eigenvectors of an $n \times n$ matrix $\mathbf{A}$ may (or may not!) form a basis for R^n. If we are interested in a transformation $\mathbf{y} = \mathbf{Ax}$, such an **"eigenbasis"** (basis of eigenvectors)—if it exists—is of great advantage because then we can represent any $\mathbf{x}$ in R^n uniquely as a linear combination of the eigenvectors $\mathbf{x}_1, \cdots, \mathbf{x}_n$, say,

$$\mathbf{x} = c_1\mathbf{x}_1 + c_2\mathbf{x}_2 + \cdots + c_n\mathbf{x}_n.$$

And, denoting the corresponding (not necessarily distinct) eigenvalues of the matrix $\mathbf{A}$ by $\lambda_1, \cdots, \lambda_n$, we have $\mathbf{Ax}_j = \lambda_j\mathbf{x}_j$, so that we simply obtain

$$\begin{aligned} \mathbf{y} = \mathbf{Ax} &= \mathbf{A}(c_1\mathbf{x}_1 + \cdots + c_n\mathbf{x}_n) \\ &= c_1\mathbf{Ax}_1 + \cdots + c_n\mathbf{Ax}_n \\ &= c_1\lambda_1\mathbf{x}_1 + \cdots + c_n\lambda_n\mathbf{x}_n. \end{aligned} \tag{1}$$

This shows that we have decomposed the complicated action of $\mathbf{A}$ on an arbitrary vector $\mathbf{x}$ into a sum of simple actions (multiplication by scalars) on the eigenvectors of $\mathbf{A}$. This is the point of an eigenbasis.

Now if the n eigenvalues are all different, we do obtain a basis:

THEOREM 1

Basis of Eigenvectors

*If an $n \times n$ matrix $\mathbf{A}$ has n **distinct** eigenvalues, then $\mathbf{A}$ has a basis of eigenvectors $\mathbf{x}_1, \cdots, \mathbf{x}_n$ for R^n.*

PROOF All we have to show is that $\mathbf{x}_1, \cdots, \mathbf{x}_n$ are linearly independent. Suppose they are not. Let r be the largest integer such that $\{\mathbf{x}_1, \cdots, \mathbf{x}_r\}$ is a linearly independent set. Then $r < n$ and the set $\{\mathbf{x}_1, \cdots, \mathbf{x}_r, \mathbf{x}_{r+1}\}$ is linearly dependent. Thus there are scalars $c_1, \cdots, c_{r+1}$, not all zero, such that

$$c_1\mathbf{x}_1 + \cdots + c_{r+1}\mathbf{x}_{r+1} = \mathbf{0} \tag{2}$$

(see Sec. 7.4). Multiplying both sides by $\mathbf{A}$ and using $\mathbf{Ax}_j = \lambda_j\mathbf{x}_j$, we obtain

$$c_1\lambda_1\mathbf{x}_1 + \cdots + c_{r+1}\lambda_{r+1}\mathbf{x}_{r+1} = \mathbf{0}. \tag{3}$$

To get rid of the last term, we subtract λ_{r+1} times (2) from this, obtaining

$$c_1(\lambda_1 - \lambda_{r+1})\mathbf{x}_1 + \cdots + c_r(\lambda_r - \lambda_{r+1})\mathbf{x}_r = \mathbf{0}.$$

Here $c_1(\lambda_1 - \lambda_{r+1}) = 0, \cdots, c_r(\lambda_r - \lambda_{r+1}) = 0$ since $\{x_1, \cdots, x_r\}$ is linearly independent. Hence $c_1 = \cdots = c_r = 0$, since all the eigenvalues are distinct. But with this, (2) reduces to $c_{r+1}\mathbf{x}_{r+1} = \mathbf{0}$, hence $c_{r+1} = 0$, since $\mathbf{x}_{r+1} \neq \mathbf{0}$ (an eigenvector!). This contradicts the fact that not all scalars in (2) are zero. Hence the conclusion of the theorem must hold. ■

EXAMPLE 1 **Eigenbasis. Nondistinct Eigenvalues. Nonexistence**

The matrix $\mathbf{A} = \begin{bmatrix} 5 & 3 \\ 3 & 5 \end{bmatrix}$ has a basis of eigenvectors $\begin{bmatrix} 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ -1 \end{bmatrix}$ corresponding to the eigenvalues $\lambda_1 = 8, \lambda_2 = 2$. (See Example 1 in Sec. 8.2.)

Even if not all n eigenvalues are different, a matrix $\mathbf{A}$ may still provide an eigenbasis for R^n. See Example 2 in Sec. 8.1, where $n = 3$.

On the other hand, $\mathbf{A}$ ***may not have enough linearly independent eigenvectors to make up a basis.*** For instance, $\mathbf{A}$ in Example 3 of Sec. 8.1 is

$$\mathbf{A} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \quad \text{and has only one eigenvector} \quad \begin{bmatrix} k \\ 0 \end{bmatrix} \quad (k \neq 0, \text{ arbitrary}). \ ■$$

Actually, eigenbases exist under much more general conditions than those in Theorem 1. An important case is the following.

THEOREM 2 **Symmetric Matrices**

A symmetric matrix has an orthonormal basis of eigenvectors for R^n.

For a proof (which is involved) see Ref. [B3], vol. 1, pp. 270–272.

EXAMPLE 2 **Orthonormal Basis of Eigenvectors**

The first matrix in Example 1 is symmetric, and an orthonormal basis of eigenvectors is $[1/\sqrt{2} \quad 1/\sqrt{2}]^\mathsf{T}$, $[1/\sqrt{2} \quad -1/\sqrt{2}]^\mathsf{T}$. ■

Diagonalization of Matrices

Eigenbases also play a role in reducing a matrix $\mathbf{A}$ to a diagonal matrix whose entries are the eigenvalues of $\mathbf{A}$. This is done by a "similarity transformation," which is defined as follows (and will have various applications in numerics in Chap. 20).

DEFINITION **Similar Matrices. Similarity Transformation**

An $n \times n$ matrix $\hat{\mathbf{A}}$ is called **similar** to an $n \times n$ matrix $\mathbf{A}$ if

$$\hat{\mathbf{A}} = \mathbf{P}^{-1}\mathbf{A}\mathbf{P} \tag{4}$$

for some (nonsingular!) $n \times n$ matrix $\mathbf{P}$. This transformation, which gives $\hat{\mathbf{A}}$ from $\mathbf{A}$, is called a **similarity transformation.**

The key property of this transformation is that it preserves the eigenvalues of $\mathbf{A}$:

THEOREM 3

Eigenvalues and Eigenvectors of Similar Matrices

If $\hat{\mathbf{A}}$ is similar to $\mathbf{A}$, then $\hat{\mathbf{A}}$ *has the same eigenvalues as* $\mathbf{A}$.

Furthermore, if $\mathbf{x}$ is an eigenvector of $\mathbf{A}$, then $\mathbf{y} = \mathbf{P}^{-1}\mathbf{x}$ *is an eigenvector of $\hat{\mathbf{A}}$ corresponding to the same eigenvalue.*

PROOF From $\mathbf{Ax} = \lambda\mathbf{x}$ (λ an eigenvalue, $\mathbf{x} \neq \mathbf{0}$) we get $\mathbf{P}^{-1}\mathbf{Ax} = \lambda\mathbf{P}^{-1}\mathbf{x}$. Now $\mathbf{I} = \mathbf{PP}^{-1}$. By this ***"identity trick"*** the previous equation gives

$$\mathbf{P}^{-1}\mathbf{Ax} = \mathbf{P}^{-1}\mathbf{AIx} = \mathbf{P}^{-1}\mathbf{APP}^{-1}\mathbf{x} = \hat{\mathbf{A}}(\mathbf{P}^{-1}\mathbf{x}) = \lambda\mathbf{P}^{-1}\mathbf{x}.$$

Hence λ is an eigenvalue of $\hat{\mathbf{A}}$ and $\mathbf{P}^{-1}\mathbf{x}$ a corresponding eigenvector. Indeed, $\mathbf{P}^{-1}\mathbf{x} = \mathbf{0}$ would give $\mathbf{x} = \mathbf{Ix} = \mathbf{PP}^{-1}\mathbf{x} = \mathbf{P0} = \mathbf{0}$, contradicting $\mathbf{x} \neq \mathbf{0}$. ■

EXAMPLE 3 **Eigenvalues and Vectors of Similar Matrices**

Let $\mathbf{A} = \begin{bmatrix} 6 & -3 \\ 4 & -1 \end{bmatrix}$ and $\mathbf{P} = \begin{bmatrix} 1 & 3 \\ 1 & 4 \end{bmatrix}$.

Then $\hat{\mathbf{A}} = \begin{bmatrix} 4 & -3 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} 6 & -3 \\ 4 & -1 \end{bmatrix} \begin{bmatrix} 1 & 3 \\ 1 & 4 \end{bmatrix} = \begin{bmatrix} 3 & 0 \\ 0 & 2 \end{bmatrix}$.

Here $\mathbf{P}^{-1}$ was obtained from (4*) in Sec. 7.8 with $\det \mathbf{P} = 1$. We see that $\hat{\mathbf{A}}$ has the eigenvalues $\lambda_1 = 3$, $\lambda_2 = 2$. The characteristic equation of $\mathbf{A}$ is $(6 - \lambda)(-1 - \lambda) + 12 = \lambda^2 - 5\lambda + 6 = 0$. It has the roots (the eigenvalues of $\mathbf{A}$) $\lambda_1 = 3$, $\lambda_2 = 2$, confirming the first part of Theorem 3.

We confirm the second part. From the first component of $(\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}$ we have $(6 - \lambda)x_1 - 3x_2 = 0$. For $\lambda = 3$ this gives $3x_1 - 3x_2 = 0$, say, $\mathbf{x}_1 = [1 \quad 1]^\mathsf{T}$. For $\lambda = 2$ it gives $4x_1 - 3x_2 = 0$, say, $\mathbf{x}_2 = [3 \quad 4]^\mathsf{T}$. In Theorem 3 we thus have

$$\mathbf{y}_1 = \mathbf{P}^{-1}\mathbf{x}_1 = \begin{bmatrix} 4 & -3 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \qquad \mathbf{y}_2 = \mathbf{P}^{-1}\mathbf{x}_2 = \begin{bmatrix} 4 & -3 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} 3 \\ 4 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

Indeed, these are eigenvectors of the diagonal matrix $\hat{\mathbf{A}}$.

Perhaps we see that $\mathbf{x}_1$ and $\mathbf{x}_2$ are the columns of $\mathbf{P}$. This suggests the general method of transforming a matrix $\mathbf{A}$ to diagonal form $\mathbf{D}$ by using $\mathbf{P} = \mathbf{X}$, the matrix with eigenvectors as columns: ■

THEOREM 4

Diagonalization of a Matrix

If an $n \times n$ matrix $\mathbf{A}$ has a basis of eigenvectors, then

$$\mathbf{D} = \mathbf{X}^{-1}\mathbf{AX} \tag{5}$$

is diagonal, with the eigenvalues of $\mathbf{A}$ as the entries on the main diagonal. Here $\mathbf{X}$ is the matrix with these eigenvectors as column vectors. Also,

$$\mathbf{D}^m = \mathbf{X}^{-1}\mathbf{A}^m\mathbf{X} \qquad (m = 2, 3, \cdn) \tag{5*}$$

PROOF Let $\mathbf{x}_1, \cdots, \mathbf{x}_n$ constitute a basis of eigenvectors of $\mathbf{A}$ for R^n. Let the corresponding eigenvalues of $\mathbf{A}$ be $\lambda_1, \cdots, \lambda_n$, respectively, so that $\mathbf{A}\mathbf{x}_1 = \lambda_1\mathbf{x}_1, \cdots, \mathbf{A}\mathbf{x}_n = \lambda_n\mathbf{x}_n$. Then $\mathbf{X} = [\mathbf{x}_1 \quad \cdots \quad \mathbf{x}_n]$ has rank n, by Theorem 3 in Sec. 7.4. Hence $\mathbf{X}^{-1}$ exists by Theorem 1 in Sec. 7.8. We claim that

$$(6) \qquad \mathbf{AX} = \mathbf{A}[\mathbf{x}_1 \quad \cdots \quad \mathbf{x}_n] = [\mathbf{A}\mathbf{x}_1 \quad \cdots \quad \mathbf{A}\mathbf{x}_n] = [\lambda_1\mathbf{x}_1 \quad \cdots \quad \lambda_n\mathbf{x}_n] = \mathbf{XD}$$

where $\mathbf{D}$ is the diagonal matrix as in (5). The fourth equality in (6) follows by direct calculation. (Try it for $n = 2$ and then for general n.) The third equality uses $\mathbf{A}\mathbf{x}_k = \lambda_k\mathbf{x}_k$. The second equality results if we note that the first column of $\mathbf{AX}$ is $\mathbf{A}$ times the first column of $\mathbf{X}$, and so on. For instance, when $n = 2$ and we write $\mathbf{x}_1 = [x_{11} \quad x_{21}]^\mathsf{T}$, $\mathbf{x}_2 = [x_{12} \quad x_{22}]^\mathsf{T}$, we have

$$\mathbf{AX} = \mathbf{A}[x_1 \quad \mathbf{x}_2] = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{bmatrix}$$

$$= \begin{bmatrix} a_{11}x_{11} + a_{12}x_{21} & a_{11}x_{12} + a_{12}x_{22} \\ a_{21}x_{11} + a_{22}x_{21} & a_{21}x_{12} + a_{22}x_{22} \end{bmatrix} = [\mathbf{A}\mathbf{x}_1 \quad \mathbf{A}\mathbf{x}_2].$$

Column 1 Column 2

If we multiply (6) by $\mathbf{X}^{-1}$ from the left, we obtain (5). Since (5) is a similarity transformation, Theorem 3 implies that $\mathbf{D}$ has the same eigenvalues as $\mathbf{A}$. Equation (5*) follows if we note that

$$\mathbf{D}^2 = \mathbf{DD} = \mathbf{X}^{-1}\mathbf{AX}\mathbf{X}^{-1}\mathbf{AX} = \mathbf{X}^{-1}\mathbf{AAX} = \mathbf{X}^{-1}\mathbf{A}^2\mathbf{X}, \qquad \text{etc.}$$

■

EXAMPLE 4 Diagonalization

Diagonalize

$$\mathbf{A} = \begin{bmatrix} 7.3 & 0.2 & -3.7 \\ -11.5 & 1.0 & 5.5 \\ 17.7 & 1.8 & -9.3 \end{bmatrix}.$$

Solution. The characteristic determinant gives the characteristic equation $-\lambda^3 - \lambda^2 + 12\lambda = 0$. The roots (eigenvalues of $\mathbf{A}$) are $\lambda_1 = 3$, $\lambda_2 = -4$, $\lambda_3 = 0$. By the Gauss elimination applied to $(\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}$ with $\lambda = \lambda_1, \lambda_2, \lambda_3$ we find eigenvectors and then $\mathbf{X}^{-1}$ by the Gauss–Jordan elimination (Sec. 7.8, Example 1). The results are

$$\begin{bmatrix} -1 \\ 3 \\ -1 \end{bmatrix}, \quad \begin{bmatrix} 1 \\ -1 \\ 3 \end{bmatrix}, \quad \begin{bmatrix} 2 \\ 1 \\ 4 \end{bmatrix}, \quad \mathbf{X} = \begin{bmatrix} -1 & 1 & 2 \\ 3 & -1 & 1 \\ -1 & 3 & 4 \end{bmatrix}, \quad \mathbf{X}^{-1} = \begin{bmatrix} -0.7 & 0.2 & 0.3 \\ -1.3 & -0.2 & 0.7 \\ 0.8 & 0.2 & -0.2 \end{bmatrix}.$$

Calculating $\mathbf{AX}$ and multiplying by $\mathbf{X}^{-1}$ from the left, we thus obtain

$$\mathbf{D} = \mathbf{X}^{-1}\mathbf{AX} = \begin{bmatrix} -0.7 & 0.2 & 0.3 \\ -1.3 & -0.2 & 0.7 \\ 0.8 & 0.2 & -0.2 \end{bmatrix} \begin{bmatrix} -3 & -4 & 0 \\ 9 & 4 & 0 \\ -3 & -12 & 0 \end{bmatrix} = \begin{bmatrix} 3 & 0 & 0 \\ 0 & -4 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

■

Quadratic Forms. Transformation to Principal Axes

By definition, a **quadratic form** Q in the components $x_1, \cdots, x_n$ of a vector $\mathbf{x}$ is a sum of n^2 terms, namely,

$$Q = \mathbf{x}^\mathsf{T}\mathbf{A}\mathbf{x} = \sum_{j=1}^{n}\sum_{k=1}^{n} a_{jk}x_j x_k$$

$$= a_{11}x_1^2 + a_{12}x_1x_2 + \cdots + a_{1n}x_1x_n$$
$$+ a_{21}x_2x_1 + a_{22}x_2^2 + \cdots + a_{2n}x_2x_n \quad (7)$$
$$+ \cdots\cdots\cdots\cdots\cdots\cdots$$
$$+ a_{n1}x_nx_1 + a_{n2}x_nx_2 + \cdots + a_{nn}x_n^2.$$

$\mathbf{A} = [a_{jk}]$ is called the **coefficient matrix** of the form. We may assume that $\mathbf{A}$ is ***symmetric,*** because we can take off-diagonal terms together in pairs and write the result as a sum of two equal terms; see the following example.

EXAMPLE 5 Quadratic Form. Symmetric Coefficient Matrix

Let

$$\mathbf{x}^\mathsf{T}\mathbf{A}\mathbf{x} = [x_1 \quad x_2]\begin{bmatrix}3 & 4\\ 6 & 2\end{bmatrix}\begin{bmatrix}x_1\\ x_2\end{bmatrix} = 3x_1^2 + 4x_1x_2 + 6x_2x_1 + 2x_2^2 = 3x_1^2 + 10x_1x_2 + 2x_2^2.$$

Here $4 + 6 = 10 = 5 + 5$. From the corresponding ***symmetric*** matrix $\mathbf{C} = [c_{jk}]$, where $c_{jk} = \frac{1}{2}(a_{jk} + a_{kj})$, thus $c_{11} = 3$, $c_{12} = c_{21} = 5$, $c_{22} = 2$, we get the same result; indeed,

$$\mathbf{x}^\mathsf{T}\mathbf{C}\mathbf{x} = [x_1 \quad x_2]\begin{bmatrix}3 & 5\\ 5 & 2\end{bmatrix}\begin{bmatrix}x_1\\ x_2\end{bmatrix} = 3x_1^2 + 5x_1x_2 + 5x_2x_1 + 2x_2^2 = 3x_1^2 + 10x_1x_2 + 2x_2^2. \quad \blacksquare$$

Quadratic forms occur in physics and geometry, for instance, in connection with conic sections (ellipses $x_1^2/a^2 + x_2^2/b^2 = 1$, etc.) and quadratic surfaces (cones, etc.). Their transformation to principal axes is an important practical task related to the diagonalization of matrices, as follows.

By Theorem 2 the *symmetric* coefficient matrix $\mathbf{A}$ of (7) has an orthonormal basis of eigenvectors. Hence if we take these as column vectors, we obtain a matrix $\mathbf{X}$ that is orthogonal, so that $\mathbf{X}^{-1} = \mathbf{X}^\mathsf{T}$. From (5) we thus have $\mathbf{A} = \mathbf{X}\mathbf{D}\mathbf{X}^{-1} = \mathbf{X}\mathbf{D}\mathbf{X}^\mathsf{T}$. Substitution into (7) gives

$$Q = \mathbf{x}^\mathsf{T}\mathbf{X}\mathbf{D}\mathbf{X}^\mathsf{T}\mathbf{x}. \quad (8)$$

If we set $\mathbf{X}^\mathsf{T}\mathbf{x} = \mathbf{y}$, then, since $\mathbf{X}^\mathsf{T} = \mathbf{X}^{-1}$, we get

$$\mathbf{x} = \mathbf{X}\mathbf{y}. \quad (9)$$

Furthermore, in (8) we have $\mathbf{x}^\mathsf{T}\mathbf{X} = (\mathbf{X}^\mathsf{T}\mathbf{x})^\mathsf{T} = \mathbf{y}^\mathsf{T}$ and $\mathbf{X}^\mathsf{T}\mathbf{x} = \mathbf{y}$, so that Q becomes simply

$$Q = \mathbf{y}^\mathsf{T}\mathbf{D}\mathbf{y} = \lambda_1 y_1^2 + \lambda_2 y_2^2 + \cdots + \lambda_n y_n^2. \quad (10)$$

This proves the following basic theorem.

THEOREM 5

Principal Axes Theorem

The substitution (9) *transforms a quadratic form*

$$Q = \mathbf{x}^T\mathbf{A}\mathbf{x} = \sum_{j=1}^{n}\sum_{k=1}^{n} a_{jk}x_j x_k \qquad (a_{kj} = a_{jk})$$

to the principal axes form or **canonical form** (10), *where* $\lambda_1, \cdots, \lambda_n$ *are the (not necessarily distinct) eigenvalues of the (symmetric!) matrix* $\mathbf{A}$, *and* $\mathbf{X}$ *is an orthogonal matrix with corresponding eigenvectors* $\mathbf{x}_1, \cdots, \mathbf{x}_n$, *respectively, as column vectors.*

EXAMPLE 6 **Transformation to Principal Axes. Conic Sections**

Find out what type of conic section the following quadratic form represents and transform it to principal axes:

$$Q = 17x_1^2 - 30x_1x_2 + 17x_2^2 = 128.$$

Solution. We have $Q = \mathbf{x}^T\mathbf{A}\mathbf{x}$, where

$$\mathbf{A} = \begin{bmatrix} 17 & -15 \\ -15 & 17 \end{bmatrix}, \qquad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}.$$

This gives the characteristic equation $(17 - \lambda)^2 - 15^2 = 0$. It has the roots $\lambda_1 = 2$, $\lambda_2 = 32$. Hence (10) becomes

$$Q = 2y_1^2 + 32y_2^2.$$

We see that $Q = 128$ represents the ellipse $2y_1^2 + 32y_2^2 = 128$, that is,

$$\frac{y_1^2}{8^2} + \frac{y_2^2}{2^2} = 1.$$

If we want to know the direction of the principal axes in the x_1x_2-coordinates, we have to determine normalized eigenvectors from $(\mathbf{A} - \lambda\mathbf{I})\mathbf{x} = \mathbf{0}$ with $\lambda = \lambda_1 = 2$ and $\lambda = \lambda_2 = 32$ and then use (9). We get

$$\begin{bmatrix} 1/\sqrt{2} \\ 1/\sqrt{2} \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} -1/\sqrt{2} \\ 1/\sqrt{2} \end{bmatrix},$$

hence

$$\mathbf{x} = \mathbf{X}\mathbf{y} = \begin{bmatrix} 1/\sqrt{2} & -1/\sqrt{2} \\ 1/\sqrt{2} & 1/\sqrt{2} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}, \qquad \begin{aligned} x_1 &= y_1/\sqrt{2} - y_2/\sqrt{2} \\ x_2 &= y_1/\sqrt{2} + y_2/\sqrt{2}. \end{aligned}$$

This is a 45° rotation. Our results agree with those in Sec. 8.2, Example 1, except for the notations. See also Fig. 158 in that example. ■

PROBLEM SET 8.4

1–9 DIAGONALIZATION OF MATRICES

Find an eigenbasis (a basis of eigenvectors) and diagonalize. (Show the details.)

1. $\begin{bmatrix} 3 & 2 \\ 2 & 6 \end{bmatrix}$

2. $\begin{bmatrix} 0 & 16 \\ 4 & 0 \end{bmatrix}$

3. $\begin{bmatrix} 5 & 1 \\ 1 & 5 \end{bmatrix}$

4. $\begin{bmatrix} 3 & 2 \\ -5 & -4 \end{bmatrix}$

5. $\begin{bmatrix} 1.0 & 6.0 \\ 1.5 & 1.0 \end{bmatrix}$

6. $\begin{bmatrix} 2 & 7 \\ 6 & -9 \end{bmatrix}$

7. $\begin{bmatrix} 1 & 0 & 1 \\ 0 & 3 & 2 \\ 0 & 0 & 2 \end{bmatrix}$

8. $\begin{bmatrix} -6 & -6 & 10 \\ -5 & -5 & 5 \\ -9 & -9 & 13 \end{bmatrix}$

9. $\begin{bmatrix} 3 & 10 & -15 \\ -18 & 39 & 9 \\ -24 & 40 & -15 \end{bmatrix}$

10. (Orthonormal basis) Illustrate Theorem 2 with further examples.

11. (No basis) Find further 2×2 and 3×3 matrices without eigenbases.

12. PROJECT. Similarity of Matrices. Similarity is basic, for instance in designing numeric methods.

(a) Trace. By definition, the **trace** of an $n \times n$ matrix $\mathbf{A} = [a_{jk}]$ is the sum of the diagonal entries,

$$\text{trace } \mathbf{A} = a_{11} + a_{22} + \cdots + a_{nn}.$$

Show that the trace equals the sum of the eigenvalues, each counted as often as its algebraic multiplicity indicates. Illustrate this with the matrices in Probs. 1, 3, 5, 7, 9.

(b) Trace of product. Let $\mathbf{B} = [b_{jk}]$ be $n \times n$. Show that similar matrices have equal traces, by first proving

$$\text{trace } \mathbf{AB} = \sum_{i=1}^{n} \sum_{l=1}^{n} a_{il} b_{li} = \text{trace } \mathbf{BA}.$$

(c) Find a relationship between $\hat{\mathbf{A}}$ in (4) and $\tilde{\mathbf{A}} = \mathbf{PAP}^{-1}$.

(d) Diagonalization. What can you do in (5) if you want to change the order of the eigenvalues in $\mathbf{D}$, for instance, interchange $d_{11} = \lambda_1$ and $d_{22} = \lambda_2$?

13–18 SIMILAR MATRICES HAVE EQUAL SPECTRA

Verify this for $\mathbf{A}$ and $\hat{\mathbf{A}} = \mathbf{P}^{-1}\mathbf{AP}$. Find eigenvectors $\mathbf{y}$ of $\hat{\mathbf{A}}$. Show that $\mathbf{x} = \mathbf{Py}$ are eigenvectors of $\mathbf{A}$. (Show the details of your work.)

13. $\mathbf{A} = \begin{bmatrix} -5 & 0 \\ 0 & 2 \end{bmatrix}$, $\mathbf{P} = \begin{bmatrix} 4 & -2 \\ -3 & 1 \end{bmatrix}$

14. $\mathbf{A} = \begin{bmatrix} 3 & 4 \\ 4 & -3 \end{bmatrix}$, $\mathbf{P} = \begin{bmatrix} 5 & 2 \\ 2 & 1 \end{bmatrix}$

15. $\mathbf{A} = \begin{bmatrix} 4 & 2 \\ -4 & -2 \end{bmatrix}$, $\mathbf{P} = \begin{bmatrix} 1 & 3 \\ 3 & 6 \end{bmatrix}$

16. $\mathbf{A} = \begin{bmatrix} 3 & 0 \\ 7 & -2 \end{bmatrix}$, $\mathbf{P} = \begin{bmatrix} 8 & 2 \\ 1 & 4 \end{bmatrix}$

17. $\mathbf{A} = \begin{bmatrix} 4 & 0 & 0 \\ 12 & -2 & 0 \\ 21 & -6 & 1 \end{bmatrix}$, $\mathbf{P} = \begin{bmatrix} 4 & 0 & 6 \\ 0 & 2 & 0 \\ 6 & 0 & 10 \end{bmatrix}$

18. $\mathbf{A} = \begin{bmatrix} -5 & 0 & 15 \\ 3 & 4 & -9 \\ -5 & 0 & 15 \end{bmatrix}$, $\mathbf{P} = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

19–28 TRANSFORMATION TO PRINCIPAL AXES. CONIC SECTIONS

What kind of conic section (or pair of straight lines) is given by the quadratic form? Transform it to principal axes. Express $\mathbf{x}^\mathsf{T} = [x_1 \quad x_2]$ in terms of the new coordinate vector $\mathbf{y}^\mathsf{T} = [y_1 \quad y_2]$, as in Example 6.

19. $x_1^2 + 24x_1x_2 - 6x_2^2 = 5$

20. $3x_1^2 + 4\sqrt{3}x_1x_2 + 7x_2^2 = 9$

21. $3x_1^2 - 8x_1x_2 - 3x_2^2 = 0$

22. $6x_1^2 + 16x_1x_2 - 6x_2^2 = 20$

23. $4x_1^2 + 2\sqrt{3}x_1x_2 + 2x_2^2 = 10$

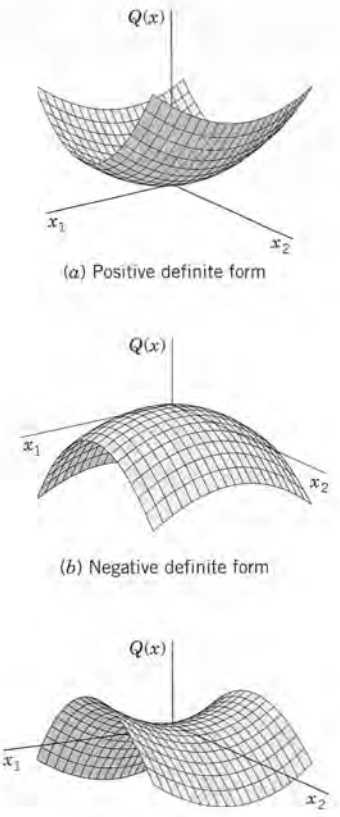
24. $7x_1^2 - 24x_1x_2 = 144$

25. $x_1^2 - 12x_1x_2 + x_2^2 = 35$

26. $3x_1^2 + 22x_1x_2 + 3x_2^2 = 0$

27. $12x_1^2 + 32x_1x_2 + 12x_2^2 = 112$

28. $6.5x_1^2 + 5.0x_1x_2 + 6.5x_2^2 = 36$



29. (Definiteness) A quadratic form $Q(\mathbf{x}) = \mathbf{x}^\mathsf{T}\mathbf{A}\mathbf{x}$ and its (symmetric!) matrix $\mathbf{A}$ are called **(a) positive definite** if $Q(\mathbf{x}) > 0$ for all $\mathbf{x} \neq \mathbf{0}$, **(b) negative definite** if $Q(\mathbf{x}) < 0$ for all $\mathbf{x} \neq 0$, **(c) indefinite** if $Q(\mathbf{x})$ takes both positive and negative values. (See Fig. 160.) [$Q(\mathbf{x})$ and $\mathbf{A}$ are called *positive semidefinite* (*negative semidefinite*) if $Q(\mathbf{x}) \geqq 0$ ($Q(\mathbf{x}) \leqq 0$) for all $\mathbf{x}$.] A necessary and sufficient condition for positive definiteness is that all the **"principal minors"** are positive (see Ref. [B3], vol. 1, p. 306), that is,

$$a_{11} > 0, \qquad \begin{vmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{vmatrix} > 0,$$

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{12} & a_{22} & a_{23} \\ a_{13} & a_{23} & a_{33} \end{vmatrix} > 0, \qquad \cdots, \qquad \det \mathbf{A} > 0.$$

Show that the form in Prob. 23 is positive definite, whereas that in Prob. 19 is indefinite.

30. (Definiteness) Show that necessary and sufficient for (a), (b), (c) in Prob. 29 is that the eigenvalues of $\mathbf{A}$ are (a) all positive, (b) all negative, (c) both positive and negative. *Hint.* Use Theorem 5.

(a) Positive definite form

(b) Negative definite form

(c) Indefinite form

Fig. 160. Quadratic forms in two variables

8.5 Complex Matrices and Forms. *Optional*

The three classes of real matrices in Sec. 8.3 have complex counterparts that are of practical interest in certain applications, mainly because of their spectra (see Theorem 1 in this section), for instance, in quantum mechanics. To define these classes, we need the following standard

Notations

$\bar{\mathbf{A}} = [\bar{a}_{jk}]$ is obtained from $\mathbf{A} = [a_{jk}]$ by replacing each entry $a_{jk} = \alpha + i\beta$ (α, β real) with its complex conjugate $\bar{a}_{jk} = \alpha - i\beta$. Also, $\bar{\mathbf{A}}^\mathsf{T} = [\bar{a}_{kj}]$ is the transpose of $\bar{\mathbf{A}}$, hence the conjugate transpose of $\mathbf{A}$.

EXAMPLE 1 Notations

$$\text{If } \mathbf{A} = \begin{bmatrix} 3 + 4i & 1 - i \\ 6 & 2 - 5i \end{bmatrix}, \text{ then } \bar{\mathbf{A}} = \begin{bmatrix} 3 - 4i & 1 + i \\ 6 & 2 + 5i \end{bmatrix} \text{ and } \bar{\mathbf{A}}^\mathsf{T} = \begin{bmatrix} 3 - 4i & 6 \\ 1 + i & 2 + 5i \end{bmatrix}. \blacksquare$$

DEFINITION

Hermitian, Skew-Hermitian, and Unitary Matrices

A square matrix $\mathbf{A} = [a_{kj}]$ is called

Hermitian	if $\bar{\mathbf{A}}^{\mathsf{T}} = \mathbf{A}$,	that is,	$\bar{a}_{kj} = a_{jk}$
skew-Hermitian	if $\bar{\mathbf{A}}^{\mathsf{T}} = -\mathbf{A}$,	that is,	$\bar{a}_{kj} = -a_{jk}$
unitary	if $\bar{\mathbf{A}}^{\mathsf{T}} = \mathbf{A}^{-1}$.		

The first two classes are named after Hermite (see footnote 13 in Problem Set 5.8).

From the definitions we see the following. If $\mathbf{A}$ is Hermitian, the entries on the main diagonal must satisfy $\bar{a}_{jj} = a_{jj}$; that is, they are real. Similarly, if $\mathbf{A}$ is skew-Hermitian, then $\bar{a}_{jj} = -a_{jj}$. If we set $a_{jj} = \alpha + i\beta$, this becomes $\alpha - i\beta = -(\alpha + i\beta)$. Hence $\alpha = 0$, so that a_{jj} must be pure imaginary or 0.

EXAMPLE 2 **Hermitian, Skew-Hermitian, and Unitary Matrices**

$$\mathbf{A} = \begin{bmatrix} 4 & 1 - 3i \\ 1 + 3i & 7 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 3i & 2 + i \\ -2 + i & -i \end{bmatrix}, \quad \mathbf{C} = \begin{bmatrix} \frac{1}{2}i & \frac{1}{2}\sqrt{3} \\ \frac{1}{2}\sqrt{3} & \frac{1}{2}i \end{bmatrix}$$

are Hermitian, skew-Hermitian, and unitary matrices, respectively, as you may verify by using the definitions. ■

If a Hermitian matrix is real, then $\bar{\mathbf{A}}^{\mathsf{T}} = \mathbf{A}^{\mathsf{T}} = \mathbf{A}$. Hence a real Hermitian matrix is a symmetric matrix (Sec. 8.3.).

Similarly, if a skew-Hermitian matrix is real, then $\bar{\mathbf{A}}^{\mathsf{T}} = \mathbf{A}^{\mathsf{T}} = -\mathbf{A}$. Hence a real skew-Hermitian matrix is a skew-symmetric matrix.

Finally, if a unitary matrix is real, then $\bar{\mathbf{A}}^{\mathsf{T}} = \mathbf{A}^{\mathsf{T}} = \mathbf{A}^{-1}$. Hence a real unitary matrix is an orthogonal matrix.

This shows that *Hermitian, skew-Hermitian, and unitary matrices generalize symmetric, skew-symmetric, and orthogonal matrices, respectively.*

Eigenvalues

It is quite remarkable that the matrices under consideration have spectra (sets of eigenvalues; see Sec. 8.1) that can be characterized in a general way as follows (see Fig. 161).

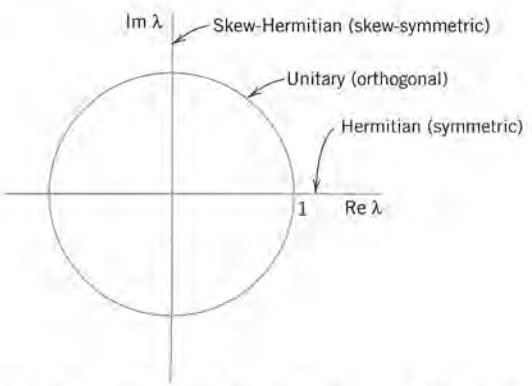


Fig. 161. Location of the eigenvalues of Hermitian, skew-Hermitian, and unitary matrices in the complex λ-plane

THEOREM 1

Eigenvalues

(a) *The eigenvalues of a Hermitian matrix (and thus of a symmetric matrix) are real.*

(b) *The eigenvalues of a skew-Hermitian matrix (and thus of a skew-symmetric matrix) are pure imaginary or zero.*

(c) *The eigenvalues of a unitary matrix (and thus of an orthogonal matrix) have absolute value* 1.

EXAMPLE 3 **Illustration of Theorem 1**

For the matrices in Example 2 we find by direct calculation

Matrix		Characteristic Equation	Eigenvalues
A	Hermitian	$\lambda^2 - 11\lambda + 18 = 0$	$9, \quad 2$
B	Skew-Hermitian	$\lambda^2 - 2i\lambda + 8 = 0$	$4i, \quad -2i$
C	Unitary	$\lambda^2 - i\lambda - 1 = 0$	$\frac{1}{2}\sqrt{3} + \frac{1}{2}i, \quad -\frac{1}{2}\sqrt{3} + \frac{1}{2}i$

and $|\pm\frac{1}{2}\sqrt{3} + \frac{1}{2}i|^2 = \frac{3}{4} + \frac{1}{4} = 1$. ■

PROOF We prove Theorem 1. Let λ be an eigenvalue and $\mathbf{x}$ an eigenvector of $\mathbf{A}$. Multiply $\mathbf{Ax} = \lambda\mathbf{x}$ from the left by $\bar{\mathbf{x}}^\mathsf{T}$, thus $\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax} = \lambda\bar{\mathbf{x}}^\mathsf{T}\mathbf{x}$, and divide by $\bar{\mathbf{x}}^\mathsf{T}\mathbf{x} = \bar{x}_1x_1 + \cdots + \bar{x}_nx_n = |x_1|^2 + \cdots + |x_n|^2$, which is real and not 0 because $\mathbf{x} \neq \mathbf{0}$. This gives

$$\lambda = \frac{\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax}}{\bar{\mathbf{x}}^\mathsf{T}\mathbf{x}}. \tag{1}$$

(a) If $\mathbf{A}$ is Hermitian, $\bar{\mathbf{A}}^\mathsf{T} = \mathbf{A}$ or $\mathbf{A}^\mathsf{T} = \bar{\mathbf{A}}$ and we show that then the numerator in (1) is real, which makes λ real. $\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax}$ is a scalar; hence taking the transpose has no effect. Thus

$$\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax} = (\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax})^\mathsf{T} = \mathbf{x}^\mathsf{T}\mathbf{A}^\mathsf{T}\bar{\mathbf{x}} = \mathbf{x}^\mathsf{T}\overline{\mathbf{A}}\bar{\mathbf{x}} = \overline{(\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax})}. \tag{2}$$

Hence, $\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax}$ equals its complex conjugate, so that it must be real. ($a + ib = a - ib$ implies $b = 0$.)

(b) If $\mathbf{A}$ is skew-Hermitian, $\mathbf{A}^\mathsf{T} = -\overline{\mathbf{A}}$ and instead of (2) we obtain

$$\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax} = -\overline{(\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax})} \tag{3}$$

so that $\bar{\mathbf{x}}^\mathsf{T}\mathbf{Ax}$ equals minus its complex conjugate and is pure imaginary or 0. ($a + ib = -(a - ib)$ implies $a = 0$.)

(c) Let $\mathbf{A}$ be unitary. We take $\mathbf{Ax} = \lambda\mathbf{x}$ and its conjugate transpose

$$(\overline{\mathbf{A}}\bar{\mathbf{x}})^\mathsf{T} = (\bar{\lambda}\bar{\mathbf{x}})^\mathsf{T} = \bar{\lambda}\bar{\mathbf{x}}^\mathsf{T}$$

and multiply the two left sides and the two right sides,

$$(\overline{\mathbf{A}}\bar{\mathbf{x}})^\mathsf{T}\mathbf{Ax} = \bar{\lambda}\lambda\bar{\mathbf{x}}^\mathsf{T}\mathbf{x} = |\lambda|^2\bar{\mathbf{x}}^\mathsf{T}\mathbf{x}.$$

But $\mathbf{A}$ is unitary, $\bar{\mathbf{A}}^{\mathsf{T}} = \mathbf{A}^{-1}$, so that on the left we obtain

$$(\bar{\mathbf{A}}\bar{\mathbf{x}})^{\mathsf{T}}\mathbf{A}\mathbf{x} = \bar{\mathbf{x}}^{\mathsf{T}}\bar{\mathbf{A}}^{\mathsf{T}}\mathbf{A}\mathbf{x} = \bar{\mathbf{x}}^{\mathsf{T}}\mathbf{A}^{-1}\mathbf{A}\mathbf{x} = \bar{\mathbf{x}}^{\mathsf{T}}\mathbf{I}\,\mathbf{x} = \bar{\mathbf{x}}^{\mathsf{T}}\mathbf{x}.$$

Together, $\bar{\mathbf{x}}^{\mathsf{T}}\mathbf{x} = |\lambda|^2\bar{\mathbf{x}}^{\mathsf{T}}\mathbf{x}$. We now divide by $\bar{\mathbf{x}}^{\mathsf{T}}\mathbf{x}$ $(\neq 0)$ to get $|\lambda|^2 = 1$. Hence $|\lambda| = 1$.

This proves Theorem 1 as well as Theorems 1 and 5 in Sec. 8.3. ∎

Key properties of orthogonal matrices (invariance of the inner product, orthonormality of rows and columns; see Sec. 8.3) generalize to unitary matrices in a remarkable way.

To see this, instead of R^n we now use the **complex vector space** C^n of all complex vectors with n complex numbers as components, and complex numbers as scalars. For such complex vectors the **inner product** is defined by (note the overbar for the complex conjugate)

$$\mathbf{(4)} \qquad \mathbf{a} \bullet \mathbf{b} = \bar{\mathbf{a}}^{\mathsf{T}}\mathbf{b}.$$

The **length** or **norm** of such a complex vector is a *real* number defined by

$$\mathbf{(5)} \qquad \|\mathbf{a}\| = \sqrt{\mathbf{a} \bullet \mathbf{a}} = \sqrt{\bar{\mathbf{a}}^{\mathsf{T}}\mathbf{a}} = \sqrt{\bar{a}_1 a_1 + \cdots + \bar{a}_n a_n} = \sqrt{|a_1|^2 + \cdots + |a_n|^2}.$$

THEOREM 2

Invariance of Inner Product

A **unitary transformation,** *that is,* $\mathbf{y} = \mathbf{A}\mathbf{x}$ *with a unitary matrix* $\mathbf{A}$**,** *preserves the value of the inner product* (4)*, hence also the norm* (5)*.*

PROOF The proof is the same as that of Theorem 2 in Sec. 8.3, which the theorem generalizes. In the analog of (9), Sec. 8.3, we now have bars,

$$\mathbf{u} \bullet \mathbf{v} = \bar{\mathbf{u}}^{\mathsf{T}}\mathbf{v} = (\bar{\mathbf{A}}\bar{\mathbf{a}})^{\mathsf{T}}\mathbf{A}\mathbf{b} = \bar{\mathbf{a}}^{\mathsf{T}}\bar{\mathbf{A}}^{\mathsf{T}}\mathbf{A}\mathbf{b} = \bar{\mathbf{a}}^{\mathsf{T}}\mathbf{I}\,\mathbf{b} = \bar{\mathbf{a}}^{\mathsf{T}}\mathbf{b} = \mathbf{a} \bullet \mathbf{b}.$$ ∎

The complex analog of an orthonormal systems of real vectors (see Sec. 8.3) is defined as follows.

DEFINITION

Unitary System

A *unitary system* is a set of complex vectors satisfying the relationships

$$\mathbf{(6)} \qquad \mathbf{a}_j \bullet \mathbf{a}_k = \bar{\mathbf{a}}_j^{\mathsf{T}}\mathbf{a}_k = \begin{cases} 0 & \text{if } j \neq k \\ 1 & \text{if } j = k. \end{cases}$$

Theorem 3 in Sec. 8.3 extends to complex as follows.

THEOREM 3

Unitary Systems of Column and Row Vectors

A complex square matrix is unitary if and only if its column vectors (and also its row vectors) form a unitary system.

PROOF The proof is the same as that of Theorem 3 in Sec. 8.3, except for the bars required in $\overline{\mathbf{A}}^{\mathsf{T}} = \mathbf{A}^{-1}$ and in (4) and (6) of the present section. ∎

THEOREM 4

Determinant of a Unitary Matrix

Let $\mathbf{A}$ *be a unitary matrix. Then its determinant has absolute value one, that is,* $|\det \mathbf{A}| = 1$.

PROOF Similarly as in Sec. 8.3 we obtain

$$1 = \det(\mathbf{A}\mathbf{A}^{-1}) = \det(\mathbf{A}\overline{\mathbf{A}}^{\mathsf{T}}) = \det \mathbf{A} \det \overline{\mathbf{A}}^{\mathsf{T}} = \det \mathbf{A} \det \overline{\mathbf{A}}$$
$$= \det \mathbf{A}\, \overline{\det \mathbf{A}} = |\det \mathbf{A}|^2.$$

Hence $|\det \mathbf{A}| = 1$ (where $\det \mathbf{A}$ may now be complex). ∎

EXAMPLE 4 **Unitary Matrix Illustrating Theorems 1c and 2–4**

For the vectors $\mathbf{a}^{\mathsf{T}} = [2 \quad -i]$ and $\mathbf{b}^{\mathsf{T}} = [1+i \quad 4i]$ we get $\bar{\mathbf{a}}^{\mathsf{T}} = [2 \quad i]^{\mathsf{T}}$ and $\bar{\mathbf{a}}^{\mathsf{T}}\mathbf{b} = 2(1+i) - 4 = -2 + 2i$ and with

$$\mathbf{A} = \begin{bmatrix} 0.8i & 0.6 \\ 0.6 & 0.8i \end{bmatrix} \quad \text{also} \quad \mathbf{A}\mathbf{a} = \begin{bmatrix} i \\ 2 \end{bmatrix} \quad \text{and} \quad \mathbf{A}\mathbf{b} = \begin{bmatrix} -0.8 + 3.2i \\ -2.6 + 0.6i \end{bmatrix},$$

as one can readily verify. This gives $(\overline{\mathbf{A}\bar{\mathbf{a}}})^{\mathsf{T}}\mathbf{A}\mathbf{b} = -2 + 2i$, illustrating Theorem 2. The matrix is unitary. Its columns form a unitary system,

$$\bar{\mathbf{a}}_1^{\mathsf{T}}\mathbf{a}_1 = -0.8i \cdot 0.8i + 0.6^2 = 1, \qquad \bar{\mathbf{a}}_1^{\mathsf{T}}\mathbf{a}_2 = -0.8i \cdot 0.6 + 0.6 \cdot 0.8i = 0,$$
$$\bar{\mathbf{a}}_2^{\mathsf{T}}\mathbf{a}_2 = 0.6^2 + (-0.8i)0.8i = 1$$

and so do its rows. Also, $\det \mathbf{A} = -1$. The eigenvalues are $0.6 + 0.8i$ and $-0.6 + 0.8i$, with eigenvectors $[1 \quad 1]^{\mathsf{T}}$ and $[1 \quad -1]^{\mathsf{T}}$, respectively. ∎

Theorem 2 in Sec. 8.4 on the existence of an eigenbasis extends to complex matrices as follows.

THEOREM 5

Basis of Eigenvectors

A Hermitian, skew-Hermitian, or unitary matrix has a basis of eigenvectors for C^n *that is a unitary system.*

For a proof see Ref. [B3], vol. 1, pp. 270–272 and p. 244 (Definition 2).

EXAMPLE 5 **Unitary Eigenbases**

The matrices **A, B, C** in Example 2 have the following unitary systems of eigenvectors, as you should verify.

A: $\frac{1}{\sqrt{35}}[1 - 3i \quad 5]^{\mathsf{T}}$ $(\lambda = 9)$, $\frac{1}{\sqrt{14}}[1 - 3i \quad -2]^{\mathsf{T}}$ $(\lambda = 2)$

B: $\frac{1}{\sqrt{30}}[1 - 2i \quad -5]^{\mathsf{T}}$ $(\lambda = -2i)$, $\frac{1}{\sqrt{30}}[5 \quad 1 + 2i]^{\mathsf{T}}$ $(\lambda = 4i)$

C: $\frac{1}{\sqrt{2}}[1 \quad 1]^{\mathsf{T}}$ $(\lambda = \frac{1}{2}(i + \sqrt{3}))$, $\frac{1}{\sqrt{2}}[1 \quad -1]^{\mathsf{T}}$ $(\lambda = \frac{1}{2}(i - \sqrt{3}))$. ∎

Hermitian and Skew-Hermitian Forms

The concept of a quadratic form (Sec. 8.4) can be extended to complex. We call the numerator $\bar{\mathbf{x}}^\mathsf{T}\mathbf{A}\mathbf{x}$ in (1) a **form** in the components $x_1, \cdots, x_n$ of $\mathbf{x}$, which may now be complex. This form is again a sum of n^2 terms

$$\begin{aligned}\bar{\mathbf{x}}^\mathsf{T}\mathbf{A}\mathbf{x} &= \sum_{j=1}^{n}\sum_{k=1}^{n} a_{jk}\bar{x}_j x_k \\ &= a_{11}\bar{x}_1x_1 + \cdots + a_{1n}\bar{x}_1x_n \\ &\quad + a_{21}\bar{x}_2x_1 + \cdots + a_{2n}\bar{x}_2x_n \\ &\quad + \cdots\cdots\cdots\cdots\cdots \\ &\quad + a_{n1}\bar{x}_nx_1 + \cdots + a_{nn}\bar{x}_nx_n.\end{aligned} \tag{7}$$

$\mathbf{A}$ is called its **coefficient matrix.** The form is called a **Hermitian** or **skew-Hermitian form** if $\mathbf{A}$ is Hermitian or skew-Hermitian, respectively. *The value of a Hermitian form is real, and that of a skew-Hermitian form is pure imaginary or zero.* This can be seen directly from (2) and (3) and accounts for the importance of these forms in physics. Note that (2) and (3) are valid for any vectors because in the proof of (2) and (3) we did not use that $\mathbf{x}$ is an eigenvector but only that $\bar{\mathbf{x}}^\mathsf{T}\mathbf{x}$ is real and not 0.

EXAMPLE 6 **Hermitian Form**

For $\mathbf{A}$ in Example 2 and, say, $\mathbf{x} = [1 + i \quad 5i]^\mathsf{T}$ we get

$$\bar{\mathbf{x}}^\mathsf{T}\mathbf{A}\mathbf{x} = [1 - i \quad -5i]\begin{bmatrix} 4 & 1 - 3i \\ 1 + 3i & 7 \end{bmatrix}\begin{bmatrix} 1 + i \\ 5i \end{bmatrix} = [1 - i \quad -5i]\begin{bmatrix} 4(1 + i) + (1 - 3i)\cdot 5i \\ (1 + 3i)(1 + i) + 7\cdot 5i \end{bmatrix} = 223. \quad \blacksquare$$

Clearly, if $\mathbf{A}$ and $\mathbf{x}$ in (4) are real, then (7) reduces to a quadratic form, as discussed in the last section.

PROBLEM SET 8.5

1. **(Verification)** Verify the statements in Examples 2 and 3.
2. **(Product)** Show $(\overline{\mathbf{B}\mathbf{A}})^\mathsf{T} = -\mathbf{A}\mathbf{B}$ for $\mathbf{A}$ and $\mathbf{B}$ in Example 2. For any $n \times n$ Hermitian $\mathbf{A}$ and skew-Hermitian $\mathbf{B}$.
3. Show that $(\overline{\mathbf{A}\mathbf{B}\mathbf{C}})^\mathsf{T} = -\mathbf{C}^{-1}\mathbf{B}\mathbf{A}$ for any $n \times n$ Hermitian $\mathbf{A}$, skew-Hermitian $\mathbf{B}$, and unitary $\mathbf{C}$.
4. **(Eigenvectors)** Find eigenvectors of $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$ in Examples 2 and 3.

5–11 EIGENVALUES AND EIGENVECTORS

Are the matrices in Probs. 5–11 Hermitian? Skew-Hermitian? Unitary? Find their eigenvalues (thereby verifying Theorem 1) and eigenvectors.

5. $\begin{bmatrix} 4 & i \\ -i & 2 \end{bmatrix}$

6. $\begin{bmatrix} 0 & 2i \\ 2i & 0 \end{bmatrix}$

7. $\begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{i}{\sqrt{2}} \\ -\frac{i}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \end{bmatrix}$

8. $\begin{bmatrix} 0 & i \\ i & 0 \end{bmatrix}$

9. $\begin{bmatrix} 5i & 0 & 0 \\ 0 & 0 & 5i \\ 0 & 5i & 0 \end{bmatrix}$

10. $\begin{bmatrix} 0 & 1 + i & 0 \\ 1 - i & 0 & 1 + i \\ 0 & 1 - i & 0 \end{bmatrix}$

11. $\begin{bmatrix} 0 & 0 & i \\ 0 & i & 0 \\ i & 0 & 0 \end{bmatrix}$

12. PROJECT. Complex Matrices

(a) Decomposition. Show that any square matrix may be written as the sum of a Hermitian and a skew-Hermitian matrix. Give examples.

(b) Normal matrix. This important concept denotes a matrix that commutes with its conjugate transpose, $\mathbf{A}\overline{\mathbf{A}}^{\mathsf{T}} = \overline{\mathbf{A}}^{\mathsf{T}}\mathbf{A}$. Prove that Hermitian, skew-Hermitian, and unitary matrices are normal. Give corresponding examples of your own.

(c) Normality criterion. Prove that $\mathbf{A}$ is normal if and only if the Hermitian and skew-Hermitian matrices in (a) commute.

(d) Find a simple matrix that is not normal. Find a normal matrix that is not Hermitian, skew-Hermitian, or unitary.

(e) Unitary matrices. Prove that the product of two unitary $n \times n$ matrices and the inverse of a unitary matrix are unitary. Give examples.

(f) Powers of unitary matrices in applications may sometimes be very simple. Show that $\mathbf{C}^{12} = \mathbf{I}$ in Example 2. Find further examples.

13–15 COMPLEX FORMS

Is the given matrix (call it $\mathbf{A}$) Hermitian or skew-Hermitian? Find $\bar{\mathbf{x}}^{\mathsf{T}}\mathbf{A}\mathbf{x}$. (Show all the details.) a, b, c, k are real.

13. $\begin{bmatrix} 0 & -3i \\ -3i & 0 \end{bmatrix}$, $\mathbf{x} = \begin{bmatrix} 4+i \\ 3-i \end{bmatrix}$

14. $\begin{bmatrix} a & b+ic \\ b-ic & k \end{bmatrix}$, $\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$

15. $\begin{bmatrix} 2 & 1+i \\ 1-i & 1 \end{bmatrix}$, $\mathbf{x} = \begin{bmatrix} i \\ 2i \end{bmatrix}$

16. (Pauli spin matrices) Find the eigenvalues and eigenvectors of the so-called *Pauli spin matrices* and show that $\mathbf{S}_x\mathbf{S}_y = i\mathbf{S}_z$, $\mathbf{S}_y\mathbf{S}_x = -i\mathbf{S}_z$, $\mathbf{S}_x^2 = \mathbf{S}_y^2 = \mathbf{S}_z^2 = \mathbf{I}$, where

$$\mathbf{S}_x = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \qquad \mathbf{S}_y = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix},$$

$$\mathbf{S}_z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}.$$

CHAPTER 8 REVIEW QUESTIONS AND PROBLEMS

1. In solving an eigenvalue problem, what is given and what is sought?
2. Do there exist square matrices without eigenvalues? Eigenvectors corresponding to more than one eigenvalue of a given matrix?
3. What is the defect? Why is it important? Give examples.
4. Can a complex matrix have real eigenvalues? Real eigenvectors? Give reasons.
5. What is diagonalization of a matrix? Transformation of a form to principal axes?
6. What is an eigenbasis? When does it exist? Why is it important?
7. Does a 3×3 matrix always have a real eigenvalue?
8. Give a few typical applications in which eigenvalue problems occur.

9–14 DIAGONALIZATION

Find an eigenbasis and diagonalize. (Show the details.)

9. $\begin{bmatrix} 101 & 72 \\ -144 & -103 \end{bmatrix}$

10. $\begin{bmatrix} 14.4 & -11.2 \\ -11.2 & 102.6 \end{bmatrix}$

11. $\begin{bmatrix} -14 & 10 \\ -10 & 11 \end{bmatrix}$

12. $\begin{bmatrix} 15 & 4 & -4 \\ 6 & 10 & 8 \\ -12 & -2 & -7 \end{bmatrix}$, $\lambda = 18$

13. $\begin{bmatrix} 5 & \frac{8}{3} & -\frac{2}{3} \\ 2 & \frac{2}{3} & \frac{4}{3} \\ -4 & -\frac{4}{3} & -\frac{8}{3} \end{bmatrix}$

14. $\begin{bmatrix} -6 & 11 & 3 \\ 4 & 1 & 3 \\ -4 & 10 & 8 \end{bmatrix}$, $\lambda = 2$

15–17 SIMILARITY

Verify that $\mathbf{A}$ and $\hat{\mathbf{A}} = \mathbf{P}^{-1}\mathbf{A}\mathbf{P}$ have the same spectrum. Here, $\mathbf{A}$, $\mathbf{P}$ are:

15. $\begin{bmatrix} 3.8 & 2.4 \\ 2.4 & 0.2 \end{bmatrix}, \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix}$

16. $\begin{bmatrix} -22 & 20 & 10 \\ -4 & 20 & -8 \\ 28 & -14 & 29 \end{bmatrix}, \begin{bmatrix} 1 & 0 & 2 \\ 0 & 2 & 4 \\ 2 & 8 & 0 \end{bmatrix}$

17. $\begin{bmatrix} 2 & 2 & -2 \\ 3 & 1 & -3 \\ 1 & -1 & -1 \end{bmatrix}, \begin{bmatrix} 1 & 2 & 3 \\ 2 & 0 & 2 \\ 3 & 2 & 4 \end{bmatrix}$

Transformation to Canonical Form. Reduce the quadratic form to principal axes.

18. $11.56x_1^2 + 20.16x_1x_2 + 17.44x_2^2 = 100$

19. $1.09x_1^2 - 0.06x_1x_2 + 1.01x_2^2 = 1$

20. $14x_1^2 + 24x_1x_2 - 4x_2^2 = 20$

SUMMARY OF CHAPTER 8
Linear Algebra: Matrix Eigenvalue Problems

The practical importance of matrix eigenvalue problems can hardly be overrated. The problems are defined by the vector equation

$$\mathbf{A}\mathbf{x} = \lambda\mathbf{x}. \tag{1}$$

$\mathbf{A}$ is a given square matrix. All matrices in this chapter are ***square.*** λ is a scalar. To *solve* the problem (1) means to determine values of λ, called **eigenvalues** (or **characteristic values**) of $\mathbf{A}$, such that (1) has a nontrivial solution $\mathbf{x}$ (that is, $\mathbf{x} \neq \mathbf{0}$), called an **eigenvector** of $\mathbf{A}$ corresponding to that λ. An $n \times n$ matrix has at least one and at most n numerically different eigenvalues. These are the solutions of the **characteristic equation** (Sec. 8.1)

$$D(\lambda) = \det(\mathbf{A} - \lambda\mathbf{I}) = \begin{vmatrix} a_{11} - \lambda & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} - \lambda & \cdots & a_{2n} \\ \cdot & \cdot & \cdots & \cdot \\ a_{n1} & a_{n2} & \cdots & a_{nn} - \lambda \end{vmatrix} = 0. \tag{2}$$

$D(\lambda)$ is called the **characteristic determinant** of $\mathbf{A}$. By expanding it we get the **characteristic polynomial** of $\mathbf{A}$, which is of degree n in λ. Some typical applications are shown in Sec. 8.2.

Section 8.3 is devoted to eigenvalue problems for **symmetric** ($\mathbf{A}^\mathsf{T} = \mathbf{A}$), **skew-symmetric** ($\mathbf{A}^\mathsf{T} = -\mathbf{A}$), and **orthogonal matrices** ($\mathbf{A}^\mathsf{T} = \mathbf{A}^{-1}$). Section 8.4 concerns the diagonalization of matrices and the transformation of quadratic forms to principal axes and its relation to eigenvalues.

Section 8.5 extends Sec. 8.3 to the complex analogs of those real matrices, called **Hermitian** ($\bar{\mathbf{A}}^\mathsf{T} = \mathbf{A}$), **skew-Hermitian** ($\bar{\mathbf{A}}^\mathsf{T} = -\mathbf{A}$), and **unitary matrices** ($\bar{\mathbf{A}}^\mathsf{T} = \mathbf{A}^{-1}$). All the eigenvalues of a Hermitian matrix (and a symmetric one) are real. For a skew-Hermitian (and a skew-symmetric) matrix they are pure imaginary or zero. For a unitary (and an orthogonal) matrix they have absolute value 1.

CHAPTER 9

Vector Differential Calculus. Grad, Div, Curl

This chapter deals with vectors and vector functions in **3-space,** the space of three dimensions with the usual measurement of distance (given by the Pythagorean theorem). This includes **2-space** (the plane) as a special case. It extends the differential calculus to those vector functions and the vector fields they represent. Forces, velocities, and various other quantities are vectors. This makes the algebra, geometry, and calculus of these vector functions the natural instrument for the engineer and physicist in solid mechanics, fluid flow, heat flow, electrostatics, and so on. The engineer must understand these vector functions and fields as the basis of the design and construction of systems, such as airplanes, laser generators, and robots.

In Secs. 9.1–9.3 we explain the basic *algebraic* operations with vectors in 3-space. *Calculus* begins in Sec. 9.4 with the extension of differentiation to vector functions in a simple and natural fashion. Application to curves and their use in mechanics follows in Sec. 9.5.

We finally discuss three physically important concepts related to scalar and vector fields, namely, the gradient (Sec. 9.7), divergence (Sec. 9.8), and curl (Sec. 9.9). (The use of these concepts in integral theorems follows in the next chapter. Their form in **curvilinear coordinates** is given in App. A3.4.)

We shall keep this chapter ***independent of Chaps. 7 and 8.*** Our present approach is in harmony with Chap. 7, with the restriction to two and three dimensions providing for a richer theory with basic physical, engineering, and geometric applications.

Prerequisite: Elementary use of second- and third-order determinants in Sec. 9.3.
Sections that may be omitted in a shorter course: 9.5, 9.6.
References and Answers to Problems: App. 1 Part B, App. 2.

9.1 Vectors in 2-Space and 3-Space

In physics and geometry and its engineering applications we use two kinds of quantities: scalars and vectors. A **scalar** is a quantity that is determined by its magnitude; this is the number of units measured on a suitable scale. For instance, length, voltage, and temperature are scalars.

A **vector** is a quantity that is determined by both its magnitude and its direction. Thus it is an **arrow** or **directed line segment.** For instance, a force is a vector, and so is a velocity, giving the speed and direction of motion (Fig. 162).

We denote vectors by lowercase boldface letters **a, b, v,** etc. In handwriting you may use arrows, for instance $\vec{a}$ (in place of **a**), $\vec{b}$, etc.

A vector (arrow) has a tail, called its **initial point,** and a tip, called its **terminal point.** This is motivated in the **translation** (displacement without rotation) of the triangle in Fig. 163, where the initial point P of the vector **a** is the original position of a point, and the terminal point Q is the terminal position of that point, its position *after* the translation. The length of the arrow equals the distance between P and Q. This is called the **length** (or *magnitude*) of the vector **a** and is denoted by $|\mathbf{a}|$. Another name for *length* is **norm** (or *Euclidean norm*).

A vector of length 1 is called a **unit vector.**

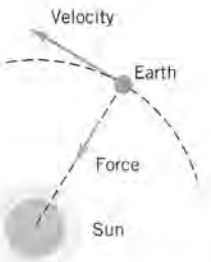

Fig. 162. Force and velocity

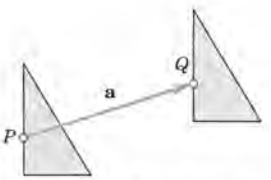

Fig. 163. Translation

Of course, we would like to calculate with vectors. For instance, we want to find the resultant of forces or compare parallel forces of different magnitude. This motivates our next ideas: to define *components* of a vector, and then the two basic algebraic operations of *vector addition* and *scalar multiplication.*

For this we must first define *equality of vectors* in a way that is practical in connection with forces and other applications.

DEFINITION

Equality of Vectors

Two vectors **a** and **b** are equal, written $\mathbf{a} = \mathbf{b}$, if they have the same length and the same direction [as explained in Fig. 164; in particular, note (B)]. Hence a vector can be arbitrarily translated; that is, its initial point can be chosen arbitrarily.

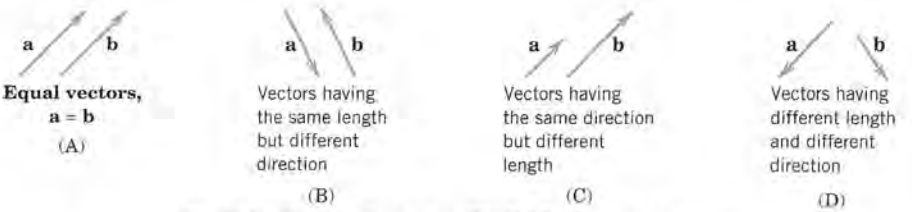

Fig. 164. (A) Equal vectors. (B)–(D) Different vectors

Components of a Vector

We choose an xyz **Cartesian coordinate system**[1] in space (Fig. 165), that is, a usual rectangular coordinate system with the same scale of measurement on the three mutually perpendicular coordinate axes. Let **a** be a given vector with initial point P: (x_1, y_1, z_1) and terminal point Q: (x_2, y_2, z_2). Then the three coordinate differences

$$\textbf{(1)} \qquad a_1 = x_2 - x_1, \qquad a_2 = y_2 - y_1, \qquad a_3 = z_2 - z_1$$

are called the **components** of the vector **a** with respect to that coordinate system, and we write simply $\mathbf{a} = [a_1, a_2, a_3]$. See Fig. 166.

The **length** $|\mathbf{a}|$ of **a** can now readily be expressed in terms of components because from (1) and the Pythagorean theorem we have

$$\textbf{(2)} \qquad |\mathbf{a}| = \sqrt{a_1^2 + a_2^2 + a_3^2}.$$

EXAMPLE 1 **Components and Length of a Vector**

The vector **a** with initial point P: (4, 0, 2) and terminal point Q: (6, −1, 2) has the components

$$a_1 = 6 - 4 = 2, \qquad a_2 = -1 - 0 = -1, \qquad a_3 = 2 - 2 = 0.$$

Hence $\mathbf{a} = [2, -1, 0]$. (Can you sketch **a**, as in Fig. 166?) Equation (2) gives the length

$$|\mathbf{a}| = \sqrt{2^2 + (-1)^2 + 0^2} = \sqrt{5}.$$

If we choose (−1, 5, 8) as the initial point of **a**, the corresponding terminal point is (1, 4, 8).

If we choose the origin (0, 0, 0) as the initial point of **a**, the corresponding terminal point is (2, −1, 0); its coordinates equal the components of **a**. This suggests that we can determine each point in space by a vector, called the *position vector* of the point, as follows. ■

A Cartesian coordinate system being given, the **position vector r** of a point A: (x, y, z) is the vector with the origin (0, 0, 0) as the initial point and A as the terminal point (see Fig. 167). Thus in components, $\mathbf{r} = [x, y, z]$. This can be seen directly from (1) with $x_1 = y_1 = z_1 = 0$.

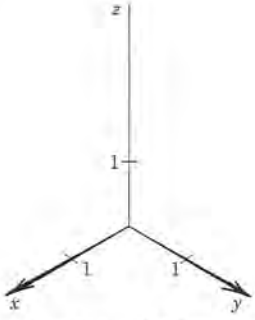

Fig. 165. Cartesian coordinate system

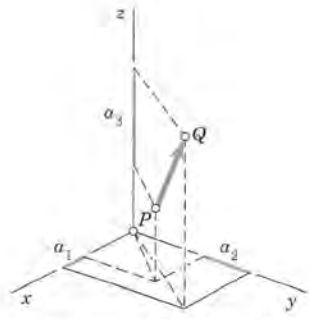

Fig. 166. Components of a vector

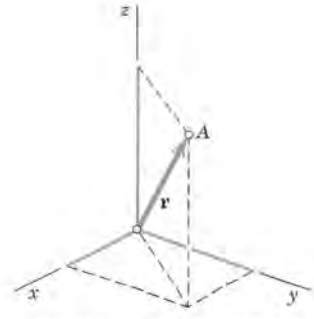

Fig. 167. Position vector **r** of a point A: (x, y, z)

[1]Named after the French philosopher and mathematician RENATUS CARTESIUS, latinized for RENÉ DESCARTES (1596–1650), who invented analytic geometry. His basic work *Géométrie* appeared in 1637, as an appendix to his *Discours de la méthode*.

Furthermore, if we translate a vector **a,** with initial point P and terminal point Q, then corresponding coordinates of P and Q change by the same amount, so that the differences in (1) remain unchanged. This proves

THEOREM 1

Vectors as Ordered Triples of Real Numbers

A fixed Cartesian coordinate system being given, each vector is uniquely determined by its ordered triple of corresponding components. Conversely, to each ordered triple of real numbers (a_1, a_2, a_3) *there corresponds precisely one vector* $\mathbf{a} = [a_1, a_2, a_3]$, *with* $(0, 0, 0)$ *corresponding to the* **zero vector 0,** *which has length* 0 *and no direction.*

Hence a vector equation $\mathbf{a} = \mathbf{b}$ *is equivalent to the three equations* $a_1 = b_1$, $a_2 = b_2$, $a_3 = b_3$ *for the components.*

We now see that from our "geometric" definition of a vector as an arrow we have arrived at an "algebraic" characterization of a vector by Theorem 1. We could have started from the latter and reversed our process. This shows that the two approaches are equivalent.

Vector Addition, Scalar Multiplication

Applications suggest calculation with vectors that are practically useful and are almost as simple as the arithmetics for real numbers. The first is addition and the second is multiplication by a number.

DEFINITION

Addition of Vectors

The **sum** $\mathbf{a} + \mathbf{b}$ of two vectors $\mathbf{a} = [a_1, a_2, a_3]$ and $\mathbf{b} = [b_1, b_2, b_3]$ is obtained by adding the corresponding components,

$$\mathbf{a} + \mathbf{b} = [a_1 + b_1, \quad a_2 + b_2, \quad a_3 + b_3]. \tag{3}$$

Geometrically, place the vectors as in Fig. 168 (the initial point of **b** at the terminal point of **a**); then $\mathbf{a} + \mathbf{b}$ is the vector drawn from the initial point of **a** to the terminal point of **b.**

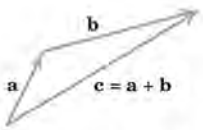

Fig. 168. Vector addition

For forces, this addition is the parallelogram law by which we obtain the **resultant** of two forces in mechanics. See Fig. 169.

Figure 170 shows (for the plane) that the "algebraic" way and the "geometric way" of vector addition give the same vector.

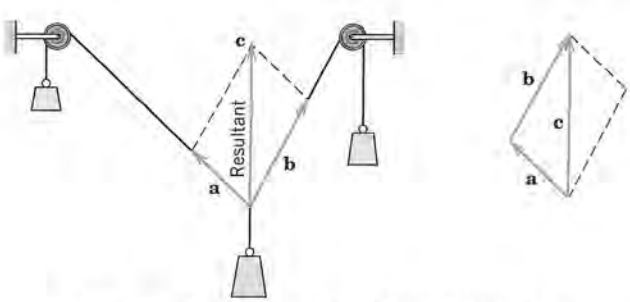

Fig. 169. Resultant of two forces **(parallelogram law)**

Basic Properties of Vector Addition. Familiar laws for real numbers give immediately (see also Figs. 171 and 172)

$$\textbf{(4)}\qquad \begin{aligned} &\text{(a)} && \mathbf{a}+\mathbf{b}=\mathbf{b}+\mathbf{a} && \textit{(Commutativity)}\\ &\text{(b)} && (\mathbf{u}+\mathbf{v})+\mathbf{w}=\mathbf{u}+(\mathbf{v}+\mathbf{w}) && \textit{(Associativity)}\\ &\text{(c)} && \mathbf{a}+\mathbf{0}=\mathbf{0}+\mathbf{a}=\mathbf{a} &&\\ &\text{(d)} && \mathbf{a}+(-\mathbf{a})=\mathbf{0}. && \end{aligned}$$

Here $-\mathbf{a}$ denotes the vector having the length $|\mathbf{a}|$ and the direction opposite to that of $\mathbf{a}$.

In (4b) we may simply write $\mathbf{u}+\mathbf{v}+\mathbf{w}$, and similarly for sums of more than three vectors. Instead of $\mathbf{a}+\mathbf{a}$ we also write $2\mathbf{a}$, and so on. This (and the notation $-\mathbf{a}$ used just before) motivates defining the second algebraic operation for vectors as follows.

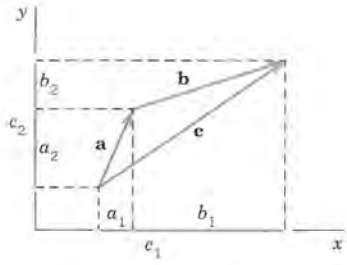

Fig. 170. Vector addition

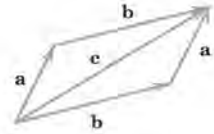

Fig. 171. Cummutativity of vector addition

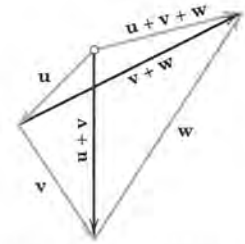

Fig. 172. Associativity of vector addition

DEFINITION

Scalar Multiplication (Multiplication by a Number)

The product $c\mathbf{a}$ of any vector $\mathbf{a}=[a_1, a_2, a_3]$ and any scalar c (real number c) is the vector obtained by multiplying each component of $\mathbf{a}$ by c,

$$\textbf{(5)}\qquad c\mathbf{a}=[ca_1, ca_2, ca_3].$$

Geometrically, if $\mathbf{a}\neq\mathbf{0}$, then $c\mathbf{a}$ with $c>0$ has the direction of $\mathbf{a}$ and with $c<0$ the direction opposite to $\mathbf{a}$. In any case, the length of $c\mathbf{a}$ is $|c\mathbf{a}|=|c||\mathbf{a}|$, and $c\mathbf{a}=\mathbf{0}$ if $\mathbf{a}=\mathbf{0}$ or $c=0$ (or both). (See Fig. 173.)

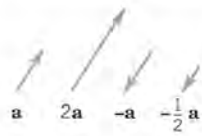

Fig. 173. Scalar multiplication [multiplication of vectors by scalars (numbers)]

Basic Properties of Scalar Multiplication. From the definitions we obtain directly

$$\textbf{(6)}\qquad \begin{aligned} &\text{(a)} && c(\mathbf{a}+\mathbf{b})=c\mathbf{a}+c\mathbf{b} && \\ &\text{(b)} && (c+k)\mathbf{a}=c\mathbf{a}+k\mathbf{a} && \\ &\text{(c)} && c(k\mathbf{a})=(ck)\mathbf{a} && \text{(written } ck\mathbf{a}\text{)}\\ &\text{(d)} && 1\mathbf{a}=\mathbf{a}. && \end{aligned}$$

You may prove that (4) and (6) imply for any vector $\mathbf{a}$

$$\text{(7)} \qquad \begin{aligned} &\text{(a)} \qquad 0\mathbf{a} = \mathbf{0} \\ &\text{(b)} \qquad (-1)\mathbf{a} = -\mathbf{a}. \end{aligned}$$

Instead of $\mathbf{b} + (-\mathbf{a})$ we simply write $\mathbf{b} - \mathbf{a}$ (Fig. 174).

EXAMPLE 2 Vector Addition. Multiplication by Scalars

With respect to a given coordinate system, let

$$\mathbf{a} = [4, 0, 1] \qquad \text{and} \qquad \mathbf{b} = [2, -5, \tfrac{1}{3}].$$

Then $-\mathbf{a} = [-4, 0, -1]$, $7\mathbf{a} = [28, 0, 7]$, $\mathbf{a} + \mathbf{b} = [6, -5, \frac{4}{3}]$, and

$$2(\mathbf{a} - \mathbf{b}) = 2[2, 5, \tfrac{2}{3}] = [4, 10, \tfrac{4}{3}] = 2\mathbf{a} - 2\mathbf{b}.$$

■

Unit Vectors i, j, k. Besides $\mathbf{a} = [a_1, a_2, a_3]$ another popular way of writing vectors is

$$\text{(8)} \qquad \mathbf{a} = a_1\mathbf{i} + a_2\mathbf{j} + a_3\mathbf{k}$$

In this representation, **i, j, k** are the unit vectors in the positive directions of the axes of a Cartesian coordinate system (Fig. 175). Hence, in components,

$$\text{(9)} \qquad \mathbf{i} = [1, \ 0, \ 0], \qquad \mathbf{j} = [0, \ 1, \ 0], \qquad \mathbf{k} = [0, \ 0, \ 1]$$

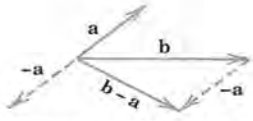
and the right side of (8) is a sum of three vectors parallel to the three axes.

EXAMPLE 3 ijk Notation for Vectors

In Example 2 we have $\mathbf{a} = 4\mathbf{i} + \mathbf{k}$, $\mathbf{b} = 2\mathbf{i} - 5\mathbf{j} + \frac{1}{3}\mathbf{k}$, and so on. ■

All the vectors $\mathbf{a} = [a_1, a_2, a_3] = a_1\mathbf{i} + a_2\mathbf{j} + a_3\mathbf{k}$ (with real numbers as components) form the **real vector space** R^3 with the two *algebraic operations* of vector addition and scalar multiplication as just defined. R^3 has **dimension** 3. The triple of vectors **i, j, k** is called a **standard basis** of R^3. A Cartesian coordinate system being given, the representation (8) of a given vector is unique.

Vector space R^3 is a model of a general vector space, as discussed in Sec. 7.9, but is not needed in this chapter.



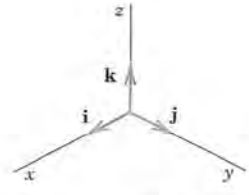


Fig. 174. Difference of vectors

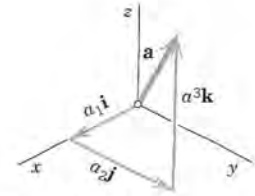

Fig. 175. The unit vectors **i, j, k** and the representation (8)

PROBLEM SET 9.1

1–6 COMPONENTS AND LENGTH

Find the components of the vector $\mathbf{v}$ with given initial point P and terminal point Q. Find $|\mathbf{v}|$. Sketch $|\mathbf{v}|$. Find the **unit vector** in the direction of $\mathbf{v}$.

1. P: (3, 2, 0), Q: (5, −2, 0)
2. P: (1, 1, 1), Q: (−4, −4, −4)
3. P: (1, 0, 1.2), Q: (0, 0, 6.2)
4. P: (2, −2, 0), Q: (0, 4, 6)
5. P: (4, 3, 2), Q: (−4, −3, 2)
6. P: (0, 0, 0), Q: (6, 8, 10)

7–12

Given the components v_1, v_2, v_3 of a vector $\mathbf{v}$ and a particular initial point P, find the corresponding terminal point Q and the length of $\mathbf{v}$.

7. 3, −1, 0; P: (4, 6, 0)
8. 8, 4, −2; P: (−8, −4, 2)
9. $\frac{1}{4}, 2, \frac{3}{4}$; P: $(0, -\frac{1}{2}, \frac{3}{2})$;
10. 3, 2, 6; P: (0, 0, 0)
11. $4, \frac{1}{2}, -\frac{3}{2}$; P: $(-4, \frac{1}{2}, 2)$
12. 3, −3, 3; P: (1, 3, −3)

13–20 VECTOR ADDITION AND SCALAR MULTIPLICATION

Let $\mathbf{a} = [2, -1, 0] = 2\mathbf{i} - \mathbf{j}$, $\mathbf{b} = [-4, 2, 5] = -4\mathbf{i} + 2\mathbf{j} + 5\mathbf{k}$, $\mathbf{c} = [0, 0, 3] = 3\mathbf{k}$. Find:

13. $2\mathbf{a}, -\mathbf{a}, -\frac{1}{2}\mathbf{a}$
14. $\mathbf{a} + 2\mathbf{b}, 2\mathbf{b} + \mathbf{a}$
15. $5(\mathbf{a} - \mathbf{c}), 5\mathbf{a} - 5\mathbf{c}$
16. $(3\mathbf{a} - 5\mathbf{b}) + 2\mathbf{c}, 3\mathbf{a} + (-5\mathbf{b} + 2\mathbf{c})$
17. $6\mathbf{a} - 4\mathbf{b} + 2\mathbf{c}, 2(3\mathbf{a} - 2\mathbf{b} + \mathbf{c})$
18. $(1/|\mathbf{a}|)\mathbf{a}, (1/|\mathbf{c}|)\mathbf{c}$
19. $\mathbf{a} + \mathbf{b} + \mathbf{c}, -3\mathbf{a} - 3\mathbf{b} - 3\mathbf{c}$
20. $|\mathbf{a} + \mathbf{b}|, |\mathbf{a}| + |\mathbf{b}|$
21. What laws do Probs. 14–17 illustrate?
22. Prove (4) and (6).
23. Find the midpoint of the segment PQ in Probs. 7 and 9.

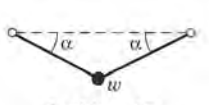
24–28 FORCES

Find the resultant (in components) and its magnitude.

24. $\mathbf{p} = [1, 2, 0], \mathbf{q} = [0, 4, -1], \mathbf{u} = [4, 0, -3], \mathbf{v} = [6, 2, 4]$
25. $\mathbf{p} = [2, 2, 2], \mathbf{q} = [-4, -4, 0], \mathbf{u} = [2, 2, 7]$
26. $\mathbf{p} = [-1, -3, -5], \mathbf{q} = [6, 4, 2], \mathbf{u} = [-5, -1, 3]$
27. $\mathbf{p} = [8, 2, -4], \mathbf{q} = 3\mathbf{p}, \mathbf{u} = -5\mathbf{p}$
28. $\mathbf{p} = [3, 0, -2], \mathbf{q} = [2, 5, 1], \mathbf{u} = 4\mathbf{q}$
29. Find $\mathbf{v}$ so that $\mathbf{v}, \mathbf{p}, \mathbf{q}, \mathbf{u}$ in Prob. 25 are in equilibrium.
30. For what c is the resultant of [3, 1, 7], [4, 4, 5], and [3, 2, c] parallel to the xy-plane?
31. Find forces $\mathbf{p}, \mathbf{q}, \mathbf{u}$ in the direction of the coordinate axes such that $\mathbf{p}, \mathbf{q}, \mathbf{u}, \mathbf{v} = [2, 3, 0], \mathbf{w} = [7, -1, 11]$ are in equilibrium. Are $\mathbf{p}, \mathbf{q}, \mathbf{u}$ uniquely determined?
32. If $|\mathbf{p}| = 1$ and $|\mathbf{q}| = 2$, what can be said about the magnitude and direction of the resultant? Can you think of an application where this matters?
33. Same question as in Prob. 32 if $|\mathbf{p}| = 3$, $|\mathbf{q}| = 2$, $|\mathbf{u}| = 1$.
34. **(Relative velocity)** If airplanes A and B are moving southwest with speed $|\mathbf{v}_A| = 500$ mph and northwest with speed $|\mathbf{v}_B| = 400$ mph, respectively, what is the relative velocity $\mathbf{v} = \mathbf{v}_B - \mathbf{v}_A$ of B with respect to A?
35. **(Relative velocity)** Same question as in Prob. 34 for two ships moving northwest with speed $|\mathbf{v}_A| = 20$ knots and northeast with speed $|\mathbf{v}_B| = 25$ knots.
36. **(Reflection)** If a ray of light is reflected once in each of two mutually perpendicular mirrors, what can you say about the reflected ray?
37. **(Rope)** Find the magnitude of the force in each rope in the figure for any weight $\mathbf{w}$ and angle α.
38. **TEAM PROJECT. Geometric Applications.** To increase your skill in dealing with vectors, use vectors to prove the following (see the figures).

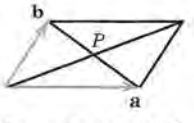
(a) The diagonals of a parallelogram bisect each other.

(b) The line through the midpoints of adjacent sides of a parallelogram bisects one of the diagonals in the ratio 1 : 3.



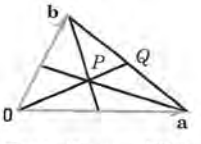
(c) Obtain (b) from (a).

(d) The three medians of a triangle (the segments from a vertex to the midpoint of the opposite side) meet at a single point, which divides the medians in the ratio 2 : 1.



(e) The quadrilateral whose vertices are the midpoints of the sides of an arbitrary quadrilateral is a parallelogram.

(f) The four space diagonals of a parallelepiped meet and bisect each other.



(g) The sum of the vectors drawn from the center of a regular polygon to its vertices is the zero vector.

Team Project 38(e)

9.2 Inner Product (Dot Product)

We shall now define a multiplication of two vectors that gives a scalar as the product and is suggested by various applications, in particular when angles between vectors and lengths of vectors are involved.

DEFINITION

Inner Product (Dot Product) of Vectors

The **inner product** or **dot product** $\mathbf{a} \cdot \mathbf{b}$ (read "**a** dot **b**") of two vectors **a** and **b** is the product of their lengths times the cosine of their angle (see Fig. 176),

$$\text{(1)} \qquad \begin{aligned} \mathbf{a} \cdot \mathbf{b} &= |\mathbf{a}||\mathbf{b}| \cos \gamma \quad && \text{if } \mathbf{a} \neq \mathbf{0}, \mathbf{b} \neq \mathbf{0} \\ \mathbf{a} \cdot \mathbf{b} &= 0 && \text{if } \mathbf{a} = \mathbf{0} \text{ or } \mathbf{b} = \mathbf{0}. \end{aligned}$$

The angle γ, $0 \leqq \gamma \leqq \pi$, between **a** and **b** is measured when the initial points of the vectors coincide, as in Fig. 176. In components, $\mathbf{a} = [a_1, a_2, a_3]$, $\mathbf{b} = [b_1, b_2, b_3]$, and

$$\text{(2)} \qquad \mathbf{a} \cdot \mathbf{b} = a_1 b_1 + a_2 b_2 + a_3 b_3.$$

The second line in (1) is needed because γ is undefined when $\mathbf{a} = \mathbf{0}$ or $\mathbf{b} = \mathbf{0}$. The derivation of (2) from (1) is shown below.

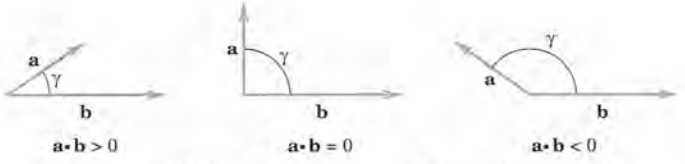

Fig. 176. Angle between vectors and value of inner product

Orthogonality. Since the cosine in (1) may be positive, 0, or negative, so may be the inner product (Fig. 176). The case that the inner product is zero is of particular practical interest and suggests the following concept.

A vector **a** is called **orthogonal** to a vector **b** if $\mathbf{a} \cdot \mathbf{b} = 0$. Then **b** is also orthogonal to **a,** and we call **a** and **b orthogonal vectors.** Clearly, this happens for nonzero vectors if and only if $\cos \gamma = 0$; thus $\gamma = \pi/2$ (90°). This proves the important

THEOREM 1

Orthogonality

The inner product of two nonzero vectors is 0 *if and only if these vectors are perpendicular.*

Length and Angle. Equation (1) with $\mathbf{b} = \mathbf{a}$ gives $\mathbf{a} \cdot \mathbf{a} = |\mathbf{a}|^2$. Hence

$$|\mathbf{a}| = \sqrt{\mathbf{a} \cdot \mathbf{a}}. \tag{3}$$

From (3) and (1) we obtain for the angle γ between two nonzero vectors

$$\cos \gamma = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}||\mathbf{b}|} = \frac{\mathbf{a} \cdot \mathbf{b}}{\sqrt{\mathbf{a} \cdot \mathbf{a}}\sqrt{\mathbf{b} \cdot \mathbf{b}}}. \tag{4}$$

EXAMPLE 1 **Inner Product. Angle Between Vectors**

Find the inner product and the lengths of $\mathbf{a} = [1, 2, 0]$ and $\mathbf{b} = [3, -2, 1]$ as well as the angle between these vectors.

Solution. $\mathbf{a} \cdot \mathbf{b} = 1 \cdot 3 + 2 \cdot (-2) + 0 \cdot 1 = -1$, $|\mathbf{a}| = \sqrt{\mathbf{a} \cdot \mathbf{a}} = \sqrt{5}$, $|\mathbf{b}| = \sqrt{\mathbf{b} \cdot \mathbf{b}} = \sqrt{14}$, and (4) gives the angle

$$\gamma = \arccos \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}||\mathbf{b}|} = \arccos (-0.11952) = 1.69061 = 96.865°. \qquad \blacksquare$$

From the definition we see that the inner product has the following properties. For any vectors **a, b, c** and scalars q_1, q_2,

$$\begin{aligned} &\text{(a)} \quad (q_1\mathbf{a} + q_2\mathbf{b}) \cdot \mathbf{c} = q_1\mathbf{a} \cdot \mathbf{c} + q_2\mathbf{b} \cdot \mathbf{c} && \textit{(Linearity)} \\ &\text{(b)} \quad \mathbf{a} \cdot \mathbf{b} = \mathbf{b} \cdot \mathbf{a} && \textit{(Symmetry)} \\ &\text{(c)} \quad \left.\begin{array}{l} \mathbf{a} \cdot \mathbf{a} \geqq 0 \\ \mathbf{a} \cdot \mathbf{a} = 0 \quad \text{if and only if} \quad \mathbf{a} = \mathbf{0} \end{array}\right\} && \textit{(Positive-definiteness).} \end{aligned} \tag{5}$$

Hence *dot multiplication is commutative* [see (5b)] *and is distributive with respect to vector addition;* in fact, from (5a) with $q_1 = 1$ and $q_2 = 1$ we have

$$(\mathbf{a} + \mathbf{b}) \cdot \mathbf{c} = \mathbf{a} \cdot \mathbf{c} + \mathbf{b} \cdot \mathbf{c} \qquad \textit{(Distributivity).} \tag{5a*}$$

Furthermore, from (1) and $|\cos \gamma| \leqq 1$ we see that

$$|\mathbf{a} \cdot \mathbf{b}| \leqq |\mathbf{a}||\mathbf{b}| \qquad \textit{(Cauchy–Schwarz inequality).} \tag{6}$$

Using this and (3), you may prove (see Prob. 18)

$$|\mathbf{a} + \mathbf{b}| \leqq |\mathbf{a}| + |\mathbf{b}| \qquad \textbf{(Triangle inequality).} \tag{7}$$

Geometrically, (7) with $<$ says that one side of a triangle must be shorter than the other two sides together; this motivates the name of (7).

A simple direct calculation with inner products shows that

$$|\mathbf{a} + \mathbf{b}|^2 + |\mathbf{a} - \mathbf{b}|^2 = 2(|\mathbf{a}|^2 + |\mathbf{b}|^2) \quad \textit{(Parallelogram equality).} \tag{8}$$

Equations (6)–(8) play a basic role in so-called *Hilbert spaces* (abstract inner product spaces), which form the basis of quantum mechanics (see Ref. [GR7] listed in App. 1).

Derivation of (2) from (1). We write $\mathbf{a} = a_1\mathbf{i} + a_2\mathbf{j} + a_3\mathbf{k}$ and $\mathbf{b} = b_1\mathbf{i} + b_2\mathbf{j} + b_3\mathbf{k}$, as in (8) of Sec. 9.1. If we substitute this into $\mathbf{a}\cdot\mathbf{b}$ and use (5a*), we first have a sum of $3 \times 3 = 9$ products

$$\mathbf{a}\cdot\mathbf{b} = a_1b_1\mathbf{i}\cdot\mathbf{i} + a_1b_2\mathbf{i}\cdot\mathbf{j} + \cdots + a_3b_3\mathbf{k}\cdot\mathbf{k}.$$

Now **i, j, k** are unit vectors, so that $\mathbf{i}\cdot\mathbf{i} = \mathbf{j}\cdot\mathbf{j} = \mathbf{k}\cdot\mathbf{k} = 1$ by (3). Since the coordinate axes are perpendicular, so are **i, j, k,** and Theorem 1 implies that the other six of those nine products are 0, namely, $\mathbf{i}\cdot\mathbf{j} = \mathbf{j}\cdot\mathbf{i} = \mathbf{j}\cdot\mathbf{k} = \mathbf{k}\cdot\mathbf{j} = \mathbf{k}\cdot\mathbf{i} = \mathbf{i}\cdot\mathbf{k} = 0$. But this reduces our sum for $\mathbf{a}\cdot\mathbf{b}$ to (2). ■

Applications of Inner Products

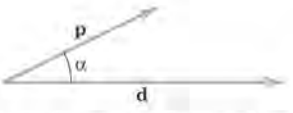
Typical applications of inner products are shown in the following examples and in Problem Set 9.2.

EXAMPLE 2 Work Done by a Force Expressed as an Inner Product

This is a major application. It concerns a body on which a *constant* force **p** acts. (For a *variable* force, see Sec. 10.1.) Let the body be given a displacement **d.** Then the work done by **p** in the displacement is defined as

(9) $$W = |\mathbf{p}||\mathbf{d}| \cos\alpha = \mathbf{p}\cdot\mathbf{d},$$

that is, magnitude $|\mathbf{p}|$ of the force times length $|\mathbf{d}|$ of the displacement times the cosine of the angle α between **p** and **d** (Fig. 177). If $\alpha < 90°$, as in Fig. 177, then $W > 0$. If **p** and **d** are orthogonal, then the work is zero (why?). If $\alpha > 90°$, then $W < 0$, which means that in the displacement one has to do work against the force. (Think of swimming across a river at some angle α against the current.) ■



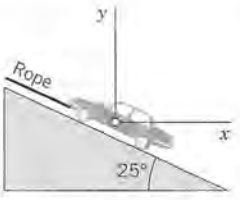


Fig. 177. Work done by a force

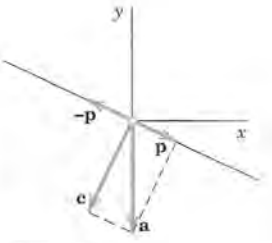

Fig. 178. Example 3

EXAMPLE 3 Component of a Force in a Given Direction

What force in the rope in Fig. 178 will hold a car of 5000 lb in equilibrium if the ramp makes an angle of 25° with the horizontal?

Solution. Introducing coordinates as shown, the weight is $\mathbf{a} = [0, -5000]$ because this force points downward, in the negative y-direction. We have to represent **a** as a sum (resultant) of two forces, $\mathbf{a} = \mathbf{c} + \mathbf{p}$, where **c** is the force the car exerts on the ramp, which is of no interest to us, and **p** is parallel to the rope, of magnitude (see Fig. 178)

$$|\mathbf{p}| = |\mathbf{a}| \cos\gamma = 5000 \cos 65° = 2113 \text{ [lb]}$$

and direction of the unit vector **u** opposite to the direction of the rope; here $\gamma = 90° - 25° = 65°$ is the angle between **a** and **p.** Now a vector in the direction of the rope is

$$\mathbf{b} = [-1, \tan 25°] = [-1, 0.46631], \quad \text{thus} \quad |\mathbf{b}| = 1.10338.$$

so that

$$\mathbf{u} = -\frac{1}{|\mathbf{b}|}\,\mathbf{b} = [0.90631,\ -0.42262].$$

Since $|\mathbf{u}| = 1$ and $\cos\gamma > 0$, we see that we can also write our result as

$$|\mathbf{p}| = (|\mathbf{a}|\cos\gamma)|\mathbf{u}| = \mathbf{a}\cdot\mathbf{u} = -\frac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{b}|} = \frac{5000\cdot 0.46631}{1.10338} = 2113\ [\text{lb}].$$

Answer: About 2100 lb. ■

Example 3 is typical of applications in which one uses the concept of the **component** or **projection** *of a vector* **a** *in the direction of a vector* **b** ($\neq \mathbf{0}$), defined by (see Fig. 179)

$$p = |\mathbf{a}|\cos\gamma. \tag{10}$$

Thus p is the length of the orthogonal projection of **a** on a straight line l parallel to **b,** taken with the plus sign if $p\mathbf{b}$ has the direction of **b** and with the minus sign if $p\mathbf{b}$ has the direction opposite to **b;** see Fig. 179.

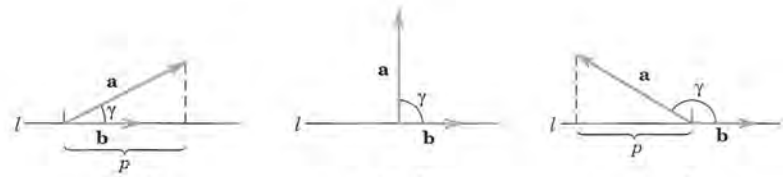

Fig. 179. Component of a vector **a** in the direction of a vector **b**

Multiplying (10) by $|\mathbf{b}|/|\mathbf{b}| = 1$, we have $\mathbf{a}\cdot\mathbf{b}$ in the numerator and thus

$$p = \frac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{b}|} \qquad (\mathbf{b} \neq \mathbf{0}). \tag{11}$$

If **b** is a unit vector, as it is often used for fixing a direction, then (11) simply gives

$$p = \mathbf{a}\cdot\mathbf{b} \qquad (|\mathbf{b}| = 1). \tag{12}$$

Figure 180 shows the projection p of **a** in the direction of **b** (as in Fig. 179) and the projection $q = |\mathbf{b}|\cos\gamma$ of **b** in the direction of **a.**

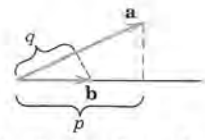

Fig. 180. Projections p of **a** on **b** and q of **b** on **a**

EXAMPLE 4 Orthonormal Basis

By definition, an *orthonormal basis* for 3-space is a basis $\{\mathbf{a}, \mathbf{b}, \mathbf{c}\}$ consisting of orthogonal unit vectors. It has the great advantage that the determination of the coefficients in representations $\mathbf{v} = l_1\mathbf{a} + l_2\mathbf{b} + l_3\mathbf{c}$ of a given vector $\mathbf{v}$ is very simple. We claim that $l_1 = \mathbf{a} \cdot \mathbf{v}$, $l_2 = \mathbf{b} \cdot \mathbf{v}$, $l_3 = \mathbf{c} \cdot \mathbf{v}$. Indeed, this follows simply by taking the inner products of the representation with $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$, respectively, and using the orthonormality of the basis, $\mathbf{a} \cdot \mathbf{v} = l_1\mathbf{a} \cdot \mathbf{a} + l_2\mathbf{a} \cdot \mathbf{b} + l_3\mathbf{a} \cdot \mathbf{c} = l_1$, etc.

For example, the unit vectors $\mathbf{i}, \mathbf{j}, \mathbf{k}$ in (8), Sec. 9.1, associated with a Cartesian coordinate system form an orthonormal basis, called the **standard basis** with respect to the given coordinate system. ■

EXAMPLE 5 Orthogonal Straight Lines in the Plane

Find the straight line L_1 through the point P: (1, 3) in the xy-plane and perpendicular to the straight line L_2: $x - 2y + 2 = 0$; see Fig. 181.

Solution. The idea is to write a general straight line L_1: $a_1x + a_2y = c$ as $\mathbf{a} \cdot \mathbf{r} = c$ with $\mathbf{a} = [a_1, a_2] \neq \mathbf{0}$ and $\mathbf{r} = [x, y]$, according to (2). Now the line L_1^* through the origin and parallel to L_1 is $\mathbf{a} \cdot \mathbf{r} = 0$. Hence, by Theorem 1, the vector $\mathbf{a}$ is perpendicular to $\mathbf{r}$. Hence it is perpendicular to L_1^* and also to L_1 because L_1 and L_1^* are parallel. $\mathbf{a}$ is called a **normal vector** of L_1 (and of L_1^*).

Now a normal vector of the given line $x - 2y + 2 = 0$ is $\mathbf{b} = [1, -2]$. Thus L_1 is perpendicular to L_2 if $\mathbf{b} \cdot \mathbf{a} = a_1 - 2a_2 = 0$, for instance, if $\mathbf{a} = [2, 1]$. Hence L_1 is given by $2x + y = c$. It passes through P: (1, 3) when $2 \cdot 1 + 3 = c = 5$. *Answer:* $y = -2x + 5$. Show that the point of intersection is $(x, y) = (1.6, 1.8)$. ■

EXAMPLE 6 Normal Vector to a Plane

Find a unit vector perpendicular to the plane $4x + 2y + 4z = -7$.

Solution. Using (2), we may write any plane in space as

$$\mathbf{a} \cdot \mathbf{r} = a_1x + a_2y + a_3z = c \tag{13}$$

where $\mathbf{a} = [a_1, a_2, a_3] \neq \mathbf{0}$ and $\mathbf{r} = [x, y, z]$. The unit vector in the direction of $\mathbf{a}$ is (Fig. 182)

$$\mathbf{n} = \frac{1}{|\mathbf{a}|}\,\mathbf{a}.$$

Dividing by $|\mathbf{a}|$, we obtain from (13)

$$\mathbf{n} \cdot \mathbf{r} = p \qquad \text{where} \qquad p = \frac{c}{|\mathbf{a}|}. \tag{14}$$

From (12) we see that p is the projection of $\mathbf{r}$ in the direction of $\mathbf{n}$. This projection has the same constant value $c/|\mathbf{a}|$ for the position vector $\mathbf{r}$ of any point in the plane. Clearly this holds if and only if $\mathbf{n}$ is perpendicular to the plane. $\mathbf{n}$ is called a **unit normal vector** of the plane (the other being $-\mathbf{n}$).

Furthermore, from this and the definition of projection it follows that $|p|$ is the distance of the plane from the origin. Representation (14) is called **Hesse's**[2] **normal form** of a plane. In our case, $\mathbf{a} = [4, 2, 4]$, $c = -7$, $|\mathbf{a}| = 6$, $\mathbf{n} = \frac{1}{6}\mathbf{a} = [\frac{2}{3}, \frac{1}{3}, \frac{2}{3}]$, and the plane has the distance 7/6 from the origin. ■

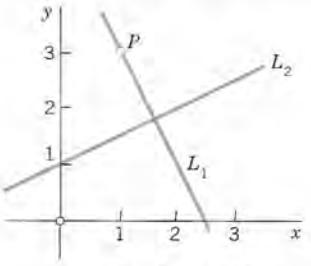

Fig. 181. Example 5

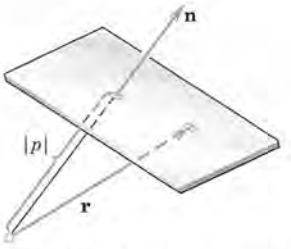

Fig. 182. Normal vector to a plane

[2]LUDWIG OTTO HESSE (1811–1874), German mathematician who contributed to the theory of curves and surfaces.

PROBLEM SET 9.2

1–12 INNER PRODUCT

Let $\mathbf{a} = [2, 1, 4]$, $\mathbf{b} = [-4, 0, 3]$, $\mathbf{c} = [3, -2, 1]$. Find

1. $\mathbf{a} \cdot \mathbf{b}$, $\mathbf{b} \cdot \mathbf{a}$
2. $|\mathbf{a}|$, $|\mathbf{b}|$, $|\mathbf{c}|$
3. $|3\mathbf{a} - 2\mathbf{b}|$, $|2\mathbf{b} - 3\mathbf{a}|$
4. $\mathbf{a} \cdot (\mathbf{b} + \mathbf{c})$, $\mathbf{a} \cdot \mathbf{b} + \mathbf{a} \cdot \mathbf{c}$
5. $(\mathbf{a} \cdot \mathbf{b})\mathbf{c}$, $\mathbf{a}(\mathbf{b} \cdot \mathbf{c})$
6. $\mathbf{a} \cdot \mathbf{b} + \mathbf{b} \cdot \mathbf{c} + \mathbf{c} \cdot \mathbf{a}$
7. $(\mathbf{a} - \mathbf{b}) \cdot \mathbf{c}$, $\mathbf{a} \cdot \mathbf{c} - \mathbf{b} \cdot \mathbf{c}$
8. $4\mathbf{a} \cdot 3\mathbf{c}$, $12\mathbf{a} \cdot \mathbf{c}$
9. $\mathbf{a} \cdot (\mathbf{b} - \mathbf{c})$, $\mathbf{a} \cdot (\mathbf{c} - \mathbf{b})$
10. $|\mathbf{b} + \mathbf{c}|$, $|\mathbf{b}| + |\mathbf{c}|$
11. $6(\mathbf{a} + \mathbf{b}) \cdot (\mathbf{a} - \mathbf{b})$
12. $|\mathbf{a} \cdot \mathbf{c}|$, $|\mathbf{a}||\mathbf{c}|$

13. What laws do Probs. 1, 3, 4, 7, 8 illustrate?
14. Does $\mathbf{u} \cdot \mathbf{v} = \mathbf{u} \cdot \mathbf{w}$ with $\mathbf{u} \neq \mathbf{0}$ imply that $\mathbf{v} = \mathbf{w}$?
15. Prove the Cauchy–Schwarz inequality.
16. Verify the Cauchy–Schwarz inequality, the triangle inequality, and the parallelogram equality for the above **a** and **b**.
17. Prove the parallelogram equality.
18. **(Triangle inequality)** Prove (7). *Hint.* Use (3) for $|\mathbf{a} + \mathbf{b}|$ and (6) to prove the square of (7), then take roots.

19–22 WORK

Find the work done by a force **p** acting on a body if the body is displaced from a point A to a point B along the straight segment $\overrightarrow{AB}$. Sketch **p** and $\overrightarrow{AB}$. (Show the details of your work.)

19. $\mathbf{p} = [8, -4, 11]$, A: (1, 2, 0), B: (3, 6, 0)
20. $\mathbf{p} = [2, 7, -4]$, A: (3, 1, 0), B: (0, 2, 0)
21. $\mathbf{p} = [5, -2, 1]$, A: (4, 0, 3), B: (6, 0, 8)
22. $\mathbf{p} = [4, 3, 6]$, A: (5, 2, 10), B: (1, 3, 1)

23. Why is the work in Prob. 19 zero? Can work be negative? Explain.
24. Show that the work done by the resultant of **p** and **q** in a displacement from A to B is the sum of the work done by each force in that displacement.
25. Find the work $W = \mathbf{p} \cdot \mathbf{d}$ if $\mathbf{d} = 2\mathbf{i}$ and $\mathbf{p} = \mathbf{i}$, $\mathbf{i} + \mathbf{j}$, $\mathbf{j}$, $-\mathbf{i} + \mathbf{j}$ and sketch a figure similar to Fig. 177.

26–30 ANGLE BETWEEN VECTORS. ORTHOGONALITY

Let $\mathbf{a} = [1, 1, 1]$, $\mathbf{b} = [2, 3, 1]$, $\mathbf{c} = [-1, 1, 0]$. Find the angle between:

26. **a, b**
27. **b, c**
28. $\mathbf{a} - \mathbf{c}$, $\mathbf{b} - \mathbf{c}$
29. $\mathbf{a} + \mathbf{b}$, **c**
30. **a**, $\mathbf{b} + \mathbf{c}$

31. **(Planes)** Find the angle between the planes $x + y + z = 1$ and $2x - y + 2z = 0$.
32. **(Cosine law)** Deduce the law of cosines by using vectors **a**, **b**, and $\mathbf{a} - \mathbf{b}$.
33. **(Triangle)** Find the angles of the triangle with vertices [0, 0, 0], [1, 2, 3], [4, −1, 3].
34. **(Addition law)** Obtain
$$\cos(\alpha - \beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta$$
by using $\mathbf{a} = [\cos\alpha, \sin\alpha]$, $\mathbf{b} = [\cos\beta, \sin\beta]$, where $0 \leqq \alpha \leqq \beta = 2\pi$.
35. **(Parallelogram)** Find the angles if the sides are [5, 0] and [1, 2].
36. **(Distance)** Find the distance of the plane $5x + 2y + z = 10$ from the origin.

37–40 COMPONENTS IN THE DIRECTION OF A VECTOR

Find the component of **a** in the direction of **b.**

37. $\mathbf{a} = [1, 1, 3]$, $\mathbf{b} = [0, 0, 5]$
38. $\mathbf{a} = [2, 0, 6]$, $\mathbf{b} = [3, 4, -1]$
39. $\mathbf{a} = [0, 4, -3]$, $\mathbf{b} = [0, 4, 3]$
40. $\mathbf{a} = [-1, 2, 0]$, $\mathbf{b} = [1, -2, 0]$

41. Under what condition will the projection of **a** in the direction of **b** equal the projection of **b** in the direction of **a?**
42. **TEAM PROJECT. Orthogonality** is particularly important, mainly because of the use of orthogonal coordinates, such as **Cartesian coordinates,** whose **"natural basis"** (9), Sec. 9.1, consists of three orthogonal unit vectors.

(a) Show that $\mathbf{a} = [2, -2, 4]$, $\mathbf{b} = [0, 8, 4]$, $\mathbf{c} = [-20, -4, 8]$ are orthogonal.

(b) For what values of a_1 are $\mathbf{a} = [a_1, 2, 0]$ and $\mathbf{b} = [3, 4, -1]$ orthogonal?

(c) Show that the straight lines $4x + 2y = 1$ and $5x - 10y = 7$ are orthogonal.

(d) Find all unit vectors $\mathbf{a} = [a_1, a_2]$ in the plane orthogonal to [4, 3].

(e) Find all vectors orthogonal to $\mathbf{a} = [2, 1, 0]$. Do they form a vector space?

(f) For what c are the planes $4x - 2y + 3z = 6$ and $2x - cy + 5z = 1$ orthogonal?

(g) Under what condition will the diagonals of a parallelogram be orthogonal? (Prove your answer.)

(h) What is the angle between a light ray and its reflection in three orthogonal plane mirrors (known as a **"corner reflector"**)?

(i) Discuss further applications in physics and geometry in which orthogonality plays a role.

9.3 Vector Product (Cross Product)

The dot product in Sec. 9.2 is a *scalar*. We shall see that in some applications, for instance, in connection with rotations, we shall need a product that is again a *vector*:

DEFINITION

Vector Product (Cross Product, Outer Product) of Vectors

The **vector product** (also called **cross product** or **outer product**) $\mathbf{a} \times \mathbf{b}$ (read "**a** cross **b**") of two vectors **a** and **b** is the vector

$$\mathbf{v} = \mathbf{a} \times \mathbf{b}$$

as follows. If **a** and **b** have the same or opposite direction, or if $\mathbf{a} = \mathbf{0}$ or $\mathbf{b} = \mathbf{0}$, then $\mathbf{v} = \mathbf{a} \times \mathbf{b} = \mathbf{0}$. In any other case $\mathbf{v} = \mathbf{a} \times \mathbf{b}$ has the length

$$|\mathbf{v}| = |\mathbf{a} \times \mathbf{b}| = |\mathbf{a}||\mathbf{b}| \sin \gamma. \tag{1}$$

This is the area of the blue parallelogram in Fig. 183. γ is the angle between **a** and **b** (as in Sec. 9.2). The direction of $\mathbf{v} = \mathbf{a} \times \mathbf{b}$ is perpendicular to both **a** and **b** and such that **a, b, v,** in this order, form a *right-handed triple* as in Figs. 183–185 (explanation below).

In components, let $\mathbf{a} = [a_1, a_2, a_3]$ and $\mathbf{b} = [b_1, b_2, b_3]$. Then $\mathbf{v} = [v_1, v_2, v_3] = \mathbf{a} \times \mathbf{b}$ has the components

$$v_1 = a_2b_3 - a_3b_2, \qquad v_2 = a_3b_1 - a_1b_3, \qquad v_3 = a_1b_2 - a_2b_1. \tag{2}$$

Here the Cartesian coordinate system is *right-handed*, as explained below (see also Fig. 186). (For a left-handed system, each component of **v** must be multiplied by -1. Derivation of (2) in App. 4.)

Right-Handed Triple. A triple of vectors **a, b, v** is *right-handed* if the vectors in the given order assume the same sort of orientation as the thumb, index finger, and middle finger of the right hand when these are held as in Fig. 184. We may also say that if **a** is rotated into the direction of **b** through the angle γ ($< \pi$), then **v** advances in the same direction as a right-handed screw would if turned in the same way (Fig. 185).

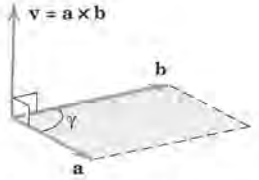

Fig. 183. Vector product

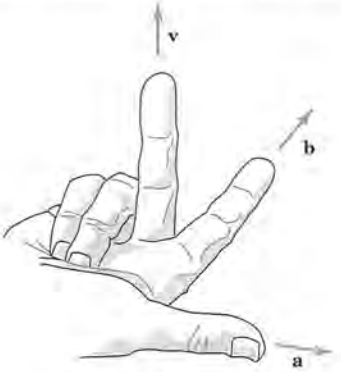

Fig. 184. Right-handed triple of vectors **a, b, v**

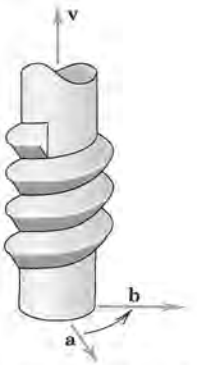

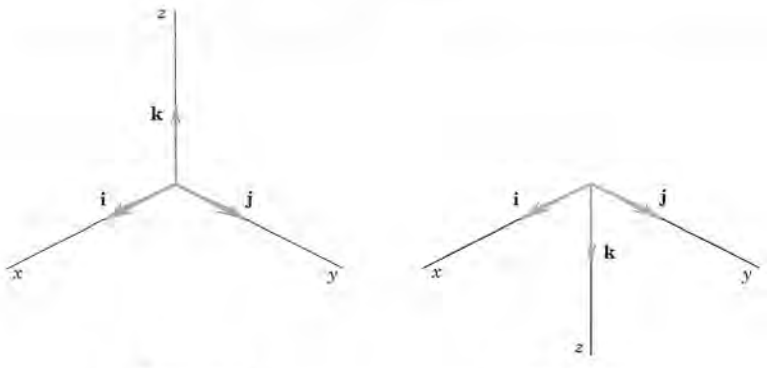

Fig. 185. Right-handed screw

(a) Right-handed (b) Left-handed

Fig. 186. The two types of Cartesian coordinate systems

Right-Handed Cartesian Coordinate System. The system is called **right-handed** if the corresponding unit vectors **i, j, k** in the positive directions of the axes (see Sec. 9.1) form a right-handed triple as in Fig. 186a. The system is called **left-handed** if the sense of **k** is reversed, as in Fig. 186b. In applications, we prefer right-handed systems.

How to Memorize (2). If you know second- and third-order determinants, you see that (2) can be written

$$(2^*) \qquad v_1 = \begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix}, \qquad v_2 = -\begin{vmatrix} a_1 & a_3 \\ b_1 & b_3 \end{vmatrix} = +\begin{vmatrix} a_3 & a_1 \\ b_3 & b_1 \end{vmatrix}, \qquad v_3 = \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix}$$

and $\mathbf{v} = [v_1, v_2, v_3] = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$ is the expansion of the following symbolic determinant by its first row. (We call the determinant "symbolic" because the first row consists of vectors rather than of numbers.)

$$(2^{**}) \qquad \mathbf{v} = \mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix} = \begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} a_1 & a_3 \\ b_1 & b_3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} a_1 & a_2 \\ b_1 & b_2 \end{vmatrix}\mathbf{k}.$$

For a left-handed system the determinant has a minus sign in front.

EXAMPLE 1 **Vector Product**

For the vector product $\mathbf{v} = \mathbf{a} \times \mathbf{b}$ of $\mathbf{a} = [1, 1, 0]$ and $\mathbf{b} = [3, 0, 0]$ in right-handed coordinates we obtain from (2)

$$v_1 = 0, \qquad v_2 = 0, \qquad v_3 = 1 \cdot 0 - 1 \cdot 3 = -3.$$

We confirm this by (2**):

$$\mathbf{v} = \mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & 0 \\ 3 & 0 & 0 \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ 0 & 0 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 0 \\ 3 & 0 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 1 \\ 3 & 0 \end{vmatrix}\mathbf{k} = -3\mathbf{k} = [0, 0, -3].$$

To check the result in this simple case, sketch **a, b,** and **v.** Can you see that two vectors in the xy-plane must always have their vector product parallel to the z-axis (or equal to the zero vector)? ■

EXAMPLE 2 **Vector Products of the Standard Basis Vectors**

$$\mathbf{i} \times \mathbf{j} = \mathbf{k}, \qquad \mathbf{j} \times \mathbf{k} = \mathbf{i}, \qquad \mathbf{k} \times \mathbf{i} = \mathbf{j}$$
$$\mathbf{j} \times \mathbf{i} = -\mathbf{k}, \qquad \mathbf{k} \times \mathbf{j} = -\mathbf{i}, \qquad \mathbf{i} \times \mathbf{k} = -\mathbf{j}. \tag{3}$$

We shall use this in the next proof. ∎

THEOREM 1 **General Properties of Vector Products**

(a) *For every scalar l,*

$$(l\mathbf{a}) \times \mathbf{b} = l(\mathbf{a} \times \mathbf{b}) = \mathbf{a} \times (l\mathbf{b}). \tag{4}$$

(b) *Cross multiplication is distributive with respect to vector addition; that is,*

$$(\alpha) \quad \mathbf{a} \times (\mathbf{b} + \mathbf{c}) = (\mathbf{a} \times \mathbf{b}) + (\mathbf{a} \times \mathbf{c}),$$
$$(\beta) \quad (\mathbf{a} + \mathbf{b}) \times \mathbf{c} = (\mathbf{a} \times \mathbf{c}) + (\mathbf{b} \times \mathbf{c}). \tag{5}$$

(c) *Cross multiplication is* ***not commutative*** *but* ***anticommutative;*** *that is,*

$$\mathbf{b} \times \mathbf{a} = -(\mathbf{a} \times \mathbf{b}) \tag{6}$$

(Fig. 187).

(d) *Cross multiplication is* ***not associative;*** *that is, in general,*

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) \neq (\mathbf{a} \times \mathbf{b}) \times \mathbf{c} \tag{7}$$

so that the parentheses cannot be omitted.

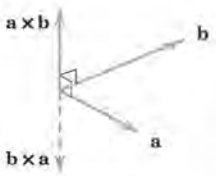

Fig. 187. Anticommutativity of cross multiplication

PROOF (4) follows directly from the definition. In (5α), formula (2*) gives for the first component on the left

$$\begin{vmatrix} a_2 & a_3 \\ b_2 + c_2 & b_3 + c_3 \end{vmatrix} = a_2(b_3 + c_3) - a_3(b_2 + c_2)$$
$$= (a_2b_3 - a_3b_2) + (a_2c_3 - a_3c_2)$$
$$= \begin{vmatrix} a_2 & a_3 \\ b_2 & b_3 \end{vmatrix} + \begin{vmatrix} a_2 & a_3 \\ c_2 & c_3 \end{vmatrix}.$$

By (2*) the sum of the two determinants is the first component of $(\mathbf{a} \times \mathbf{b}) + (\mathbf{a} \times \mathbf{c})$, the right side of (5a). For the other components in (5α) and in (5β), equality follows by the same idea.

Anticommutativity (6) follows from (2**) by noting that the interchange of Rows 2 and 3 multiplies the determinant by -1. We can confirm this geometrically if we set $\mathbf{a} \times \mathbf{b} = \mathbf{v}$ and $\mathbf{b} \times \mathbf{a} = \mathbf{w}$; then $|\mathbf{v}| = |\mathbf{w}|$ by (1), and for **b, a, w** to form a *right-handed* triple, we must have $\mathbf{w} = -\mathbf{v}$.

Finally, $\mathbf{i} \times (\mathbf{i} \times \mathbf{j}) = \mathbf{i} \times \mathbf{k} = -\mathbf{j}$, whereas $(\mathbf{i} \times \mathbf{i}) \times \mathbf{j} = \mathbf{0} \times \mathbf{j} = \mathbf{0}$ (see Example 2). This proves (7). ∎

Typical Applications of Vector Products

EXAMPLE 3 Moment of a Force

In mechanics the moment m of a force $\mathbf{p}$ about a point Q is defined as the product $m = |\mathbf{p}|d$, where d is the (perpendicular) distance between Q and the line of action L of $\mathbf{p}$ (Fig. 188). If $\mathbf{r}$ is the vector from Q to any point A on L, then $d = |\mathbf{r}| \sin \gamma$ (Fig. 188) and

$$m = |\mathbf{r}|\,|\mathbf{p}| \sin \gamma.$$

Since γ is the angle between $\mathbf{r}$ and $\mathbf{p}$, we see from (1) that $m = |\mathbf{r} \times \mathbf{p}|$. The vector

$$\mathbf{m} = \mathbf{r} \times \mathbf{p} \tag{8}$$

is called the **moment vector** or **vector moment** of $\mathbf{p}$ about Q. Its magnitude is m. If $\mathbf{m} \neq \mathbf{0}$, its direction is that of the axis of the rotation about Q that $\mathbf{p}$ has the tendency to produce. This axis is perpendicular to both $\mathbf{r}$ and $\mathbf{p}$. ■

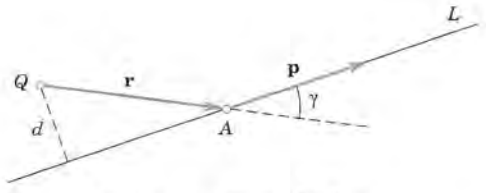

Fig. 188. Moment of a force $\mathbf{p}$

EXAMPLE 4 Moment of a Force

Find the moment of the force $\mathbf{p}$ in Fig. 189 about the center Q of the wheel.

Solution. Introducing coordinates as shown in Fig. 189, we have

$$\mathbf{p} = [1000 \cos 30°, \quad 1000 \sin 30°, \quad 0] = [866, \quad 500, \quad 0], \qquad \mathbf{r} = [0, \quad 1.5, \quad 0].$$

(Note that the center of the wheel is at $y = -1.5$ on the y-axis.) Hence (8) and (2**) give

$$\mathbf{m} = \mathbf{r} \times \mathbf{p} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 1.5 & 0 \\ 866 & 500 & 0 \end{vmatrix} = 0\mathbf{i} - 0\mathbf{j} + \begin{vmatrix} 0 & 1.5 \\ 866 & 500 \end{vmatrix} \mathbf{k} = [0, 0, -1299].$$

This moment vector is normal (perpendicular) to the plane of the wheel; hence it has the direction of the axis of rotation about the center of the wheel that the force has the tendency to produce. $\mathbf{m}$ points in the negative z-direction, the direction in which a right-handed screw would advance if turned in that way. ■

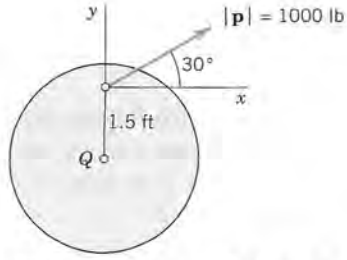

Fig. 189. Moment of a force $\mathbf{p}$

EXAMPLE 5 **Velocity of a Rotating Body**

A rotation of a rigid body B in space can be simply and uniquely described by a vector $\mathbf{w}$ as follows. The direction of $\mathbf{w}$ is that of the axis of rotation and such that the rotation appears clockwise if one looks from the initial point of $\mathbf{w}$ to its terminal point. The length of $\mathbf{w}$ is equal to the **angular speed** ω (> 0) of the rotation, that is, the linear (or tangential) speed of a point of B divided by its distance from the axis of rotation.

Let P be any point of B and d its distance from the axis. Then P has the speed ωd. Let $\mathbf{r}$ be the position vector of P referred to a coordinate system with origin 0 on the axis of rotation. Then $d = |\mathbf{r}| \sin \gamma$, where γ is the angle between $\mathbf{w}$ and $\mathbf{r}$. Therefore,

$$\omega d = |\mathbf{w}|\,|\mathbf{r}| \sin \gamma = |\mathbf{w} \times \mathbf{r}|.$$

From this and the definition of vector product we see that the velocity vector $\mathbf{v}$ of P can be represented in the form (Fig. 190)

$$\mathbf{v} = \mathbf{w} \times \mathbf{r}. \tag{9}$$

This simple formula is useful for determining $\mathbf{v}$ at any point of B. ■

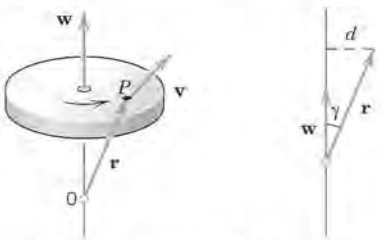

Fig. 190. Rotation of a rigid body

Scalar Triple Product

The most important product of vectors with more than two factors is the **scalar triple product** or **mixed triple product** of three vectors **a, b, c.** It is denoted by $(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c})$ and defined by

$$(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c}) = \mathbf{a} \bullet (\mathbf{b} \times \mathbf{c}). \tag{10*}$$

Because of the dot product it is a scalar. In terms of components $\mathbf{a} = [a_1, a_2, a_3]$, $\mathbf{b} = [b_1, b_2, b_3]$, $\mathbf{c} = [c_1, c_2, c_3]$ we can write it as a third-order determinant. For this we set $\mathbf{b} \times \mathbf{c} = \mathbf{v} = [v_1, v_2, v_3]$. Then from the dot product in components [formula (2) in Sec. 9.2] and from (2*) with $\mathbf{b}$ and $\mathbf{c}$ instead of $\mathbf{a}$ and $\mathbf{b}$ we first obtain

$$\begin{aligned}\mathbf{a} \bullet (\mathbf{b} \times \mathbf{c}) = \mathbf{a} \bullet \mathbf{v} &= a_1 v_1 + a_2 v_2 + a_3 v_3 \\ &= a_1 \begin{vmatrix} b_2 & b_3 \\ c_2 & c_3 \end{vmatrix} + a_2 \begin{vmatrix} b_3 & b_1 \\ c_3 & c_1 \end{vmatrix} + a_3 \begin{vmatrix} b_1 & b_2 \\ c_1 & c_2 \end{vmatrix}.\end{aligned}$$

The sum on the right is the expansion of a third-order determinant by its first row. Thus

$$(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c}) = \mathbf{a} \bullet (\mathbf{b} \times \mathbf{c}) = \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix}. \tag{10}$$

The most important properties of the scalar triple product are as follows.

THEOREM 2

Properties and Applications of Scalar Triple Products

(a) *In* (10) *the dot and cross can be interchanged:*

$$(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c}) = \mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = (\mathbf{a}\times\mathbf{b})\cdot\mathbf{c}. \tag{11}$$

(b) Geometric interpretation. *The absolute value* $|(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c})|$ *of* (10) *is the volume of the parallelepiped* (oblique box) *with* **a, b, c** *as edge vectors* (Fig. 191).

(c) Linear independence. *Three vectors in* R^3 *are linearly independent if and only if their scalar triple product is not zero.*

PROOF **(a)** Dot multiplication is commutative, so that by (10)

$$(\mathbf{a}\times\mathbf{b})\cdot\mathbf{c} = \mathbf{c}\cdot(\mathbf{a}\times\mathbf{b}) = \begin{vmatrix} c_1 & c_2 & c_3 \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}.$$

From this we obtain the determinant in (10) by interchanging Rows 1 and 2 and in the result Rows 2 and 3. But this does not change the value of the determinant because each interchange produces a factor -1, and $(-1)(-1) = 1$. This proves (11).

(b) The volume of that box equals the height $h = |\mathbf{a}||\cos\gamma|$ (Fig. 191) times the area of the base, which is the area $|\mathbf{b}\times\mathbf{c}|$ of the parallelogram with sides **b** and **c.** Hence the volume is

$$|\mathbf{a}||\mathbf{b}\times\mathbf{c}|\,|\cos\gamma| = |\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})| \qquad \text{(Fig. 191)}$$

as given by the absolute value of (11).

(c) Three nonzero vectors, if we let their initial points coincide, are linearly independent if and only if they do not lie in the same plane (or do not lie on the same straight line). This happens if and only if the triple product in (b) is not zero, so that the independence criterion follows. (The case that one of the vectors is the zero vector is trivial.) ∎

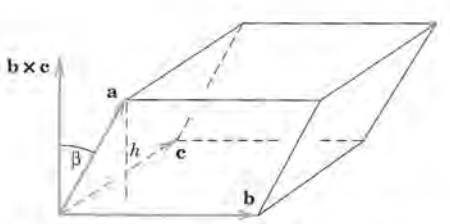

Fig. 191. Geometric interpretation of a scalar triple product

EXAMPLE 6 **Tetrahedron**

A tetrahedron is determined by three edge vectors **a, b, c,** as indicated in Fig. 192. Find its volume when $\mathbf{a} = [2, 0, 3]$, $\mathbf{b} = [0, 4, 1]$, $\mathbf{c} = [5, 6, 0]$.

Solution. The volume V of the parallelepiped with these vectors as edge vectors is the absolute value of the scalar triple product

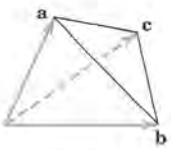

Fig. 192.
Tetrahedron

$$(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c}) = \begin{vmatrix} 2 & 0 & 3 \\ 0 & 4 & 1 \\ 5 & 6 & 0 \end{vmatrix} = 2\begin{vmatrix} 4 & 1 \\ 6 & 0 \end{vmatrix} + 3\begin{vmatrix} 0 & 4 \\ 5 & 6 \end{vmatrix} = -12 - 60 = -72.$$

Hence $V = 72$. The minus sign indicates that if the coordinates are right-handed, the triple **a, b, c** is left-handed. The volume of a tetrahedron is $\frac{1}{6}$ of that of the parallelepiped (can you prove it?), hence 12.

Can you sketch the tetrahedron, choosing the origin as the common initial point of the vectors? What are the coordinates of the four vertices? ■

This is the end of vector *algebra* (in space R^3 and in the plane). Vector *calculus* (differentiation) begins in the next section.

PROBLEM SET 9.3

1–20 VECTOR PRODUCT, SCALAR TRIPLE PRODUCT

With respect to right-handed Cartesian coordinates, let $\mathbf{a} = [1, 2, 0]$, $\mathbf{b} = [3, -4, 0]$, $\mathbf{c} = [3, 5, 2]$, $\mathbf{d} = [6, 2, -3]$. Showing details, find:

1. $\mathbf{a} \times \mathbf{b}$, $\mathbf{b} \times \mathbf{a}$
2. $\mathbf{a} \times \mathbf{c}$, $|\mathbf{a} \times \mathbf{c}|$, $\mathbf{a} \cdot \mathbf{c}$
3. $(\mathbf{a} + \mathbf{b}) \times \mathbf{c}$, $\mathbf{a} \times \mathbf{c} + \mathbf{b} \times \mathbf{c}$
4. $(\mathbf{c} + \mathbf{d}) \times \mathbf{d}$, $\mathbf{c} \times \mathbf{d}$
5. $2\mathbf{a} \times 3\mathbf{b}$, $3\mathbf{a} \times 2\mathbf{b}$, $6\mathbf{a} \times \mathbf{b}$
6. $\mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{b}$
7. $\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})$, $(\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c}$
8. $(\mathbf{a} + \mathbf{b}) \times (\mathbf{b} + \mathbf{a})$
9. $(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{c} \times \mathbf{d})$, $(\mathbf{b} \times \mathbf{a}) \cdot (\mathbf{d} \times \mathbf{c})$
10. $(\mathbf{a} \times \mathbf{b}) \times \mathbf{c}$, $\mathbf{a} \times (\mathbf{b} \times \mathbf{c})$
11. $\mathbf{d} \times \mathbf{c}$, $|\mathbf{d} \times \mathbf{c}|$, $|\mathbf{c} \times \mathbf{d}|$
12. $(\mathbf{a} + \mathbf{b}) \times (\mathbf{c} + \mathbf{d})$
13. $\mathbf{a} \times (\mathbf{b} + \mathbf{c} - \mathbf{d})$
14. $(\mathbf{i}\ \ \mathbf{j}\ \ \mathbf{k})$, $(\mathbf{i}\ \ \mathbf{k}\ \ \mathbf{j})$
15. $(\mathbf{i} + \mathbf{j}\ \ \mathbf{j} + \mathbf{k}\ \ \mathbf{k} + \mathbf{i})$
16. $(\mathbf{b} \times \mathbf{c}) \cdot \mathbf{d}$, $\mathbf{b} \cdot (\mathbf{c} \times \mathbf{d})$
17. $(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{d})$, $|(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{d})|$, $(\mathbf{b}\ \ \mathbf{a}\ \ \mathbf{d})$
18. $(\mathbf{a} + \mathbf{b}\ \ \mathbf{b} + \mathbf{c}\ \ \mathbf{c} + \mathbf{d})$
19. $(\mathbf{a} - \mathbf{c}\ \ \mathbf{b} - \mathbf{c}\ \ \mathbf{c})$, $(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c})$
20. $(4\mathbf{a}\ \ 3\mathbf{b}\ \ 2\mathbf{c})$, $24(\mathbf{b}\ \ \mathbf{c}\ \ \mathbf{a})$

21. What properties of cross multiplication do Probs. 1, 3, 8, 10 illustrate?
22. Give the details of the proofs of (4) and (5).
23. Give the details of the proofs of (6) and (11).
24. **TEAM PROJECT. Useful Formulas for Two and More Vectors.** Prove (12)–(16), which are often useful in practical work, and illustrate each formula with two examples. *Hints.* For (13) choose Cartesian coordinates such that $\mathbf{d} = [d_1, 0, 0]$ and $\mathbf{c} = [c_1, c_2, 0]$. Show that each side of (13) then equals $[-b_2c_2d_1, b_1c_2d_1, 0]$, and give reasons why the two sides are then equal in any Cartesian coordinate system. For (14) and (15) use (13).

Formula (15) is called **Lagrange's identity.**

(12) $$|\mathbf{a} \times \mathbf{b}| = \sqrt{(\mathbf{a} \cdot \mathbf{a})(\mathbf{b} \cdot \mathbf{b}) - (\mathbf{a} \cdot \mathbf{b})^2}$$

(13) $$\mathbf{b} \times (\mathbf{c} \times \mathbf{d}) = (\mathbf{b} \cdot \mathbf{d})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{d}$$

(14) $$(\mathbf{a} \times \mathbf{b}) \times (\mathbf{c} \times \mathbf{d}) = (\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{d})\mathbf{c} - (\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c})\mathbf{d}$$

(15) $$(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{c} \times \mathbf{d}) = (\mathbf{a} \cdot \mathbf{c})(\mathbf{b} \cdot \mathbf{d}) - (\mathbf{a} \cdot \mathbf{d})(\mathbf{b} \cdot \mathbf{c})$$

(16) $$(\mathbf{a}\ \ \mathbf{b}\ \ \mathbf{c}) = (\mathbf{b}\ \ \mathbf{c}\ \ \mathbf{a}) = (\mathbf{c}\ \ \mathbf{a}\ \ \mathbf{b}) = -(\mathbf{c}\ \ \mathbf{b}\ \ \mathbf{a}) = -(\mathbf{a}\ \ \mathbf{c}\ \ \mathbf{b})$$

25–28 MOMENT OF A FORCE

Find the moment vector **m** and the moment m of a force **p** about a point Q when **p** acts on a line through A.

25. $\mathbf{p} = [4, 4, 0]$, Q: (2, 1, 0), A: (0, 3, 0)
26. $\mathbf{p} = [0, 0, 5]$, Q: (3, 3, 0), A: (0, 0, 0)
27. $\mathbf{p} = [1, 2, 3]$, Q: (0, 1, 1), A: (1, 0, 3)
28. $\mathbf{p} = [4, 12, 8]$, Q: (3, 0, 5), A: (4, 3, 7)

29. **(Rotation)** A wheel is rotating about the y-axis with angular speed $\omega = 10\ \text{sec}^{-1}$. The rotation appears clockwise if one looks from the origin in the positive y-direction. Find the velocity and speed at the point (4, 3, 0).
30. **(Rotation)** What are the velocity and speed in Prob. 29 at the point (4, 2, −2) if the wheel rotates about the line $y = x$, $z = 0$ with $\omega = 5\ \text{sec}^{-1}$.

GEOMETRIC APPLICATIONS

31. **(Parallelogram)** Find the area if the vertices are (2, 2), (9, 2), (10, 3), (3, 3).

32. (Parallelogram) Find the area if the vertices are (3, 9, 8), (0, 5, 1), (−1, −3, −3), (2, 1, 4).

33. (Triangle) Find the area if the vertices are (1, 0, 0), (0, 1, 0), (0, 0, 1).

34. (Triangle) Find the area if the vertices are (4, 6, 5), (4, 9, 5), (8, 6, 7).

35. (Plane) Find a normal vector and a representation of the plane through the points (4, 8, 0), (0, 2, 6), (3, 0, 5).

36. (Plane) Find the plane through (2, 1, 3), (4, 4, 5), (1, 6, 0).

37. (Parallelepiped) Find the volume of the parallelepiped determined by the vertices (1, 1, 1), (4, 7, 2), (3, 2, 1), (5, 4, 3).

38. (Tetrahedron) Find the volume of the tetrahedron with vertices (0, 2, 1), (4, 3, 0), (6, 6, 5), (4, 7, 8).

39. (Linear dependence) For what c are the vectors [9, 1, 2], [−1, c, 5], [4, c, 5] linearly dependent?

40. WRITING PROJECT. Applications of Cross Products. Summarize the most important applications we have discussed in this section and give a few simple examples. No proofs.

9.4 Vector and Scalar Functions and Fields. Derivatives

We now begin with vector calculus. This calculus concerns two kinds of functions, namely, **vector functions,** whose values are vectors

$$\mathbf{v} = \mathbf{v}(P) = [v_1(P), v_2(P), v_3(P)]$$

depending on the points P in space, and **scalar functions,** whose values are scalars

$$f = f(P)$$

depending on P. Here, P is a point in the domain of definition, which in applications is a (three-dimensional) domain or a surface or a curve in space. We say that a vector function defines a **vector field,** and a scalar function defines a **scalar field** in that domain or on that surface or curve. Examples of vector functions are shown in Figs. 193–196. Examples of scalar fields are the temperature field in a body or the pressure field of the air in the earth's atmosphere. Vector and scalar functions may also depend on time t or on some other parameters.

Notation. If we introduce Cartesian coordinates x, y, z, then instead of $\mathbf{v}(P)$ we can also write

$$\mathbf{v}(x, y, z) = [v_1(x, y, z), \quad v_2(x, y, z), \quad v_3(x, y, z)],$$

Fig. 193. Field of tangent vectors of a curve

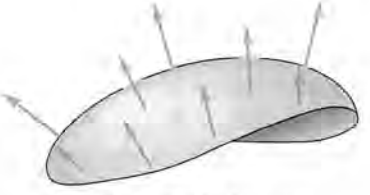

Fig. 194. Field of normal vectors of a surface

but we keep in mind that components depend on the choice of a coordinate system, whereas a vector field that has a physical or a geometric meaning should have magnitude and direction depending only on P, not on that choice. Similarly for the value of a scalar field $f(P) = f(x, y, z)$.

EXAMPLE 1 **Scalar Function (Euclidean Distance in Space)**

The distance $f(P)$ of any point P from a fixed point P_0 in space is a scalar function whose domain of definition is the whole space. $f(P)$ defines a scalar field in space. If we introduce a Cartesian coordinate system and P_0 has the coordinates x_0, y_0, z_0, then f is given by the well-known formula

$$f(P) = f(x, y, z) = \sqrt{(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2}$$

where x, y, z are the coordinates of P. If we replace the given Cartesian coordinate system with another such system by translating and rotating the given system, then the values of the coordinates of P and P_0 will in general change, but $f(P)$ will have the same value as before. Hence $f(P)$ is a scalar function. The direction cosines of the straight line through P and P_0 are not scalars because their values depend on the choice of the coordinate system. ■

EXAMPLE 2 **Vector Field (Velocity Field)**

At any instant the velocity vectors $\mathbf{v}(P)$ of a rotating body B constitute a vector field, called the **velocity field** of the rotation. If we introduce a Cartesian coordinate system having the origin on the axis of rotation, then (see Example 5 in Sec. 9.3)

$$\mathbf{v}(x, y, z) = \mathbf{w} \times \mathbf{r} = \mathbf{w} \times [x, y, z] = \mathbf{w} \times (x\mathbf{i} + y\mathbf{j} + z\mathbf{k}) \tag{1}$$

where x, y, z are the coordinates of any point P of B at the instant under consideration. If the coordinates are such that the z-axis is the axis of rotation and $\mathbf{w}$ points in the positive z-direction, then $\mathbf{w} = \omega\mathbf{k}$ and

$$\mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 0 & \omega \\ x & y & z \end{vmatrix} = \omega[-y, x, 0] = \omega(-y\mathbf{i} + x\mathbf{j}).$$

An example of a rotating body and the corresponding velocity field are shown in Fig. 195. ■

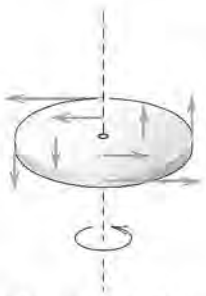

Fig. 195. Velocity field of a rotating body

EXAMPLE 3 **Vector Field (Field of Force, Gravitational Field)**

Let a particle A of mass M be fixed at a point P_0 and let a particle B of mass m be free to take up various positions P in space. Then A attracts B. According to **Newton's law of gravitation** the corresponding gravitational force $\mathbf{p}$ is directed from P to P_0, and its magnitude is proportional to $1/r^2$, where r is the distance between P and P_0, say,

$$|\mathbf{p}| = \frac{c}{r^2}, \qquad c = GMm \tag{2}$$

Here $G = 6.67 \cdot 10^{-8}$ cm^3/(gm $\cdot$ sec^2) is the gravitational constant. Hence $\mathbf{p}$ defines a vector field in space. If we introduce Cartesian coordinates such that P_0 has the coordinates x_0, y_0, z_0 and P has the coordinates x, y, z, then by the Pythagorean theorem,

$$r = \sqrt{(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2} \qquad (\geqq 0).$$

Assuming that $r > 0$ and introducing the vector

$$\mathbf{r} = [x - x_0, \quad y - y_0, \quad z - z_0] = (x - x_0)\mathbf{i} + (y - y_0)\mathbf{j} + (z - z_0)\mathbf{k},$$

we have $|\mathbf{r}| = r$, and $(-1/r)\mathbf{r}$ is a unit vector in the direction of $\mathbf{p}$; the minus sign indicates that $\mathbf{p}$ is directed from P to P_0 (Fig. 196). From this and (2) we obtain

(3)
$$\mathbf{p} = |\mathbf{p}| \left(-\frac{1}{r}\,\mathbf{r}\right) = -\frac{c}{r^3}\,\mathbf{r} = \left[-c\,\frac{x - x_0}{r^3}, \quad -c\,\frac{y - y_0}{r^3}, \quad -c\,\frac{z - z_0}{r^3}\right]$$
$$= -c\,\frac{x - x_0}{r^3}\,\mathbf{i} - c\,\frac{y - y_0}{r^3}\,\mathbf{j} - c\,\frac{z - z_0}{r^3}\,\mathbf{k}.$$

This vector function describes the gravitational force acting on B. ■

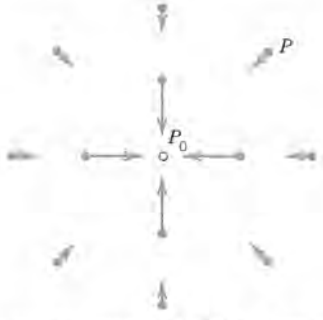

Fig. 196. Gravitational field in Example 3

Vector Calculus

We show next that the basic concepts of calculus, namely, convergence, continuity, and differentiability, can be defined for vector functions in a simple and natural way. Most important here is the derivative.

Convergence. An infinite sequence of vectors $\mathbf{a}_{(n)}$, $n = 1, 2, \cdots$, is said to **converge** if there is a vector $\mathbf{a}$ such that

(4)
$$\lim_{n \to \infty} |\mathbf{a}_{(n)} - \mathbf{a}| = 0.$$

$\mathbf{a}$ is called the **limit vector** of that sequence, and we write

(5)
$$\lim_{n \to \infty} \mathbf{a}_{(n)} = \mathbf{a}.$$

Cartesian coordinates being given, this sequence of vectors converges to $\mathbf{a}$ if and only if the three sequences of components of the vectors converge to the corresponding components of $\mathbf{a}$. We leave the simple proof to the student.

Similarly, a vector function $\mathbf{v}(t)$ of a real variable t is said to have the **limit** $\boldsymbol{l}$ as t approaches t_0, if $\mathbf{v}(t)$ is defined in some neighborhood of t_0 (possibly except at t_0) and

$$\lim_{t \to t_0} |\mathbf{v}(t) - \boldsymbol{l}| = 0. \tag{6}$$

Then we write

$$\lim_{t \to t_0} \mathbf{v}(t) = \boldsymbol{l}. \tag{7}$$

Here, a *neighborhood* of t_0 is an interval (segment) on the t-axis containing t_0 as an interior point (not as an endpoint).

Continuity. A vector function $\mathbf{v}(t)$ is said to be **continuous** at $t = t_0$ if it is defined in some neighborhood of t_0 (including at t_0 itself!) and

$$\lim_{t \to t_0} \mathbf{v}(t) = \mathbf{v}(t_0). \tag{8}$$

If we introduce a Cartesian coordinate system, we may write

$$\mathbf{v}(t) = [v_1(t), v_2(t), v_3(t)] = v_1(t)\mathbf{i} + v_2(t)\mathbf{j} + v_3(t)\mathbf{k}.$$

Then $\mathbf{v}(t)$ is continuous at t_0 if and only if its three components are continuous at t_0.

We now state the most important of these definitions.

DEFINITION

Derivative of a Vector Function

A vector function $\mathbf{v}(t)$ is said to be **differentiable** at a point t if the following limit exists:

$$\mathbf{v}'(t) = \lim_{\Delta t \to 0} \frac{\mathbf{v}(t + \Delta t) - \mathbf{v}(t)}{\Delta t}. \tag{9}$$

This vector $\mathbf{v}'(t)$ is called the **derivative** of $\mathbf{v}(t)$. See Fig. 197.

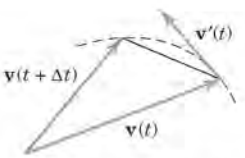

Fig. 197. Derivative of a vector function

In components with respect to a given Cartesian coordinate system,

$$\mathbf{v}'(t) = [v_1'(t), \quad v_2'(t), \quad v_3'(t)]. \tag{10}$$

Hence the derivative $\mathbf{v}'(t)$ ***is obtained by differentiating each component separately.*** For instance, if $\mathbf{v} = [t, t^2, 0]$, then $\mathbf{v}' = [1, 2t, 0]$.

Equation (10) follows from (9) and conversely because (9) is a "vector form" of the usual formula of calculus by which the derivative of a function of a single variable is defined. [The curve in Fig. 197 is the locus of the terminal points representing $\mathbf{v}(t)$ for values of the independent variable in some interval containing t and $t + \Delta t$ in (9)]. It follows that the familiar differentiation rules continue to hold for differentiating vector functions, for instance,

$$(c\mathbf{v})' = c\mathbf{v}' \qquad (c \text{ constant}),$$

$$(\mathbf{u} + \mathbf{v})' = \mathbf{u}' + \mathbf{v}'$$

and in particular

(11) $$(\mathbf{u} \cdot \mathbf{v})' = \mathbf{u}' \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{v}'$$

(12) $$(\mathbf{u} \times \mathbf{v})' = \mathbf{u}' \times \mathbf{v} + \mathbf{u} \times \mathbf{v}'$$

(13) $$(\mathbf{u} \quad \mathbf{v} \quad \mathbf{w})' = (\mathbf{u}' \quad \mathbf{v} \quad \mathbf{w}) + (\mathbf{u} \quad \mathbf{v}' \quad \mathbf{w}) + (\mathbf{u} \quad \mathbf{v} \quad \mathbf{w}').$$

The simple proofs are left to the student. In (12), note the order of the vectors carefully because cross multiplication is not commutative.

EXAMPLE 4 **Derivative of a Vector Function of Constant Length**

Let $\mathbf{v}(t)$ be a vector function whose length is constant, say, $|\mathbf{v}(t)| = c$. Then $|\mathbf{v}|^2 = \mathbf{v} \cdot \mathbf{v} = c^2$, and $(\mathbf{v} \cdot \mathbf{v})' = 2\mathbf{v} \cdot \mathbf{v}' = 0$, by differentiation [see (11)]. This yields the following result. *The derivative of a vector function $\mathbf{v}(t)$ of constant length is either the zero vector or is perpendicular to $\mathbf{v}(t)$.* ■

Partial Derivatives of a Vector Function

Our present discussion shows that partial differentiation of vector functions of two or more variables can be introduced as follows. Suppose that the components of a vector function

$$\mathbf{v} = [v_1, \quad v_2, \quad v_3] = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$$

are differentiable functions of n variables $t_1, \cdots, t_n$. Then the **partial derivative** of $\mathbf{v}$ with respect to t_m is denoted by $\partial\mathbf{v}/\partial t_m$ and is defined as the vector function

$$\frac{\partial \mathbf{v}}{\partial t_m} = \frac{\partial v_1}{\partial t_m}\,\mathbf{i} + \frac{\partial v_2}{\partial t_m}\,\mathbf{j} + \frac{\partial v_3}{\partial t_m}\,\mathbf{k}.$$

Similarly, second partial derivatives are

$$\frac{\partial^2 \mathbf{v}}{\partial t_l \partial t_m} = \frac{\partial^2 v_1}{\partial t_l \partial t_m}\,\mathbf{i} + \frac{\partial^2 v_2}{\partial t_l \partial t_m}\,\mathbf{j} + \frac{\partial^2 v_3}{\partial t_l \partial t_m}\,\mathbf{k},$$

and so on.

EXAMPLE 5 **Partial Derivatives**

Let $\mathbf{r}(t_1, t_2) = a\cos t_1\,\mathbf{i} + a\sin t_1\,\mathbf{j} + t_2\mathbf{k}$. Then $\dfrac{\partial \mathbf{r}}{\partial t_1} = -a\sin t_1\,\mathbf{i} + a\cos t_1\,\mathbf{j}$ and $\dfrac{\partial \mathbf{r}}{\partial t_2} = \mathbf{k}$. ■

Various physical and geometric applications of derivatives of vector functions will be discussed in the next sections and in Chap. 10.

PROBLEM SET 9.4

1–6 SCALAR FIELDS

Determine the **isotherms** (curves of constant temperature T) of the temperature fields in the plane given by the following scalar functions. Sketch some isotherms.

1. $T = xy$
2. $T = 4x - 3y$
3. $T = y^2 - x^2$
4. $T = x/(x^2 + y^2)$
5. $T = y/(x^2 + y^2)$
6. $T = x^2 - y^2 + 8y$

7. **(Isobars)** For the pressure field $f(x, y) = 9x^2 + 16y^2$ find the *isobars* $f(x, y) = const$, the pressure at (4, 3), (−2, 2), (1, 5), and the region in which the pressure is between 4 and 16.

8. **CAS PROJECT. Scalar Fields in the Plane.** Sketch or graph isotherms of the following fields and describe what they look like.
   (a) $x^2 - 4x - y^2$ (b) $x^2y - y^3/3$
   (c) $\cos x \sinh y$ (d) $\sin x \sinh y$
   (e) $e^x \sin y$ (f) $e^{2x} \cos 2y$
   (g) $x^4 - 6x^2y^2 + y^4$ (h) $x^2 - 2x - y^2$

9–14 SCALAR FIELDS IN SPACE

What kind of surfaces are the level surfaces $f(x, y, z) = const$?

9. $f = x^2 + y^2 + 4z^2$
10. $f = x^2 + 4y^2$
11. $f = z - \sqrt{x^2 + y^2}$
12. $f = 4y^2 - z$
13. $f = 4x + 3y - 5z$
14. $f = z - x^2 - 4y^2$

15–20 VECTOR FIELDS

Sketch figures similar to Fig. 196.

15. $\mathbf{v} = \mathbf{i} - \mathbf{j}$
16. $\mathbf{v} = y\mathbf{i} + x\mathbf{j}$
17. $\mathbf{v} = \mathbf{i} + x^2\mathbf{j}$
18. $\mathbf{v} = x\mathbf{i} + y\mathbf{j}$
19. $\mathbf{v} = y\mathbf{i} - x\mathbf{j}$
20. $\mathbf{v} = (x - y)\mathbf{i} + (x + y)\mathbf{j}$

21–25 DIFFERENTIATION

21. Prove (11)–(13). Give two examples for each formula.
22. Find the first and second derivatives of $[4 \cos t, 4 \sin t, 2t]$.
23. Find the first partial derivatives of $[4x^2, 9z^2, xyz]$ and $[yz, zx, xy]$.
24. Find the first partial derivatives of $[\sin x \cosh y, \cos x \sinh y]$ and $[e^x \cos y, e^x \sin y]$.
25. **WRITING PROJECT. Differentiation of Vector Functions.** Summarize the essential ideas and facts and give examples of your own.

9.5 Curves. Arc Length. Curvature. Torsion

A major application of vector calculus concerns curves (this section) and surfaces (Sec. 10.5) and their use in physics and geometry. This field is called **differential geometry.** It plays a role in mechanics, computer-aided and traditional engineering design, geodesy and geography, space travel, and relativity theory (see Refs. [GR8], [GR9] in App. 1).

Curves C in space may occur as paths of moving bodies. This and other applications motivate **parametric representations** with **parameter** t, which may be time or something else (see Fig. 198)

$$\mathbf{r}(t) = [x(t), \quad y(t), \quad z(t)] = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}. \tag{1}$$

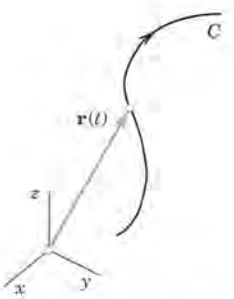

Fig. 198. Parametric representation of a curve

Here x, y, z are Cartesian coordinates (the usual rectangular coordinates; see Sec. 9.1). To each value $t = t_0$ there corresponds a point of C with position vector $\mathbf{r}(t_0)$, that is, with coordinates $x(t_0)$, $y(t_0)$, $z(t_0)$.

Parametric representations (1) have a key advantage over representations of a curve C in terms of its projections into the xy-plane and into the xz-plane, that is,

$$y = f(x), \qquad z = g(x) \tag{2}$$

(or by a pair of equations with y or with z as the independent variable). The advantage is that in (1) the coordinates x, y, z play the same role: all three are *dependent* variables. Moreover, the sense of increasing t, called the **positive sense** on C, induces an **orientation** of C, a direction of travel along C. The sense of decreasing t is then called the *negative sense* on C, given by (1).

EXAMPLE 1 Circle

The circle $x^2 + y^2 = 4$, $z = 0$ in the xy-plane with center 0 and radius 2 can be represented parametrically by

$$\mathbf{r}(t) = [2\cos t,\ 2\sin t,\ 0] \qquad \text{or simply by} \qquad \mathbf{r}(t) = [2\cos t,\ 2\sin t] \qquad \text{(Fig. 199)}$$

where $0 \leqq t \leqq 2\pi$. Indeed, $x^2 + y^2 = (2\cos t)^2 + (2\sin t)^2 = 4(\cos^2 t + \sin^2 t) = 4$. For $t = 0$ we have $\mathbf{r}(0) = [2, 0]$, for $t = \frac{1}{2}\pi$ we get $\mathbf{r}(\frac{1}{2}\pi) = [0, 2]$, and so on. The positive sense induced by this representation is the counterclockwise sense.

If we replace t with $t^* = -t$, we have $t = -t^*$ and get

$$\mathbf{r}^*(t^*) = [2\cos(-t^*),\ 2\sin(-t^*)] = [2\cos t^*,\ -2\sin t^*].$$

This has reversed the orientation, and the circle is now oriented clockwise. ■

EXAMPLE 2 Ellipse

The vector function

$$\mathbf{r}(t) = [a\cos t,\quad b\sin t,\quad 0] = a\cos t\ \mathbf{i} + b\sin t\ \mathbf{j} \tag{3}$$

(Fig. 200)

represents an ellipse in the xy-plane with center at the origin and principal axes in the direction of the x and y axes. In fact, since $\cos^2 t + \sin^2 t = 1$, we obtain from (3)

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \qquad z = 0.$$

If $b = a$, then (3) represents a *circle* of radius a. ■

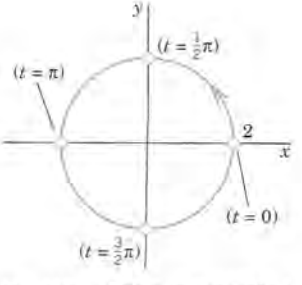

Fig. 199. Circle in Example 1

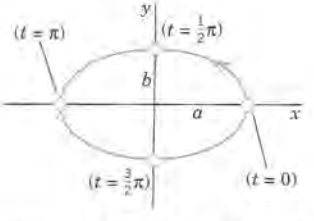

Fig. 200. Ellipse in Example 2

EXAMPLE 3 Straight Line

A straight line L through a point A with position vector $\mathbf{a}$ in the direction of a constant vector $\mathbf{b}$ (see Fig. 201) can be represented parametrically in the form

$$\mathbf{r}(t) = \mathbf{a} + t\mathbf{b} = [a_1 + tb_1, \quad a_2 + tb_2, \quad a_3 + tb_3]. \tag{4}$$

If $\mathbf{b}$ is a unit vector, its components are the **direction cosines** of L. In this case, $|t|$ measures the distance of the points of L from A. For instance, the straight line in the xy-plane through A: (3, 2) having slope 1 is (sketch it)

$$\mathbf{r}(t) = [3, \quad 2, \quad 0] + t[1, \quad 1, \quad 0] = [3 + t, \quad 2 + t, \quad 0].$$

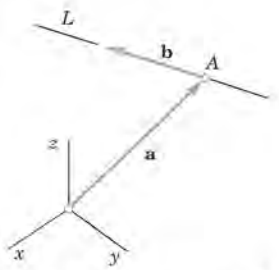

Fig. 201. Parametric representation of a straight line

A **plane curve** is a curve that lies in a plane in space. A curve that is not plane is called a **twisted curve.** A standard example of a twisted curve is the following.

EXAMPLE 4 Circular Helix

The twisted curve C represented by the vector function

$$\mathbf{r}(t) = [a\cos t, \quad a\sin t, \quad ct] = a\cos t\,\mathbf{i} + a\sin t\,\mathbf{j} + ct\,\mathbf{k} \qquad (c \neq 0) \tag{5}$$

is called a *circular helix.* It lies on the cylinder $x^2 + y^2 = a^2$. If $c > 0$, the helix is shaped like a right-handed screw (Fig. 202). If $c < 0$, it looks like a left-handed screw (Fig. 203). If $c = 0$, then (5) is a circle.

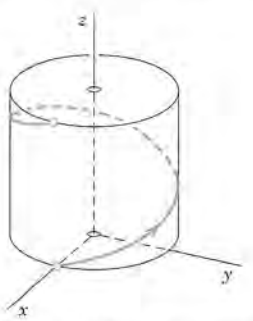

Fig. 202. Right-handed circular helix

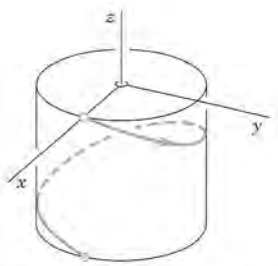

Fig. 203. Left-handed circular helix

A **simple curve** is a curve without **multiple points,** that is, without points at which the curve intersects or touches itself. Circle and helix are simple. Figure 204 shows curves that are not simple. An example is $[\sin 2t, \quad \cos t, \quad 0]$. Can you sketch it?

An **arc** of a curve is the portion between any two points of the curve. For simplicity, we say "curve" for curves as well as for arcs.

Fig. 204. Curves with multiple points

Tangent to a Curve

The next idea is the approximation of a curve by straight lines, leading to tangents and to a definition of length. Tangents are straight lines touching a curve. The **tangent** to a simple curve C at a point P of C is the limiting position of a straight line L through P and a point Q of C as Q approaches P along C. See Fig. 205.

If C is given by $\mathbf{r}(t)$, and P and Q correspond to t and $t + \Delta t$, then a vector in the direction of L is

$$\frac{1}{\Delta t}\,[\mathbf{r}(t + \Delta t) - \mathbf{r}(t)]. \tag{6}$$

In the limit this vector becomes the derivative

$$\mathbf{r}'(t) = \lim_{\Delta t \to 0} \frac{1}{\Delta t}\,[\mathbf{r}(t + \Delta t) - \mathbf{r}(t)], \tag{7}$$

provided $\mathbf{r}(t)$ is differentiable, as we shall assume from now on. If $\mathbf{r}'(t) \neq \mathbf{0}$, we call $\mathbf{r}'(t)$ a **tangent vector** of C at P because it has the direction of the tangent. The corresponding unit vector is the **unit tangent vector** (see Fig. 205)

$$\mathbf{u} = \frac{1}{|\mathbf{r}'|}\,\mathbf{r}'. \tag{8}$$

Note that both $\mathbf{r}'$ and $\mathbf{u}$ point in the direction of increasing t. Hence their sense depends on the orientation of C. It is reversed if we reverse the orientation.

It is now easy to see that the **tangent** to C at P is given by

$$\mathbf{q}(w) = \mathbf{r} + w\mathbf{r}' \qquad \text{(Fig. 206).} \tag{9}$$

This is the sum of the position vector $\mathbf{r}$ of P and a multiple of the tangent vector $\mathbf{r}'$ of C at P. Both vectors depend on P. The variable w is the parameter in (9).

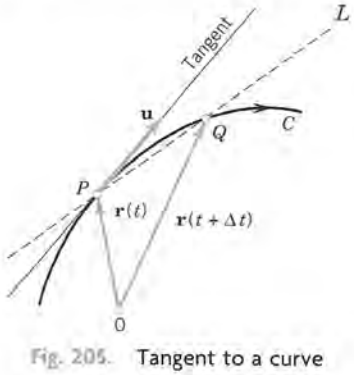

Fig. 205. Tangent to a curve

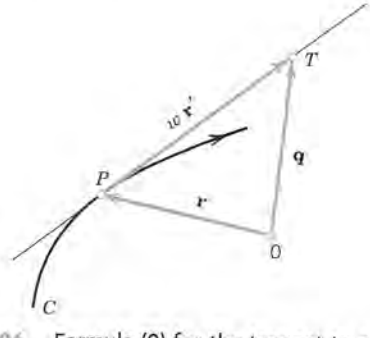

Fig. 206. Formula (9) for the tangent to a curve

EXAMPLE 5 **Tangent to an Ellipse**

Find the tangent to the ellipse $\frac{1}{4}x^2 + y^2 = 1$ at P: $(\sqrt{2}, 1/\sqrt{2})$.

Solution. Equation (3) with semi-axes $a = 2$ and $b = 1$ gives $\mathbf{r}(t) = [2\cos t, \sin t]$. The derivative is $\mathbf{r}'(t) = [-2\sin t, \cos t]$. Now P corresponds to $t = \pi/4$ because

$$\mathbf{r}(\pi/4) = [2\cos(\pi/4), \sin(\pi/4)] = [\sqrt{2}, \quad 1/\sqrt{2}].$$

Hence $\mathbf{r}'(\pi/4) = [-\sqrt{2}, \quad 1/\sqrt{2}]$. From (9) we thus get the *answer*

$$\mathbf{q}(w) = [\sqrt{2}, \quad 1/\sqrt{2}] + w[-\sqrt{2}, \quad 1/\sqrt{2}] = [\sqrt{2}(1 - w), \quad (1/\sqrt{2})(1 + w)].$$

To check the result, sketch or graph the ellipse and the tangent. ■

Length of a Curve

We are now ready to define the length l of a curve. l will be the limit of the lengths of broken lines of n chords (see Fig. 207, where $n = 5$) with larger and larger n. For this, let $\mathbf{r}(t)$, $a \leqq t \leqq b$, represent C. For each $n = 1, 2, \cdots$ we subdivide ("partition") the interval $a \leqq t \leqq b$ by points

$$t_0 (= a), \quad t_1, \quad \cdots, \quad t_{n-1}, \quad t_n (= b), \qquad \text{where} \qquad t_0 < t_1 < \cdots < t_n.$$

This gives a broken line of chords with endpoints $\mathbf{r}(t_0), \cdots, \mathbf{r}(t_n)$. We do this arbitrarily but so that the greatest $|\Delta t_m| = |t_m - t_{m-1}|$ approaches 0 as $n \to \infty$. The lengths $l_1, l_2, \cdots$ of these chords can be obtained from the Pythagorean theorem. If $\mathbf{r}(t)$ has a continuous derivative $\mathbf{r}'(t)$, it can be shown that the sequence $l_1, l_2, \cdots$ has a limit, which is independent of the particular choice of the representation of C and of the choice of subdivisions. This limit is given by the integral

(10)
$$l = \int_a^b \sqrt{\mathbf{r}' \bullet \mathbf{r}'}\, dt \qquad \left(\mathbf{r}' = \frac{d\mathbf{r}}{dt}\right).$$

l is called the **length** of C, and C is called **rectifiable.** Formula (10) is made plausible in calculus for plane curves and is proved for curves in space in [GR8] listed in App. 1. The practical evaluation of the integral (10) will be difficult in general. Some simple cases are given in the problem set.

Arc Length s of a Curve

The length (10) of a curve C is a constant, a positive number. But if we replace the fixed b in (10) with a variable t, the integral becomes a function of t, denoted by $s(t)$ and called the *arc length function* or simply the **arc length** of C. Thus

(11)
$$s(t) = \int_a^t \sqrt{\mathbf{r}' \bullet \mathbf{r}'}\, d\tilde{t} \qquad \left(\mathbf{r}' = \frac{d\mathbf{r}}{d\tilde{t}}\right).$$

Fig. 207. Length of a curve

Here the variable of integration is denoted by $\tilde{t}$ because t is now used in the upper limit.

Geometrically, $s(t_0)$ with some $t_0 > a$ is the length of the arc of C between the points with parametric values a and t_0. The choice of a (the point $s = 0$) is arbitrary; changing a means changing s by a constant.

Linear Element *ds*. If we differentiate (11) and square, we have

$$\textbf{(12)} \qquad \left(\frac{ds}{dt}\right)^2 = \frac{d\mathbf{r}}{dt} \bullet \frac{d\mathbf{r}}{dt} = |\mathbf{r}'(t)|^2 = \left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2.$$

It is customary to write

$$(13^*) \qquad d\mathbf{r} = [dx, dy, dz] = dx\,\mathbf{i} + dy\,\mathbf{j} + dz\,\mathbf{k}$$

and

$$\textbf{(13)} \qquad ds^2 = d\mathbf{r} \bullet d\mathbf{r} = dx^2 + dy^2 + dz^2.$$

ds is called the **linear element** of C.

Arc Length as Parameter. The use of s in (1) instead of an arbitrary t simplifies various formulas. For the unit tangent vector (8) we simply obtain

$$\textbf{(14)} \qquad \mathbf{u}(s) = \mathbf{r}'(s).$$

Indeed, $|\mathbf{r}'(s)| = (ds/ds) = 1$ in (12) shows that $\mathbf{r}'(s)$ is a unit vector. Even greater simplifications due to the use of s will occur in curvature and torsion (below).

EXAMPLE 6 **Circular Helix. Circle. Arc Length as Parameter**

The **helix** $\mathbf{r}(t) = [a\cos t, a\sin t, ct]$ in (5) has the derivative $\mathbf{r}'(t) = [-a\sin t, a\cos t, c]$. Hence $\mathbf{r}' \bullet \mathbf{r}' = a^2 + c^2$, a constant, which we denote by K^2. Hence the integrand in (11) is constant, equal to K, and the integral is $s = Kt$. Thus $t = s/K$, so that a representation of the helix with the arc length s as parameter is

$$\textbf{(15)} \qquad \mathbf{r}^*(s) = \mathbf{r}\left(\frac{s}{K}\right) = \left[a\cos\frac{s}{K},\ a\sin\frac{s}{K},\ \frac{cs}{K}\right], \qquad K = \sqrt{a^2 + c^2}.$$

A **circle** is obtained if we set $c = 0$. Then $K = a$, $t = s/a$, and a representation with arc length s as parameter is

$$\mathbf{r}^*(s) = \mathbf{r}\left(\frac{s}{a}\right) = \left[a\cos\frac{s}{a},\ a\sin\frac{s}{a}\right].$$

Curves in Mechanics. Velocity, Acceleration

Curves play a basic role in mechanics, where they may serve as paths of moving bodies. Then such a curve C should be represented by a parametric representation $\mathbf{r}(t)$ with **time** t as parameter. The tangent vector (7) of C is then called the **velocity vector v** because, being tangent, it points in the instantaneous direction of motion and its length gives the **speed** $|\mathbf{v}| = |\mathbf{r}'| = \sqrt{\mathbf{r}' \bullet \mathbf{r}'} = ds/dt$; see (12). The second derivative of $\mathbf{r}(t)$ is called the

acceleration vector and is denoted by **a.** Its length $|\mathbf{a}|$ is called the **acceleration** of the motion. Thus

$$\mathbf{v}(t) = \mathbf{r}'(t), \qquad \mathbf{a}(t) = \mathbf{v}'(t) = \mathbf{r}''(t). \tag{16}$$

Tangential and Normal Acceleration. Whereas the velocity vector is always tangent to the path of motion, the acceleration vector will generally have another direction, so that it will be of the form

$$\mathbf{a} = \mathbf{a}_{\text{tan}} + \mathbf{a}_{\text{norm}}, \tag{17}$$

where the **tangential acceleration vector** $\mathbf{a}_{\text{tan}}$ is tangent to the path (or, sometimes, $\mathbf{0}$) and the **normal acceleration vector** $\mathbf{a}_{\text{norm}}$ is normal (perpendicular) to the path (or, sometimes, $\mathbf{0}$).

Expressions for the vectors in (17) are obtained from (16) by the chain rule. We first have

$$\mathbf{v}(t) = \frac{d\mathbf{r}}{dt} = \frac{d\mathbf{r}}{ds}\frac{ds}{dt} = \mathbf{u}(s)\frac{ds}{dt}$$

where $\mathbf{u}(s)$ is the unit tangent vector (14). Another differentiation gives

$$\mathbf{a}(t) = \frac{d\mathbf{v}}{dt} = \frac{d}{dt}\left(\mathbf{u}(s)\frac{ds}{dt}\right) = \frac{d\mathbf{u}}{ds}\left(\frac{ds}{dt}\right)^2 + \mathbf{u}(s)\frac{d^2s}{dt^2}. \tag{18}$$

Since the tangent vector $\mathbf{u}(s)$ has constant length (one), its derivative $d\mathbf{u}/ds$ is perpendicular to $\mathbf{u}(s)$ (by Example 4 in Sec. 9.4). Hence the first term on the right of (18) is the normal acceleration vector, and the second term on the right is the tangential acceleration vector, so that (18) is of the form (17).

Now the length of $\mathbf{a}_{\text{tan}}$ is the projection of $\mathbf{a}$ in the direction of $\mathbf{v}$, given by (11) in Sec. 9.2 with $\mathbf{b} = \mathbf{v}$; that is, $|\mathbf{a}_{\text{tan}}| = \mathbf{a} \cdot \mathbf{v}/|\mathbf{v}|$. Hence $\mathbf{a}_{\text{tan}}$ is this expression times the unit vector $(1/|\mathbf{v}|)\mathbf{v}$ in the direction of $\mathbf{v}$; that is,

$$\mathbf{a}_{\text{tan}} = \frac{\mathbf{a} \cdot \mathbf{v}}{\mathbf{v} \cdot \mathbf{v}}\,\mathbf{v}. \qquad \text{Also,} \qquad \mathbf{a}_{\text{norm}} = \mathbf{a} - \mathbf{a}_{\text{tan}}. \tag{18*}$$

Let us consider two basic examples, involving *centripetal* and *centrifugal accelerations* and *Coriolis acceleration,* as it occurs, for instance, in space travel.

EXAMPLE 7 **Centripetal Acceleration. Centrifugal Force**

The vector function

$$\mathbf{r}(t) = [R\cos\omega t, \quad R\sin\omega t] = R\cos\omega t\,\mathbf{i} + R\sin\omega t\,\mathbf{j} \qquad \text{(Fig. 208)}$$

(with fixed $\mathbf{i}$ and $\mathbf{j}$) represents a circle C of radius R with center at the origin of the xy-plane and describes the motion of a small body B counterclockwise around the circle. Differentiation gives the velocity vector

$$\mathbf{v} = \mathbf{r}' = [-R\omega\sin\omega t, \quad R\omega\cos\omega t] = -R\omega\sin\omega t\,\mathbf{i} + R\omega\cos\omega t\,\mathbf{j} \qquad \text{(Fig. 208).}$$

$\mathbf{v}$ is tangent to C. Its magnitude, the speed, is

$$|\mathbf{v}| = |\mathbf{r}'| = \sqrt{\mathbf{r}' \cdot \mathbf{r}'} = R\omega.$$

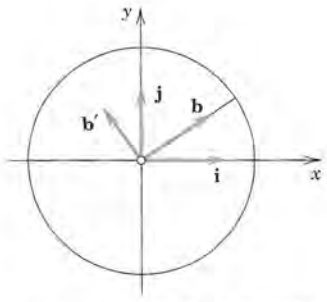

Fig. 208. Centripetal acceleration **a**

Hence it is constant. The speed divided by the distance R from the center is called the **angular speed.** It equals ω, so that it is constant, too. Differentiating the velocity vector, we obtain the acceleration vector

$$\mathbf{a} = \mathbf{v}' = [-R\omega^2 \cos \omega t, \quad -R\omega^2 \sin \omega t] = -R\omega^2 \cos \omega t\, \mathbf{i} - R\omega^2 \sin \omega t\, \mathbf{j}. \tag{19}$$

This shows that $\mathbf{a} = -\omega^2 \mathbf{r}$ (Fig. 208), so that there is an acceleration toward the center, called the **centripetal acceleration** of the motion. It occurs because the velocity vector is changing direction at a constant rate. Its magnitude is constant, $|\mathbf{a}| = \omega^2 |\mathbf{r}| = \omega^2 R$. Multiplying **a** by the mass m of B, we get the **centripetal force** $m\mathbf{a}$. The opposite vector $-m\mathbf{a}$ is called the **centrifugal force.** At each instant these two forces are in equilibrium.

We see that in this motion the acceleration vector is normal (perpendicular) to C; hence there is no tangential acceleration. ■

EXAMPLE 8 Superposition of Rotations. Coriolis Acceleration

A projectile is moving with constant speed along a meridian of the rotating earth in Fig. 209. Find its acceleration.

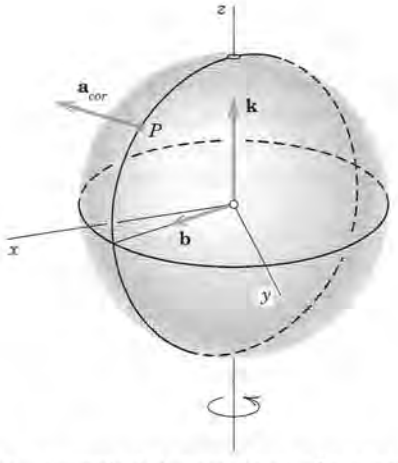

Fig. 209. Example 8. Superposition of two rotations

Solution. Let x, y, z be a fixed Cartesian coordinate system in space, with unit vectors **i, j, k** in the directions of the axes. Let the earth, together with a unit vector **b,** be rotating about the z-axis with angular speed $\omega > 0$ (see Example 7). Since **b** is rotaing together with the earth, it is of the form

$$\mathbf{b}(t) = \cos \omega t\, \mathbf{i} + \sin \omega t\, \mathbf{j}.$$

Let the projectile be moving on the meridian whose plane is spanned by **b** and **k** (Fig. 209) with constant angular speed $\gamma > 0$. Then its position vector in terms of **b** and **k** is

$$\mathbf{r}(t) = R \cos \gamma t\, \mathbf{b}(t) + R \sin \gamma t\, \mathbf{k} \qquad (R = \text{Radius of the earth}).$$

This is the model. The rest is calculation. The result will be unexpected and highly relevant for air and space travel. The first and second derivatives of $\mathbf{b}$ with respect to t are

$$\mathbf{b}'(t) = -\omega \sin \omega t\, \mathbf{i} + \omega \cos \omega t\, \mathbf{j}$$
$$\mathbf{b}''(t) = -\omega^2 \cos \omega t\, \mathbf{i} - \omega^2 \sin \omega t\, \mathbf{j} = -\omega^2 \mathbf{b}(t). \tag{20}$$

The first and second derivatives of $\mathbf{r}(t)$ with respect to t are

$$\mathbf{v} = \mathbf{r}'(t) = R \cos \gamma t\, \mathbf{b}' - \gamma R \sin \gamma t\, \mathbf{b} + \gamma R \cos \gamma t\, \mathbf{k}$$
$$\mathbf{a} = \mathbf{v}' = R \cos \gamma t\, \mathbf{b}'' - 2\gamma R \sin \gamma t\, \mathbf{b}' - \gamma^2 R \cos \gamma t\, \mathbf{b} - \gamma^2 R \sin \gamma t\, \mathbf{k} \tag{21}$$
$$= R \cos \gamma t\, \mathbf{b}'' - 2\gamma R \sin \gamma t\, \mathbf{b}' - \gamma^2 \mathbf{r}.$$

By analogy with Example 7 and because of $\mathbf{b}'' = -\omega^2 \mathbf{b}$ in (20) we conclude that the first term in $\mathbf{a}$ (involving ω in $\mathbf{b}''$!) is the centripetal acceleration due to the rotation of the earth. Similarly, the third term in the last line (involving γ!) is the centripetal acceleration due to the motion of the projectile on the meridian M of the rotating earth.

The second, unexpected term $-2\gamma R \sin \gamma t\, \mathbf{b}'$ in $\mathbf{a}$ is called the **Coriolis acceleration**[3] (Fig. 209) and is due to the interaction of the two rotations. On the Northern Hemisphere, $\sin \gamma t > 0$ (for $t > 0$; also $\gamma > 0$ by assumption), so that $\mathbf{a}_{\text{cor}}$ has the direction of $-\mathbf{b}'$, that is, opposite to the rotation of the earth. $|\mathbf{a}_{\text{cor}}|$ is maximum at the North Pole and zero at the equator. The projectile B of mass m_0 experiences a force $-m_0 \mathbf{a}_{\text{cor}}$ opposite to $m_0 \mathbf{a}_{\text{cor}}$, which tends to let B deviate from M to the right (and in the Southern Hemisphere, where $\sin \gamma t < 0$, to the left). This deviation has been observed for missiles, rockets, shells, and atmospheric air flow. ■

Curvature and Torsion. *Optional*

This optional portion of the section completes our discussion of curves from the viewpoint of vector calculus.

The **curvature** $\kappa(s)$ of a curve C: $\mathbf{r}(s)$ (s the arc length) at a point P of C measures the rate of change $|\mathbf{u}'(s)|$ of the unit tangent vector $\mathbf{u}(s)$ at P. Hence $\kappa(s)$ measures the deviation of C at P from a straight line (its tangent at P). Since $\mathbf{u}(s) = \mathbf{r}'(s)$, the definition is

$$\kappa(s) = |\mathbf{u}'(s)| = |\mathbf{r}''(s)| \qquad (' = d/ds). \tag{22}$$

The **torsion** $\tau(s)$ of C at P measures the rate of change of the **osculating plane** O (the plane spanned by $\mathbf{u}$ and $\mathbf{u}'$, see Fig. 210) of C at P. Hence $\tau(s)$ measures the deviation

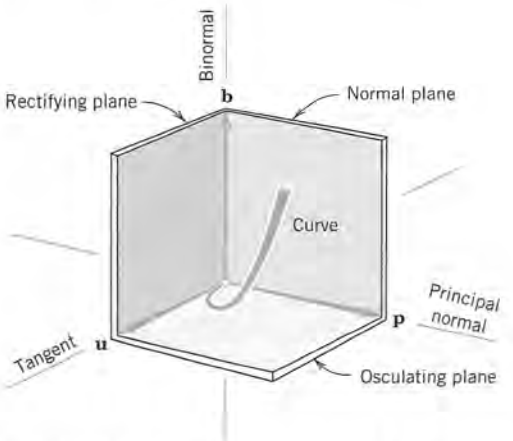

Fig. 210. Trihedron. Unit vectors **u**, **p**, **b** and planes

[3]GUSTAVE GASPARD CORIOLIS (1792–1843), French engineer who did research in mechanics.

of C at P from a plane (from O at P). Now the rate of change is also measured by the derivative $\mathbf{b}'$ of a normal vector $\mathbf{b}$ at O. By the definition of vector product, a unit normal vector of O is $\mathbf{b} = \mathbf{u} \times (1/\kappa)\mathbf{u}' = \mathbf{u} \times \mathbf{p}$, where $\mathbf{p} = (1/\kappa)\mathbf{u}'$ is called the **unit principal normal vector** and $\mathbf{b}$ is called the **unit binormal vector** of C at P; see Fig. 210. Here we must assume that $\kappa \neq 0$; hence $\kappa > 0$. The absolute value of the torsion is now defined by

$$|\tau(s)| = |\mathbf{b}'(s)|. \tag{23*}$$

Whereas $\kappa(s)$ is nonnegative, it is practical to give the torsion a sign, motivated by "right-handed" and "left-handed" (see Figs. 202, 203). This needs a little further calculation. Since $\mathbf{b}$ is a unit vector, it has constant length. Hence $\mathbf{b}'$ is perpendicular to $\mathbf{b}$ (see Example 4 in Sec. 9.4). Now $\mathbf{b}'$ is also perpendicular to $\mathbf{u}$ because by the definition of vector product we have $\mathbf{b} \bullet \mathbf{u} = 0$, $\mathbf{b} \bullet \mathbf{u}' = 0$. This implies

$$(\mathbf{b} \bullet \mathbf{u})' = 0; \qquad \text{that is,} \qquad \mathbf{b}' \bullet \mathbf{u} + \mathbf{b} \bullet \mathbf{u}' = \mathbf{b}' \bullet \mathbf{u} + 0 = 0.$$

Hence if $\mathbf{b}' \neq \mathbf{0}$ at P, it must have the direction of $\mathbf{p}$ or $-\mathbf{p}$, so that it must be of the form $\mathbf{b}' = -\tau\mathbf{p}$. Taking the dot product of this by $\mathbf{p}$ and using $\mathbf{p} \bullet \mathbf{p} = 1$ gives

$$\tau(s) = -\mathbf{p}(s) \bullet \mathbf{b}'(s). \tag{23}$$

The minus sign is chosen to make the torsion of a *right-handed* helix *positive* and that of a *left-handed* helix *negative* (Figs. 202, 203). The orthonormal vector triple $\mathbf{u}, \mathbf{p}, \mathbf{b}$ is called the **trihedron** of C. Figure 210 also shows the names of the three straight lines in the directions of $\mathbf{u}, \mathbf{p}, \mathbf{b}$, which are the intersections of the **osculating plane,** the **normal plane,** and the **rectifying plane.**

PROBLEM SET 9.5

1–10 PARAMETRIC REPRESENTATIONS

Find a parametric representation of the following curves.

1. Circle of radius 3, center (4, 6)
2. Straight line through (5, 1, 2) and (11, 3, 0)
3. Straight line through (2, 0, 4) and (−3, 0, 9)
4. Straight line $y = 2x + 3$, $z = 7x$
5. Circle $y^2 + 4y + z^2 = 5$, $x = 3$
6. Ellipse $x^2 + y^2 = 1$, $z = y$
7. Straight line through (a, b, c) and $(a + 3, b - 2, c + 5)$
8. Intersection of $x + y - z = 2$, $2x - 5y + z = 3$
9. Circle $\frac{1}{2}x^2 + y^2 = 1$, $z = y$
10. Helix $x^2 + y^2 = 9$, $z = 4 \arctan (y/x)$

11–18

What curves are represented as follows?

11. $[2 + r \cos 4t, 6 + r \sin 4t, 2t]$
12. $[4 - 2t, 8t, -3 + 5t]$
13. $[2 + \cos 3t, -2 + \sin 3t, 5]$
14. $[t, t^2, t^3]$
15. $[\sqrt{\cos t}, \sqrt{\sin t}, 0]$ (*"Lamé curve"*)
16. $[\cosh t, \sinh t, 0]$
17. $[t, 1/t, 0]$
18. $[1, 5 + t, -5 + 1/t]$
19. Show that setting $t = -t^*$ reverses the orientation of $[a \cos t, a \sin t, 0]$.
20. If we set $t = e^{\tilde{t}}$ in Prob. 12, do we get the entire line? Explain.
21. **CAS PROJECT. Curves.** Graph the following more complicated curves.

    (a) $\mathbf{r}(t) = [2 \cos t + \cos 2t, \ 2 \sin t - \sin 2t]$ (*Steiner's hypocycloid*)

    (b) $\mathbf{r}(t) = [\cos t + k \cos 2t, \ \sin t - k \sin 2t]$ with $k = 10, 2, 1, \frac{1}{2}, 0, -\frac{1}{2}, -1$

    (c) $\mathbf{r}(t) = [\cos t, \ \sin 5t]$ (a *Lissajous curve*)

    (d) $\mathbf{r}(t) = [\cos t, \ \sin kt]$. For what k's will it be closed?

    (e) $\mathbf{r}(t) = [R \sin \omega t + \omega R t, \ R \cos \omega t + R]$ (*cycloid*).

22–25 TANGENT

Given a curve C: $\mathbf{r}(t)$, find a tangent vector $\mathbf{r}'(t)$, a unit tangent vector $\mathbf{u}'(t)$, and the tangent of C at P. Sketch the curve and the tangent.

22. $\mathbf{r}(t) = [t, \ t^2, \ 0]$, P: (2, 4, 0)

23. $\mathbf{r}(t) = [5\cos t, \ 5\sin t, \ 0]$, P: (4, 3, 0)

24. $\mathbf{r}(t) = [3\cos t, \ 3\sin t, \ 4t]$, P: $(3, 0, 8\pi)$

25. $\mathbf{r}(t) = [\cosh t, \ \sinh t]$, P: $(\frac{5}{3}, \frac{4}{3})$

26–28 LENGTH

Find the length and sketch the curve.

26. Circular helix $\mathbf{r}(t) = [2\cos t, \ 2\sin t, \ 6t]$ from (2, 0, 0) to $(2, 0, 24\pi)$

27. Catenary $\mathbf{r}(t) = [t, \ \cosh t]$ from $t = 0$ to $t = 1$

28. Hypocycloid $\mathbf{r}(t) = [a\cos^3 t, \ a\sin^3 t]$, total length

29. Show that (10) implies $\ell = \int_a^b \sqrt{1 + y'^2}\, dx$ for the length of a plane curve C: $y = f(x)$, $z = 0$, $a \leqq x \leqq b$.

30. Polar coordinates $\rho = \sqrt{x^2 + y^2}$, $\theta = \arctan(y/x)$ give $\ell = \int_\alpha^\beta \sqrt{\rho^2 + \rho'^2}\, d\theta$, where $\rho' = d\rho/d\theta$. Derive this. Use it to find the total length of the **cardioid** $\rho = a(1 - \cos\theta)$. Sketch this curve. *Hint.* Use (10) in App. 3.1.

31. CAS PROJECT. Polar Representations. Use your CAS to graph the following famous curves[4] and investigate their form depending on parameters a and b.

$\rho = a\theta$ *Spiral of Archimedes*

$\rho = ae^{b\theta}$ *Logarithmic spiral*

$\rho = \dfrac{2a\sin^2\theta}{\cos\theta}$ *Cissoid of Diocles*

$\rho = \dfrac{a}{\cos\theta} + b$ *Conchoid of Nicomedes*

$\rho = a/\theta$ *Hyperbolic spiral*

$\rho = \dfrac{3a\sin 2\theta}{\cos^3\theta + \sin^3\theta}$ *Folium of Descartes*

$\rho = 2a\dfrac{\sin 3\theta}{\sin 2\theta}$ *Maclaurin's trisectrix*

$\rho = 2a\cos\theta + b$ *Pascal's snail*

32–34 CURVES IN MECHANICS

Velocity and Acceleration. Forces on moving objects (cars, airplanes, etc.) require that the engineer knows corresponding **tangential** and **normal accelerations.** Find them, along with the **velocity** and **speed,** for the following motions. Sketch the path.

32. $\mathbf{r}(t) = [4t, \ -3t, \ 0]$

33. $\mathbf{r}(t) = [t, \ t^2, \ 0]$

34. $\mathbf{r}(t) = [\cos t, \ 2\sin t, \ 0]$

35. (Cycloid) Given

$$\mathbf{r}(t) = (R\sin\omega t + \omega R t)\mathbf{i} + (R\cos\omega t + R)\mathbf{j}.$$

This cycloid is the path of a point on the rim of a wheel of radius R that rolls without slipping along the x-axis. Find $\mathbf{v}$ and $\mathbf{a}$ at the maximum y-values of the curve.

36. CAS PROJECT. Paths of Motions. Gear transmissions and other engineering constructions often involve complicated paths whose study is greatly facilitated by the use of a CAS. To grasp the idea, graph the following paths and find the velocity, the speed, and the tangential and normal accelerations.

(a) $\mathbf{r}(t) = [2\cos t + \cos 2t, \ 2\sin t - \sin 2t]$ *(Steiner's hypocycloid)*

(b) $\mathbf{r}(t) = [\cos t + \cos 2t, \ \sin t - \sin 2t]$

(c) $\mathbf{r}(t) = [\cos t, \ \sin 2t, \ \cos 2t]$

(d) $\mathbf{r}(t) = [ct\cos t, \ ct\sin t, \ ct]$ $(c \neq 0)$

37. (Sun and earth) Find the acceleration of the earth toward the sun from (19) and the fact that the earth revolves about the sun in a nearly circular orbit with an almost constant speed of 30 km/sec.

38. (Earth and moon) Find the centripetal acceleration of the moon toward the earth, assuming that the orbit of the moon is a circle of radius 239,000 miles $= 3.85 \cdot 10^8$ m, and the time for one complete revolution is 27.3 days $= 2.36 \cdot 10^6$ sec.

39. (Satellite) Find the speed of an artificial earth satellite traveling at an altitude of 80 miles above the earth's surface, where $g = 31$ ft/sec^2. (The radius of the earth is 3960 miles.)

40. (Satellite) A satellite moves in a circular orbit 450 miles above the earth's surface and completes 1 revolution in 100 min. Find the acceleration of gravity at the orbit from these data and from the radius of the earth (3960 miles).

---

[4]Named after ARCHIMEDES (c. 287–212 B.C.), DESCARTES (Sec. 9.1), DIOCLES (200 B.C.), MACLAURIN (Sec. 15.4), NICOMEDES (250? B.C.) ÉTIENNE PASCAL (1588–1651), father of BLAISE PASCAL (1623–1662).

41–50 CURVATURE AND TORSION

41. Show that a circle of radius a has curvature $1/a$.

42. Using (22), show that if C is represented by $\mathbf{r}(t)$ with arbitrary t, then

$$(22^*) \quad \kappa(t) = \frac{\sqrt{(\mathbf{r}' \bullet \mathbf{r}')(\mathbf{r}'' \bullet \mathbf{r}'') - (\mathbf{r}' \bullet \mathbf{r}'')^2}}{(\mathbf{r}' \bullet \mathbf{r}')^{3/2}}.$$

43. Using (22*), show that for a curve $y = f(x)$ in the xy-plane,

$$(22^{**}) \quad \kappa(x) = \frac{|y''|}{(1 + y'^2)^{3/2}} \qquad \left(y' = \frac{dy}{dx}, \text{ etc.}\right).$$

44. Using $\mathbf{b} = \mathbf{u} \times \mathbf{p}$ and (23), show that

$$(23^{**}) \quad \tau(s) = (\mathbf{u} \quad \mathbf{p} \quad \mathbf{p}') = (\mathbf{r}' \quad \mathbf{r}'' \quad \mathbf{r}''')/\kappa^2 \qquad (\kappa > 0).$$

45. Show that the torsion of a plane curve (with $\kappa > 0$) is identically zero.

46. Show that if C is represented by $\mathbf{r}(t)$ with arbitrary parameter t, then, assuming $\kappa > 0$ as before,

$$(23^{***}) \quad \tau(t) = \frac{(\mathbf{r}' \quad \mathbf{r}'' \quad \mathbf{r}''')}{(\mathbf{r}' \bullet \mathbf{r}')(\mathbf{r}'' \bullet \mathbf{r}'') - (\mathbf{r}' \bullet \mathbf{r}'')^2}.$$

47. Find the torsion of C: $\mathbf{r}(t) = [t, t^2, t^3]$ (which looks similar to the curve in Fig. 210).

48. **(Helix)** Show that the helix $[a \cos t, \quad a \sin t, \quad ct]$ can be represented by $[a \cos (s/K), \quad a \sin (s/K), \quad cs/K]$, where $K = \sqrt{a^2 + c^2}$ and s is the arc length. Show that it has constant curvature $\kappa = a/K^2$ and torsion $\tau = c/K^2$.

49. Obtain κ and τ in Prob. 48 from (22*) and (23***) and the original representation in Prob. 48 with parameter t.

50. **(Frenet[5] formulas)** Show that $\mathbf{u}' = \kappa\mathbf{p}, \quad \mathbf{p}' = -\kappa\mathbf{u} + \tau\mathbf{b}, \quad \mathbf{b}' = -\tau\mathbf{p}$.

9.6 Calculus Review: Functions of Several Variables. *Optional*

Curves required vector functions of a *single* variable x or s, and we now proceed to vector functions of *several* variables, beginning with a review from calculus. ***Go on to the next section, consulting this material only when needed.*** (We include this short section to keep the book reasonably self-contained. For partial derivatives see App. A3.2.)

Chain Rules

Figure 211 shows the notations in the following basic theorem.

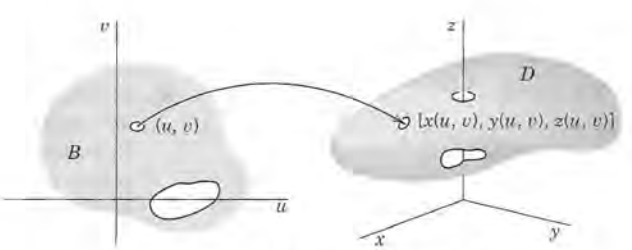

Fig. 211. Notations in Theorem 1

[5]JEAN-FRÉDÉRIC FRENET (1816–1900), French mathematician.

THEOREM 1

Chain Rule

Let $w = f(x, y, z)$ be continuous and have continuous first partial derivatives in a domain D in xyz-space. Let $x = x(u, v)$, $y = y(u, v)$, $z = z(u, v)$ be functions that are continuous and have first partial derivatives in a domain B in the uv-plane, where B is such that for every point (u, v) in B, the corresponding point $[x(u, v), y(u, v), z(u, v)]$ lies in D. See Fig. 211. *Then the function*

$$w = f(x(u, v), y(u, v), z(u, v))$$

is defined in B, has first partial derivatives with respect to u and v in B, and

(1)
$$\frac{\partial w}{\partial u} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial u} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial u}$$
$$\frac{\partial w}{\partial v} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial v} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial v}.$$

In this theorem, a **domain** D is an open connected point set in xyz-space, where "connected" means that any two points of D can be joined by a broken line of finitely many linear segments all of whose points belong to D. "Open" means that every point P of D has a neighborhood (a little ball with center P) all of whose points belong to D. For example, the interior of a cube or of an ellipsoid (the solid without the boundary surface) is a domain.

In calculus, x, y, z are often called the **intermediate variables,** in contrast with the **independent variables** u, v and the **dependent variable** w.

Special Cases of Practical Interest

If $w = f(x, y)$ and $x = x(u, v)$, $y = y(u, v)$ as before, then (1) becomes

(2)
$$\frac{\partial w}{\partial u} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial u}$$
$$\frac{\partial w}{\partial v} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial v}.$$

If $w = f(x, y, z)$ and $x = x(t)$, $y = y(t)$, $z = z(t)$, then (1) gives

(3)
$$\frac{dw}{dt} = \frac{\partial w}{\partial x}\frac{dx}{dt} + \frac{\partial w}{\partial y}\frac{dy}{dt} + \frac{\partial w}{\partial z}\frac{dz}{dt}.$$

If $w = f(x, y)$ and $x = x(t)$, $y = y(t)$, then (3) reduces to

(4)
$$\frac{dw}{dt} = \frac{\partial w}{\partial x}\frac{dx}{dt} + \frac{\partial w}{\partial y}\frac{dy}{dt}.$$

Finally, the simplest case $w = f(x)$, $x = x(t)$ gives

$$\frac{dw}{dt} = \frac{dw}{dx}\frac{dx}{dt}. \tag{5}$$

EXAMPLE 1 **Chain Rule**

If $w = x^2 - y^2$ and we define polar coordinates r, θ by $x = r\cos\theta$, $y = r\sin\theta$, then (2) gives

$$\frac{\partial w}{\partial r} = 2x\cos\theta - 2y\sin\theta = 2r\cos^2\theta - 2r\sin^2\theta = 2r\cos 2\theta$$
$$\frac{\partial w}{\partial \theta} = 2x(-r\sin\theta) - 2y(r\cos\theta) = -2r^2\cos\theta\sin\theta - 2r^2\sin\theta\cos\theta = -2r^2\sin 2\theta.$$ ■

Mean Value Theorems

THEOREM 2 **Mean Value Theorem**

Let $f(x, y, z)$ be continuous and have continuous first partial derivatives in a domain D in xyz-space. Let P_0: (x_0, y_0, z_0) and P: $(x_0 + h, y_0 + k, z_0 + l)$ be points in D such that the straight line segment P_0P joining these points lies entirely in D. Then

$$f(x_0 + h, y_0 + k, z_0 + l) - f(x_0, y_0, z_0) = h\frac{\partial f}{\partial x} + k\frac{\partial f}{\partial y} + l\frac{\partial f}{\partial z}, \tag{6}$$

the partial derivatives being evaluated at a suitable point of that segment.

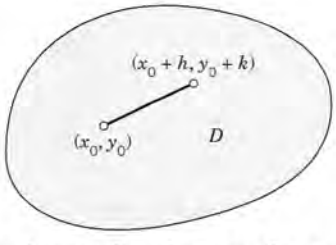

Fig. 212. Mean value theorem for a function of two variables [Formula (7)]

Special Cases

For a function $f(x, y)$ of two variables (satisfying assumptions as in the theorem), formula (6) reduces to (Fig. 212)

$$f(x_0 + h, y_0 + k) - f(x_0, y_0) = h\frac{\partial f}{\partial x} + k\frac{\partial f}{\partial y}, \tag{7}$$

and for a function $f(x)$ of a single variable, (6) becomes

$$(8) \qquad f(x_0 + h) - f(x_0) = h\frac{df}{dx},$$

where in (8), the domain D is a segment of the x-axis and the derivative is taken at a suitable point between x_0 and $x_0 + h$.

PROBLEM SET 9.6

1–5 DERIVATIVE

Find dw/dt by (3) or (4). Check the result by substitution and differentiation. (Show the details.)

1. $w = \sqrt{x^2 + y^2}$, $x = e^{2t}$, $y = e^{-2t}$
2. $w = y/x$, $x = g(t)$, $y = h(t)$
3. $w = x^y$, $x = \cosh t$, $y = \sinh t$
4. $w = xy + yz + zx$, $x = 2\cos t$, $y = 2\sin t$, $z = 5t$
5. $w = (x^2 + y^2 + z^2)^3$, $x = t^2$, $y = t^4$, $z = t^2$

6–9 PARTIAL DERIVATIVES

Find $\partial w/\partial u$ and $\partial w/\partial v$ by (1) and (2). Check the result by substitution and differentiation. (Show the details.)

6. $w = 4x^2 - 4y^2$, $x = u + 2v$, $y = 2u - v$
7. $w = x^2y^2$, $x = e^u \cos v$, $y = e^u \sin v$
8. $w = x^4 - 4x^2y^2 + y^4$, $x = uv$, $y = u/v$
9. $w = 1/(x^2 + y^2 + z^2)$, $x = u^2 + v^2$, $y = u^2 - v^2$, $z = 2uv$
10. **(Partial derivatives on a surface)** Let $w = f(x, y, z)$, and let $z = g(x, y)$ represent a surface S in space. Then on S, the function becomes

$$\tilde{w}(x, y) = f[x, y, g(x, y)].$$

Show that its partial derivatives are obtained from

$$\frac{\partial \tilde{w}}{\partial x} = \frac{\partial f}{\partial x} + \frac{\partial f}{\partial z}\frac{\partial g}{\partial x}, \qquad \frac{\partial \tilde{w}}{\partial y} = \frac{\partial f}{\partial y} + \frac{\partial f}{\partial z}\frac{\partial g}{\partial y}$$

$[z = g(x, y)]$.

Apply this to $f = x^3 + y^3 + z^2$, $g = x^2 + y^2$ and check by substitution and direct differentiation. (The general formula will be needed in Sec. 10.9.)

9.7 Gradient of a Scalar Field. Directional Derivative

We shall see that some of the vector fields in applications—not all of them!—can be obtained from scalar fields. This is a considerable advantage because scalar fields can be handled more easily. The relation between these two kinds of fields is obtained by the "gradient," which is thus of great practical importance.

DEFINITION 1

Gradient

The **gradient** of a given scalar function $f(x, y, z)$ is denoted by grad f or ∇f (read **nabla** f) and is the vector function defined by

$$(1) \qquad \text{grad } f = \nabla f = \left[\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right] = \frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k}.$$

Here x, y, z are Cartesian coordinates in a domain in 3-space in which f is defined and differentiable. (For curvilinear coordinates see App. 3.4.)

For instance, if $f(x, y, z) = 2y^3 + 4xz + 3x$, then grad $f = [4z + 3, \quad 6y^2, \quad 4x]$.

The notation ∇f is suggested by the *differential operator* ∇ (read *nabla*) defined by

$$\nabla = \frac{\partial}{\partial x}\mathbf{i} + \frac{\partial}{\partial y}\mathbf{j} + \frac{\partial}{\partial z}\mathbf{k}. \tag{1*}$$

Gradients are useful in several ways, notably in giving the rate of change of $f(x, y, z)$ in any direction in space, in obtaining surface normal vectors, and in deriving vector fields from scalar fields, as we are going to show in this section.

Directional Derivative

From calculus we know that the partial derivatives in (1) give the rates of change of $f(x, y, z)$ in the directions of the three coordinate axes. It seems natural to extend this and ask for the rate of change of f *in an arbitrary direction* in space. This leads to the following concept.

DEFINITION 2

Directional Derivative

The directional derivative $D_{\mathbf{b}}f$ or df/ds of a function $f(x, y, z)$ at a point P in the direction of a vector $\mathbf{b}$ is defined by (see Fig. 213)

$$D_{\mathbf{b}}f = \frac{df}{ds} = \lim_{s \to 0} \frac{f(Q) - f(P)}{s}. \tag{2}$$

Here Q is a variable point on the straight line L in the direction of $\mathbf{b}$, and $|s|$ is the distance between P and Q. Also, $s > 0$ if Q lies in the direction of $\mathbf{b}$ (as in Fig. 213), $s < 0$ if Q lies in the direction of $-\mathbf{b}$, and $s = 0$ if $Q = P$.

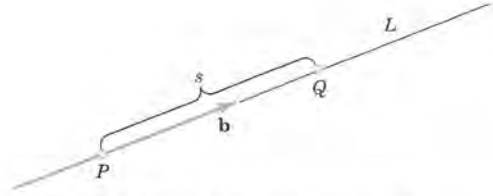

Fig. 213. Directional derivative

The next idea is to use Cartesian xyz-coordinates and for $\mathbf{b}$ a unit vector. Then the line L is given by

$$\mathbf{r}(s) = x(s)\mathbf{i} + y(s)\mathbf{j} + z(s)\mathbf{k} = \mathbf{p}_0 + s\mathbf{b} \qquad (|\mathbf{b}| = 1) \tag{3}$$

where $\mathbf{p}_0$ the position vector of P. Equation (2) now shows that $D_{\mathbf{b}}f = df/ds$ is the derivative of the function $f(x(s), y(s), z(s))$ with respect to the arc length s of L. Hence, assuming that f has continuous partial derivatives and applying the chain rule [formula (3) in the previous section], we obtain

$$D_{\mathbf{b}}f = \frac{df}{ds} = \frac{\partial f}{\partial x}x' + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial z}z' \tag{4}$$

where primes denote derivatives with respect to s (which are taken at $s = 0$). But here, differentiating (3) gives $\mathbf{r}' = x'\mathbf{i} + y'\mathbf{j} + z'\mathbf{k} = \mathbf{b}$. Hence (4) is simply the inner product of grad f and $\mathbf{b}$ [see (2), Sec. 9.2]; that is,

$$D_{\mathbf{b}}f = \frac{df}{ds} = \mathbf{b} \cdot \operatorname{grad} f \qquad (|\mathbf{b}| = 1). \tag{5}$$

ATTENTION! If the direction is given by a vector $\mathbf{a}$ of any length ($\neq 0$), then

$$D_{\mathbf{a}}f = \frac{df}{ds} = \frac{1}{|\mathbf{a}|}\,\mathbf{a} \cdot \operatorname{grad} f. \tag{5*}$$

EXAMPLE 1 **Gradient. Directional Derivative**

Find the directional derivative of $f(x, y, z) = 2x^2 + 3y^2 + z^2$ at P: (2, 1, 3) in the direction of $\mathbf{a} = [1, 0, -2]$.

Solution. grad $f = [4x, 6y, 2z]$ gives at P the vector grad $f(P) = [8, 6, 6]$. From this and (5*) we obtain, since $|\mathbf{a}| = \sqrt{5}$,

$$D_{\mathbf{a}}f(P) = \frac{1}{\sqrt{5}}\,[1, 0, -2] \cdot [8, 6, 6] = \frac{1}{\sqrt{5}}\,(8 + 0 - 12) = -\frac{4}{\sqrt{5}} = -1.789.$$

The minus sign indicates that at P the function f is decreasing in the direction of $\mathbf{a}$. ■

Gradient Is a Vector. Maximum Increase

grad f in (1) *looks* like a vector—after all, it has three components! But to prove that it *actually is* a vector, since it is defined in terms of components depending on the Cartesian coordinates, we must show that grad f has a length and direction independent of the choice of those coordinates. In contrast, $[\partial f/\partial x, \quad 2\partial f/\partial y, \quad \partial f/\partial z]$ also looks like a vector but does not have a length and direction independent of the choice of Cartesian coordinates.

Incidentally, the direction makes the gradient eminently useful: grad f *points in the direction of maximum increase of* f.

THEOREM 1 **Vector Character of Gradient. Maximum Increase**

Let $f(P) = f(x, y, z)$ be a scalar function having continuous first partial derivatives in some domain B in space. Then grad f *exists in B and is a vector, that is, its length and direction are independent of the particular choice of Cartesian coordinates. If* grad $f(P) \neq \mathbf{0}$ *at some point P, it has the direction of maximum increase of f at P.*

PROOF From (5) and the definition of inner product [(1) in Sec. 9.2] we have

$$D_{\mathbf{b}}f = |\mathbf{b}|\,|\operatorname{grad} f| \cos\gamma = |\operatorname{grad} f| \cos\gamma \tag{6}$$

where γ is the angle between $\mathbf{b}$ and grad f. Now f is a scalar function. Hence its value at a point P depends on P but not on the particular choice of coordinates. The same holds for the arc length s of the line L in Fig. 213, hence also for $D_{\mathbf{b}}f$. Now (6) shows that $D_{\mathbf{b}}f$ is maximum when $\cos\gamma = 1$, $\gamma = 0$, and then $D_{\mathbf{b}}f = |\operatorname{grad} f|$. It follows that the length and direction of grad f are independent of the choice of coordinates. Since $\gamma = 0$ if and only if $\mathbf{b}$ has the direction of grad f, the latter is the direction of maximum increase of f at P, provided grad $f \neq \mathbf{0}$ at P. ■

Gradient as Surface Normal Vector

Gradients have an important application in connection with surfaces, namely, as surface normal vectors, as follows. Let S be a surface represented by $f(x, y, z) = c = const$, where f is differentiable. Such a surface is called a **level surface** of f, and for different c we get different level surfaces. Now let C be a curve on S through a point P of S. As a curve in space, C has a representation $\mathbf{r}(t) = [x(t), y(t), z(t)]$. For C to lie on the surface S, the components of $\mathbf{r}(t)$ must satisfy $f(x, y, z) = c$, that is,

$$f(x(t), y(t), z(t)) = c. \tag{7}$$

Now a tangent vector of C is $\mathbf{r}'(t) = [x'(t), y'(t), z'(t)]$. And the tangent vectors of all curves on S passing through P will generally form a plane, called the **tangent plane** of S at P. (Exceptions occur at edges or cusps of S, for instance, for the cone in Fig. 215 at the apex.) The normal of this plane (the straight line through P perpendicular to the tangent plane) is called the **surface normal** to S at P. A vector in the direction of the surface normal is called a **surface normal vector** of S at P. We can obtain such a vector quite simply by differentiating (7) with respect to t. By the chain rule,

$$\frac{\partial f}{\partial x}x' + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial z}z' = (\text{grad } f) \bullet \mathbf{r}' = 0.$$

Hence grad f is orthogonal to all the vectors $\mathbf{r}'$ in the tangent plane, so that it is a normal vector of S at P. Our result is as follows (see Fig. 214).

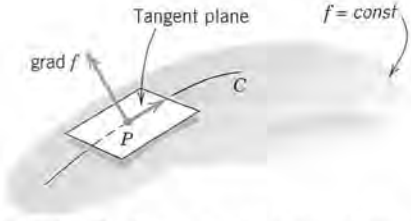

Fig. 214. Gradient as surface normal vector

THEOREM 2

Gradient as Surface Normal Vector

Let f be a differentiable scalar function in space. Let $f(x, y, z) = c = const$ represent a surface S. Then if the gradient of f at a point P of S is not the zero vector, it is a normal vector of S at P.

EXAMPLE 2 **Gradient as Surface Normal Vector. Cone**

Find a unit normal vector $\mathbf{n}$ of the cone of revolution $z^2 = 4(x^2 + y^2)$ at the point P: $(1, 0, 2)$.

Solution. The cone is the level surface $f = 0$ of $f(x, y, z) = 4(x^2 + y^2) - z^2$. Thus (Fig. 215),

$$\text{grad } f = [8x, \quad 8y, \quad -2z], \qquad \text{grad } f(P) = [8, \quad 0, \quad -4]$$

$$\mathbf{n} = \frac{1}{|\text{grad } f(P)|}\,\text{grad } f(P) = \left[\frac{2}{\sqrt{5}}, \quad 0, \quad -\frac{1}{\sqrt{5}}\right].$$

$\mathbf{n}$ points downward since it has a negative z-component. The other unit normal vector of the cone at P is $-\mathbf{n}$. ■

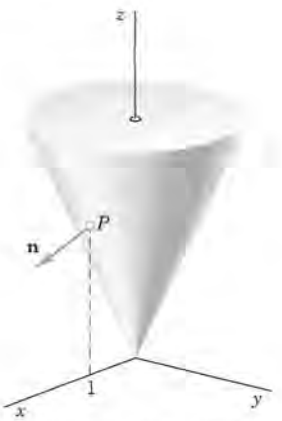

Fig. 215. Cone and unit normal vector **n**

Vector Fields That Are Gradients of Scalar Fields ("Potentials")

At the beginning of this section we mentioned that some vector fields have the advantage that they can be obtained from scalar fields, which can be handled more easily. Such a vector field is given by a vector function $\mathbf{v}(P)$, which is obtained as the gradient of a scalar function, say, $\mathbf{v}(P) = \text{grad } f(P)$. The function $f(P)$ is called a *potential function* or a **potential** of $\mathbf{v}(P)$. Such a $\mathbf{v}(P)$ and the corresponding vector field are called **conservative** because in such a vector field, energy is conserved; that is, no energy is lost (or gained) in displacing a body (or a charge in the case of an electrical field) from a point P to another point in the field and back to P. We show this in Sec. 10.2.

Conservative fields play a central role in physics and engineering. A basic application concerns the gravitational force (see Example 3 in Sec. 9.4) and we show that it has a potential which satisfies Laplace's equation, the most important partial differential equation in physics and its applications.

THEOREM 3

Gravitational Field. Laplace's Equation

The force of attraction

$$\mathbf{p} = -\frac{c}{r^3}\mathbf{r} = -c\left[\frac{x - x_0}{r^3}, \frac{y - y_0}{r^3}, \frac{z - z_0}{r^3}\right] \tag{8}$$

between two particles at points P_0: (x_0, y_0, z_0) *and* P: (x, y, z) (as given by Newton's law of gravitation) *has the potential* $f(x, y, z) = c/r$, *where* $r\ (> 0)$ *is the distance between* P_0 *and* P.

Thus $\mathbf{p} = \text{grad } f = \text{grad } (c/r)$. *This potential* f *is a solution of* **Laplace's equation**

$$\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2} = 0. \tag{9}$$

[$\nabla^2 f$ (read *nabla squared* f) is called the **Laplacian** of f.]

PROOF That distance is $r = ((x - x_0)^2 + (y - y_0)^2 + (z - z_2)^2)^{1/2}$. The key observation now is that for the components of $\mathbf{p} = [p_1, p_2, p_3]$ we obtain by partial differentiation

$$\text{(10a)} \qquad \frac{\partial}{\partial x}\left(\frac{1}{r}\right) = \frac{-2(x - x_0)}{2[(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2]^{3/2}} = -\frac{x - x_0}{r^3}$$

and similarly

$$\text{(10b)} \qquad \frac{\partial}{\partial y}\left(\frac{1}{r}\right) = -\frac{y - y_0}{r^3}, \qquad \frac{\partial}{\partial z}\left(\frac{1}{r}\right) = -\frac{z - z_0}{r^3}.$$

From this we see that, indeed, $\mathbf{p}$ is the gradient of the scalar function $f = c/r$. The second statement of the theorem follows by partially differentiating (10), that is,

$$\frac{\partial^2}{\partial x^2}\left(\frac{1}{r}\right) = -\frac{1}{r^3} + \frac{3(x - x_0)^2}{r^5},$$

$$\frac{\partial^2}{\partial y^2}\left(\frac{1}{r}\right) = -\frac{1}{r^3} + \frac{3(y - y_0)^2}{r^5},$$

$$\frac{\partial^2}{\partial z^2}\left(\frac{1}{r}\right) = -\frac{1}{r^3} + \frac{3(z - z_0)^2}{r^5},$$

and then adding these three expressions. Their common denominator is r^5. Hence the three terms $-1/r^3$ contribute $-3r^2$ to the numerator, and the three other terms give the sum

$$3(x - x_0)^2 + 3(y - y_0)^2 + 3(z - z_0)^2 = 3r^2,$$

so that the numerator is 0, and we obtain (9). ∎

$\nabla^2 f$ is also denoted by Δf. The differential operator

$$\textbf{(11)} \qquad \nabla^2 = \Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$$

(read "nabla squared" or "delta") is called the **Laplace operator.** It can be shown that the field of force produced by any distribution of masses is given by a vector function that is the gradient of a scalar function f, and f satisfies (9) in any region that is free of matter.

The great importance of the Laplace equation also results from the fact that there are other laws in physics that are of the same form as Newton's law of gravitation. For instance, in electrostatics the force of attraction (or repulsion) between two particles of opposite (or

like) charge Q_1 and Q_2 is

$$\mathbf{p} = \frac{k}{r^3}\mathbf{r} \qquad \textbf{(Coulomb's law}^6\textbf{)}. \tag{12}$$

Laplace's equation will be discussed in detail in Chaps. 12 and 18.

A method for finding out whether a given vector field has a potential will be explained in Sec. 9.9.

PROBLEM SET 9.7

1–6 CALCULATION OF GRADIENTS

Find ∇f. Graph some level curves $f = const$. Indicate ∇f by arrows at some points of these curves.

1. $f = x^2 + y^2$
2. $f = x^2 + \frac{1}{9}y^2$
3. $f = \dfrac{x}{y}$
4. $f = x^4 + y^4$
5. $f = (x - 2)(y + 2)$
6. $f = (x - 3)^2 + (y - 1)^2$

7–12 USE OF GRADIENTS. VELOCITY FIELDS

Given the velocity potential f of a flow, find the velocity $\mathbf{v} = \nabla f$ of the flow and its value at P. Make a sketch of $\mathbf{v}(P)$.

7. $f = x^2 + y^2 + z^2$, P: (3, 2, 2)
8. $f = \ln(x^2 + y^2)$, P: (4, 3)
9. $f = \cos x \cosh y$, P: $(\frac{1}{2}\pi, \ln 2)$
10. $f = x^2 + 4y^2 + 9z^2$, P: (3, 2, 1)
11. $f = e^x \sin y$, P: $(1, \pi)$
12. $f = (x^2 + y^2 + z^2)^{-1/2}$, P: (2, 1, 2)

13–18 HEAT FLOW

Experiments show that in a temperature field, heat flows in the direction of maximum decrease of temperature T. Find this direction in general and at a given point P. Sketch that direction at P as an arrow.

13. $T = x^2 - y^2$, P: (2, 1)
14. $T = \arctan \dfrac{y}{x}$, P: (2, 2)
15. $T = x^3 - 3xy^2$, P: $(\sqrt{8}, \sqrt{2})$
16. $T = x/(x^2 + y^2)$, P: (4, 0)
17. $T = 3x^2y - y^3$, P: (4, −2)
18. $T = \sin x \cosh y$, P: $(\frac{1}{4}\pi, \ln 5)$

19–24 ELECTRIC FORCE

The force in an electrostatic field $f(x, y, z)$ has the direction of the gradient of f. Find ∇f and its value at P.

19. $f = (x - 1)^2 - (y + 1)^2$, P: (4, −3)
20. $f = y/(x^2 + y^2)$, P: (5, 3)
21. $f = x^2 - 2x - y^2$, P: (−2, 6)
22. $f = \ln(x^2 + y^2)$, P: (3, 3)
23. $f = (x^2 + y^2 + z^2)^{-1/2}$, P: (12, 0, 16)
24. $f = x^2y - \frac{1}{3}y^3$, P: (2, 3)
25. **(Gradient)** What does it mean if $|\text{grad } f(P)| < |\text{grad } f(Q)|$ at two points P and Q in a scalar field?
26. **(Landscape)** If $z(x, y) = 2000 - 4x^2 - y^2$ [meters] gives the elevation of a mountain above sea level, what is the direction of steepest ascent at P: (3, −6)? What does the mountain look like?

27–32 SURFACE NORMAL

Find a normal vector of the surface at the given point P.

27. $ax + by + cz = d$, any P
28. $x^2 + 3y^2 + z^2 = 28$, P: (4, 1, 3)
29. $x^2 + y^2 = 25$, P: (4, 3, 8)
30. $x^2 - y^2 + 4z^2 = 67$, P: (−2, 1, 4)
31. $x^4 + y^4 + z^4 = 243$, P: (3, 3, 3)
32. $z = x^2 + y^2$, P: (3, 4, 25)

33–38 DIRECTIONAL DERIVATIVE

Find the directional derivative of f at P in the direction of $\mathbf{a}$.

33. $f = x^2 + y^2 - z$, P: (1, 1, −2), $\mathbf{a} = [1, 1, 2]$
34. $f = x^2 + y^2 + z^2$, P: (2, −2, 1), $\mathbf{a} = [-1, -1, 0]$
35. $f = xyz$, P: (−1, 1, 3), $\mathbf{a} = [1, -2, 2]$

---

[6]CHARLES AUGUSTIN DE COULOMB (1736–1806), French physicist and engineer. Coulomb's law was derived by him from his own very precise measurements.

36. $f = (x^2 + y^2 + z^2)^{-1/2}$, P: (4, 2, −4), $\mathbf{a} = [1, 2, -2]$

37. $f = e^x \sin y$, P: $(2, \frac{1}{2}\pi, 0)$, $\mathbf{a} = [2, 3, 0]$

38. $f = 4x^2 + y^2 + 9z^2$, P: (2, 4, 0), $\mathbf{a} = [-2, -4, 3]$

39–41 POTENTIALS

for a given vector field—if they exist!—can be obtained by a method to be discussed in Sec. 9.9. In simpler cases, use inspection. Find a potential $f = \text{grad } \mathbf{v}$ for given $\mathbf{v}(x, y, z)$.

39. $\mathbf{v} = [3x, \quad 5y, \quad -4z]$

40. $\mathbf{v} = [ye^x, e^x, 2z]$

41. $\mathbf{v} = [4x^3, 3y^2, -6z]$

42. Project. Useful Formulas for Gradients and Laplacians. Prove the following formulas and give for each of them two examples showing when they are advantageous.

$$\nabla(fg) = f\nabla g + g\nabla f$$

$$\nabla(f^n) = nf^{n-1}\nabla f$$

$$\nabla(f/g) = (1/g^2)(g\nabla f - f\nabla g)$$

$$\nabla^2(fg) = g\nabla^2 f + 2\nabla f \bullet \nabla g + f\nabla^2 g$$

43. CAS PROJECT. Equipotential Curves. Graph some **isotherms** (curves of constant temperature) and indicate directions of heat flow by arrows when the temperature $T(x, y)$ equals:

(a) $x^3 - 3xy^2$ (b) $\sin x \sinh y$ (c) $e^x \sin y$.

9.8 Divergence of a Vector Field

Vector calculus owes much of its importance in engineering and physics to the gradient, divergence, and curl. From a scalar field we can obtain a vector field by the gradient (Sec. 9.7). Conversely, from a vector field we can obtain a scalar field by the divergence, or another vector field by the curl (to be discussed in Sec. 9.9). These concepts were suggested by basic physical applications, as we shall see.

To begin, let $\mathbf{v}(x, y, z)$ be a differentiable vector function, where x, y, z are Cartesian coordinates, and let v_1, v_2, v_3 be the components of $\mathbf{v}$. Then the function

$$\text{(1)} \qquad \text{div } \mathbf{v} = \frac{\partial v_1}{\partial x} + \frac{\partial v_2}{\partial y} + \frac{\partial v_3}{\partial z}$$

is called the **divergence** of $\mathbf{v}$ or the *divergence of the vector field defined by* $\mathbf{v}$. For example, if

$$\mathbf{v} = [3xz, 2xy, -yz^2] = 3xz\mathbf{i} + 2xy\mathbf{j} - yz^2\mathbf{k}, \qquad \text{then} \qquad \text{div } \mathbf{v} = 3z + 2x - 2yz.$$

Another common notation for the divergence is

$$\text{div } \mathbf{v} = \nabla \bullet \mathbf{v} = \left[\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right] \bullet [v_1, v_2, v_3]$$

$$= \left(\frac{\partial}{\partial x}\mathbf{i} + \frac{\partial}{\partial y}\mathbf{j} + \frac{\partial}{\partial z}\mathbf{k}\right) \bullet (v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k})$$

$$= \frac{\partial v_1}{\partial x} + \frac{\partial v_2}{\partial y} + \frac{\partial v_3}{\partial z},$$

with the understanding that the "product" $(\partial/\partial x)v_1$ in the dot product means the partial derivative $\partial v_1/\partial x$, etc. This is a convenient notation, but nothing more. Note that $\nabla \bullet \mathbf{v}$ means the scalar div $\mathbf{v}$, whereas ∇f means the vector grad f defined in Sec. 9.7.

In Example 2 we shall see that the divergence has an important physical meaning. Clearly, the values of a function that characterizes a physical or geometric property must be independent of the particular choice of coordinates; that is, those values must be invariant with respect to coordinate transformations. Accordingly, the following theorem should hold.

THEOREM 1

Invariance of the Divergence

The divergence div $\mathbf{v}$ *is a scalar function, that is, its values depend only on the points in space* (and, of course, on $\mathbf{v}$) *but not on the choice of the coordinates in* (1), *so that with respect to other Cartesian coordinates* x^*, y^*, z^* *and corresponding components* v_1^*, v_2^*, v_3^* *of* $\mathbf{v}$,

(2)
$$\operatorname{div} \mathbf{v} = \frac{\partial v_1^*}{\partial x^*} + \frac{\partial v_2^*}{\partial y^*} + \frac{\partial v_3^*}{\partial z^*}.$$

We shall prove this theorem in Sec. 10.7, using integrals.

Presently, let us turn to the more immediate practical task of gaining a feel for the significance of the divergence as follows. Let $f(x, y, z)$ be a twice differentiable scalar function. Then its gradient exists,

$$\mathbf{v} = \operatorname{grad} f = \left[\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right] = \frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k}$$

and we can differentiate once more, the first component with respect to x, the second with respect to y, the third with respect to z, and then form the divergence,

$$\operatorname{div} \mathbf{v} = \operatorname{div} (\operatorname{grad} f) = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}.$$

Hence we have the basic result that *the divergence of the gradient is the Laplacian* (Sec. 9.7),

(3)
$$\operatorname{div} (\operatorname{grad} f) = \nabla^2 f.$$

EXAMPLE 1 **Gravitational Force. Laplace's Equation**

The gravitational force $\mathbf{p}$ in Theorem 3 of the last section is the gradient of the scalar function $f(x, y, z) = c/r$, which satisfies Laplaces equation $\nabla^2 f = 0$. According to (3) this implies that div $\mathbf{p} = 0$ $(r > 0)$. ■

The following example from hydrodynamics shows the physical significance of the divergence of a vector field. (More physical details on this significance will be added in Sec. 10.8.)

EXAMPLE 2 Flow of a Compressible Fluid. Physical Meaning of the Divergence

We consider the motion of a fluid in a region R having no **sources** or **sinks** in R, that is, no points at which fluid is produced or disappears. The concept of **fluid state** is meant to cover also gases and vapors. Fluids in the restricted sense, or **liquids** (water or oil, for instance), have very small compressibility, which can be neglected in many problems. Gases and vapors have large compressibility; that is, their density ρ (= mass per unit volume) depends on the coordinates x, y, z in space (and may depend on time t). We assume that our fluid is compressible.

We consider the flow through a rectangular box B of small edges Δx, Δy, Δz parallel to the coordinate axes (Fig. 216), (Δ is a standard notation for small quantities; of course, it has nothing to do with the notation for the Laplacian in (11) of Sec. 9.7.) The box B has the volume $\Delta V = \Delta x\, \Delta y\, \Delta z$. Let $\mathbf{v} = [v_1, v_2, v_3] = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$ be the velocity vector of the motion. We set

$$\mathbf{u} = \rho\mathbf{v} = [u_1, u_2, u_3] = u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k} \tag{4}$$

and assume that $\mathbf{u}$ and $\mathbf{v}$ are continuously differentiable vector functions of x, y, z, and t (that is, they have first partial derivatives which are continuous). Let us calculate the change in the mass included in B by considering the **flux** across the boundary, that is, the total loss of mass leaving B per unit time. Consider the flow through the left of the three faces of B that are visible in Fig. 216, whose area is $\Delta x\, \Delta z$. Since the vectors $v_1\,\mathbf{i}$ and $v_3\,\mathbf{k}$ are parallel to that face, the components v_1 and v_3 of $\mathbf{v}$ contribute nothing to this flow. Hence the mass of fluid entering through that face during a short time interval Δt is given approximately by

$$(\rho v_2)_y\, \Delta x\, \Delta z\, \Delta t = (u_2)_y\, \Delta x\, \Delta z\, \Delta t,$$

where the subscript y indicates that this expression refers to the left face. The mass of fluid leaving the box B through the opposite face during the same time interval is approximately $(u_2)_{y+\Delta y}\, \Delta x\, \Delta z\, \Delta t$, where the subscript $y + \Delta y$ indicates that this expression refers to the right face (which is not visible in Fig. 216). The difference

$$\Delta u_2\, \Delta x\, \Delta z\, \Delta t = \frac{\Delta u_2}{\Delta y}\, \Delta V\, \Delta t \qquad [\Delta u_2 = (u_2)_{y+\Delta y} - (u_2)_y]$$

is the approximate loss of mass. Two similar expressions are obtained by considering the other two pairs of parallel faces of B. If we add these three expressions, we find that the total loss of mass in B during the time interval Δt is approximately

$$\left(\frac{\Delta u_1}{\Delta x} + \frac{\Delta u_2}{\Delta y} + \frac{\Delta u_3}{\Delta z}\right) \Delta V\, \Delta t,$$

where

$$\Delta u_1 = (u_1)_{x+\Delta x} - (u_1)_x \qquad \text{and} \qquad \Delta u_3 = (u_3)_{z+\Delta z} - (u_3)_z.$$

This loss of mass in B is caused by the time rate of change of the density and is thus equal to

$$-\frac{\partial p}{\partial t}\, \Delta V\, \Delta t.$$

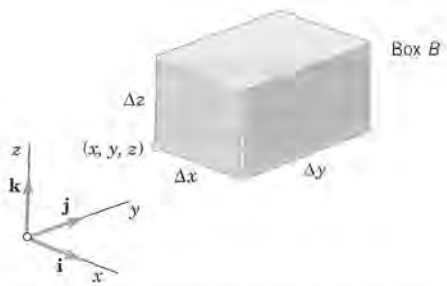

Fig. 216. Physical interpretation of the divergence

If we equate both expressions, divide the resulting equation by $\Delta V\,\Delta t$, and let Δx, Δy, Δz, and Δt approach zero, then we obtain

$$\operatorname{div} \mathbf{u} = \operatorname{div} (\rho \mathbf{v}) = -\frac{\partial \rho}{\partial t}$$

or

$$\frac{\partial \rho}{\partial t} + \operatorname{div} (\rho \mathbf{v}) = 0. \tag{5}$$

This important relation is called the *condition for the conservation of mass* or the **continuity equation** *of a compressible fluid flow.*

If the flow is **steady,** that is, independent of time, then $\partial \rho / \partial t = 0$ and the continuity equation is

$$\operatorname{div} (\rho \mathbf{v}) = 0. \tag{6}$$

If the density ρ is constant, so that the fluid is incompressible, then equation (6) becomes

$$\operatorname{div} \mathbf{v} = 0. \tag{7}$$

This relation is known as the **condition of incompressibility.** It expresses the fact that the balance of outflow and inflow for a given volume element is zero at any time. Clearly, the assumption that the flow has no sources or sinks in R is essential to our argument.

From this discussion you should conclude and remember that, roughly speaking, ***the divergence measures outflow minus inflow.*** ■

Comment. The **divergence theorem** of Gauss, an integral theorem involving the divergence, follows in the next chapter (Sec. 10.7).

PROBLEM SET 9.8

1–7 CALCULATION OF THE DIVERGENCE

Find the divergence of the following vector functions.

1. $[x^3 + y^3, \quad 3xy^2, \quad 3zy^2]$
2. $[e^{2x} \cos 2y, \quad e^{2x} \sin 2y, \quad 5e^{2z}]$
3. $[x^2 + y^2, \quad 2xyz, \quad z^2 + x^2]$
4. $(x^2 + y^2 + z^2)^{-3/2}[x, \quad y, \quad z]$
5. $[\sin xy, \quad \sin xy, \quad z \cos xy]$
6. $[v_1(y, z), \quad v_2(z, x), \quad v_3(x, y)]$
7. $x^2y^2z^2[x, \quad y, \quad z]$
8. Let $\mathbf{v} = [x, \quad y, \quad v_3]$. Find a v_3 such that (a) $\operatorname{div} \mathbf{v} > 0$ everywhere, (b) $\operatorname{div} \mathbf{v} > 0$ if $|z| < 1$ and $\operatorname{div} \mathbf{v} < 0$ if $|z| > 1$.
9. **(Incompressible flow)** Show that the flow with velocity vector $\mathbf{v} = y\mathbf{i}$ is incompressible. Show that the particles that at time $t = 0$ are in the cube whose faces are portions of the planes $x = 0, x = 1, y = 0, y = 1, z = 0, z = 1$ occupy at $t = 1$ the volume 1.
10. **(Compressible flow)** Consider the flow with velocity vector $\mathbf{v} = x\mathbf{i}$. Show that the individual particles have the position vectors $\mathbf{r}(t) = c_1e^t\mathbf{i} + c_2\mathbf{j} + c_3\mathbf{k}$ with constant c_1, c_2, c_3. Show that the particles that at $t = 0$ are in the cube of Prob. 9 at $t = 1$ occupy the volume e.
11. **(Rotational flow)** The velocity vector $\mathbf{v}(x, y, z)$ of an incompressible fluid rotating in a cylindrical vessel is of the form $\mathbf{v} = \mathbf{w} \times \mathbf{r}$, where $\mathbf{w}$ is the (constant) rotation vector; see Example 5 in Sec. 9.3. Show that $\operatorname{div} \mathbf{v} = 0$. Is this plausible because of our present Example 2?
12. **CAS PROJECT. Visualizing the Divergence.** Graph the given velocity field $\mathbf{v}$ of a fluid flow in a square centered at the origin with sides parallel to the coordinate axes. Recall that the divergence measures outflow minus inflow. By looking at the flow near the sides of the square, can you see whether $\operatorname{div} \mathbf{v}$ must be positive or negative or may perhaps be zero? Then calculate $\operatorname{div} \mathbf{v}$. First do the given flows and then do some of your own. Enjoy it.
    (a) $\mathbf{v} = \mathbf{i}$
    (b) $\mathbf{v} = x\mathbf{i}$
    (c) $\mathbf{v} = x\mathbf{i} - y\mathbf{j}$
    (d) $\mathbf{v} = x\mathbf{i} + y\mathbf{j}$
    (e) $\mathbf{v} = -x\mathbf{i} - y\mathbf{j}$
    (f) $\mathbf{v} = (x^2 + y^2)^{-1}(-y\mathbf{i} + x\mathbf{j})$

13. PROJECT. Useful Formulas for the Divergence. Prove

(a) div $(k\mathbf{v}) = k$ div $\mathbf{v}$ (k constant)

(b) div $(f\mathbf{v}) = f$ div $\mathbf{v} + \mathbf{v} \cdot \nabla f$

(c) div $(f\nabla g) = f\nabla^2 g + \nabla f \cdot \nabla g$

(d) div $(f\nabla g)$ − div $(g\nabla f) = f\nabla^2 g - g\nabla^2 f$.

Verify (b) for $f = e^{xyz}$ and $\mathbf{v} = ax\mathbf{i} + by\mathbf{j} + cz\mathbf{k}$. Obtain the answer to Prob. 4 from (b). Verify (c) for $f = x^2 - y^2$ and $g = e^{x+y}$. Give examples of your own for which (a)−(d) are advantageous.

14–20 CALCULATION OF THE LAPLACIAN BY (3)

Find $\nabla^2 f$ by (3). Check by differentiation. Indicate when (3) is simpler. (Show the details of your work.)

14. $f = xy/z^2$

15. $f = (y + x)/(y - x)$

16. $f = z - 4\sqrt{x^2 + y^2}$

17. $f = e^{x^2 - y^2} \cos 2xy$

18. $f = \arctan(y/x)$

19. $f = e^{xyz}$

20. $f = \cos^2 x - \sin^2 y$

9.9 Curl of a Vector Field

Gradient (Sec. 9.7), divergence (Sec. 9.8), and curl are basic in connection with fields, and we now define and discuss the curl.

Let $\mathbf{v}(x, y, z) = [v_1, v_2, v_3] = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$ be a differentiable vector function of the Cartesian coordinates x, y, z. Then the **curl** *of the vector function* $\mathbf{v}$ or *of the vector field given by* $\mathbf{v}$ is defined by the "symbolic" determinant

$$\text{(1)} \qquad \operatorname{curl} \mathbf{v} = \nabla \times \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ v_1 & v_2 & v_3 \end{vmatrix}$$

$$= \left(\frac{\partial v_3}{\partial y} - \frac{\partial v_2}{\partial z}\right)\mathbf{i} + \left(\frac{\partial v_1}{\partial z} - \frac{\partial v_3}{\partial x}\right)\mathbf{j} + \left(\frac{\partial v_2}{\partial x} - \frac{\partial v_1}{\partial y}\right)\mathbf{k}.$$

This is the formula when x, y, z are *right-handed*. If they are *left-handed*, the determinant has a minus sign in front (just as in (2**) in Sec. 9.3).

Instead of curl $\mathbf{v}$ one also uses the notation rot $\mathbf{v}$ (suggested by "rotation"; see Example 2).

EXAMPLE 1 Curl of a Vector Function

Let $\mathbf{v} = [yz, \ 3zx, \ z] = yz\mathbf{i} + 3zx\mathbf{j} + z\mathbf{k}$ with right-handed x, y, z. Then (1) gives

$$\operatorname{curl} \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ yz & 3zx & z \end{vmatrix} = -3x\mathbf{i} + y\mathbf{j} + (3z - z)\mathbf{k} = -3x\mathbf{i} + y\mathbf{j} + 2z\mathbf{k}. \qquad \blacksquare$$

The curl plays an important role in many applications. Let us illustrate this with a typical basic example. More about the nature and significance of the curl will be said in Sec. 10.9.

EXAMPLE 2 Rotation of a Rigid Body. Relation to the Curl

We have seen in Example 5, Sec. 9.3, that a rotation of a rigid body B about a fixed axis in space can be described by a vector $\mathbf{w}$ of magnitude ω in the direction of the axis of rotation, where ω (> 0) is the angular speed of the rotation, and $\mathbf{w}$ is directed so that the rotation appears clockwise if we look in the direction of $\mathbf{w}$. According to (9), Sec. 9.3, the velocity field of the rotation can be represented in the form

$$\mathbf{v} = \mathbf{w} \times \mathbf{r}$$

where $\mathbf{r}$ is the position vector of a moving point with respect to a Cartesian coordinate system *having the origin on the axis of rotation*. Let us choose right-handed Cartesian coordinates such that the axis of rotation is the z-axis. Then (see Example 2 in Sec. 9.4)

$$\mathbf{w} = [0, \quad 0, \quad \omega] = \omega\mathbf{k}, \qquad \mathbf{v} = \mathbf{w} \times \mathbf{r} = [-\omega y, \quad \omega x, \quad 0] = -\omega y\mathbf{i} + \omega x\mathbf{j}.$$

Hence

$$\operatorname{curl} \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ -\omega y & \omega x & 0 \end{vmatrix} = [0, \quad 0, \quad 2\omega] = 2\omega\mathbf{k} = 2\mathbf{w}.$$

This proves the following theorem. ■

THEOREM 1

Rotating Body and Curl

The curl of the velocity field of a rotating rigid body has the direction of the axis of the rotation, and its magnitude equals twice the angular speed of the rotation.

The following two relations among grad, div, and curl are basic and shed further light on the nature of the curl.

THEOREM 2

Grad, Div, Curl

***Gradient fields** are **irrotational.** That is, if a continuously differentiable vector function is the gradient of a scalar function f, then its curl is the zero vector,*

$$\text{(2)} \qquad \operatorname{curl}(\operatorname{grad} f) = \mathbf{0}.$$

Furthermore, the divergence of the curl of a twice continuously differentiable vector function $\mathbf{v}$ is zero,

$$\text{(3)} \qquad \operatorname{div}(\operatorname{curl} \mathbf{v}) = 0.$$

PROOF Both (2) and (3) follow directly from the definitions by straightforward calculation. In the proof of (3) the six terms cancel in pairs. ■

EXAMPLE 3 **Rotational and Irrotational Fields**

The field in Example 2 is not irrotational. A similar velocity field is obtained by stirring tea or coffee in a cup. The gravitational field in Theorem 3 of Sec. 9.7 has curl $\mathbf{p} = \mathbf{0}$. It is an irrotational gradient field. ■

The term "irrotational" for curl $\mathbf{v} = \mathbf{0}$ is suggested by the use of the curl for characterizing the rotation in a field. If a gradient field occurs elsewhere, not as a velocity field, it is usually called **conservative** (see Sec. 9.7). Relation (3) is plausible because of the interpretation of the curl as a rotation and of the divergence as a flux (see Example 2 in Sec. 9.8).

Finally, since the curl is defined in terms of coordinates, we should do what we did for the gradient in Sec. 9.7, namely, to find out whether the curl is a vector. This is true, as follows.

THEOREM 3

Invariance of the Curl

curl **v** *is a vector. That is, it has a length and direction that are independent of the particular choice of a Cartesian coordinate system in space.* (Proof in App. 4.)

PROBLEM SET 9.9

1–6 CALCULATION OF CURL

Find curl **v** for **v** given with respect to right-handed Cartesian coordinates. Show the details of your work.

1. $[y, \quad 2x^2, \quad 0]$
2. $[y^n, \quad z^n, \quad x^n] \qquad (n > 0, \text{ integer})$
3. $[e^x \cos y, \quad e^x \sin y, \quad 0]$
4. $(x^2 + y^2 + z^2)^{-3/2}[x, \quad y, \quad z]$
5. $[\ln (x^2 + y^2), \ 2 \arctan (y/x), \quad 0]$
6. $[\sin y, \quad \cos z, \quad -\tan x]$
7. What direction does curl **v** have if **v** is a vector parallel to the xz-plane?
8. Prove Theorem 2. Give two examples for (2) and (3) each.

9–14 FLUID FLOW

Let **v** be the velocity vector of a steady fluid flow. Is the flow irrotational? Incompressible? Find the **streamlines** (the paths of the particles). *Hint.* See the answers to Probs. 9 and 11 for a determination of a path.

9. $\mathbf{v} = [0, \quad z^2, \quad 0]$
10. $\mathbf{v} = [-y^2, \quad 4, \quad 0]$
11. $\mathbf{v} = [y, \quad -x, \quad 0]$
12. $\mathbf{v} = [\csc x, \quad \sec x, \quad 0]$
13. $\mathbf{v} = [x, \quad -y, \quad z]$
14. $\mathbf{v} = [y^3, \quad -x^3, \quad 0]$
15. **WRITING PROJECT. Summary on Grad, Div, Curl.** List the definition and most important facts and formulas for grad, div, curl, and ∇^2. Use your list to write a corresponding essay of 3–4 pages. Include typical examples of your own.
16. **PROJECT. Useful Formulas for the Curl.** Assuming sufficient differentiability, show that
    (a) curl $(\mathbf{u} + \mathbf{v})$ = curl **u** + curl **v**
    (b) div (curl **v**) = 0
    (c) curl $(f\mathbf{v})$ = (grad f) × **v** + f curl **v**
    (d) curl (grad f) = **0**
    (e) div $(\mathbf{u} \times \mathbf{v})$ = **v**•curl **u** − **u**•curl **v**.

17–20 EXPRESSIONS INVOLVING THE CURL

With respect to right-handed coordinates, let $\mathbf{u} = [y^2, \quad z^2, \quad x^2]$, $\mathbf{v} = [yz, \quad zx, \quad xy]$, $f = xyz$, and $g = x + y + z$. Find the following expressions. If one of the formulas in Project 16 applies, use it to check your result. (Show the details of your work.)

17. curl **v**, curl $(f\mathbf{v})$, curl $(g\mathbf{v})$
18. curl $(f\mathbf{u})$, curl $(g\mathbf{u})$
19. **u** × curl **v**, **v** × curl **v**, **u**•curl **v**, **v**•curl **u**
20. curl $(\mathbf{u} \times \mathbf{v})$, curl $(\mathbf{v} \times \mathbf{u})$

CHAPTER 9 REVIEW QUESTIONS AND PROBLEMS

1. Why did we discuss vectors in R^2 and R^3 in a separate chapter, in addition to Chap. 7 on R^n?
2. What are applications that motivate inner products, vector products, scalar triple products?
3. What is wrong with the expression **a** × **b** × **c**? With **a**•**b**•**c**? With (**a**•**b**) × **c**?
4. What are scalar fields? Vector fields? Potentials? Give examples.
5. What is the gradient? How is it related to directional derivatives?
6. Explain "right-handed coordinates," "orthonormal basis," "tangential acceleration."
7. What is the definition of the divergence? Its physical meaning? Its relation to the Laplacian?
8. Granted sufficient differentiability of a scalar function f and a vector function **v**, which of the following make sense? grad f, f grad f, **v** grad f, **v**•grad f, div f, div **v**, div $(f\mathbf{v})$, curl $(f\mathbf{v})$, curl f, f curl **v**, **v** curl f.
9. If $\mathbf{r}(t)$ represents a motion, what is $\mathbf{r}'(t)$, $|\mathbf{r}'(t)|$, $\mathbf{r}''(t)$, $|\mathbf{r}''(t)|$?

10. How do you express the resultant of forces, the moment of a force, and the work done by a force in terms of vectors?

11–20 VECTOR ADDITION, SCALAR MULTIPLICATION, PRODUCTS

In right-handed coordinates let $\mathbf{a} = [3, 2, 7]$, $\mathbf{b} = [6, 5, -4]$, $\mathbf{c} = [1, 8, 0]$, $\mathbf{d} = [9, -2, 0]$. Find

11. $4\mathbf{a} + \mathbf{b} - \mathbf{c} - 2\mathbf{d}$

12. $\mathbf{a} \cdot \mathbf{b}$, $\mathbf{a} \cdot \mathbf{c}$, $\mathbf{a} \times \mathbf{c}$

13. $\mathbf{b} \times \mathbf{b}$, $\mathbf{a} \times \mathbf{b}$, $\mathbf{b} \times \mathbf{a}$

14. $3\mathbf{a} \cdot 4\mathbf{a}$, $12\mathbf{a} \cdot \mathbf{a}$, $12|\mathbf{a}|^2$, $|\mathbf{b}|^2$

15. $2\mathbf{c} \times 5\mathbf{d}$, $10\mathbf{c} \times \mathbf{d}$

16. $(\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c}$, $\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})$, $(\mathbf{a} \quad \mathbf{b} \quad \mathbf{c})$

17. $(\mathbf{a} \times \mathbf{b}) \times \mathbf{c}$, $\mathbf{a} \times (\mathbf{b} \times \mathbf{c})$

18. $(1/|\mathbf{a}|)\mathbf{a}$, $(1/|\mathbf{c}|)\mathbf{c}$

19. $(\mathbf{a} \quad \mathbf{b} \quad \mathbf{d})$, $(\mathbf{d} \quad \mathbf{a} \quad \mathbf{b})$

20. $\big||\mathbf{a}| - |\mathbf{b}|\big|$, $|\mathbf{a} + \mathbf{b}|$, $|\mathbf{a}| + |\mathbf{b}|$

21. (Angle) Find the angle between $\mathbf{a}$ and $\mathbf{b}$. Between $\mathbf{c}$ and $\mathbf{d}$. Sketch $\mathbf{c}$ and $\mathbf{d}$.

22. (Angle) Find the angle between the planes $4x + 3y - z = 2$ and $x + y + z = 1$.

23. In what case is $\mathbf{u} \times \mathbf{v} = \mathbf{v} \times \mathbf{u}$? $\mathbf{u} \cdot \mathbf{v} = \mathbf{v} \cdot \mathbf{u}$?

24. (Resultant) Find $\mathbf{u}$ such that $\mathbf{a}, \mathbf{b}, \mathbf{c}, \mathbf{d}$ above, and $\mathbf{u}$ are in equilibrium.

25. (Resultant) Find the most general $\mathbf{v}$ such that the resultant of $\mathbf{a}, \mathbf{b}, \mathbf{c}, \mathbf{d}$ above, and $\mathbf{v}$ is parallel to the xy-plane.

26. (Work) Find the work done by $\mathbf{q} = [5, 1, 0]$ in the displacement from $(4, 4, 0)$ to $(6, -1, 0)$.

27. (Component) Find the component of $\mathbf{u} = [-1, 5, 0]$ in the direction of $\mathbf{v} = [3, 4, 0]$.

28. (Component) In what cases is the component of $\mathbf{a}$ in the direction of $\mathbf{b}$ equal to the component of $\mathbf{b}$ in the direction of $\mathbf{a}$?

29. (Component) When is the component of $\mathbf{a}$ in the direction of $\mathbf{b}$ negative? Zero?

30. (Moment) Find the moment vector $\mathbf{m}$ of $\mathbf{p} = [4, 2, 0]$ about P: $(5, 1, 0)$ if $\mathbf{p}$ acts on a line through $(1, 4, 0)$. Make a sketch.

31. (Moment) In what cases is the moment of a force $\mathbf{p} \neq \mathbf{0}$ zero?

32. (Velocity, acceleration) Find the velocity, speed, and acceleration of the motion given by

$$\mathbf{r}(t) = [5 \cos t, \quad \sin t, \quad 2t]$$

at the point P: $[5/\sqrt{2}, \ 1/\sqrt{2}, \ \pi/2]$. What kind of curve is the path?

33. (Tetrahedron) Find the volume of the tetrahedron with vertices $(0, 0, 0)$, $(1, 2, 0)$, $(3, -3, 0)$, $(1, 1, 5)$.

34. (Plane) Find an equation of the plane through $(1, 0, 2)$, $(2, 3, 5)$, $(3, 5, 7)$.

35. (Linear dependence) Are $[2, -1, 3]$, $[4, 2, -5]$, $[-1, 6, 0]$ linearly dependent? (Give reason.)

36–45 GRAD, DIV, CURL, ∇^2, DIRECTIONAL DERIVATIVE

Let $f = zy + yx$, $\mathbf{v} = [y, z, 4z - x]$, $\mathbf{w} = [y^2, z^2, x^2]$. Find

36. grad f and f grad f at $(3, 4, 0)$

37. (grad f) $\times$ grad f, (grad f) $\cdot$ grad f

38. div $\mathbf{v}$, div $\mathbf{w}$

39. curl $\mathbf{v}$, curl $\mathbf{w}$

40. curl (grad f), div (grad f), div $\mathbf{v}$

41. $\nabla^2(f)$, $\nabla^2(f^2)$

42. $D_{\mathbf{w}}f$ at $(1, 2, 0)$

43. $D_{\mathbf{v}}f$ at $(3, 7, 5)$

44. div $(\mathbf{v} \times \mathbf{w})$

45. curl $(\mathbf{v} \times \mathbf{w})$ + curl $(\mathbf{w} \times \mathbf{v})$

SUMMARY OF CHAPTER 9

Vector Differential Calculus. Grad, Div, Curl

All vectors of the form $\mathbf{a} = [a_1, a_2, a_3] = a_1\mathbf{i} + a_2\mathbf{j} + a_3\mathbf{k}$ constitute the **real vector space** R^3 with componentwise vector addition

$$(1) \qquad [a_1, a_2, a_3] + [b_1, b_2, b_3] = [a_1 + b_1, a_2 + b_2, a_3 + b_3]$$

and componentwise scalar multiplication (c a scalar, a real number)

$$(2) \qquad c[a_1, a_2, a_3] = [ca_1, ca_2, ca_3] \qquad \text{(Sec. 9.1).}$$

For instance, the *resultant* of forces **a** and **b** is the sum **a** + **b.**

The **inner product** or **dot product** of two vectors is defined by

$$\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}||\mathbf{b}| \cos \gamma = a_1 b_1 + a_2 b_2 + a_3 b_3 \tag{3}$$

(Sec. 9.2)

where γ is the angle between **a** and **b.** This gives for the **norm** or **length** $|\mathbf{a}|$ of **a**

$$|\mathbf{a}| = \sqrt{\mathbf{a} \cdot \mathbf{a}} = \sqrt{a_1^2 + a_2^2 + a_3^2} \tag{4}$$

as well as a formula for γ. If $\mathbf{a} \cdot \mathbf{b} = 0$, we call **a** and **b orthogonal.** The dot product is suggested by the *work* $W = \mathbf{p} \cdot \mathbf{d}$ done by a force **p** in a displacement **d.**

The **vector product** or **cross product** $\mathbf{v} = \mathbf{a} \times \mathbf{b}$ is a vector of length

$$|\mathbf{a} \times \mathbf{b}| = |\mathbf{a}|\,|\mathbf{b}| \sin \gamma \tag{5}$$

(Sec. 9.3)

and perpendicular to both **a** and **b** such that **a, b, v** form a *right-handed* triple. In terms of components with respect to right-handed coordinates,

$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix} \tag{6}$$

(Sec. 9.3).

The vector product is suggested, for instance, by moments of forces or by rotations. CAUTION! This multiplication is *anti*commutative, $\mathbf{a} \times \mathbf{b} = -\mathbf{b} \times \mathbf{a}$, and is *not* associative.

An (oblique) box with edges **a, b, c** has volume equal to the absolute value of the **scalar triple product**

$$(\mathbf{a} \quad \mathbf{b} \quad \mathbf{c}) = \mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c}. \tag{7}$$

Sections 9.4–9.9 extend differential calculus to vector functions

$$\mathbf{v}(t) = [v_1(t), v_2(t), v_3(t)] = v_1(t)\mathbf{i} + v_2(t)\mathbf{j} + v_3(t)\mathbf{k}$$

and to vector functions of more than one variable (see below). The derivative of $\mathbf{v}(t)$ is

$$\mathbf{v}' = \frac{d\mathbf{v}}{dt} = \lim_{\Delta t \to 0} \frac{\mathbf{v}(t + \Delta t) - \mathbf{v}(t)}{\Delta t} = [v_1', v_2', v_3'] = v_1'\mathbf{i} + v_2'\mathbf{j} + v_3'\mathbf{k}. \tag{8}$$

Differentiation rules are as in calculus. They imply (Sec. 9.4)

$$(\mathbf{u} \cdot \mathbf{v})' = \mathbf{u}' \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{v}', \qquad (\mathbf{u} \times \mathbf{v})' = \mathbf{u}' \times \mathbf{v} + \mathbf{u} \times \mathbf{v}'.$$

Curves C in space represented by the position vector $\mathbf{r}(t)$ have $\mathbf{r}'(t)$ as a **tangent vector** (the **velocity** in mechanics when t is time), $\mathbf{r}'(s)$ (s arc length, Sec. 9.5) as the *unit tangent vector,* and $|\mathbf{r}''(s)| = \kappa$ as the *curvature* (the *acceleration* in mechanics).

Vector functions $\mathbf{v}(x, y, z) = [v_1(x, y, z), v_2(x, y, z), v_3(x, y, z)]$ represent vector fields in space. Partial derivatives with respect to the Cartesian coordinates x, y, z are obtained componentwise, for instance,

$$\frac{\partial \mathbf{v}}{\partial x} = \left[\frac{\partial v_1}{\partial x}, \frac{\partial v_2}{\partial x}, \frac{\partial v_3}{\partial x}\right] = \frac{\partial v_1}{\partial x}\mathbf{i} + \frac{\partial v_2}{\partial x}\mathbf{j} + \frac{\partial v_3}{\partial x}\mathbf{k} \quad \text{(Sec. 9.6).}$$

The **gradient** of a scalar function f is

$$\text{grad } f = \nabla f = \left[\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right] \tag{9}$$ (Sec. 9.7).

The **directional derivative** of f in the direction of a vector $\mathbf{a}$ is

$$D_{\mathbf{a}} f = \frac{df}{ds} = \frac{1}{|\mathbf{a}|}\,\mathbf{a} \bullet \nabla f \tag{10}$$ (Sec. 9.7).

The **divergence** of a vector function $\mathbf{v}$ is

$$\text{div } \mathbf{v} = \nabla \bullet \mathbf{v} = \frac{\partial v_1}{\partial x} + \frac{\partial v_2}{\partial y} + \frac{\partial v_3}{\partial z}, \tag{11}$$ (Sec. 9.8).

The **curl** of $\mathbf{v}$ is

$$\text{curl } \mathbf{v} = \nabla \times \mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ v_1 & v_2 & v_3 \end{vmatrix} \tag{12}$$ (Sec. 9.9)

or minus the determinant if the coordinates are left-handed.

Some basic formulas for grad, div, curl are (Secs. 9.7–9.9)

$$\begin{aligned} \nabla(fg) &= f\nabla g + g\nabla f \\ \nabla(f/g) &= (1/g^2)(g\nabla f - f\nabla g) \end{aligned} \tag{13}$$

$$\begin{aligned} \text{div } (f\mathbf{v}) &= f \text{ div } \mathbf{v} + \mathbf{v} \bullet \nabla f \\ \text{div } (f\nabla g) &= f\nabla^2 g + \nabla f \bullet \nabla g \end{aligned} \tag{14}$$

$$\begin{aligned} \nabla^2 f &= \text{div } (\nabla f) \\ \nabla^2(fg) &= g\nabla^2 f + 2\nabla f \bullet \nabla g + f\nabla^2 g \end{aligned} \tag{15}$$

$$\begin{aligned} \text{curl } (f\mathbf{v}) &= \nabla f \times \mathbf{v} + f \text{ curl } \mathbf{v} \\ \text{div } (\mathbf{u} \times \mathbf{v}) &= \mathbf{v} \bullet \text{curl } \mathbf{u} - \mathbf{u} \bullet \text{curl } \mathbf{v} \end{aligned} \tag{16}$$

$$\begin{aligned} \text{curl } (\nabla f) &= \mathbf{0} \\ \text{div } (\text{curl } \mathbf{v}) &= 0. \end{aligned} \tag{17}$$

For grad, div, curl, and ∇^2 in **curvilinear coordinates** see App. A3.4.

CHAPTER 10

Vector Integral Calculus. Integral Theorems

This chapter is the companion to Chap. 9. Whereas the previous chapter dealt with differentiation in vector calculus, this chapter concerns integration. This vector integral calculus extends integrals as known from calculus to integrals over curves ("line integrals"), surfaces ("surface integrals"), and solids. We shall see that these integrals have basic engineering applications in solid mechanics, in fluid flow, and in heat problems.

These different kinds of integrals can be transformed into one another. This is done to simplify evaluations or to gain useful general formulas, for instance, in potential theory (see Sec. 10.8). Such transformations are done by the powerful formulas of Green (line integrals into double integrals or conversely, Sec. 10.4), Gauss (surface integrals into triple integrals or conversely, Sec. 10.7), and Stokes (line integrals into surface integrals or conversely, Sec. 10.9).

The root of these transformations was largely physical intuition. The corresponding formulas involve the divergence and the curl and will thus lead to a deeper physical understanding of these two operations.

Prerequisite: Elementary integral calculus, Secs. 9.7–9.9
Sections that may be omitted in a shorter course: 10.3, 10.5, 10.8
References and Answers to Problems: App. 1 Part B, App. 2

10.1 Line Integrals

The concept of a line integral is a simple and natural generalization of a definite integral

$$\int_a^b f(x)\,dx \tag{1}$$

known from calculus. In (1) we integrate the *integrand* $f(x)$ from $x = a$ along the x-axis to $x = b$. In a line integral we shall integrate a given function, also called the **integrand,** along a curve C in space (or in the plane). Hence *curve integral* would be a better name, but line integral is standard.

We represent the curve C by a parametric representation (as in Sec. 9.5)

$$\mathbf{r}(t) = [x(t), y(t), z(t)] = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k} \qquad (a \leqq t \leqq b). \tag{2}$$

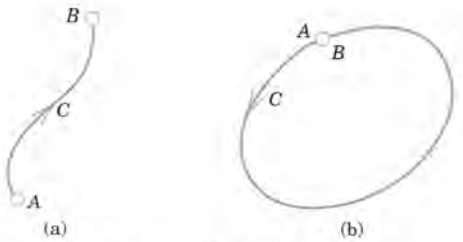

Fig. 217. Oriented curve

The curve C is called the **path of integration,** A: $\mathbf{r}(a)$ its *initial point,* and B: $\mathbf{r}(b)$ its terminal point. C is now *oriented.* The direction from A to B, in which t increases, is called the *positive direction* on C and can be marked by an arrow (as in Fig. 217a). The points A and B may coincide (as in Fig. 217b). Then C is called a *closed path.*

C is called a **smooth curve** if it has at each point a unique tangent whose direction varies continuously as we move along C. Technically: $\mathbf{r}(t)$ in (2) is differentiable and the derivative $\mathbf{r}'(t) = d\mathbf{r}/dt$ is continuous and different from the zero vector at every point of C.

General Assumption

In this book, every path of integration of a line integral is assumed to be **piecewise smooth;** *that is, it consists of* ***finitely many*** *smooth curves.*

For example, the boundary curve of a square is piecewise smooth, consisting of four smooth curves (segments, the four sides).

Definition and Evaluation of Line Integrals

A **line integral** of a vector function $\mathbf{F}(\mathbf{r})$ over a curve C: $\mathbf{r}(t)$ [as in (2)] is defined by

$$\int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_a^b \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\, dt \qquad \mathbf{r}' = \frac{d\mathbf{r}}{dt} \tag{3}$$

(see Sec. 9.2 for the dot product). In terms of components, with $d\mathbf{r} = [dx,\ dy,\ dz]$ as in Sec. 9.5 and $' = d/dt$, formula (3) becomes

$$\begin{aligned} \int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} &= \int_C (F_1\, dx + F_2\, dy + F_3\, dz) \\ &= \int_a^b (F_1 x' + F_2 y' + F_3 z')\, dt. \end{aligned} \tag{3'}$$

If the path of integration C in (3) is a *closed* curve, then instead of

$$\int_C \qquad \text{we also write} \qquad \oint_C.$$

Note that the integrand in (3) is a scalar, not a vector, because we take the dot product. Indeed, $\mathbf{F} \cdot \mathbf{r}'/|\mathbf{r}'|$ is the tangential component of $\mathbf{F}$. (For "component" see (11) in Sec. 9.2.)

We see that the integral in (3) on the right is a definite integral of a function of t taken over the interval $a \leqq t \leqq b$ on the t-axis in the ***positive*** direction (the direction of increasing t). This definite integral exists for continuous $\mathbf{F}$ and piecewise smooth C, because this makes $\mathbf{F} \cdot \mathbf{r}'$ piecewise continuous.

Line integrals (3) arise naturally in mechanics, where they give the work done by a force $\mathbf{F}$ in a displacement along C (details and examples below). We may thus call the line integral (3) the **work integral.** Other forms of the line integral will be discussed later in this section.

EXAMPLE 1 **Evaluation of a Line Integral in the Plane**

Find the value of the line integral (3) when $\mathbf{F}(\mathbf{r}) = [-y, \quad -xy] = -y\mathbf{i} - xy\mathbf{j}$ and C is the circular arc in Fig. 218 from A to B.

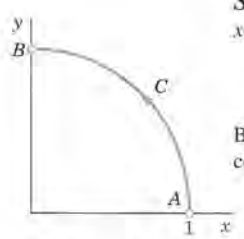

Fig. 218. Example 1

Solution. We may represent C by $\mathbf{r}(t) = [\cos t, \sin t] = \cos t\ \mathbf{i} + \sin t\ \mathbf{j}$, where $0 \leqq t \leqq \pi/2$. Then $x(t) = \cos t, \quad y(t) = \sin t,$ and

$$\mathbf{F}(\mathbf{r}(t)) = -y(t)\mathbf{i} - x(t)y(t)\mathbf{j} = [-\sin t, \quad -\cos t \sin t] = -\sin t\,\mathbf{i} - \cos t \sin t\,\mathbf{j}.$$

By differentiation, $\mathbf{r}'(t) = [-\sin t, \quad \cos t] = -\sin t\ \mathbf{i} + \cos t\ \mathbf{j}$, so that by (3) [use (10) in App. 3.1; set $\cos t = u$ in the second term]

$$\int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_0^{\pi/2} [-\sin t, -\cos t \sin t] \cdot [-\sin t, \cos t]\, dt = \int_0^{\pi/2} (\sin^2 t - \cos^2 t \sin t)\, dt$$

$$= \int_0^{\pi/2} \frac{1}{2}(1 - \cos 2t)\, dt - \int_1^0 u^2(-du) = \frac{\pi}{4} - 0 - \frac{1}{3} \approx 0.4521. \quad \blacksquare$$

EXAMPLE 2 **Line Integral in Space**

The evaluation of line integrals in space is practically the same as it is in the plane. To see this, find the value of (3) when $\mathbf{F}(\mathbf{r}) = [z, x, y] = z\mathbf{i} + x\mathbf{j} + y\mathbf{k}$ and C is the helix (Fig. 219)

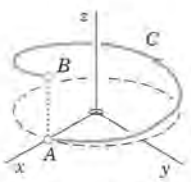

Fig. 219. Example 2

$$\mathbf{r}(t) = [\cos t, \sin t, 3t] = \cos t\,\mathbf{i} + \sin t\,\mathbf{j} + 3t\mathbf{k} \qquad (0 \leqq t \leqq 2\pi). \tag{4}$$

Solution. From (4) we have $x(t) = \cos t, \ y(t) = \sin t, \ z(t) = 3t$. Thus

$$\mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) = (3t\mathbf{i} + \cos t\,\mathbf{j} + \sin t\,\mathbf{k}) \cdot (-\sin t\,\mathbf{i} + \cos t\,\mathbf{j} + 3\mathbf{k}).$$

The dot product is $3t(-\sin t) + \cos^2 t + 3 \sin t$. Hence (3) gives

$$\int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_0^{2\pi} (-3t \sin t + \cos^2 t + 3 \sin t)\, dt = 6\pi + \pi + 0 = 7\pi \approx 21.99. \quad \blacksquare$$

Simple general properties of the line integral (3) follow directly from corresponding properties of the definite integral in calculus, namely,

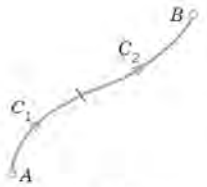

Fig. 220. Formula (5c)

$$\int_C k\mathbf{F} \cdot d\mathbf{r} = k \int_C \mathbf{F} \cdot d\mathbf{r} \qquad (k \text{ constant}) \tag{5a}$$

$$\int_C (\mathbf{F} + \mathbf{G}) \cdot d\mathbf{r} = \int_C \mathbf{F} \cdot d\mathbf{r} + \int_C \mathbf{G} \cdot d\mathbf{r} \tag{5b}$$

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \mathbf{F} \cdot d\mathbf{r} + \int_{C_2} \mathbf{F} \cdot d\mathbf{r} \qquad \text{(Fig. 220)} \tag{5c}$$

where in (5c) the path C is subdivided into two arcs C_1 and C_2 that have the same orientation as C (Fig. 220). In (5b) the orientation of C is the same in all three integrals. If the sense of integration along C is reversed, the value of the integral is multiplied by -1. However, we note the following independence if the sense is preserved.

THEOREM 1

Direction-Preserving Parametric Transformations

Any representations of C that give the same positive direction on C also yield the same value of the line integral (3).

PROOF A proof follows by the chain rule, where $\mathbf{r}(t)$ is the given representation, $t = \phi(t^*)$ with a positive derivative dt/dt^* is the transformation, with $a^* \leqq t^* \leqq b^*$ corresponding to $a \leqq t \leqq b$ in (3), and we write $\mathbf{r}(t) = \mathbf{r}(\phi(t^*)) = \mathbf{r}^*(t^*)$. Then $dt = (dt/dt^*)\, dt^*$ and

$$\int_C \mathbf{F}(\mathbf{r}^*) \cdot d\mathbf{r}^* = \int_{a^*}^{b^*} \mathbf{F}(\mathbf{r}(\phi(t^*))) \cdot \frac{d\mathbf{r}}{dt} \frac{dt}{dt^*}\, dt^*$$

$$= \int_a^b \mathbf{F}(\mathbf{r}(t)) \cdot \frac{d\mathbf{r}}{dt}\, dt = \int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r}. \qquad \blacksquare$$

Motivation of the Line Integral (3): Work Done by a Force

The work W done by a *constant* force $\mathbf{F}$ in the displacement along a *straight* segment $\mathbf{d}$ is $W = \mathbf{F} \cdot \mathbf{d}$; see Example 2 in Sec. 9.2. This suggests that we define the work W done by a *variable* force $\mathbf{F}$ in the displacement along a curve C: $\mathbf{r}(t)$ as the limit of sums of works done in displacements along small chords of C. We show that this definition amounts to defining W by the line integral (3).

For this we choose points $t_0\ (= a) < t_1 < \cdots < t_n\ (= b)$. Then the work ΔW_m done by $\mathbf{F}(\mathbf{r}(t_m))$ in the straight displacement from $\mathbf{r}(t_m)$ to $\mathbf{r}(t_{m+1})$ is

$$\Delta W_m = \mathbf{F}(\mathbf{r}(t_m)) \cdot [\mathbf{r}(t_{m+1}) - \mathbf{r}(t_m)] \approx \mathbf{F}(\mathbf{r}(t_m)) \cdot \mathbf{r}'(t_m) \Delta t_m \qquad (\Delta t_m = t_{m+1} - t_m).$$

The sum of these n works is $W_n = \Delta W_0 + \cdots + \Delta W_{n-1}$. If we choose points and consider W_n for every n arbitrarily but so that the greatest Δt_m approaches zero as $n \to \infty$, then the limit of W_n as $n \to \infty$ is the line integral (3). This integral exists because of our general assumption that $\mathbf{F}$ is continuous and C is piecewise smooth; this makes $\mathbf{r}'(t)$ continuous, except at finitely many points where C may have corners or cusps. $\blacksquare$

EXAMPLE 3 **Work Done by a Variable Force**

If $\mathbf{F}$ in Example 1 is a force, the work done by $\mathbf{F}$ in the displacement along the quarter-circle is 0.4521, measured in suitable units, say, newton-meters (nt·m, also called joules, abbreviation J; see also front cover). Similarly in Example 2. $\blacksquare$

EXAMPLE 4 **Work Done Equals the Gain in Kinetic Energy**

Let $\mathbf{F}$ be a force, so that (3) is work. Let t be time, so that $d\mathbf{r}/dt = \mathbf{v}$, velocity. Then we can write (3) as

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_a^b \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{v}(t)\, dt. \tag{6}$$

Now by Newton's second law (force = mass × acceleration),

$$\mathbf{F} = m\mathbf{r}''(t) = m\mathbf{v}'(t),$$

where m is the mass of the body displaced. Substitution into (5) gives [see (11), Sec. 9.4]

$$W = \int_a^b m\mathbf{v}' \cdot \mathbf{v}\, dt = \int_a^b m \left(\frac{\mathbf{v} \cdot \mathbf{v}}{2} \right)' dt = \frac{m}{2} |\mathbf{v}|^2 \Big|_{t=a}^{t=b}.$$

On the right, $m|\mathbf{v}|^2/2$ is the kinetic energy. Hence *the work done equals the gain in kinetic energy.* This is a basic law in mechanics. ■

Other Forms of Line Integrals

The line integrals

$$\int_C F_1\, dx, \qquad \int_C F_2\, dy, \qquad \int_C F_3\, dz \tag{7}$$

are special cases of (3) when $\mathbf{F} = F_1\mathbf{i}$ or $F_2\mathbf{j}$ or $F_3\mathbf{k}$, respectively.

Furthermore, without taking a dot product as in (3) we can obtain a line integral whose value is a vector rather than a scalar, namely,

$$\int_C \mathbf{F}(\mathbf{r})\, dt = \int_a^b \mathbf{F}(\mathbf{r}(t))\, dt = \int_a^b [F_1(\mathbf{r}(t)),\quad F_2(\mathbf{r}(t)),\quad F_3(\mathbf{r}(t))]\, dt. \tag{8}$$

Obviously, a special case of (7) is obtained by taking $F_1 = f$, $F_2 = F_3 = 0$. Then

$$\int_C f(\mathbf{r})\, dt = \int_a^b f(\mathbf{r}(t))\, dt \tag{8*}$$

with C as in (2). The evaluation is similar to that before.

EXAMPLE 5 **A Line Integral of the Form (8)**

Integrate $\mathbf{F}(\mathbf{r}) = [xy,\ yz,\ z]$ along the helix in Example 2.

Solution. $\mathbf{F}(\mathbf{r}(t)) = [\cos t \sin t,\ 3t \sin t,\ 3t]$ integrated with respect to t from 0 to 2π gives

$$\int_0^{2\pi} \mathbf{F}(\mathbf{r}(t))\, dt = \left[-\frac{1}{2}\cos^2 t,\quad 3\sin t - 3t\cos t,\quad \frac{3}{2}t^2 \right] \Big|_0^{2\pi} = [0,\quad -6\pi,\quad 6\pi^2].$$ ■

Path Dependence

Path dependence of line integrals is practically and theoretically so important that we formulate it as a theorem. And a whole section (Sec. 10.2) will be devoted to conditions under which path dependence does not occur.

THEOREM 2

Path Dependence

The line integral (3) *generally depends not only on* $\mathbf{F}$ *and on the endpoints A and B of the path, but also on the path itself along which the integral is taken.*

PROOF Almost any example will show this. Take, for instance, the straight segment C_1: $\mathbf{r}_1(t) = [t, t, 0]$ and the parabola C_2: $\mathbf{r}_2(t) = [t, t^2, 0]$ with $0 \leqq t \leqq 1$ (Fig. 221) and integrate $\mathbf{F} = [0, xy, 0]$. Then $\mathbf{F}(\mathbf{r}_1(t)) \bullet \mathbf{r}_1'(t) = t^2$, $\mathbf{F}(\mathbf{r}_2(t)) \bullet \mathbf{r}_2'(t) = 2t^4$, so that integration gives 1/3 and 2/5, respectively. ■

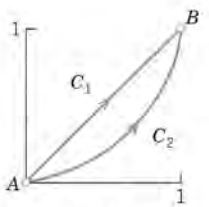

Fig. 221. Proof of Theorem 2

PROBLEM SET 10.1

1–12 LINE INTEGRAL. WORK DONE BY A FORCE

Calculate $\int_C \mathbf{F}(\mathbf{r}) \bullet d\mathbf{r}$ for the following data. If $\mathbf{F}$ is a force, this gives the work done in the displacement along C. (Show the details.)

1. $\mathbf{F} = [y^3, \ x^3]$, C the parabola $y = 5x^2$ from A: (0, 0) to B: (2, 20)
2. $\mathbf{F}$ as in Prob. 1, C the shortest path from A to B. Is the integral smaller? Give reason.
3. $\mathbf{F}$ as in Prob. 1, C from A straight to (2, 0), then vertically up to B
4. $\mathbf{F} = [x^2, \ y^2, \ 0]$, C the semicircle from (2, 0) to $(-2, 0)$, $y \geqq 0$
5. $\mathbf{F} = [xy^2, \ x^2y]$, C: $\mathbf{r} = [\cosh t, \ \sinh t, \ 0]$, $0 \leqq t \leqq 2$. Sketch C.
6. $\mathbf{F} = [e^x, \ e^y]$ clockwise along the circle with center (0, 0) from (1, 0) to (0, −1)
7. $\mathbf{F} = [z, \ x, \ y]$, C: $\mathbf{r} = [\cos t, \ \sin t, \ t]$ from (1, 0, 0) to $(1, 0, 4\pi)$
8. $\mathbf{F} = [\cosh x, \ \sinh y, \ e^z]$, C: $\mathbf{r} = [t, \ t^2, \ t^3]$ from (0, 0, 0) to $(\frac{1}{2}, \frac{1}{4}, \frac{1}{8})$
9. $\mathbf{F}$ as in Prob. 8, C the straight segment from (0, 0, 0) to $(\frac{1}{2}, \frac{1}{4}, \frac{1}{8})$
10. $\mathbf{F} = [x, \ -z, \ 2y]$ from (0, 0, 0) straight to (1, 1, 0), then to (1, 1, 1), back to (0, 0, 0)
11. $\mathbf{F} = [e^x, \ e^y, \ e^z]$, $\mathbf{r} = [t, \ t^2, \ t^2]$ from (0, 0, 0) to (2, 4, 4). Sketch C.
12. $\mathbf{F} = [y^2, \ x^2, \ \cos^2 z]$, C as in Prob. 7. Sketch C.
13. **WRITING PROJECT. From Definite Integrals to Line Integrals.** Write a short report (1–2 pages) with examples on line integrals as generalizations of definite integrals. The latter give the area under a curve. Explain the corresponding geometric interpretation of a line integral.
14. **PROJECT. Independence of Representation.**

    Dependence on Path. Consider the integral $\int_C \mathbf{F}(\mathbf{r}) \bullet d\mathbf{r}$, where $\mathbf{F} = [xy, \ -y^2]$.

    (a) One path, several representations. Find the value of the integral when $\mathbf{r} = [\cos t, \ \sin t]$, $0 \leqq t \leqq \pi/2$. Show that the value remains the same if you set $t = -p$ or $t = p^2$ or apply two other parametric transformations of your own choice.

    (b) Several paths. Evaluate the integral when C: $y = x^n$, thus $\mathbf{r} = [t, \ t^n]$, $0 \leqq t \leqq 1$, where $n = 1, 2, 3, \cdots$. Note that these infinitely many paths have the same endpoints.

    (c) Limit. What is the limit in (b) as $n \to \infty$? Can you confirm your result by direct integration without referring to (b)?

    (d) Show path dependence with a simple example of your choice involving two paths.

15–18 INTEGRALS OF THE FORMS (8) AND (8*)

Evaluate (8) or (8*) with $\mathbf{F}$ or f and C as follows.

15. $f = x^2 + y^2$, C: $\mathbf{r} = [t, \quad 4t, \quad 0]$, $0 \leqq t \leqq 1$

16. $f = 1 - \sinh^2 x$, C the catenary $\mathbf{r} = [t, \quad \cosh t]$, $0 \leqq t \leqq 2$

17. $\mathbf{F} = [y^2, \quad z^2, \quad x^2]$, C the helix $[3\cos t, \quad 3\sin t, \quad 2t]$, $0 \leqq t \leqq 8\pi$

18. $\mathbf{F} = [(xy)^{1/3}, \quad (y/x)^{1/3}, \quad 0]$, C the hypocycloid $\mathbf{r} = [\cos^3 t, \quad \sin^3 t, \quad 0]$, $0 \leqq t \leqq \pi/4$

19. (*ML*-Inequality, Estimation of Line Integrals) Let $\mathbf{F}$ be a vector function defined on a curve C. Let $|\mathbf{F}|$ be bounded, say, $|\mathbf{F}| \leqq M$ on C, where M is some positive number. Show that

$$\text{(9)} \qquad \left| \int_C \mathbf{F} \cdot d\mathbf{r} \right| \leqq ML \qquad (L = \text{Length of } C).$$

20. Using (9), find a bound for the absolute value of the work W done by the force $\mathbf{F} = [x^2, \quad y]$ in the displacement along the segment from (0, 0) to (3, 4).

10.2 Path Independence of Line Integrals

In this section we consider line integrals

$$\text{(1)} \qquad \int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_C (F_1\,dx + F_2\,dy + F_3\,dz) \qquad (d\mathbf{r} = [dx, \quad dy, \quad dz])$$

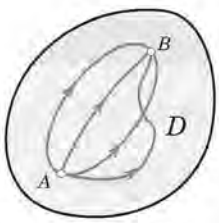

Fig. 222. Path independence

as before, and we shall now find conditions under which (1) is **path independent in a domain D in space.** By definition this means that for every pair of endpoints A, B in D the integral (1) has the same value for all paths in D that begin at A and end at B. (See Fig. 222. See Sec. 9.6 for "domain.")

Path independence is important. For instance, in mechanics it may mean that we have to do the same amount of work regardless of the path to the mountaintop, be it short and steep or long and gentle. Or it may mean that in releasing an elastic spring we get back the work done in expanding it. Not all forces are of this type—think of swimming in a big round pool in which the water is rotating as in a whirlpool.

We shall follow up three ideas that will give path independence of (1) in a domain D if and only if:

(*Theorem* 1) $\mathbf{F} = \text{grad } f$ (see Sec. 9.7 for the gradient).

(*Theorem* 2) Integration around closed curves C in D always gives 0.

(*Theorem* 3) curl $\mathbf{F} = \mathbf{0}$ (provided D is simply connected, as defined below).

Do you see that these theorems can help in understanding the examples and counterexample just mentioned?

Let us begin our discussion with the following very practical criterion for path independence.

THEOREM 1

Path Independence

A line integral (1) *with continuous* F_1, F_2, F_3 *in a domain* D *in space is path independent in* D *if and only if* $\mathbf{F} = [F_1, \quad F_2, \quad F_3]$ *is the gradient of some function* f *in* D,

$$\text{(2)} \qquad \mathbf{F} = \text{grad } f, \qquad \text{thus,} \qquad F_1 = \frac{\partial f}{\partial x}, \qquad F_2 = \frac{\partial f}{\partial y}, \qquad F_3 = \frac{\partial f}{\partial z}.$$

PROOF **(a)** We assume that (2) holds for some function f in D and show that this implies path independence. Let C be any path in D from any point A to any point B in D, given by $\mathbf{r}(t) = [x(t), \quad y(t), \quad z(t)]$, where $a \leqq t \leqq b$. Then from (2), the chain rule in Sec. 9.6, and (3′) in the last section we obtain

$$\begin{aligned}\int_C (F_1\,dx + F_2\,dy + F_3\,dz) &= \int_C \left(\frac{\partial f}{\partial x}\,dx + \frac{\partial f}{\partial y}\,dy + \frac{\partial f}{\partial z}\,dz\right) \\ &= \int_a^b \left(\frac{\partial f}{\partial x}\,\frac{dx}{dt} + \frac{\partial f}{\partial y}\,\frac{dy}{dt} + \frac{\partial f}{\partial z}\,\frac{dz}{dt}\right) dt \\ &= \int_a^b \frac{df}{dt}\,dt = f[x(t), y(t), z(t)]\,\Big|_{t=a}^{t=b} \\ &= f(x(b), y(b), z(b)) - f(x(a), y(a), z(a)) \\ &= f(B) - f(A).\end{aligned}$$

(b) The more complicated proof of the converse, that path independence implies (2) for some f, is given in App. 4. ■

The last formula in part (a) of the proof,

$$\textbf{(3)} \qquad \int_A^B (F_1\,dx + F_2\,dy + F_3\,dz) = f(B) - f(A) \qquad [\mathbf{F} = \operatorname{grad} f]$$

is the analog of the usual formula for definite integrals in calculus,

$$\int_a^b g(x)\,dx = G(x)\,\Big|_a^b = G(b) - G(a) \qquad [G'(x) = g(x)].$$

Formula (3) should be applied whenever a line integral is independent of path.

Potential theory relates to our present discussion if we remember from Sec. 9.7 that f is called a *potential* of $\mathbf{F} = \operatorname{grad} f$. Thus the integral (1) is independent of path in D if and only if $\mathbf{F}$ is the gradient of a potential in D.

EXAMPLE 1 **Path Independence**

Show that the integral $\int_C \mathbf{F} \cdot d\mathbf{r} = \int_C (2x\,dx + 2y\,dy + 4z\,dz)$ is path independent in any domain in space and find its value in the integration from A: (0, 0, 0) to B: (2, 2, 2).

Solution. $\mathbf{F} = [2x, 2y, 4z] = \operatorname{grad} f$, where $f = x^2 + y^2 + 2z^2$ because $\partial f/\partial x = 2x = F_1$, $\partial f/\partial y = 2y = F_2$, $\partial f/\partial z = 4z = F_3$. Hence the integral is independent of path according to Theorem 1, and (3) gives $f(B) - f(A) = f(2, 2, 2) - f(0, 0, 0) = 4 + 4 + 8 = 16$.

If you want to check this, use the most convenient path C: $\mathbf{r}(t) = [t, \quad t, \quad t]$, $0 \leqq t \leqq 2$, on which $\mathbf{F}(\mathbf{r}(t)) = [2t, \quad 2t, \quad 4t]$, so that $\mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) = 2t + 2t + 4t = 8t$, and integration from 0 to 2 gives $8 \cdot 2^2/2 = 16$.

If you did not see the potential by inspection, use the method in the next example. ■

EXAMPLE 2 **Path Independence. Determination of a Potential**

Evaluate the integral $I = \int_C (3x^2\,dx + 2yz\,dy + y^2\,dz)$ from A: (0, 1, 2) to B: (1, −1, 7) by showing that $\mathbf{F}$ has a potential and applying (3).

Solution. If **F** has a potential f, we should have

$$f_x = F_1 = 3x^2, \qquad f_y = F_2 = 2yz, \qquad f_z = F_3 = y^2.$$

We show that we can satisfy these conditions. By integration of f_x and differentiation,

$$f = x^3 + g(y, z), \qquad f_y = g_y = 2yz, \qquad g = y^2z + h(z), \qquad f = x^3 + y^2z + h(z)$$
$$f_z = y^2 + h' = y^2, \qquad h' = 0 \qquad h = 0, \text{ say.}$$

This gives $f(x, y, z) = x^3 + y^2z$ and by (3),

$$I = f(1, -1, 7) - f(0, 1, 2) = 1 + 7 - (0 + 2) = 6. \quad \blacksquare$$

Path Independence and Integration Around Closed Curves

The simple idea is that two paths with common endpoints (Fig. 223) make up a single closed curve. This gives almost immediately

THEOREM 2

Path Independence

The integral (1) *is path independent in a domain D if and only if its value around every closed path in D is zero.*

PROOF If we have path independence, then integration from A to B along C_1 and along C_2 in Fig. 223 gives the same value. Now C_1 and C_2 together make up a closed curve C, and if we integrate from A along C_1 to B as before, but then in the opposite sense along C_2 back to A (so that this second integral is multiplied by -1), the sum of the two integrals is zero, but this is the integral around the closed curve C.

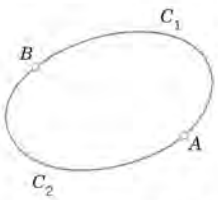

Fig. 223. Proof of Theorem 2

Conversely, assume that the integral around any closed path C in D is zero. Given any points A and B and any two curves C_1 and C_2 from A to B in D, we see that C_1 with the orientation reversed and C_2 together form a closed path C. By assumption, the integral over C is zero. Hence the integrals over C_1 and C_2, both taken from A to B, must be equal. This proves the theorem. ■

Work. Conservative and Nonconservative (Dissipative) Physical Systems

Recall from the last section that in mechanics, the integral (1) gives the work done by a force **F** in the displacement of a body along the curve C. Then Theorem 2 states that work is path independent in D if and only if its value is zero for displacement around every closed path in D. Furthermore, Theorem 1 tells us that this happens if and only if **F** is the gradient of a potential in D. In this case, **F** and the vector field defined by **F** are called **conservative** in D because in this case mechanical energy is conserved; that is, no work is done in the displacement from a point A and back to A. Similarly for the displacement of an electrical charge (an electron, for instance) in a conservative electrostatic field.

Physically, the kinetic energy of a body can be interpreted as the ability of the body to do work by virtue of its motion, and if the body moves in a conservative field of force, after the completion of a round trip the body will return to its initial position with the same kinetic energy it had originally. For instance, the gravitational force is conservative; if we throw a ball vertically up, it will (if we assume air resistance to be negligible) return to our hand with the same kinetic energy it had when it left our hand.

Friction, air resistance, and water resistance always act against the direction of motion, tending to diminish the total mechanical energy of a system (usually converting it into heat or mechanical energy of the surrounding medium, or both), and if in the motion of a body these forces are so large that they can no longer be neglected, then the resultant **F** of the forces acting on the body is no longer conservative. Quite generally, a physical system is called **conservative** if all the forces acting in it are conservative; otherwise it is called **nonconservative** or **dissipative.**

Path Independence and Exactness of Differential Forms

Theorem 1 relates path independence of the line integral (1) to the gradient and Theorem 2 to integration around closed curves. A third idea (leading to Theorems 3* and 3, below) relates path independence to the exactness of the **differential form** (or *Pfaffian form*[1])

$$\mathbf{F} \cdot d\mathbf{r} = F_1\,dx + F_2\,dy + F_3\,dz \tag{4}$$

under the integral sign in (1). This form (4) is called **exact** in a domain D in space if it is the differential

$$df = \frac{\partial f}{\partial x}\,dx + \frac{\partial f}{\partial y}\,dy + \frac{\partial f}{\partial z}\,dz = (\operatorname{grad} f) \cdot d\mathbf{r}$$

of a differentiable function $f(x, y, z)$ everywhere in D, that is, if we have

$$\mathbf{F} \cdot d\mathbf{r} = df.$$

Comparing these two formulas, we see that the form (4) is exact if and only if there is a differentiable function $f(x, y, z)$ in D such that everywhere in D,

$$\text{(5)} \qquad \mathbf{F} = \operatorname{grad} f, \qquad \text{thus,} \qquad F_1 = \frac{\partial f}{\partial x}, \qquad F_2 = \frac{\partial f}{\partial y}, \qquad F_3 = \frac{\partial f}{\partial z}.$$

Hence Theorem 1 implies

THEOREM 3*

Path Independence

The integral (1) *is path independent in a domain D in space if and only if the differential form* (4) *has continuous coefficient functions F_1, F_2, F_3 and is exact in D.*

This theorem is practically important because there is a useful exactness criterion. To formulate the criterion, we need the following concept, which is of general interest.

A domain D is called **simply connected** if every closed curve in D can be continuously shrunk to any point in D without leaving D.

For example, the interior of a sphere or a cube, the interior of a sphere with finitely many points removed, and the domain between two concentric spheres are simply

[1]JOHANN FRIEDRICH PFAFF (1765–1825), German mathematician.

connected, while the interior of a torus (a doughnut; see Fig. 247 in Sec. 10.6) and the interior of a cube with one space diagonal removed are not simply connected.

The criterion for exactness (and path independence by Theorem 3*) is now as follows.

THEOREM 3

Criterion for Exactness and Path Independence

Let F_1, F_2, F_3 in the line integral (1),

$$\int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_C (F_1\,dx + F_2\,dy + F_3\,dz),$$

be continuous and have continuous first partial derivatives in a domain D in space. Then:

(a) *If the differential form* (4) *is exact in D—and thus* (1) *is path independent by Theorem* 3*—, *then in D,*

(6) $$\text{curl } \mathbf{F} = \mathbf{0};$$

in components (see Sec. 9.9)

(6′) $$\frac{\partial F_3}{\partial y} = \frac{\partial F_2}{\partial z}, \qquad \frac{\partial F_1}{\partial z} = \frac{\partial F_3}{\partial x}, \qquad \frac{\partial F_2}{\partial x} = \frac{\partial F_1}{\partial y}.$$

(b) *If* (6) *holds in D and D is simply connected, then* (4) *is exact in D—and thus* (1) *is path independent by Theorem* 3*.

PROOF **(a)** If (4) is exact in D, then $\mathbf{F} = \text{grad } f$ in D by Theorem 3*, and, furthermore, $\text{curl } \mathbf{F} = \text{curl (grad } f) = \mathbf{0}$ by (2) in Sec. 9.9, so that (6) holds.

(b) The proof needs "Stokes's theorem" and will be given in Sec. 10.9. ■

Line Integral in the Plane. For $\int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_C (F_1\,dx + F_2\,dy)$ the curl has only one component (the z-component), so that (6′) reduces to the single relation

(6″) $$\frac{\partial F_2}{\partial x} = \frac{\partial F_1}{\partial y}$$

(which also occurs in (5) of Sec. 1.4 on exact ODEs).

EXAMPLE 3 **Exactness and Independence of Path. Determination of a Potential**

Using (6′), show that the differential form under the integral sign of

$$I = \int_C \left[2xyz^2\,dx + (x^2z^2 + z\cos yz)\,dy + (2x^2yz + y\cos yz)\,dz\right]$$

is exact, so that we have independence of path in any domain, and find the value of I from A: (0, 0, 1) to B: (1, π/4, 2).

Solution. Exactness follows from (6′), which gives

$$(F_3)_y = 2x^2z + \cos yz - yz \sin yz = (F_2)_z$$
$$(F_1)_z = 4xyz = (F_3)_x$$
$$(F_2)_x = 2xz^2 = (F_1)_y.$$

To find f, we integrate F_2 (which is "long," so that we save work) and then differentiate to compare with F_1 and F_3,

$$f = \int F_2\, dy = \int (x^2z^2 + z \cos yz)\, dy = x^2z^2y + \sin yz + g(x, z)$$
$$f_x = 2xz^2y + g_x = F_1 = 2xyz^2, \qquad g_x = 0, \qquad g = h(z)$$
$$f_z = 2x^2zy + y \cos yz + h' = F_3 = 2x^2zy + y \cos yz, \qquad h' = 0.$$

$h' = 0$ implies $h = const$ and we can take $h = 0$, so that $g = 0$ in the first line. This gives, by (3),

$$f(x, y, z) = x^2yz^2 + \sin yz, \qquad f(B) - f(A) = 1 \cdot \frac{\pi}{4} \cdot 4 + \sin \frac{\pi}{2} - 0 = \pi + 1. \quad \blacksquare$$

The assumption in Theorem 3 that D is simply connected is essential and cannot be omitted. Perhaps the simplest example to see this is the following.

EXAMPLE 4 On the Assumption of Simple Connectedness in Theorem 3

Let

(7) $$F_1 = -\frac{y}{x^2 + y^2}, \qquad F_2 = \frac{x}{x^2 + y^2}, \qquad F_3 = 0.$$

Differentiation shows that (6′) is satisfied in any domain of the xy-plane not containing the origin, for example, in the domain D: $\frac{1}{2} < \sqrt{x^2 + y^2} < \frac{3}{2}$ shown in Fig. 224. Indeed, F_1 and F_2 do not depend on z, and $F_3 = 0$, so that the first two relations in (6′) are trivially true, and the third is verified by differentiation:

$$\frac{\partial F_2}{\partial x} = \frac{x^2 + y^2 - x \cdot 2x}{(x^2 + y^2)^2} = \frac{y^2 - x^2}{(x^2 + y^2)^2},$$

$$\frac{\partial F_1}{\partial y} = -\frac{x^2 + y^2 - y \cdot 2y}{(x^2 + y^2)^2} = \frac{y^2 - x^2}{(x^2 + y^2)^2}.$$

Clearly, D in Fig. 224 is not simply connected. If the integral

$$I = \int_C (F_1\, dx + F_2\, dy) = \int_C \frac{-y\, dx + x\, dy}{x^2 + y^2}$$

were independent of path in D, then $I = 0$ on any closed curve in D, for example, on the circle $x^2 + y^2 = 1$. But setting $x = r \cos \theta$, $y = r \sin \theta$ and noting that the circle is represented by $r = 1$, we have

$$x = \cos \theta, \qquad dx = -\sin \theta\, d\theta, \qquad y = \sin \theta, \qquad dy = \cos \theta\, d\theta,$$

so that $-y\, dx + x\, dy = \sin^2 \theta\, d\theta + \cos^2 \theta\, d\theta = d\theta$ and counterclockwise integration gives

$$I = \int_0^{2\pi} \frac{d\theta}{1} = 2\pi.$$

Since D is not simply connected, we cannot apply Theorem 3 and cannot conclude that I is independent of path in D.

Although $\mathbf{F} = \operatorname{grad} f$, where $f = \arctan(y/x)$ (verify!), we cannot apply Theorem 1 either because the polar angle $f = \theta = \arctan(y/x)$ is not single-valued, as it is required for a function in calculus. $\blacksquare$

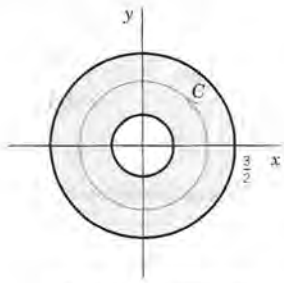

Fig. 224. Example 4

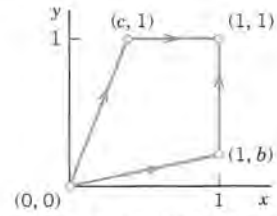
PROBLEM SET 10.2

1–8 PATH-INDEPENDENT INTEGRALS

Show that the form under the integral sign is exact in the plane (Probs. 1–4) or in space (Probs. 5–8) and evaluate the integral. (Show the details of your work.)



1. $\int_{(0,0)}^{(4,\pi/8)} (y \cos xy \, dx + x \cos xy \, dy)$
2. $\int_{(5,0)}^{(0,5)} (y^2 e^{2x} \, dx + y e^{2x} \, dy)$
3. $\int_{(-1,-1)}^{(1,1)} e^{-x^2-y^2}(x \, dx + y \, dy)$
4. $\int_{(2,0)}^{(6,\pi)} (\cos^2 y \, dx - 2x \cos y \sin y \, dy)$
5. $\int_{(2,3,0)}^{(0,1,2)} (z \, e^{xz} \, dx + dy + x e^{xz} \, dz)$
6. $\int_{(0,0,0)}^{(1,1,0)} e^{x^2+y^2-2z} \, (x \, dx + y \, dy - dz)$
7. $\int_{(1,0,0)}^{(7,8,0)} (2xy \, dx + x^2 \, dy + \sinh z \, dz)$
8. $\int_{(2,0,1)}^{(4,4,0)} [2x(y^3 - z^3) \, dx + 3x^2y^2 \, dy - 3x^2z^2 \, dz]$

9. Show that in Example 4 of the text we have $\mathbf{F} = \text{grad}\,(\arctan\,(y/x))$. Give examples of domains in which the integral is path independent.

10. **PROJECT. Path Dependence.** **(a)** Show that $I = \int_C (x^2y \, dx + 2xy^2 \, dy)$ is path dependent in the xy-plane.

(b) Integrate from (0, 0) along the straight-line segment to $(1, b)$, $0 \leqq b \leqq 1$, and then vertically up to (1, 1); see the figure. For which of these paths is I maximum? What is its maximum value?

(c) Integrate from (0, 0) along the straight-line segment to $(c, 1)$, $0 \leqq c \leqq 1$, and then horizontally to (1, 1). For $c = 1$, do you get the same value as for $b = 1$ in (b)? For which c is I maximum? What is its maximum value?

Project 10. Path Dependence

11–19 CHECK FOR PATH INDEPENDENCE

and, if independent, integrate from (0, 0, 0) to (a, b, c).

11. $(\cosh xz)(z \, dx + x \, dz)$
12. $(3x^2e^{2y} + x) \, dx + 2x^3e^{2y} \, dy$
13. $3x^2y \, dx + x^3 \, dy + y \, dz$
14. $2x \sin y \, dx + x^2 \cos y \, dy + y^2 \, dz$
15. $(ze^x - e^y) \, dx - xe^y \, dy + e^x \, dz$
16. $e^x \cos 2y \, dx - 2e^x \sin 2y \, dy - xz \, dz$
17. $xy \, z^2 \, dx + \frac{1}{2}x^2z^2 \, dy + x^2yz \, dz$
18. $yz \cosh x \, dx + z \sinh x \, dy + y \sinh x \, dz$
19. $y \, dx + (x - 2y) \, dy + 4x \, dz$

20. **WRITING PROJECT. Ideas on Path Independence.** Make a list of the main ideas on path independence and dependence in this section. Then work this list into an essay, including explanations of all definitions and on the practical usefulness of the theorems, but no proofs. Include illustrating examples of your own. Explain what happens in Example 4 if you take the domain $0 < \sqrt{x^2 + y^2} < \frac{3}{2}$.

10.3 Calculus Review: Double Integrals. Optional

Students familiar with double integrals from calculus should go on to the next section, skipping the present review, which is included to make the book reasonably self-contained.

In a definite integral (1), Sec. 10.1, we integrate a function $f(x)$ over an interval (a segment) of the x-axis. In a double integral we integrate a function $f(x, y)$, called the *integrand,* over a closed bounded region[2] R in the xy-plane, whose boundary curve has a unique tangent at each point, but may perhaps have finitely many cusps (such as the vertices of a triangle or rectangle).

The definition of the double integral is quite similar to that of the definite integral. We subdivide the region R by drawing parallels to the x- and y-axes (Fig. 225). We number the rectangles that are entirely within R from 1 to n. In each such rectangle we choose a point, say, (x_k, y_k) in the kth rectangle, whose area we denote by ΔA_k. Then we form the sum

$$J_n = \sum_{k=1}^{n} f(x_k, y_k)\, \Delta A_k.$$

This we do for larger and larger positive integers n in a completely independent manner, but so that the length of the maximum diagonal of the rectangles approaches zero as n approaches infinity. In this fashion we obtain a sequence of real numbers $J_{n_1}, J_{n_2}, \cdots$. Assuming that $f(x, y)$ is continuous in R and R is bounded by finitely many smooth curves (see Sec. 10.1), one can show (see Ref. [GR4] in App. 1) that this sequence converges and its limit is independent of the choice of subdivisions and corresponding points (x_k, y_k). This limit is called the **double integral** *of $f(x, y)$ over the region R,* and is denoted by

$$\iint_R f(x, y)\, dx\, dy \qquad \text{or} \qquad \iint_R f(x, y)\, dA.$$

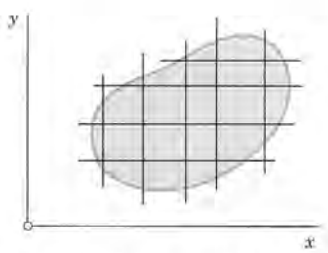


Fig. 225. Subdivision of a region R

[2]A **region** R is a domain (Sec. 9.6) plus, perhaps, some or all of its boundary points. R is **closed** if its **boundary** (all its boundary points) are regarded as belonging to R; and R is **bounded** if it can be enclosed in a circle of sufficiently large radius. A **boundary point** P of R is a point (of R or not) such that every disk with center P contains points of R and also points not of R.

Double integrals have properties quite similar to those of definite integrals. Indeed, for any functions f and g of (x, y), defined and continuous in a region R,

$$\iint_R kf\,dx\,dy = k\iint_R f\,dx\,dy \qquad (k \text{ constant})$$

(1)
$$\iint_R (f + g)\,dx\,dy = \iint_R f\,dx\,dy + \iint_R g\,dx\,dy$$

$$\iint_R f\,dx\,dy = \iint_{R_1} f\,dx\,dy + \iint_{R_2} f\,dx\,dy \qquad \text{(Fig. 226).}$$

Furthermore, if R is simply connected (see Sec. 10.2), then there exists at least one point (x_0, y_0) in R such that we have

(2)
$$\iint_R f(x, y)\,dx\,dy = f(x_0, y_0)A,$$

where A is the area of R. This is called the **mean value theorem** *for double integrals.*

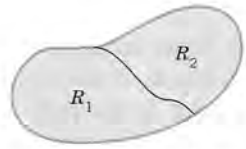

Fig. 226. Formula (1)

Evaluation of Double Integrals by Two Successive Integrations

Double integrals over a region R may be evaluated by two successive integrations. We may integrate first over y and then over x. Then the formula is

(3)
$$\iint_R f(x, y)\,dx\,dy = \int_a^b \left[\int_{g(x)}^{h(x)} f(x, y)\,dy\right] dx \qquad \text{(Fig. 227).}$$

Here $y = g(x)$ and $y = h(x)$ represent the boundary curve of R (see Fig. 227) and, keeping x constant, we integrate $f(x, y)$ over y from $g(x)$ to $h(x)$. The result is a function of x, and we integrate it from $x = a$ to $x = b$ (Fig. 227).

Similarly, for integrating first over x and then over y the formula is

(4)
$$\iint_R f(x, y)\,dx\,dy = \int_c^d \left[\int_{p(y)}^{q(y)} f(x, y)\,dx\right] dy \qquad \text{(Fig. 228).}$$

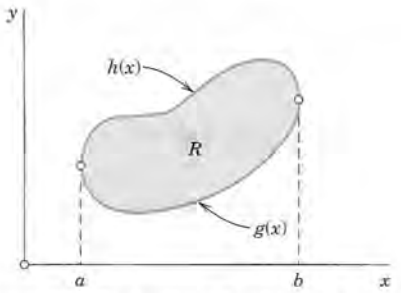

Fig. 227. Evaluation of a double integral

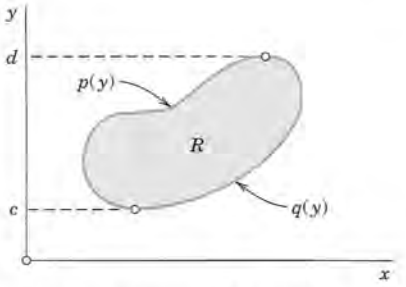

Fig. 228. Evaluation of a double integral

The boundary curve of R is now represented by $x = p(y)$ and $x = q(y)$. Treating y as a constant, we first integrate $f(x, y)$ over x from $p(y)$ to $q(y)$ (see Fig. 228) and then the resulting function of y from $y = c$ to $y = d$.

In (3) we assumed that R can be given by inequalities $a \leqq x \leqq b$ and $g(x) \leqq y \leqq h(x)$. Similarly in (4) by $c \leqq y \leqq d$ and $p(y) \leqq x \leqq q(y)$. If a region R has no such representation, then in any practical case it will at least be possible to subdivide R into finitely many portions each of which can be given by those inequalities. Then we integrate $f(x, y)$ over each portion and take the sum of the results. This will give the value of the integral of $f(x, y)$ over the entire region R.

Applications of Double Integrals

Double integrals have various physical and geometric applications. For instance, the **area** A of a region R in the xy-plane is given by the double integral

$$A = \iint_R dx\, dy.$$

The **volume** V beneath the surface $z = f(x, y)$ (> 0) and above a region R in the xy-plane is (Fig. 229)

$$V = \iint_R f(x, y)\, dx\, dy$$

because the term $f(x_k, y_k)\, \Delta A_k$ in J_n at the beginning of this section represents the volume of a rectangular box with base of area ΔA_k and altitude $f(x_k, y_k)$.

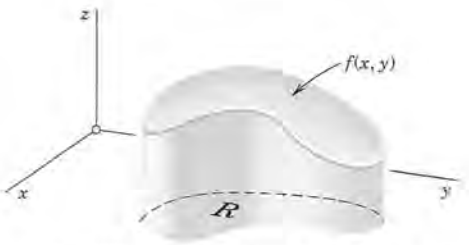

Fig. 229. Double integral as volume

As another application, let $f(x, y)$ be the density (= mass per unit area) of a distribution of mass in the xy-plane. Then the **total mass** M in R is

$$M = \iint_R f(x, y)\, dx\, dy;$$

the **center of gravity** of the mass in R has the coordinates $\bar{x}$, $\bar{y}$, where

$$\bar{x} = \frac{1}{M} \iint_R x f(x, y)\, dx\, dy \qquad \text{and} \qquad \bar{y} = \frac{1}{M} \iint_R y f(x, y)\, dx\, dy;$$

the **moments of inertia** I_x and I_y of the mass in R about the x- and y-axes, respectively, are

$$I_x = \iint_R y^2 f(x, y)\, dx\, dy, \qquad I_y = \iint_R x^2 f(x, y)\, dx\, dy;$$

and the **polar moment of inertia** I_0 about the origin of the mass in R is

$$I_0 = I_x + I_y = \iint_R (x^2 + y^2) f(x, y)\, dx\, dy.$$

An example is given below.

Change of Variables in Double Integrals. Jacobian

Practical problems often require a change of the variables of integration in double integrals. Recall from calculus that for a definite integral the formula for the change from x to u is

$$\int_a^b f(x)\, dx = \int_\alpha^\beta f(x(u)) \frac{dx}{du}\, du. \tag{5}$$

Here we assume that $x = x(u)$ is continuous and has a continuous derivative in some interval $\alpha \leqq u \leqq \beta$ such that $x(\alpha) = a$, $x(\beta) = b$ [or $x(\alpha) = b$, $x(\beta) = a$] and $x(u)$ varies between a and b when u varies between α and β.

The formula for a change of variables in double integrals from x, y to u, v is

$$\iint_R f(x, y)\, dx\, dy = \iint_{R^*} f(x(u, v), y(u, v)) \left| \frac{\partial(x, y)}{\partial(u, v)} \right| du\, dv; \tag{6}$$

that is, the integrand is expressed in terms of u and v, and $dx\, dy$ is replaced by $du\, dv$ times the absolute value of the **Jacobian**[3]

$$J = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \dfrac{\partial x}{\partial u} & \dfrac{\partial x}{\partial v} \\ \dfrac{\partial y}{\partial u} & \dfrac{\partial y}{\partial v} \end{vmatrix} = \frac{\partial x}{\partial u}\frac{\partial y}{\partial v} - \frac{\partial x}{\partial v}\frac{\partial y}{\partial u}. \tag{7}$$

[3]Named after the German mathematician CARL GUSTAV JACOB JACOBI (1804–1851), known for his contributions to elliptic functions, partial differential equations, and mechanics.

Here we assume the following. The functions

$$x = x(u, v), \qquad y = y(u, v)$$

effecting the change are continuous and have continuous partial derivatives in some region R^* in the uv-plane such that for every (u, v) in R^* the corresponding point (x, y) lies in R and, conversely, to every (x, y) in R there corresponds one and only one (u, v) in R^*; furthermore, the Jacobian J is either positive throughout R^* or negative throughout R^*. For a proof, see Ref. [GR4] in App. 1.

EXAMPLE 1 **Change of Variables in a Double Integral**

Evaluate the following double integral over the square R in Fig. 230.

$$\iint_R (x^2 + y^2)\, dx\, dy$$

Solution. The shape of R suggests the transformation $x + y = u$, $x - y = v$. Then $x = \frac{1}{2}(u + v)$, $y = \frac{1}{2}(u - v)$. The Jacobian is

$$J = \frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{vmatrix} = -\frac{1}{2}.$$

R corresponds to the square $0 \leqq u \leqq 2$, $0 \leqq v \leqq 2$. Therefore,

$$\iint_R (x^2 + y^2)\, dx\, dy = \int_0^2 \int_0^2 \frac{1}{2}(u^2 + v^2)\, \frac{1}{2}\, du\, dv = \frac{8}{3}.$$

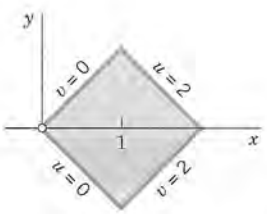

Fig. 230. Region R in Example 1

Of particular practical interest are **polar coordinates** r and θ, which can be introduced by setting $x = r\cos\theta$, $y = r\sin\theta$. Then

$$J = \frac{\partial(x, y)}{\partial(r, \theta)} = \begin{vmatrix} \cos\theta & -r\sin\theta \\ \sin\theta & r\cos\theta \end{vmatrix} = r$$

and

$$\textbf{(8)} \qquad \iint_R f(x, y)\, dx\, dy = \iint_{R^*} f(r\cos\theta, r\sin\theta)\, r\, dr\, d\theta$$

where R^* is the region in the $r\theta$-plane corresponding to R in the xy-plane.

EXAMPLE 2 Double Integrals in Polar Coordinates. Center of Gravity. Moments of Inertia

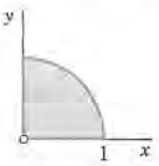

Fig. 231.
Example 2

Let $f(x, y) \equiv 1$ be the mass density in the region in Fig. 231. Find the total mass, the center of gravity, and the moments of inertia I_x, I_y, I_0.

Solution. We use the polar coordinates just defined and formula (8). This gives the total mass

$$M = \iint_R dx\,dy = \int_0^{\pi/2}\int_0^1 r\,dr\,d\theta = \int_0^{\pi/2} \frac{1}{2}\,d\theta = \frac{\pi}{4}.$$

The center of gravity has the coordinates

$$\bar{x} = \frac{4}{\pi}\int_0^{\pi/2}\int_0^1 r\cos\theta\, r\,dr\,d\theta = \frac{4}{\pi}\int_0^{\pi/2}\frac{1}{3}\cos\theta\,d\theta = \frac{4}{3\pi} = 0.4244$$

$$\bar{y} = \frac{4}{3\pi} \qquad \text{for reasons of symmetry.}$$

The moments of inertia are

$$I_x = \iint_R y^2\,dx\,dy = \int_0^{\pi/2}\int_0^1 r^2\sin^2\theta\, r\,dr\,d\theta = \int_0^{\pi/2}\frac{1}{4}\sin^2\theta\,d\theta$$

$$= \int_0^{\pi/2}\frac{1}{8}(1-\cos 2\theta)\,d\theta = \frac{1}{8}\left(\frac{\pi}{2}-0\right) = \frac{\pi}{16} = 0.1963$$

$$I_y = \frac{\pi}{16} \qquad \text{for reasons of symmetry,} \qquad I_0 = I_x + I_y = \frac{\pi}{8} = 0.3927.$$

Why are $\bar{x}$ and $\bar{y}$ less than $\frac{1}{2}$?

This is the end of our review on double integrals. These integrals will be needed in this chapter, beginning in the next section.

PROBLEM SET 10.3

1. (Mean value theorem) Illustrate (2) with an example.

2–9 DOUBLE INTEGRALS

Describe the region of integration and evaluate. (Show the details.)

2. $\displaystyle\int_0^1\int_x^{2x}(x+y)^2\,dy\,dx$

3. $\displaystyle\int_0^1\int_{x^2}^{x}(1-2xy)\,dy\,dx$

4. As Prob. 3, order reversed

5. $\displaystyle\int_0^3\int_0^{y}\cosh(x+y)\,dx\,dy$

6. As Prob. 5, order reversed

7. $\displaystyle\int_0^4\int_{-x}^{x}e^{x+2y}\,dy\,dx$

8. $\displaystyle\int_0^1\int_{1-x}^{1-x^2}x^2y\,dy\,dx$

9. $\displaystyle\int_0^{\pi/2}\int_0^{\sin y}e^x\cos y\,dx\,dy$

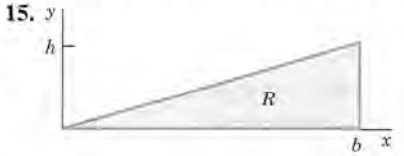
10. Integrate $xye^{x^2-y^2}$ over the triangular region with vertices (0, 0), (1, 1), (1, 2).

11–13 VOLUME

Find the volume of the following regions in space.

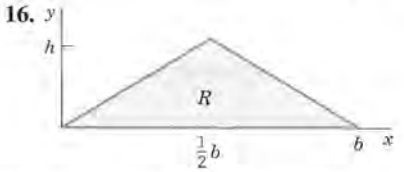
11. The region beneath $z = x^2 + y^2$ and above the square with vertices (1, 1), (−1, 1), (−1, −1), (1, −1)

12. The tetrahedron cut from the first octant by the plane $\frac{3}{2}x + 2y + z = 6$. Check by vector methods.



13. The first octant section cut from the region inside the cylinder $x^2 + z^2 = 1$ by the planes $y = 0$, $z = 0$, $x = y$.

14–16 CENTER OF GRAVITY

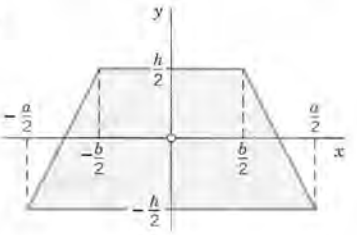


Find the center of gravity $(\bar{x}, \bar{y})$ of a mass of density $f(x, y) = 1$ in the given region R.

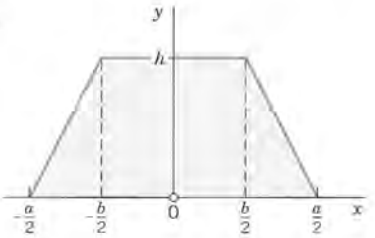
14. R the semidisk $x^2 + y^2 \leqq a^2$, $y \geqq 0$

15.

16.



17–20 MOMENTS OF INERTIA



Find the moments of inertia I_x, I_y, I_0 of a mass of density $f(x, y) = 1$ in the region R shown in the figures (which the engineer is likely to need, along with other profiles listed in engineering handbooks).

17. R as in Prob. 15. **18.** R as in Prob. 16.

19.

20.

10.4 Green's Theorem in the Plane

Double integrals over a plane region may be transformed into line integrals over the boundary of the region and conversely. This is of practical interest because it may simplify the evaluation of an integral. It also helps in the theory whenever we want to switch from one kind of integral to the other. The transformation can be done by the following theorem.

THEOREM 1

Green's Theorem in the Plane[4]
(Transformation between Double Integrals and Line Integrals)

Let R be a closed bounded region (see Sec. 10.3) *in the xy-plane whose boundary C consists of finitely many smooth curves* (see Sec. 10.1). *Let $F_1(x, y)$ and $F_2(x, y)$ be functions that are continuous and have continuous partial derivatives $\partial F_1/\partial y$ and $\partial F_2/\partial x$ everywhere in some domain containing R. Then*

$$\iint_R \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right) dx\, dy = \oint_C (F_1\, dx + F_2\, dy). \tag{1}$$

Here we integrate along the entire boundary C of R in such a sense that R is on the left as we advance in the direction of integration (see Fig. 232 on p. 440).

[4]GEORGE GREEN (1793–1841), English mathematician who was self-educated, started out as a baker, and at his death was fellow of Caius College, Cambridge. His work concerned potential theory in connection with electricity and magnetism, vibrations, waves, and elasticity theory. It remained almost unknown, even in England, until after his death.

A "domain containing R" in the theorem guarantees that the assumptions about F_1 and F_2 at boundary points of R are the same as at other points of R.

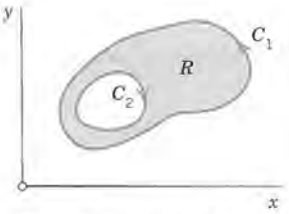


Fig. 232. Region R whose boundary C consists of two parts: C_1 is traversed counterclockwise, while C_2 is traversed clockwise in such a way that R is on the left for both curves

Setting $\mathbf{F} = [F_1, F_2] = F_1\mathbf{i} + F_2\mathbf{j}$ *and using* (1) *in* Sec. 9.9, we obtain (1) in vectorial form,

$$\textbf{(1')} \qquad \iint_R (\operatorname{curl} \mathbf{F}) \bullet \mathbf{k}\, dx\, dy = \oint_C \mathbf{F} \bullet d\mathbf{r}.$$

The proof follows after the first example. For $\oint$ see Sec. 10.1.

EXAMPLE 1 **Verification of Green's Theorem in the Plane**

Green's theorem in the plane will be quite important in our further work. Before proving it, let us get used to it by verifying it for $F_1 = y^2 - 7y$, $F_2 = 2xy + 2x$ and C the circle $x^2 + y^2 = 1$.

Solution. In (1) on the left we get

$$\iint_R \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right) dx\, dy = \iint_R [(2y + 2) - (2y - 7)]\, dx\, dy = 9 \iint_R dx\, dy = 9\pi$$

since the circular disk R has area π.

We now show that the line integral in (1) on the right gives the same value, 9π. We must orient C counterclockwise, say, $\mathbf{r}(t) = [\cos t, \sin t]$. Then $\mathbf{r}'(t) = [-\sin t, \cos t]$, and on C,

$$F_1 = y^2 - 7y = \sin^2 t - 7 \sin t, \qquad F_2 = 2xy + 2x = 2 \cos t \sin t + 2 \cos t.$$

Hence the line integral in (1) becomes, verifying Green's theorem,

$$\begin{aligned} \oint_C (F_1 x' + F_2 y')\, dt &= \int_0^{2\pi} \left[(\sin^2 t - 7 \sin t)(-\sin t) + 2(\cos t \sin t + \cos t)(\cos t) \right] dt \\ &= \int_0^{2\pi} (-\sin^3 t + 7 \sin^2 t + 2 \cos^2 t \sin t + 2 \cos^2 t)\, dt \\ &= 0 + 7\pi - 0 + 2\pi = 9\pi. \end{aligned}$$

■

PROOF We prove Green's theorem in the plane, first for a *special region* R that can be represented in both forms

$$a \leqq x \leqq b, \qquad u(x) \leqq y \leqq v(x) \qquad \text{(Fig. 233)}$$

and

$$c \leqq y \leqq d, \qquad p(y) \leqq x \leqq q(y) \qquad \text{(Fig. 234).}$$

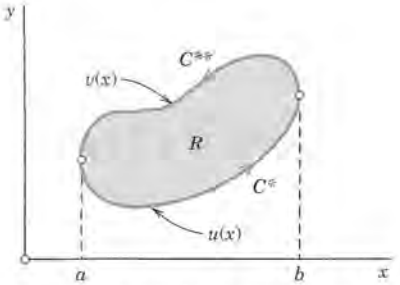

Fig. 233. Example of a special region

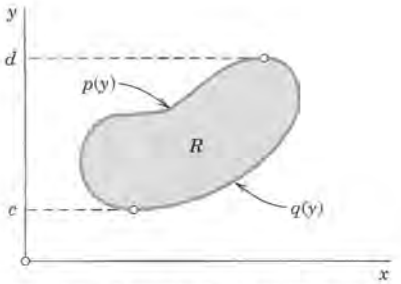

Fig. 234. Example of a special region

Using (3) in the last section, we obtain for the second term on the left side of (1) taken without the minus sign

$$\iint_R \frac{\partial F_1}{\partial y}\,dx\,dy = \int_a^b \left[\int_{u(x)}^{v(x)} \frac{\partial F_1}{\partial y}\,dy \right] dx \qquad \text{(see Fig. 233).} \tag{2}$$

(The first term will be considered later.) We integrate the inner integral:

$$\int_{u(x)}^{v(x)} \frac{\partial F_1}{\partial y}\,dy = F_1(x, y)\Big|_{y=u(x)}^{y=v(x)} = F_1[x, v(x)] - F_1[x, u(x)].$$

By inserting this into (2) we find (changing a direction of integration)

$$\begin{aligned}\iint_R \frac{\partial F_1}{\partial y}\,dx\,dy &= \int_a^b F_1[x, v(x)]\,dx - \int_a^b F_1[x, u(x)]\,dx \\ &= -\int_b^a F_1[x, v(x)]\,dx - \int_a^b F_1[x, u(x)]\,dx.\end{aligned}$$

Since $y = v(x)$ represents the curve C^{**} (Fig. 233) and $y = u(x)$ represents C^*, the last two integrals may be written as line integrals over C^{**} and C^* (oriented as in Fig. 233); therefore,

$$\begin{aligned}\iint_R \frac{\partial F_1}{\partial y}\,dx\,dy &= -\int_{C^{**}} F_1(x, y)\,dx - \int_{C^*} F_1(x, y)\,dx \\ &= -\oint_C F_1(x, y)\,dx.\end{aligned} \tag{3}$$

This proves (1) in Green's theorem if $F_2 = 0$.

The result remains valid if C has portions parallel to the y-axis (such as $\tilde{C}$ and $\tilde{\tilde{C}}$ in Fig. 235). Indeed, the integrals over these portions are zero because in (3) on the right we integrate with respect to x. Hence we may add these integrals to the integrals over C^* and C^{**} to obtain the integral over the whole boundary C in (3).

We now treat the first term in (1) on the left in the same way. Instead of (3) in the last section we use (4), and the second representation of the special region (see Fig. 234). Then (again changing a direction of integration)

$$\iint_R \frac{\partial F_2}{\partial x}\,dx\,dy = \int_c^d \left[\int_{p(y)}^{q(y)} \frac{\partial F_2}{\partial x}\,dx \right] dy$$

$$= \int_c^d F_2(q(y), y)\,dy + \int_d^c F_2(p(y), y)\,dy$$

$$= \oint_C F_2(x, y)\,dy.$$

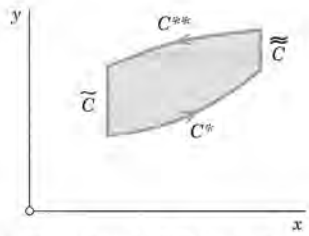

Fig. 235. Proof of Green's theorem

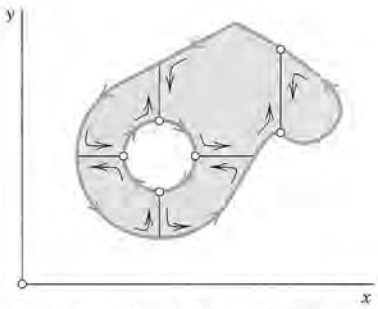

Fig. 236. Proof of Green's theorem

Together with (3) this gives (1) and proves Green's theorem for special regions.

We now prove the theorem for a region R that itself is not a special region but can be subdivided into finitely many special regions (Fig. 236). In this case we apply the theorem to each subregion and then add the results; the left-hand members add up to the integral over R while the right-hand members add up to the line integral over C plus integrals over the curves introduced for subdividing R. The simple ***key observation*** now is that each of the latter integrals occurs twice, taken once in each direction. Hence they cancel each other, leaving us with the line integral over C.

The proof thus far covers all regions that are of interest in practical problems. To prove the theorem for a most general region R satisfying the conditions in the theorem, we must approximate R by a region of the type just considered and then use a limiting process. For details of this see Ref. [GR4] in App. 1. ■

Some Applications of Green's Theorem

EXAMPLE 2 **Area of a Plane Region as a Line Integral Over the Boundary**

In (1) we first choose $F_1 = 0$, $F_2 = x$ and then $F_1 = -y$, $F_2 = 0$. This gives

$$\iint_R dx\,dy = \oint_C x\,dy \qquad \text{and} \qquad \iint_R dx\,dy = -\oint_C y\,dx$$

respectively. The double integral is the area A of R. By addition we have

(4)
$$A = \frac{1}{2}\oint_C (x\,dy - y\,dx)$$

where we integrate as indicated in Green's theorem. This interesting formula expresses the area of R in terms of a line integral over the boundary. It is used, for instance, in the theory of certain **planimeters** (mechanical instruments for measuring area). See also Prob. 17.

For an **ellipse** $x^2/a^2 + y^2/b^2 = 1$ or $x = a\cos t$, $y = b\sin t$ we get $x' = -a\sin t$, $y' = b\cos t$; thus from (4) we obtain the familiar formula for the area of the region bounded by an ellipse,

$$A = \frac{1}{2}\int_0^{2\pi} (xy' - yx')\,dt = \frac{1}{2}\int_0^{2\pi} \left[ab\cos^2 t - (-ab\sin^2 t)\right] dt = \pi ab. \qquad \blacksquare$$

EXAMPLE 3 **Area of a Plane Region in Polar Coordinates**

Let r and θ be polar coordinates defined by $x = r\cos\theta$, $y = r\sin\theta$. Then

$$dx = \cos\theta\,dr - r\sin\theta\,d\theta, \qquad dy = \sin\theta\,dr + r\cos\theta\,d\theta,$$

and (4) becomes a formula that is well known from calculus, namely,

$$A = \frac{1}{2}\oint_C r^2\,d\theta. \tag{5}$$

As an application of (5), we consider the **cardioid** $r = a(1 - \cos\theta)$, where $0 \leqq \theta \leqq 2\pi$ (Fig. 237). We find

$$A = \frac{a^2}{2}\int_0^{2\pi} (1 - \cos\theta)^2\,d\theta = \frac{3\pi}{2}a^2. \qquad \blacksquare$$

EXAMPLE 4 **Transformation of a Double Integral of the Laplacian of a Function into a Line Integral of Its Normal Derivative**

The Laplacian plays an important role in physics and engineering. A first impression of this was obtained in Sec. 9.7, and we shall discuss this further in Chap. 12. At present, let us use Green's theorem for deriving a basic integral formula involving the Laplacian.

We take a function $w(x, y)$ that is continuous and has continuous first and second partial derivatives in a domain of the xy-plane containing a region R of the type indicated in Green's theorem. We set $F_1 = -\partial w/\partial y$ and $F_2 = \partial w/\partial x$. Then $\partial F_1/\partial y$ and $\partial F_2/\partial x$ are continuous in R, and in (1) on the left we obtain

$$\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} = \frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} = \nabla^2 w, \tag{6}$$

the Laplacian of w (see Sec. 9.7). Furthermore, using those expressions for F_1 and F_2, we get in (1) on the right

$$\oint_C (F_1\,dx + F_2\,dy) = \oint_C \left(F_1\frac{dx}{ds} + F_2\frac{dy}{ds}\right) ds = \oint_C \left(-\frac{\partial w}{\partial y}\frac{dx}{ds} + \frac{\partial w}{\partial x}\frac{dy}{ds}\right) ds \tag{7}$$

where s is the arc length of C, and C is oriented as shown in Fig. 238. The integrand of the last integral may be written as the dot product

$$(\text{grad } w)\cdot\mathbf{n} = \left[\frac{\partial w}{\partial x}, \frac{\partial w}{\partial y}\right]\cdot\left[\frac{dy}{ds}, -\frac{dx}{ds}\right] = \frac{\partial w}{\partial x}\frac{dy}{ds} - \frac{\partial w}{\partial y}\frac{dx}{ds}. \tag{8}$$

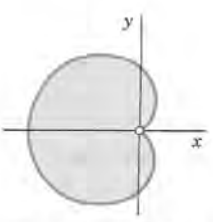

Fig. 237. Cardioid

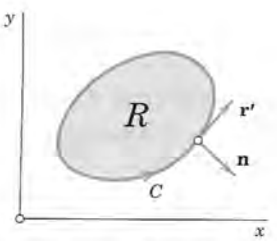

Fig. 238. Example 4

The vector $\mathbf{n}$ is a unit normal vector to C, because the vector $\mathbf{r}'(s) = d\mathbf{r}/ds = [dx/ds, \quad dy/ds]$ is the unit tangent vector of C, and $\mathbf{r}' \cdot \mathbf{n} = 0$, so that $\mathbf{n}$ is perpendicular to $\mathbf{r}'$. Also, $\mathbf{n}$ is directed to the *exterior* of C because in Fig. 238 the positive x-component dx/ds of $\mathbf{r}'$ is the negative y-component of $\mathbf{n}$, and similarly at other points. From this and (4) in Sec. 9.7 we see that the left side of (8) is the derivative of w in the direction of the outward normal of C. This derivative is called the **normal derivative** of w and is denoted by $\partial w/\partial n$; that is, $\partial w/\partial n = (\text{grad } w) \cdot \mathbf{n}$. Because of (6), (7), and (8), Green's theorem gives the desired formula relating the Laplacian to the normal derivative.

(9)
$$\iint_R \nabla^2 w \, dx \, dy = \oint_C \frac{\partial w}{\partial n} \, ds.$$

For instance, $w = x^2 - y^2$ satisfies Laplace's equation $\nabla^2 w = 0$. Hence its normal derivative integrated over a closed curve must give 0. Can you verify this directly by integration, say, for the square $0 \leqq x \leqq 1$, $0 \leqq y \leqq 1$? ■

Green's theorem in the plane may facilitate the evaluation of integrals and can be used in both directions, depending on the kind of integral that is simpler in a concrete case. This is illustrated further in the problem set. Moreover, and perhaps more fundamentally, Green's theorem will be the essential tool in the proof of a very important integral theorem, namely, Stokes's theorem in Sec. 10.9.

PROBLEM SET 10.4

1–12 EVALUATION OF LINE INTEGRALS BY GREEN'S THEOREM

Using Green's theorem, evaluate $\int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r}$ counterclockwise around the boundary curve C of the region R, where

1. $\mathbf{F} = [\frac{1}{2}xy^4, \quad \frac{1}{2}x^4y]$, R the rectangle with vertices (0, 0), (3, 0), (3, 2), (0, 2)
2. $\mathbf{F} = [y \sin x, \quad 2x \cos y]$, R the square with vertices (0, 0), $(\frac{1}{2}\pi, 0)$, $\frac{1}{2}\pi, \frac{1}{2}\pi)$, $(0, \frac{1}{2}\pi)$
3. $\mathbf{F} = [-y^3, \quad x^3]$, C the circle $x^2 + y^2 = 25$
4. $\mathbf{F} = [-e^y, \quad e^x]$, R the triangle with vertices (0, 0), (2, 0), (2, 1)
5. $\mathbf{F} = [e^{x+y}, \quad e^{x-y}]$, R the triangle with vertices (0, 0), (1, 1), (1, 2)
6. $\mathbf{F} = [x \cosh y, \quad x^2 \sinh y]$, R: $x^2 \leqq y \leqq x$. Sketch R.
7. $\mathbf{F} = [x^2 + y^2, \quad x^2 - y^2]$, R: $1 \leqq y \leqq 2 - x^2$. Sketch R.
8. $\mathbf{F} = [e^x \cos y, \quad -e^x \sin y]$, R the semidisk $x^2 + y^2 \leqq a^2$, $x \geqq 0$
9. $\mathbf{F} = \text{grad } (x^3 \cos^2 (xy))$, R the region in Prob. 7
10. $\mathbf{F} = [x \ln y, \quad ye^x]$, R the rectangle with vertices (0, 1), (3, 1), (3, 2), (0, 2)
11. $\mathbf{F} = [2x - 3y, \quad x + 5y]$, R: $16x^2 + 25y^2 \leqq 400$, $y \geqq 0$
12. $\mathbf{F} = [x^2y^2, \quad -x/y^2]$, R: $1 \leqq x^2 + y^2 \leqq 4$, $x \geqq 0$, $y \geqq x$. Sketch R.

13–16 INTEGRAL OF THE NORMAL DERIVATIVE

Using (9), evaluate $\oint_C \frac{\partial w}{\partial n} \, ds$ counterclockwise over the boundary curve C of the region R.

13. $w = \sinh x$, R the triangle with vertices (0, 0), (2, 0), (2, 1)
14. $w = x^2 + y^2$, C: $x^2 + y^2 = 1$. Confirm the answer by direct integration.
15. $w = 2 \ln (x^2 + y^2) + xy^3$, R: $1 \leqq y \leqq 5 - x^2$, $x \geqq 0$
16. $w = x^6y + xy^6$, R: $x^2 + y^2 \leqq 4$, $y \geqq 0$

17. **CAS EXPERIMENT.** Apply (4) to figures of your choice whose area can also be obtained by another method and compare the results.
18. **(Laplace's equation)** Show that for a solution $w(x, y)$ of Laplace's equation $\nabla^2 w = 0$ in a region R with boundary curve C and outer unit normal vector $\mathbf{n}$,

(10)
$$\iint_R \left[\left(\frac{\partial w}{\partial x} \right)^2 + \left(\frac{\partial w}{\partial y} \right)^2 \right] dx \, dy = \oint_C w \frac{\partial w}{\partial n} \, ds.$$

19. Show that $w = 2e^x \cos y$ satisfies Laplace's equation $\nabla^2 w = 0$ and, using (10), integrate $w(\partial w/\partial n)$ counterclockwise around the boundary curve C of the square $0 \leqq x \leqq 2$, $0 \leqq y \leqq 2$.

20. PROJECT. Other Forms of Green's Theorem in the Plane. Let R and C be as in Green's theorem, $\mathbf{r}'$ a unit tangent vector, and $\mathbf{n}$ the outer unit normal vector of C (Fig. 238 in Example 4). Show that (1) may be written

$$\textbf{(11)} \qquad \iint_R \operatorname{div} \mathbf{F}\, dx\, dy = \oint_C \mathbf{F} \cdot \mathbf{n}\, ds$$

or

$$\textbf{(12)} \qquad \iint_R (\operatorname{curl} \mathbf{F}) \cdot \mathbf{k}\, dx\, dy = \oint_C \mathbf{F} \cdot \mathbf{r}'\, ds$$

where $\mathbf{k}$ is a unit vector perpendicular to the xy-plane. Verify (11) and (12) for $\mathbf{F} = [7x, -3y]$ and C the circle $x^2 + y^2 = 4$ as well as for an example of your own choice.

10.5 Surfaces for Surface Integrals

Having introduced double integrals over regions in the plane, we turn next to surface integrals, in which we integrate over surfaces in space, such as a sphere or a portion of a cylinder. For this we must first see how to represent a surface. And we must discuss surface normals, since they are also needed in surface integrals. For simplicity we shall say "surface" also for a portion of a surface.

Representation of Surfaces

Representations of a surface S in xyz-space are

$$(1) \qquad z = f(x, y) \qquad \text{or} \qquad g(x, y, z) = 0.$$

For example, $z = +\sqrt{a^2 - x^2 - y^2}$ or $x^2 + y^2 + z^2 - a^2 = 0$ $(z \geqq 0)$ represents a hemisphere of radius a and center 0.

Now for *curves* C in line integrals, it was more practical and gave greater flexibility to use a *parametric* representation $\mathbf{r} = \mathbf{r}(t)$, where $a \leqq t \leqq b$. This is a mapping of the interval $a \leqq t \leqq b$, located on the t-axis, onto the curve C (actually a portion of it) in xyz-space. It maps every t in that interval onto the point of C with position vector $\mathbf{r}(t)$. See Fig. 239A.

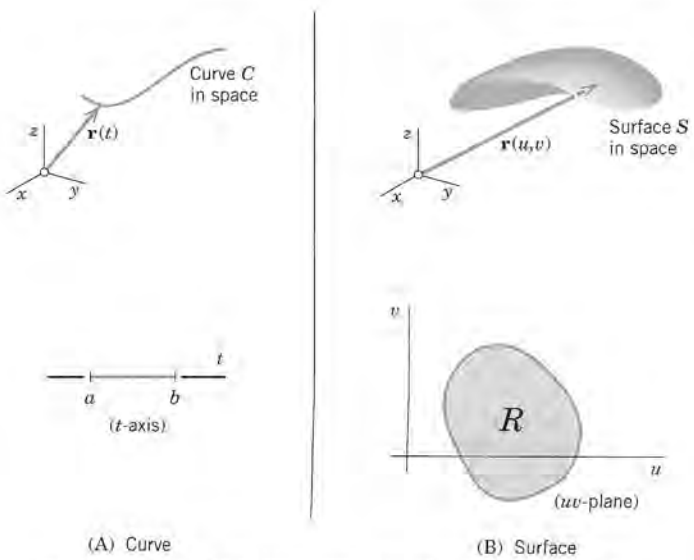

Fig. 239. Parametric representations of a curve and a surface

Similarly, for surfaces S in surface integrals, it will often be more practical to use a *parametric* representation. Surfaces are *two*-dimensional. Hence we need *two* parameters, which we call u and v. Thus a **parametric representation** of a surface S in space is of the form

$$\mathbf{(2)} \qquad \mathbf{r}(u, v) = [x(u, v), y(u, v), z(u, v)] = x(u, v)\mathbf{i} + y(u, v)\mathbf{j} + z(u, v)\mathbf{k}$$

where (u, v) varies in some region R of the uv-plane. This mapping (2) maps every point (u, v) in R onto the point of S with position vector $\mathbf{r}(u, v)$. See Fig. 239B.

EXAMPLE 1 **Parametric Representation of a Cylinder**

The circular cylinder $x^2 + y^2 = a^2$, $-1 \leqq z \leqq 1$, has radius a, height 2, and the z-axis as axis. A parametric representation is

$$\mathbf{r}(u, v) = [a \cos u, a \sin u, v] = a \cos u\, \mathbf{i} + a \sin u\, \mathbf{j} + v\mathbf{k} \qquad \text{(Fig. 240).}$$

The components of $\mathbf{r}$ are $x = a \cos u$, $y = a \sin u$, $z = v$. The parameters u, v vary in the rectangle R: $0 \leqq u \leqq 2\pi$, $-1 \leqq v \leqq 1$ in the uv-plane. The curves $u = const$ are vertical straight lines. The curves $v = const$ are parallel circles. The point P in Fig. 240 corresponds to $u = \pi/3 = 60°$, $v = 0.7$. ■

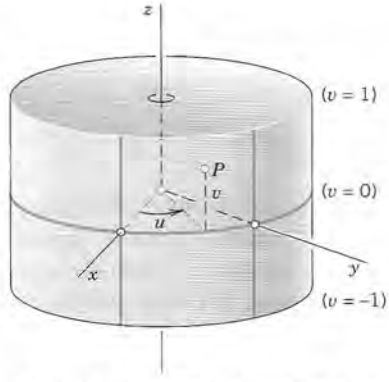

Fig. 240. Parametric representation of a cylinder

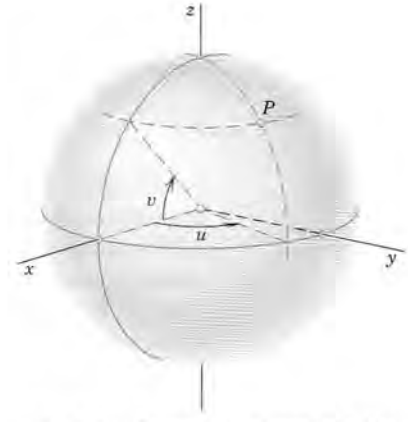

Fig. 241. Parametric representation of a sphere

EXAMPLE 2 **Parametric Representation of a Sphere**

A sphere $x^2 + y^2 + z^2 = a^2$ can be represented in the form

$$\mathbf{(3)} \qquad \mathbf{r}(u, v) = a \cos v \cos u\, \mathbf{i} + a \cos v \sin u\, \mathbf{j} + a \sin v\, \mathbf{k}$$

where the parameters u, v vary in the rectangle R in the uv-plane given by the inequalities $0 \leqq u \leqq 2\pi$, $-\pi/2 \leqq v \leqq \pi/2$. The components of $\mathbf{r}$ are

$$x = a \cos v \cos u, \qquad y = a \cos v \sin u, \qquad z = a \sin v.$$

The curves $u = const$ and $v = const$ are the "meridians" and "parallels" on S (see Fig. 241). *This representation is used in* ***geography*** *for measuring the latitude and longitude of points on the globe.*

Another parametric representation of the sphere also used in mathematics is

$$\mathbf{(3*)} \qquad \mathbf{r}(u, v) = a \cos u \sin v\, \mathbf{i} + a \sin u \sin v\, \mathbf{j} + a \cos v\, \mathbf{k}$$

where $0 \leqq u \leqq 2\pi$, $0 \leqq v \leqq \pi$. ■

EXAMPLE 3 Parametric Representation of a Cone

A circular cone $z = \sqrt{x^2 + y^2}$, $0 \leqq t \leqq H$ can be represented by

$$\mathbf{r}(u, v) = [u \cos v, u \sin v, u] = u \cos v\, \mathbf{i} + u \sin v\, \mathbf{j} + u\mathbf{k},$$

in components $x = u \cos v$, $y = u \sin v$, $z = u$. The parameters vary in the rectangle R: $0 \leqq u \leqq H$, $0 \leqq v \leqq 2\pi$. Check that $x^2 + y^2 = z^2$, as it should be. What are the curves $u = const$ and $v = const$? ■

Tangent Plane and Surface Normal

Recall from Sec. 9.7 that the tangent vectors of all the curves on a surface S through a point P of S form a plane, called the **tangent plane** of S at P (Fig. 242). Exceptions are points where S has an edge or a cusp (like a cone), so that S cannot have a tangent plane at such a point. Furthermore, a vector perpendicular to the tangent plane is called a **normal vector** of S at P.

Now since S can be given by $\mathbf{r} = \mathbf{r}(u, v)$ in (2), the new idea is that we get a curve C on S by taking a pair of differentiable functions

$$u = u(t), \qquad v = v(t)$$

whose derivatives $u' = du/dt$ and $v' = dv/dt$ are continuous. Then C has the position vector $\tilde{\mathbf{r}}(t) = \mathbf{r}(u(t), v(t))$. By differentiation and the use of the chain rule (Sec. 9.6) we obtain a tangent vector of C on S

$$\tilde{\mathbf{r}}'(t) = \frac{d\tilde{\mathbf{r}}}{dt} = \frac{\partial \mathbf{r}}{\partial u} u' + \frac{\partial \mathbf{r}}{\partial v} v'.$$

Hence the partial derivatives $\mathbf{r}_u$ and $\mathbf{r}_v$ *at* P *are tangential to* S *at* P. We assume that they are linearly independent, which geometrically means that the curves $u = const$ and $v = const$ on S intersect at P at a nonzero angle. Then $\mathbf{r}_u$ and $\mathbf{r}_v$ span the tangent plane of S at P. Hence their cross product gives a **normal vector** $\mathbf{N}$ of S at P.

$$\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v \neq \mathbf{0}. \tag{4}$$

The corresponding **unit normal vector** $\mathbf{n}$ of S at P is (Fig. 242)

$$\mathbf{n} = \frac{1}{|\mathbf{N}|} \mathbf{N} = \frac{1}{|\mathbf{r}_u \times \mathbf{r}_v|} \mathbf{r}_u \times \mathbf{r}_v. \tag{5}$$

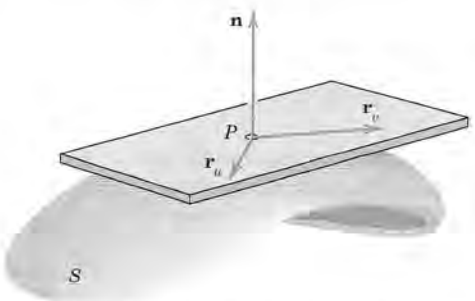

Fig. 242. Tangent plane and normal vector

Also, if S is represented by $g(x, y, z) = 0$, then, by Theorem 2 in Sec. 9.7,

$$\mathbf{(5^*)} \qquad \mathbf{n} = \frac{1}{|\text{grad } g|} \text{grad } g.$$

A surface S is called a **smooth surface** if its surface normal depends continuously on the points of S.

S is called **piecewise smooth** if it consists of finitely many smooth portions.

For instance, a sphere is smooth, and the surface of a cube is piecewise smooth (explain!). We can now summarize our discussion as follows.

THEOREM 1

Tangent Plane and Surface Normal

If a surface S is given by (2) *with continuous* $\mathbf{r}_u = \partial\mathbf{r}/\partial u$ *and* $\mathbf{r}_v = \partial\mathbf{r}/\partial v$ *satisfying* (4) *at every point of S, then S has at every point P a unique tangent plane passing through P and spanned by* $\mathbf{r}_u$ *and* $\mathbf{r}_v$, *and a unique normal whose direction depends continuously on the points of S. A normal vector is given by* (4) *and the corresponding unit normal vector by* (5). (See Fig. 242.)

EXAMPLE 4 **Unit Normal Vector of a Sphere**

From (5*) we find that the sphere $g(x, y, z) = x^2 + y^2 + z^2 - a^2 = 0$ has the unit normal vector

$$\mathbf{n}(x, y, z) = \left[\frac{x}{a}, \frac{y}{a}, \frac{z}{a}\right] = \frac{x}{a}\,\mathbf{i} + \frac{y}{a}\,\mathbf{j} + \frac{z}{a}\,\mathbf{k}.$$

We see that $\mathbf{n}$ has the direction of the position vector $[x, y, z]$ of the corresponding point. Is it obvious that this must be the case? ■

EXAMPLE 5 **Unit Normal Vector of a Cone**

At the apex of the cone $g(x, y, z) = -z + \sqrt{x^2 + y^2} = 0$ in Example 3, the unit normal vector $\mathbf{n}$ becomes undetermined because from (5*) we get

$$\mathbf{n} = \left[\frac{x}{\sqrt{2(x^2 + y^2)}}, \frac{y}{\sqrt{2(x^2 + y^2)}}, \frac{-1}{\sqrt{2}}\right] = \frac{1}{\sqrt{2}}\left(\frac{x}{\sqrt{x^2 + y^2}}\,\mathbf{i} + \frac{y}{\sqrt{x^2 + y^2}}\,\mathbf{j} - \mathbf{k}\right). \blacksquare$$

We are now ready to discuss surface integrals and their applications, beginning in the next section.

PROBLEM SET 10.5

1–10 PREPARATION FOR SURFACE INTEGRALS: PARAMETRIC REPRESENTATION, NORMAL

Familiarize yourself with parametric representations of important surfaces by deriving a representation (1), by finding the **parameter curves** (curves $u = const$ and $v = const$) of the surface and a normal vector $\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v$ of the surface. (Show the details of your work.)

1. xy-plane $\mathbf{r}(u, v) = [u, v]$ (thus $u\mathbf{i} + v\mathbf{j}$; similarly in Probs. 2–10)
2. xy-plane in polar coordinates $\mathbf{r}(u, v) = [u \cos v, u \sin v]$ (thus $u = r, v = \theta$)
3. Elliptic cylinder $\mathbf{r}(u, v) = [a \cos v, b \sin v, u]$
4. Paraboloid of revolution $\mathbf{r}(u, v) = [u \cos v, u \sin v, u^2]$
5. Cone $\mathbf{r}(u, v) = [au \cos v, au \sin v, cu]$
6. Hyperbolic paraboloid $\mathbf{r}(u, v) = [4u \cosh v, u \sinh v, u^2]$
7. Elliptic paraboloid $\mathbf{r}(u, v) = [3u \cos v, 4u \sin v, u^2]$

8. Helicoid $\mathbf{r}(u, v) = [u \cos v, \quad u \sin v, \quad v]$. Explain the name.

9. Ellipsoid
$\mathbf{r}(u, v) = [2 \cos v \cos u, \quad 3 \cos v \sin u, \quad 4 \sin v]$

10. Ellipsoid
$\mathbf{r}(u, v) = [a \cos v \cos u, \quad b \cos v \sin u, \quad c \sin v]$

11. **CAS EXPERIMENT. Graphing Surfaces, Dependence on *a, b, c*.** Graph the surfaces in Probs. 1–10. In Probs. 6–9 generalize the surfaces by introducing parameters a, b, c and then find out in Probs. 3–10 how the shape of the surfaces depends on a, b, c.

12–19 DERIVATION OF PARAMETRIC REPRESENTATIONS

Find a parametric representation and a normal vector. (The answer gives *one* of them. There are many.)

12. Plane $5x + y - 3z = 30$
13. Plane $4x - 2y + 10z = 16$
14. Sphere $(x - 1)^2 + (y + 2)^2 + z^2 = 25$
15. Sphere $(x + 2)^2 + y^2 + (z - 2)^2 = 1$
16. Elliptic paraboloid $z = 4x^2 + y^2$
17. Parabolic cylinder $z = 3y^2$
18. Hyperbolic cylinder $9x^2 - 4y^2 = 36$
19. Elliptic cone $z = \sqrt{9x^2 + y^2}$

20. **(Representation $z = f(x, y)$)** Show that $z = f(x, y)$ or $g = z - f(x, y) = 0$ can be written ($f_u = \partial f/\partial u$, etc.)

$$\mathbf{r}(u, v) = [u, \quad v, \quad f(u, v)] \quad \text{and} \quad \mathbf{N} = \operatorname{grad} g = [-f_u, \quad -f_v, \quad 1]. \tag{6}$$

21. **(Orthogonal parameters)** Show that the parameter curves $u = const$ and $v = const$ on a surface $\mathbf{r}(u, v)$ are orthogonal (intersect at right angles) if and only if $\mathbf{r}_u \cdot \mathbf{r}_v = 0$.

22. **(Condition (4))** Find the points in Probs. 2–7 at which (4) $\mathbf{N} \neq \mathbf{0}$ does not hold and state whether this is owing to the shape of the surface or to the choice of the representation.

23. **(Change of representation)** Represent the paraboloid in Prob. 4 so that $\mathbf{N}(0, 0) \neq \mathbf{0}$, and show $\mathbf{N}$.

24. **PROJECT. Tangent Planes *T(P)*** will be less important in our work, but you should know how to represent them.
(a) If S: $\mathbf{r}(u, v)$, then $T(P)$: $(\mathbf{r}^* - \mathbf{r} \quad \mathbf{r}_u \quad \mathbf{r}_v) = 0$ (a scalar triple product) or
$\mathbf{r}^*(p, q) = \mathbf{r}(P) + p\mathbf{r}_u(P) + q\mathbf{r}_v(P)$.
(b) If S: $g(x, y, z) = 0$, then $T(P)$: $(\mathbf{r}^* - \mathbf{r}(P)) \cdot \nabla g = 0$.
(c) If S: $z = f(x, y)$, then
$T(P)$: $z^* - z = (x^* - x)f_x(P) + (y^* - y)f_y(P)$.
Interpret (a)–(c) geometrically. Give two examples for (a), two for (b), and two for (c).

10.6 Surface Integrals

To define a surface integral, we take a surface S, given by a parametric representation as just discussed,

$$\mathbf{r}(u, v) = [x(u, v), y(u, v), z(u, v)] = x(u, v)\mathbf{i} + y(u, v)\mathbf{j} + z(u, v)\mathbf{k} \tag{1}$$

where (u, v) varies over a region R in the uv-plane. We assume S to be piecewise smooth (Sec. 10.5), so that S has a normal vector

$$\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v \quad \text{and unit normal vector} \quad \mathbf{n} = \frac{1}{|\mathbf{N}|}\mathbf{N} \tag{2}$$

at every point (except perhaps for some edges or cusps, as for a cube or cone). For a given vector function $\mathbf{F}$ we can now define the **surface integral** over S by

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dA = \iint_R \mathbf{F}(\mathbf{r}(u, v)) \cdot \mathbf{N}(u, v) \, du \, dv. \tag{3}$$

Here $\mathbf{N} = |\mathbf{N}|\mathbf{n}$ by (2), and $|\mathbf{N}| = |\mathbf{r}_u \times \mathbf{r}_v|$ is the area of the parallelogram with sides $\mathbf{r}_u$ and $\mathbf{r}_v$, by the definition of cross product. Hence

$$\mathbf{n}\, dA = \mathbf{n}\,|\mathbf{N}|\, du\, dv = \mathbf{N}\, du\, dv. \tag{3*}$$

And we see that $dA = |\mathbf{N}|\, du\, dv$ is the element of area of S.

Also $\mathbf{F} \cdot \mathbf{n}$ is the normal component of $\mathbf{F}$. This integral arises naturally in flow problems, where it gives the **flux** across S (= mass of fluid crossing S per unit time; see Sec. 9.8) when $\mathbf{F} = \rho\mathbf{v}$. Here, ρ is the density of the fluid and $\mathbf{v}$ the velocity vector of the flow (example below). We may thus call the surface integral (3) the **flux integral.**

We can write (3) in components, using $\mathbf{F} = [F_1, F_2, F_3]$, $\mathbf{N} = [N_1, N_2, N_3]$, and $\mathbf{n} = [\cos\alpha, \cos\beta, \cos\gamma]$. Here, α, β, γ are the angles between $\mathbf{n}$ and the coordinate axes; indeed, for the angle between $\mathbf{n}$ and $\mathbf{i}$, formula (4) in Sec. 9.2 gives $\cos\alpha = \mathbf{n}\cdot\mathbf{i}/|\mathbf{n}||\mathbf{i}| = \mathbf{n}\cdot\mathbf{i}$, and so on. We thus obtain from (3)

$$\begin{aligned} \iint_S \mathbf{F}\cdot\mathbf{n}\, dA &= \iint_S (F_1\cos\alpha + F_2\cos\beta + F_3\cos\gamma)\, dA \\ &= \iint_R (F_1N_1 + F_2N_2 + F_3N_3)\, du\, dv. \end{aligned} \tag{4}$$

In (4) we can write $\cos\alpha\, dA = dy\, dz$, $\cos\beta\, dA = dz\, dx$, $\cos\gamma\, dA = dx\, dy$. Then (4) becomes the following integral for the flux:

$$\iint_S \mathbf{F}\cdot\mathbf{n}\, dA = \iint_S (F_1\, dy\, dz + F_2\, dz\, dx + F_3\, dx\, dy). \tag{5}$$

We can use this formula to evaluate surface integrals by converting them to double integrals over regions in the coordinate planes of the xyz-coordinate system. But we must carefully take into account the orientation of S (the choice of $\mathbf{n}$). We explain this for the integrals of the F_3-terms.

$$\iint_S F_3\cos\gamma\, dA = \iint_S F_3\, dx\, dy. \tag{5'}$$

If the surface S is given by $z = h(x, y)$ with (x, y) varying in a region $\overline{R}$ in the xy-plane, and if S is oriented so that $\cos\gamma > 0$, then (5′) gives

$$\iint_S F_3\cos\gamma\, dA = +\iint_{\overline{R}} F_3(x, y, h(x, y))\, dx\, dy. \tag{5''}$$

But if $\cos\gamma < 0$, the integral on the right of (5″) gets a minus sign in front. This follows if we note that the element of area $dx\, dy$ in the xy-plane is the projection $|\cos\gamma|\, dA$ of the element of area dA of S; and we have $\cos\gamma = +|\cos\gamma|$ when $\cos\gamma > 0$, but $\cos\gamma = -|\cos\gamma|$ when $\cos\gamma < 0$. Similarly for the other two terms in (5). At the same time, this justifies the notations in (5).

Other forms of surface integrals will be discussed later in this section.

EXAMPLE 1 Flux Through a Surface

Compute the flux of water through the parabolic cylinder S: $y = x^2$, $0 \leqq x \leqq 2$, $0 \leqq z \leqq 3$ (Fig. 243) if the velocity vector is $\mathbf{v} = \mathbf{F} = [3z^2, \quad 6, \quad 6xz]$, speed being measured in meters/sec. (Generally, $\mathbf{F} = \rho\mathbf{v}$, but water has the density $\rho = 1$ gm/cm^3 $= 1$ ton/m^3.)

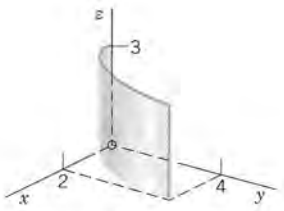

Fig. 243. Surface S in Example 1

Solution. Writing $x = u$ and $z = v$, we have $y = x^2 = u^2$. Hence a representation of S is

$$S: \qquad \mathbf{r} = [u, u^2, v] \qquad (0 \leqq u \leqq 2,\ 0 \leqq v \leqq 3).$$

By differentiation and by the definition of the cross product,

$$\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v = [1, \quad 2u, \quad 0] \times [0, \quad 0, \quad 1] = [2u, \quad -1, \quad 0].$$

On S, writing simply $\mathbf{F}(S)$ for $\mathbf{F}[\mathbf{r}(u, v)]$, we have $\mathbf{F}(S) = [3v^2, 6, 6uv]$. Hence $\mathbf{F}(S) \cdot \mathbf{N} = 6uv^2 - 6$. By integration we thus get from (3) the flux

$$\iint_S \mathbf{F} \cdot \mathbf{n}\, dA = \int_0^3 \int_0^2 (6uv^2 - 6)\, du\, dv = \int_0^3 (3u^2v^2 - 6u)\Big|_{u=0}^{2} dv$$

$$= \int_0^3 (12v^2 - 12)\, dv = (4v^3 - 12v)\Big|_{v=0}^{3} = 108 - 36 = 72 \ [\text{m}^3/\text{sec}]$$

or 72 000 liters/sec. Note that the y-component of $\mathbf{F}$ is positive (equal to 6), so that in Fig. 243 the flow goes from left to right.

Let us confirm this result by (5). Since

$$\mathbf{N} = |\mathbf{N}|\mathbf{n} = |\mathbf{N}|[\cos\alpha, \quad \cos\beta, \quad \cos\gamma] = [2u, \quad -1, \quad 0] = [2x, \quad -1, \quad 0]$$

we see that $\cos\alpha > 0$, $\cos\beta < 0$, and $\cos\gamma = 0$. Hence the second term of (5) on the right gets a minus sign, and the last term is absent. This gives, in agreement with the previous result,

$$\iint_S \mathbf{F} \cdot \mathbf{n}\, dA = \int_0^3 \int_0^4 3z^2\, dy\, dz - \int_0^2 \int_0^3 6\, dz\, dx = \int_0^3 4(3z^2)\, dz - \int_0^2 6 \cdot 3\, dx = 4 \cdot 3^3 - 6 \cdot 3 \cdot 2 = 72. \quad \blacksquare$$

EXAMPLE 2 Surface Integral

Evaluate (3) when $\mathbf{F} = [x^2, 0, 3y^2]$ and S is the portion of the plane $x + y + z = 1$ in the first octant (Fig. 244).

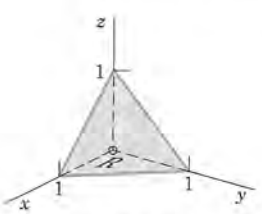

Fig. 244. Portion of a plane in Example 2

Solution. Writing $x = u$ and $y = v$, we have $z = 1 - x - y = 1 - u - v$. Hence we can represent the plane $x + y + z = 1$ in the form $\mathbf{r}(u, v) = [u, v, 1 - u - v]$. We obtain the first-octant portion S of this plane by restricting $x = u$ and $y = v$ to the projection R of S in the xy-plane. R is the triangle bounded by the two coordinate axes and the straight line $x + y = 1$, obtained from $x + y + z = 1$ by setting $z = 0$. Thus $0 \leqq x \leqq 1 - y$, $0 \leqq y \leqq 1$.

By inspection or by differentiation,

$$\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v = [1, 0, -1] \times [0, 1, -1] = [1, 1, 1].$$

Hence $\mathbf{F}(S) \cdot \mathbf{N} = [u^2, 0, 3v^2] \cdot [1, 1, 1] = u^2 + 3v^2$. By (3),

$$\iint_S \mathbf{F} \cdot \mathbf{n}\, dA = \iint_R (u^2 + 3v^2)\, du\, dv = \int_0^1 \int_0^{1-v} (u^2 + 3v^2)\, du\, dv$$

$$= \int_0^1 \left[\frac{1}{3}(1 - v)^3 + 3v^2(1 - v) \right] dv = \frac{1}{3}. \quad \blacksquare$$

Orientation of Surfaces

From (3) or (4) we see that the value of the integral depends on the choice of the unit normal vector $\mathbf{n}$. (Instead of $\mathbf{n}$ we could choose $-\mathbf{n}$.) We express this by saying that such an integral is an *integral over an* **oriented surface** S, that is, over a surface S on which we have chosen one of the two possible unit normal vectors in a continuous fashion. (For a piecewise smooth surface, this needs some further discussion, which we give below.) If we change the orientation of S, this means that we replace $\mathbf{n}$ with $-\mathbf{n}$. Then each component of $\mathbf{n}$ in (4) is multiplied by -1, so that we have

THEOREM 1

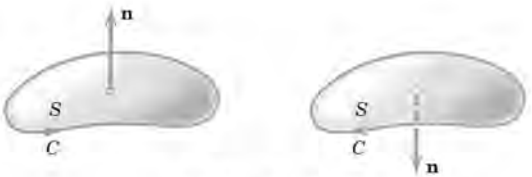
Change of Orientation in a Surface Integral

The replacement of $\mathbf{n}$ *by* $-\mathbf{n}$ *(hence of* $\mathbf{N}$ *by* $-\mathbf{N}$*) corresponds to the multiplication of the integral in* (3) *or* (4) *by* -1.

How do we effect such a change of $\mathbf{N}$ in practice if S is given in the form (1)? The simplest way is to interchange u and v, because then $\mathbf{r}_u$ becomes $\mathbf{r}_v$ and conversely, so that $\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v$ becomes $\mathbf{r}_v \times \mathbf{r}_u = -\mathbf{r}_u \times \mathbf{r}_v = -\mathbf{N}$, as wanted. Let us illustrate this.

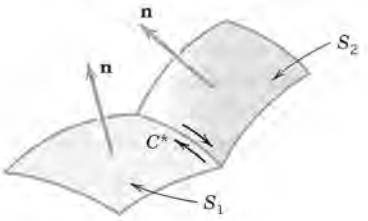
EXAMPLE 3 **Change of Orientation in a Surface Integral**

In Example 1 we now represent S by $\tilde{\mathbf{r}} = [v, v^2, u]$, $0 \leqq v \leqq 2$, $0 \leqq u \leqq 3$. Then



$$\tilde{\mathbf{N}} = \tilde{\mathbf{r}}_u \times \tilde{\mathbf{r}}_v = [0, 0, 1] \times [1, 2v, 0] = [-2v, 1, 0].$$

For $\mathbf{F} = [3z^2, 6, 6xz]$ we now get $\tilde{\mathbf{F}}(S) = [3u^2, 6, 6uv]$. Hence $\tilde{\mathbf{F}}(S) \cdot \tilde{\mathbf{N}} = -6u^2v + 6$ and integration gives the old result times -1,



$$\iint_R \tilde{\mathbf{F}}(S) \cdot \tilde{\mathbf{N}}\, dv\, du = \int_0^3 \int_0^2 (-6u^2v + 6)\, dv\, du = \int_0^3 (-12u^2 + 12)\, du = -72. \quad \blacksquare$$

Orientation of Smooth Surfaces

A smooth surface S (see Sec. 10.5) is called **orientable** if the positive normal direction, when given at an arbitrary point P_0 of S, can be continued in a unique and continuous way to the entire surface. For smooth surfaces occurring in applications this is always true.

(a) Smooth surface

(b) Piecewise smooth surface

Fig. 245. Orientation of a surface

Orientation of Piecewise Smooth Surfaces

Here the following idea will do it. For a *smooth* orientable surface S with boundary curve C we may associate with each of the two possible orientations of S an orientation of C, as shown in Fig. 245a. Then a *piecewise smooth* surface is called **orientable** if we can orient each smooth piece of S so that along each curve C^* which is a common boundary of two pieces S_1 and S_2 the positive direction of C^* relative to S_1 is opposite to the direction of C^* relative to S_2. See Fig. 245b for two adjacent pieces; note the arrows along C^*.

Theory: Nonorientable Surfaces

A sufficiently small piece of a smooth surface is always orientable. This may not hold for entire surfaces. A well-known example is the **Möbius strip**[5], shown in Fig. 246. To make a model, take the rectangular paper in Fig. 246, make a half-twist, and join the short sides together so that A goes onto A, and B onto B. At P_0 take a normal vector pointing, say, to the *left.* Displace it along C to the right (in the lower part of the figure) around the strip until you return to P_0 and see that you get a normal vector pointing to the *right,* opposite to the given one. See also Prob. 21.

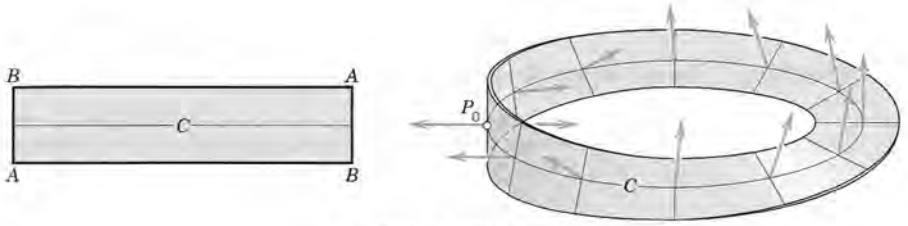


Fig. 246. Möbius strip

[5]AUGUST FERDINAND MÖBIUS (1790–1868), German mathematician, student of Gauss, known for his work in surface theory, geometry, and complex analysis (see Sec. 17.2).

Surface Integrals Without Regard to Orientation

Another type of surface integral is

$$\textbf{(6)} \qquad \iint_S G(\mathbf{r})\, dA = \iint_R G(\mathbf{r}(u, v))|\mathbf{N}(u, v)|\, du\, dv.$$

Here $dA = |\mathbf{N}|\, du\, dv = |\mathbf{r}_u \times \mathbf{r}_v|\, du\, dv$ is the element of area of the surface S represented by (1) and we disregard the orientation.

We shall need later (in Sec. 10.9) the **mean value theorem** for surface integrals, which states that if R in (6) is simply connected (see Sec. 10.2) and $G(\mathbf{r})$ is continuous in a domain containing R, then there is a point (u_0, v_0) in R such that

$$(7) \qquad \iint_S G(\mathbf{r})\, dA = G(\mathbf{r}(u_0, v_0))A \qquad (A = \text{Area of } S).$$

As for applications, if $G(\mathbf{r})$ is the mass density of S, then (6) is the total mass of S. If $G = 1$, then (6) gives the **area** $A(S)$ of S,

$$\textbf{(8)} \qquad A(S) = \iint_S dA = \iint_R |\mathbf{r}_u \times \mathbf{r}_v|\, du\, dv.$$

Examples 4 and 5 show how to apply (8) to a sphere and a torus. The final example, Example 6, explains how to calculate moments of inertia for a surface.

EXAMPLE 4 **Area of a Sphere**

For a sphere $\mathbf{r}(u, v) = [a \cos v \cos u, \quad a \cos v \sin u, \quad a \sin v]$, $0 \leqq u \leqq 2\pi$, $-\pi/2 \leqq v \leqq \pi/2$, [see (3) in Sec. 10.5] we obtain by direct calculation (verify!)

$$\mathbf{r}_u \times \mathbf{r}_v = [a^2 \cos^2 v \cos u, \qquad a^2 \cos^2 v \sin u, \qquad a^2 \cos v \sin v].$$

Using $\cos^2 u + \sin^2 u = 1$ and then $\cos^2 v + \sin^2 v = 1$, we obtain

$$|\mathbf{r}_u \times \mathbf{r}_v| = a^2(\cos^4 v \cos^2 u + \cos^4 v \sin^2 u + \cos^2 v \sin^2 v)^{1/2} = a^2 |\cos v|.$$

With this, (8) gives the familiar formula (note that $|\cos v| = \cos v$ when $-\pi/2 \leqq v \leqq \pi/2$)

$$A(S) = a^2 \int_{-\pi/2}^{\pi/2} \int_0^{2\pi} |\cos v|\, du\, dv = 2\pi a^2 \int_{-\pi/2}^{\pi/2} \cos v\, dv = 4\pi a^2. \qquad \blacksquare$$

EXAMPLE 5 **Torus Surface (Doughnut Surface): Representation and Area**

A *torus surface* S is obtained by rotating a circle C about a straight line L in space so that C does not intersect or touch L but its plane always passes through L. If L is the z-axis and C has radius b and its center has distance a ($> b$) from L, as in Fig. 247, then S can be represented by

$$\mathbf{r}(u, v) = (a + b \cos v) \cos u\, \mathbf{i} + (a + b \cos v) \sin u\, \mathbf{j} + b \sin v\, \mathbf{k}$$

where $0 \leqq u \leqq 2\pi$, $0 \leqq v \leqq 2\pi$. Thus

$$\mathbf{r}_u = -(a + b \cos v) \sin u\, \mathbf{i} + (a + b \cos v) \cos u\, \mathbf{j}$$

$$\mathbf{r}_v = -b \sin v \cos u\, \mathbf{i} - b \sin v \sin u\, \mathbf{j} + b \cos v\, \mathbf{k}$$

$$\mathbf{r}_u \times \mathbf{r}_v = b(a + b \cos v)(\cos u \cos v\, \mathbf{i} + \sin u \cos v\, \mathbf{j} + \sin v\, \mathbf{k}).$$

Hence $|\mathbf{r}_u \times \mathbf{r}_v| = b(a + b\cos v)$, and (8) gives the total area of the torus,

$$A(S) = \int_0^{2\pi}\int_0^{2\pi} b(a + b\cos v)\,du\,dv = 4\pi^2 ab. \tag{9}$$

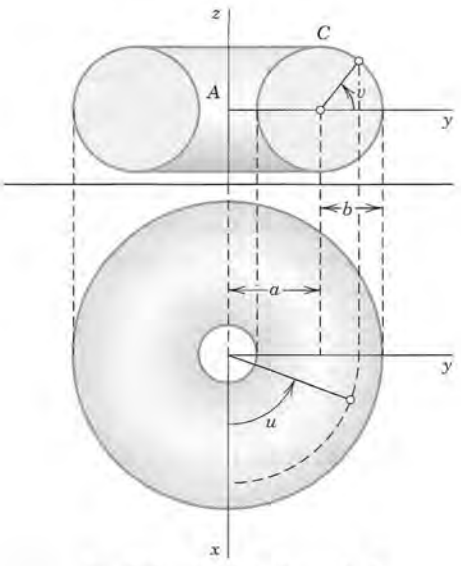

Fig. 247. Torus in Example 5

EXAMPLE 6 Moment of Inertia of a Surface

Find the moment of inertia I of a spherical lamina S: $x^2 + y^2 + z^2 = a^2$ of constant mass density and total mass M about the z-axis.

Solution. If a mass is distributed over a surface S and $\mu(x, y, z)$ is the density of the mass (= mass per unit area), then the moment of inertia I of the mass with respect to a given axis L is defined by the surface integral

$$I = \iint_S \mu D^2\,dA \tag{10}$$

where $D(x, y, z)$ is the distance of the point (x, y, z) from L. Since, in the present example, μ is constant and S has the area $A = 4\pi a^2$, we have $\mu = M/A = M/(4\pi a^2)$.

For S we use the same representation as in Example 4. Then $D^2 = x^2 + y^2 = a^2\cos^2 v$. Also, as in that example, $dA = a^2\cos v\,du\,dv$. This gives the following result. [In the integration, use $\cos^3 v = \cos v\,(1 - \sin^2 v)$.]

$$I = \iint_S \mu D^2\,dA = \frac{M}{4\pi a^2}\int_{-\pi/2}^{\pi/2}\int_0^{2\pi} a^4\cos^3 v\,du\,dv = \frac{Ma^2}{2}\int_{-\pi/2}^{\pi/2}\cos^3 v\,dv = \frac{2Ma^2}{3}.$$

Representations $z = f(x, y)$. If a surface S is given by $z = f(x, y)$, then setting $u = x$, $v = y$, $\mathbf{r} = [u, v, f]$ gives

$$|\mathbf{N}| = |\mathbf{r}_u \times \mathbf{r}_v| = |[1, 0, f_u] \times [0, 1, f_v]| = |[-f_u, -f_v, 1]| = \sqrt{1 + {f_u}^2 + {f_v}^2}$$

and, since $f_u = f_x$, $f_v = f_y$, formula (6) becomes

$$\iint_S G(\mathbf{r})\,dA = \int_{R^*}\int G(x, y, f(x, y))\sqrt{1 + \left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2}\,dx\,dy. \tag{11}$$

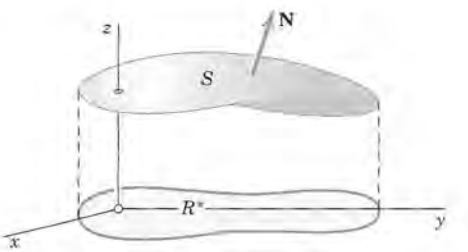

Fig. 248. Formula (11)

Here R^* is the projection of S into the xy-plane (Fig. 248) and the normal vector $\mathbf{N}$ on S points *up*. If it points *down*, the integral on the right is preceded by a minus sign.

From (11) with $G = 1$ we obtain for the **area** $A(S)$ of S: $z = f(x, y)$ the formula

$$\textbf{(12)} \qquad A(S) = \iint_{R^*} \sqrt{1 + \left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2}\, dx\, dy$$

where R^* is the projection of S into the xy-plane, as before.

PROBLEM SET 10.6

1–12 FLUX INTEGRALS (3) $\int_S \mathbf{F} \cdot \mathbf{n}\, dA$

Evaluate these integrals for the following data. Indicate the kind of surface. (Show the details of your work.)

1. $\mathbf{F} = [2x, \quad 5y, \quad 0]$, S: $\mathbf{r} = [u, \quad v, \quad 4u + 3v]$, $0 \leqq u \leqq 1, \ -8 \leqq v \leqq 8$
2. $\mathbf{F} = [x^2, \quad y^2, \quad z^2]$, S: $x + y + z = 4, \ x \geqq 0, \ y \geqq 0, \ z \geqq 0$
3. $\mathbf{F} = [x - z, \quad y - x, \quad z - y]$, S: $\mathbf{r} = [u \cos v, \quad u \sin v, \quad u]$, $0 \leqq u \leqq 3, \ 0 \leqq v \leqq \pi$
4. $\mathbf{F} = [e^y, \quad -e^z, \quad e^x]$, S: $x^2 + y^2 = 9, \ x \geqq 0, \ y \geqq 0, \ 0 \leqq z \leqq 2$
5. $\mathbf{F} = [x, \quad y, \quad z]$, S: $\mathbf{r} = [u \cos v, \quad u \sin v, \quad u^2]$, $0 \leqq u \leqq 4, \ -\pi \leqq v \leqq \pi$
6. $\mathbf{F} = [\cosh yz, \quad 0, \quad y^4]$, S: $y^2 + z^2 = 1, \ 0 \leqq x \leqq 20, \ z \geqq 0$
7. $\mathbf{F} = [1, \quad 1, \quad 1]$, S the sphere of radius 1 and center 0
8. $\mathbf{F} = [\tan xy, \quad x^2y, \quad -z]$, S: $y^2 + \frac{1}{9}z^2 = 1, \ 1 \leqq x \leqq 4$
9. $\mathbf{F} = [0, \quad x, \quad 0]$, S: $x^2 + y^2 + z^2 = a^2, \ x \geqq 0, \ y \geqq 0, \ z \geqq 0$
10. $\mathbf{F} = [y^2, \quad x^2, \quad z^4]$, S: $z = 4\sqrt{x^2 + y^2}, \ 0 \leqq z \leqq 8, \ y \geqq 0$
11. $\mathbf{F} = [y^3, \quad x^3, \quad z^3]$, S: $x^2 + 4y^2 = 4, \ x \geqq 0, \ y \geqq 0, \ 0 \leqq z \leqq h$
12. $\mathbf{F} = [\cosh y, \quad 0, \quad \sinh x]$, S: $z = x + y^2, \ 0 \leqq y \leqq x, \ 0 \leqq x \leqq 1$
13. **CAS EXPERIMENT.** Write a program for evaluating surface integrals (3) that prints intermediate results (**F**, **F** • **N**, the integral over one of the two variables). Can you experimentally obtain rules on functions and surfaces giving integrals that can be evaluated by the usual methods of calculus? Make a list of positive and negative results.

14–20 SURFACE INTEGRALS (6) $\iint_S G(\mathbf{r})\, dA$

Evaluate these integrals for the following data. Indicate the kind of surface. (Show the details.)

14. $G = \cos y + \sin x$, S: $x + y + z = 2, \ x \geqq 0, \ y \geqq 0, \ z \geqq 0$
15. $G = 5(x + y + z)$, S: $z = x + 2y, \ 0 \leqq y \leqq x, \ 0 \leqq x \leqq 2$
16. $G = ye^x + xe^y + e^z$, S: $x^2 + y^2 = 16, \ y \geqq 0, \ 0 \leqq z \leqq 4$
17. $G = (x^2 + y^2 + z^2)^2$, S: $z = \sqrt{x^2 + y^2}, \ y \geqq 0, \ 0 \leqq z \leqq 2$
18. $G = ax + by + cz$, S: $x^2 + y^2 + z^2 = 1, \ y \geqq 0, \ z \geqq 0$
19. $G = \arctan(y/x)$, S: $z = x^2 + y^2, \ 1 \leqq z \leqq 9, \ x \geqq 0, \ y \geqq 0$
20. $G = 3xy$, S: $z = xy, \ 0 \leqq x \leqq 1, \ 0 \leqq y \leqq 1$
21. **(Fun with Möbius)** Make Möbius strips from long slim rectangles R of grid paper (graph paper) by pasting the short sides together after giving the paper a half-twist. In each case count the number of parts obtained

by cutting along lines parallel to the edge. (a) Make R three squares wide and cut until you reach the beginning. (b) Make R four squares wide. Begin cutting one square away from the edge until you reach the beginning. Then cut the portion that is still two squares wide. (c) Make R five squares wide and cut similarly. (d) Make R six squares wide and cut. Formulate a conjecture about the number of parts obtained.

APPLICATIONS

22. (Center of gravity) Justify the following formulas for the mass M and the center of gravity $(\bar{x}, \bar{y}, \bar{z})$ of a lamina S of density (mass per unit area) $\sigma(x, y, z)$ in space:

$$M = \iint_S \sigma \, dA, \quad \bar{x} = \frac{1}{M} \iint_S x\sigma \, dA,$$
$$\bar{y} = \frac{1}{M} \iint_S y\sigma \, dA, \quad \bar{z} = \frac{1}{M} \iint_S z\sigma \, dA.$$

23. (Moments of inertia) Justify the following formulas for the moments of inertia of the lamina in Prob. 22 about the x-, y-, and z-axes, respectively:

$$I_x = \iint_S (y^2 + z^2)\sigma \, dA, \quad I_y = \iint_S (x^2 + z^2)\sigma \, dA,$$
$$I_z = \iint_S (x^2 + y^2)\sigma \, dA.$$

24. Find a formula for the moment of inertia of the lamina in Prob. 22 about the line $y = x$, $z = 0$.

Find the moment of inertia of a lamina S of density 1 about an axis A, where

25. S: $x^2 + y^2 = 1$, $0 \leqq z \leqq h$, A: the z-axis

26. S as in Prob. 25, A: the line $z = h/2$ in the xz-plane

27. S: $x^2 + y^2 = z^2$, $0 \leqq z \leqq h$, A: the z-axis

28. (Steiner's theorem[6]) If I_A is the moment of inertia of a mass distribution of total mass M with respect to an axis A through the center of gravity, show that its moment of inertia I_B with respect to an axis B, which is parallel to A and has the distance k from it, is

$$I_B = I_A + k^2 M.$$

29. Using Steiner's theorem, find the moment of inertia of S in Prob. 26 about the x-axis.

30. TEAM PROJECT. First Fundamental Form of a Surface. Given a surface S: $\mathbf{r}(u, v)$, the corresponding quadratic differential form

$$(13) \quad ds^2 = E\,du^2 + 2F\,du\,dv + G\,dv^2$$

with coefficients

$$(14) \quad E = \mathbf{r}_u \cdot \mathbf{r}_u, \quad F = \mathbf{r}_u \cdot \mathbf{r}_v, \quad G = \mathbf{r}_v \cdot \mathbf{r}_v$$

is called the **first fundamental form** of S. (E, F, G are standard notations that have nothing to do with F and G that occur at some other places in this chapter.) The first fundamental form is basic in the theory of surfaces, since with its help we can determine lengths, angles, and areas on S. To show this, prove the following.

(a) For a curve C: $u = u(t)$, $v = v(t)$, $a \leqq t \leqq b$, on S, formulas (10), Sec. 9.5, and (14) give the length

$$(15) \quad l = \int_a^b \sqrt{\mathbf{r}'(t) \cdot \mathbf{r}'(t)}\, dt = \int_a^b \sqrt{Eu'^2 + 2Fu'v' + Gv'^2}\, dt.$$

(b) The angle γ between two intersecting curves C_1: $u = g(t)$, $v = h(t)$ and C_2: $u = p(t)$, $v = q(t)$ on S: $\mathbf{r}(u, v)$ is obtained from

$$(16) \quad \cos\gamma = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|}$$

where $\mathbf{a} = \mathbf{r}_u g' + \mathbf{r}_v h'$ and $\mathbf{b} = \mathbf{r}_u p' + \mathbf{r}_v q'$ are tangent vectors of C_1 and C_2.

(c) The square of the length of the normal vector $\mathbf{N}$ can be written

$$(17) \quad |\mathbf{N}|^2 = |\mathbf{r}_u \times \mathbf{r}_v|^2 = EG - F^2,$$

so that formula (8) for the area $A(S)$ of S becomes

$$(18) \quad A(S) = \iint_S dA = \iint_R |\mathbf{N}|\, du\, dv = \iint_R \sqrt{EG - F^2}\, du\, dv.$$

(d) For polar coordinates u ($= r$) and v ($= \theta$) defined by $x = u\cos v$, $y = u \sin v$ we have $E = 1$, $F = 0$, $G = u^2$, so that

$$ds^2 = du^2 + u^2\,dv^2 = dr^2 + r^2\,d\theta^2.$$

Calculate from this and (18) the area of a disk of radius a.

(e) Find the first fundamental form of the torus in Example 5. Use it to calculate the area A of the torus. Show that A can also be obtained by the **theorem of**

[6]JACOB STEINER (1796–1863), Swiss geometer, born in a small village, learned to write only at age 14, became a pupil of Pestalozzi at 18, later studied at Heidelberg and Berlin and, finally, because of his outstanding research, was appointed professor at Berlin University.

Pappus,[7] which states that the area of a surface of revolution equals the product of the length of a meridian C and the length of the path of the center of gravity of C when C is rotated through the angle 2π.

(f) Calculate the first fundamental form for the usual representations of important surfaces of your own choice (cylinder, cone, etc.) and apply them to the calculation of lengths and areas on these surfaces.

10.7 Triple Integrals. Divergence Theorem of Gauss

In this section we discuss another "big" integral theorem, the divergence theorem, which transforms surface integrals into triple integrals. So let us begin with a review of the latter.

A **triple integral** is an integral of a function $f(x, y, z)$ taken over a closed bounded (three-dimensional) region T in space (where "closed" and "bounded" are defined as in footnote 2 of Sec. 10.3, with "sphere" substituted for "circle"). We subdivide T by planes parallel to the coordinate planes. Then we consider those boxes of the subdivision (rectangular parallelepipeds) that lie entirely inside T, and number them from 1 to n. In each such box we choose an arbitrary point, say, (x_k, y_k, z_k) in box k. The volume of box k we denote by ΔV_k. We now form the sum

$$J_n = \sum_{k=1}^{n} f(x_k, y_k, z_k)\, \Delta V_k.$$

This we do for larger and larger positive integers n arbitrarily but so that the maximum length of all the edges of those n boxes approaches zero as n approaches infinity. This gives a sequence of real numbers $J_{n_1}, J_{n_2}, \cdots$. We assume that $f(x, y, z)$ is continuous in a domain containing T, and T is bounded by finitely many *smooth surfaces* (see Sec. 10.5). Then it can be shown (see Ref. [GR4] in App. 1) that the sequence converges to a limit that is independent of the choice of subdivisions and corresponding points (x_k, y_k, z_k). This limit is called the **triple integral** *of $f(x, y, z)$ over the region T* and is denoted by

$$\iiint_T f(x, y, z)\, dx\, dy\, dz \qquad \text{or by} \qquad \iiint_T f(x, y, z)\, dV.$$

Triple integrals can be evaluated by three successive integrations. This is similar to the evaluation of double integrals by two successive integrations, as discussed in Sec. 10.3. An example is shown below (Example 1).

Divergence Theorem of Gauss

Triple integrals can be transformed into surface integrals over the boundary surface of a region in space and conversely. Such a transformation is of practical interest because one of the two kinds of integral is often simpler than the other. It also helps in establishing fundamental equations in fluid flow, heat conduction, etc., as we shall see. The transformation is done by the *divergence theorem,* which involves the **divergence** of a vector function $\mathbf{F} = [F_1, F_2, F_3] = F_1\mathbf{i} + F_2\mathbf{j} + F_3\mathbf{k}$, namely,

[7] PAPPUS OF ALEXANDRIA (about A.D. 300), Greek mathematician. The theorem is also called Guldin's theorem. HABAKUK GULDIN (1577–1643) was born in St. Gallen, Switzerland, and later became professor in Graz and Vienna.

(1) $$\operatorname{div} \mathbf{F} = \frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z} \qquad \text{(Sec. 9.8).}$$

THEOREM 1

Divergence Theorem of Gauss
(Transformation Between Triple and Surface Integrals)

Let T be a closed bounded region in space whose boundary is a piecewise smooth orientable surface S. Let $\mathbf{F}(x, y, z)$ be a vector function that is continuous and has continuous first partial derivatives in some domain containing T. Then

(2) $$\iiint_T \operatorname{div} \mathbf{F}\, dV = \iint_S \mathbf{F} \cdot \mathbf{n}\, dA.$$

***In components** of $\mathbf{F} = [F_1, \quad F_2, \quad F_3]$ and of the outer unit normal vector $\mathbf{n} = [\cos \alpha, \quad \cos \beta, \quad \cos \gamma]$ of S* (as in Fig. 250), *formula* (2) *becomes*

(2*) $$\begin{aligned} &\iiint_T \left(\frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z} \right) dx\, d\, y\, dz \\ &= \iint_S (F_1 \cos \alpha + F_2 \cos \beta + F_3 \cos \gamma)\, dA \\ &= \iint_S (F_1\, dy\, dz + F_2\, dz\, dx + F_3\, dx\, dy). \end{aligned}$$

The proof follows after Example 1. "Closed bounded region" is explained above, "piecewise smooth orientable" in Sec. 10.5, and "domain containing T" in footnote 4, Sec. 10.4, for the two-dimensional case.

EXAMPLE 1 **Evaluation of a Surface Integral by the Divergence Theorem**

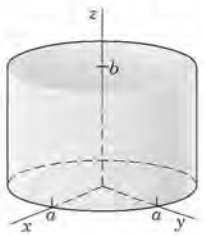

Fig. 249. Surface S in Example 1

Before we prove the theorem, let us show a typical application. Evaluate

$$I = \iint_S (x^3\, dy\, dz + x^2 y\, dz\, dx + x^2 z\, dx\, dy)$$

where S is the closed surface in Fig. 249 consisting of the cylinder $x^2 + y^2 = a^2$ $(0 \leqq z \leqq b)$ and the circular disks $z = 0$ and $z = b$ $(x^2 + y^2 \leqq a^2)$.

Solution. $F_1 = x^3$, $F_2 = x^2 y$, $F_3 = x^2 z$. Hence $\operatorname{div} \mathbf{F} = 3x^2 + x^2 + x^2 = 5x^2$. The form of the surface suggests that we introduce polar coordinates r, θ defined by $x = r \cos \theta$, $y = r \sin \theta$ (thus cylindrical coordinates r, θ, z). Then the volume element is $dx\, dy\, dz = r\, dr\, d\theta\, dz$, and we obtain

$$I = \iiint_T 5x^2\, dx\, dy\, dz = \int_{z=0}^{b} \int_{\theta=0}^{2\pi} \int_{r=0}^{a} (5r^2 \cos^2 \theta) r\, dr\, d\theta\, dz$$

$$= 5 \int_{z=0}^{b} \int_{\theta=0}^{2\pi} \frac{a^4}{4} \cos^2 \theta\, d\theta\, dz = 5 \int_{z=0}^{b} \frac{a^4 \pi}{4}\, dz = \frac{5\pi}{4} a^4 b. \qquad \blacksquare$$

PROOF We prove the divergence theorem, beginning with the first equation in (2*). This equation is true if and only if the integrals of each component on both sides are equal; that is,

$$\iiint_T \frac{\partial F_1}{\partial x}\,dx\,dy\,dz = \iint_S F_1 \cos\alpha\,dA, \tag{3}$$

$$\iiint_T \frac{\partial F_2}{\partial y}\,dx\,dy\,dz = \iint_S F_2 \cos\beta\,dA, \tag{4}$$

$$\iiint_T \frac{\partial F_3}{\partial z}\,dx\,dy\,dz = \iint_S F_3 \cos\gamma\,dA. \tag{5}$$

We first prove (5) for a ***special region*** T that is bounded by a piecewise smooth orientable surface S and has the property that any straight line parallel to any one of the coordinate axes and intersecting T has at most *one* segment (or a single point) in common with T. This implies that T can be represented in the form

$$g(x, y) \leqq z \leqq h(x, y) \tag{6}$$

where (x, y) varies in the orthogonal projection $\overline{R}$ of T in the xy-plane. Clearly, $z = g(x, y)$ represents the "bottom" S_2 of S (Fig. 250), whereas $z = h(x, y)$ represents the "top" S_1 of S, and there may be a remaining vertical portion S_3 of S. (The portion S_3 may degenerate into a curve, as for a sphere.)

To prove (5), we use (6). Since $\mathbf{F}$ is continuously differentiable in some domain containing T, we have

$$\iiint_T \frac{\partial F_3}{\partial z}\,dx\,dy\,dz = \iint_{\overline{R}} \left[\int_{g(x,\,y)}^{h(x,\,y)} \frac{\partial F_3}{\partial z}\,dz\right] dx\,dy. \tag{7}$$

Integration of the inner integral $[\cdots]$ gives $F_3[x, y, h(x, y)] - F_3[x, y, g(x, y)]$. Hence the triple integral in (7) equals

$$\iint_{\overline{R}} F_3[x, y, h(x, y)]\,dx\,dy - \iint_{\overline{R}} F_3[x, y, g(x, y)]\,dx\,dy. \tag{8}$$

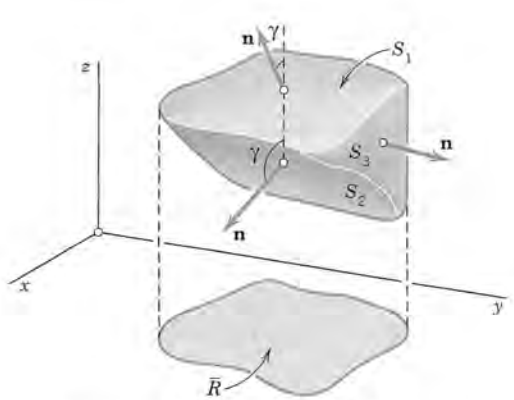

Fig. 250. Example of a special region

But the same result is also obtained by evaluating the right side of (5); that is [see also the last line of (2*)],

$$\iint_S F_3 \cos\gamma \, dA = \iint_S F_3 \, dx\, dy$$

$$= + \iint_{\bar{R}} F_3[x, y, h(x, y)] \, dx\, dy - \iint_{\bar{R}} F_3[x, y, g(x, y)] \, dx\, dy,$$

where the first integral over $\bar{R}$ gets a plus sign because $\cos\gamma > 0$ on S_1 in Fig. 250 [as in (5″), Sec. 10.6], and the second integral gets a minus sign because $\cos\gamma < 0$ on S_2. This proves (5).

The relations (3) and (4) now follow by merely relabeling the variables and using the fact that, by assumption, T has representations similar to (6), namely,

$$\tilde{g}(y, z) \leqq x \leqq \tilde{h}(y, z) \qquad \text{and} \qquad \tilde{\tilde{g}}(z, x) \leqq y \leqq \tilde{\tilde{h}}(z, x).$$

This proves the first equation in (2*) for special regions. It implies (2) because the left side of (2*) is just the definition of the divergence, and the right sides of (2) and of the first equation in (2*) are equal, as was shown in the first line of (4) in the last section. Finally, equality of the right sides of (2) and (2*), last line, is seen from (5) in the last section.

This establishes the divergence theorem for special regions.

For any region T that can be subdivided into *finitely many* special regions by means of auxiliary surfaces, the theorem follows by adding the result for each part separately; this procedure is analogous to that in the proof of Green's theorem in Sec. 10.4. The surface integrals over the auxiliary surfaces cancel in pairs, and the sum of the remaining surface integrals is the surface integral over the whole boundary surface S of T; the triple integrals over the parts of T add up to the triple integral over T.

The divergence theorem is now proved for any bounded region that is of interest in practical problems. The extension to a most general region T of the type indicated in the theorem would require a certain limit process: this is similar to the situation in the case of Green's theorem in Sec. 10.4. ■

EXAMPLE 2 **Verification of the Divergence Theorem**

Evaluate $\iint_S (7x\mathbf{i} - z\mathbf{k})\cdot\mathbf{n}\, dA$ over the sphere S: $x^2 + y^2 + z^2 = 4$ (a) by (2), (b) directly.

Solution. **(a)** $\operatorname{div}\mathbf{F} = \operatorname{div}[7x, 0, -z] = \operatorname{div}[7x\mathbf{i} - z\mathbf{k}] = 7 - 1 = 6$. *Answer:* $6\cdot(4/3)\pi\cdot 2^3 = 64\pi$.

(b) We can represent S by (3), Sec. 10.5 (with $a = 2$), and we shall use $\mathbf{n}\, dA = \mathbf{N}\, du\, dv$ [see (3*), Sec. 10.6]. Accordingly,

$$S: \quad \mathbf{r} = [2\cos v\cos u, \quad 2\cos v\sin u, \quad 2\sin v].$$

Then

$$\mathbf{r}_u = [-2\cos v\sin u, \quad 2\cos v\cos u, \quad 0]$$

$$\mathbf{r}_v = [-2\sin v\cos u, \quad -2\sin v\sin u, \quad 2\cos v]$$

$$\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v = [4\cos^2 v\cos u, \quad 4\cos^2 v\sin u, \quad 4\cos v\sin v],$$

Now on S we have $x = 2\cos v\cos u$, $z = 2\sin v$, so that $\mathbf{F} = [7x, 0, -z]$ becomes on S

$$\mathbf{F}(S) = [14\cos v\cos u, \quad 0, \quad -2\sin v]$$

and

$$\mathbf{F}(S)\cdot\mathbf{N} = (14\cos v\cos u)\cdot 4\cos^2 v\cos u + (-2\sin v)\cdot 4\cos v\sin v$$

$$= 56\cos^3 v\cos^2 u - 8\cos v\sin^2 v.$$

On S we have to integrate over u from 0 to 2π. This gives

$$\pi \cdot 56 \cos^3 v - 2\pi \cdot 8 \cos v \sin^2 v.$$

The integral of $\cos v \sin^2 v$ equals $(\sin^3 v)/3$, and that of $\cos^3 v = \cos v\,(1 - \sin^2 v)$ equals $\sin v - (\sin^3 v)/3$. On S we have $-\pi/2 \leqq v \leqq \pi/2$, so that by substituting these limits we get

$$56\pi(2 - 2/3) - 16\pi \cdot 2/3 = 64\pi$$

as hoped for. To see the point of Gauss's theorem, compare the amounts of work. ■

Coordinate Invariance of the Divergence. The divergence (1) is defined in terms of coordinates, but we can use the divergence theorem to show that div $\mathbf{F}$ has a meaning independent of coordinates.

For this purpose we first note that triple intgrals have properties quite similar to those of double integrals in Sec. 10.3. In particular, the **mean value theorem for triple integrals** asserts that for any continuous function $f(x, y, z)$ in a bounded and simply connected region T there is a point Q: (x_0, y_0, z_0) in T such that

$$\textbf{(9)} \qquad \iiint_T f(x, y, z)\, dV = f(x_0, y_0, z_0)V(T) \qquad (V(T) = \text{volume of } T).$$

In this formula we interchange the two sides, divide by $V(T)$, and set $f = \operatorname{div} \mathbf{F}$. Then by the divergence theorem we obtain for the divergence an integral over the boundary surface $S(T)$ of T,

$$\textbf{(10)} \qquad \operatorname{div} \mathbf{F}(x_0, y_0, z_0) = \frac{1}{V(T)} \iiint_T \operatorname{div} \mathbf{F}\, dV = \frac{1}{V(T)} \iint_{S(T)} \mathbf{F} \cdot \mathbf{n}\, dA.$$

We now choose a point P: (x_1, y_1, z_1) in T and let T shrink down onto P so that the maximum distance $d(T)$ of the points of T from P goes to zero. Then Q: (x_0, y_0, z_0) must approach P. Hence (10) becomes

$$\textbf{(11)} \qquad \operatorname{div} \mathbf{F}(P) = \lim_{d(T) \to 0} \frac{1}{V(T)} \iint_{S(T)} \mathbf{F} \cdot \mathbf{n}\, dA.$$

This proves

THEOREM 2

Invariance of the Divergence

The divergence of a vector function $\mathbf{F}$ *with continuous first partial derivatives in a region* T *is independent of the particular choice of Cartesian coordinates. For any* P *in* T *it is given by* (11).

Equation (11) is sometimes used as a *definition* of the divergence. Then the representation (1) in Cartesian coordinates can be derived from (11).

Further applications of the divergence theorem follow in the problem set and in the next section. The examples in the next section will also shed further light on the nature of the divergence.

PROBLEM SET 10.7

1–8 APPLICATION OF TRIPLE INTEGRALS: MASS DISTRIBUTION

Find the total mass of a mass distribution of density σ in a region T in space. (Show the details of your work.)

1. $\sigma = x^2y^2z^2$, T the box $|x| \leqq a$, $|y| \leqq b$, $|z| \leqq c$
2. $\sigma = x^2 + y^2 + z^2$, T the box $0 \leqq x \leqq 4$, $0 \leqq y \leqq 9$, $0 \leqq z \leqq 1$
3. $\sigma = \sin x \cos y$, T: $0 \leqq x \leqq \frac{1}{2}\pi$, $\frac{1}{2}\pi - x \leqq y \leqq \frac{1}{2}\pi$, $0 \leqq z \leqq 12$
4. $\sigma = e^{-x-y-z}$, T the tetrahedron with vertices (0, 0, 0), (2, 0, 0), (0, 2, 0), (0, 0, 2)
5. $\sigma = \frac{1}{2}(x^2 + y^2)^2$, T the cylinder $x^2 + y^2 \leqq 4$, $|z| \leqq 2$
6. $\sigma = 30z$, T the region in the first octant bounded by $y = 1 - x^2$ and $z = x$. Sketch it.
7. $\sigma = 1 + y + z^2$, T the cylinder $y^2 + z^2 \leqq 9$, $1 \leqq x \leqq 9$
8. $\sigma = x^2 + y^2$, T the ball $x^2 + y^2 + z^2 \leqq a^2$

9–14 APPLICATION OF TRIPLE INTEGRALS: MOMENT OF INERTIA

$I_x = \iiint_T (y^2 + z^2)\, dx\, dy\, dz$ of a mass of density 1 in a region T about the x-axis. Find I_x when T is as follows.

9. The cube $0 \leqq x \leqq a$, $0 \leqq y \leqq a$, $0 \leqq z \leqq a$
10. The box $0 \leqq x \leqq a$, $-b/2 \leqq y \leqq b/2$, $-c/2 \leqq z \leqq c/2$
11. The cylinder $y^2 + z^2 \leqq a^2$, $0 \leqq x \leqq h$
12. The ball $x^2 + y^2 + z^2 \leqq a^2$
13. The cone $y^2 + z^2 \leqq x^2$, $0 \leqq x \leqq h$
14. The paraboloid $y^2 + z^2 \leqq x$, $0 \leqq x \leqq h$
15. Show that for a solid of revolution, $I_x = \frac{1}{2}\pi \int_0^h r^4(x)\, dx$. Use this to solve Probs. 11–14.
16. Why is I_x in Prob. 13 for large h larger than I_x in Prob. 14? Why is it smaller for $h = 1$? Give physical reason.

17–25 APPLICATION OF THE DIVERGENCE THEOREM: SURFACE INTEGRALS $\iint_S \mathbf{F} \cdot \mathbf{n}\, dA$

Evaluate this integral by the divergence theorem. (Show the details.)

17. $\mathbf{F} = [x, \quad y, \quad z]$, S the sphere $x^2 + y^2 + z^2 = 9$
18. $\mathbf{F} = [4x, \quad 3z, \quad 5y]$, S the surface of the cone $x^2 + y^2 \leqq z^2$, $0 \leqq z \leqq 2$
19. $\mathbf{F} = [z - y \quad y^3, \quad 2z^3]$, S the surface of $y^2 + z^2 \leqq 4$, $-3 \leqq x \leqq 3$
20. $\mathbf{F} = [3xy^2, \quad yx^2 - y^3, \quad 3zx^2]$, S the surface of $x^2 + y^2 \leqq 25$, $0 \leqq z \leqq 2$
21. $\mathbf{F} = [\sin y, \quad \cos x, \quad \cos z]$, S the surface of $x^2 + y^2 \leqq 4$, $|z| \leqq 2$
22. $\mathbf{F} = [x^3 - y^3, \quad y^3 - z^3, \quad z^3 - x^3]$, S the surface of $x^2 + y^2 + z^2 \leqq 25$, $z \geqq 0$
23. $\mathbf{F} = [4x^2, \quad 2x + y^2, \quad x^2 + z^2]$, S the surface of the tetrahedron in Prob. 4
24. $\mathbf{F} = [4x^2, \quad y^2, \quad -2\cos \pi z]$, S the surface of the tetrahedron with vertices (0, 0, 0), (1, 0, 0), (0, 1, 0), (0, 0, 1)
25. $\mathbf{F} = [5x^3, \quad 5y^3, \quad 5z^3]$, S: $x^2 + y^2 + z^2 = 4$

10.8 Further Applications of the Divergence Theorem

We show in this section that the divergence theorem has basic applications in *fluid flow*, where it helps characterize *sources* and *sinks* of fluid, in *heat flow*, where it leads to the basic *heat equation*, and in *potential theory*, where it gives basic properties of the solutions of *Laplace's equation*. Here the region T and its boundary surface S are assumed to be such that the divergence theorem applies.

EXAMPLE 1 Fluid Flow. Physical Interpretation of the Divergence

From the divergence theorem we may obtain an intuitive interpretation of the divergence of a vector. For this purpose we consider the flow of an incompressible fluid (see Sec. 9.8) of constant density $\rho = 1$ which is **steady**, that is, does not vary with time. Such a flow is determined by the field of its velocity vector $\mathbf{v}(P)$ at any point P.

Let S be the boundary surface of a region T in space, and let $\mathbf{n}$ be the outer unit normal vector of S. Then $\mathbf{v} \cdot \mathbf{n}$ is the normal component of $\mathbf{v}$ in the direction of $\mathbf{n}$, and $|\mathbf{v} \cdot \mathbf{n}\, dA|$ is the mass of fluid *leaving* T (if $\mathbf{v} \cdot \mathbf{n} > 0$ at some P) or *entering* T (if $\mathbf{v} \cdot \mathbf{n} < 0$ at P) per unit time at some point P of S through a small portion ΔS of S of area ΔA. Hence the total mass of fluid that flows across S from T to the outside per unit time is given by the surface integral

$$\iint_S \mathbf{v} \cdot \mathbf{n}\, dA.$$

Division by the volume V of T gives the **average flow** out of T:

$$\frac{1}{V} \iint_S \mathbf{v} \cdot \mathbf{n}\, dA. \tag{1}$$

Since the flow is steady and the fluid is incompressible, the amount of fluid flowing outward must be continuously supplied. Hence, if the value of the integral (1) is different from zero, there must be **sources** (*positive sources and negative sources, called* **sinks**) in T, that is, points where fluid is produced or disappears.

If we let T shrink down to a fixed point P in T, we obtain from (1) the **source intensity** at P given by the right side of (11) in the last section with $\mathbf{F} \cdot \mathbf{n}$ replaced by $\mathbf{v} \cdot \mathbf{n}$, that is,

$$\text{div } \mathbf{v}(P) = \lim_{d(T) \to 0} \frac{1}{V(T)} \iint_{S(T)} \mathbf{v} \cdot \mathbf{n}\, dA. \tag{2}$$

Hence *the divergence of the velocity vector* $\mathbf{v}$ *of a steady incompressible flow is the source intensity of the flow at the corresponding point.*

There are no sources in T if and only if div $\mathbf{v}$ is zero everywhere in T. Then for any closed surface S in T we have

$$\iint_S \mathbf{v} \cdot \mathbf{n}\, dA = 0.$$

EXAMPLE 2 **Modeling of Heat Flow. Heat or Diffusion Equation**

Physical experiments show that in a body, heat flows in the direction of decreasing temperature, and the rate of flow is proportional to the gradient of the temperature. This means that the velocity $\mathbf{v}$ of the heat flow in a body is of the form

$$\mathbf{v} = -K \text{ grad } U \tag{3}$$

where $U(x, y, z, t)$ is temperature, t is time, and K is called the *thermal conductivity* of the body; in ordinary physical circumstances K is a constant. Using this information, set up the mathematical model of heat flow, the so-called **heat equation** or **diffusion equation.**

Solution. Let T be a region in the body bounded by a surface S with outer unit normal vector $\mathbf{n}$ such that the divergence theorem applies. Then $\mathbf{v} \cdot \mathbf{n}$ is the component of $\mathbf{v}$ in the direction of $\mathbf{n}$, and the amount of heat leaving T per unit time is

$$\iint_S \mathbf{v} \cdot \mathbf{n}\, dA.$$

This expression is obtained similarly to the corresponding surface integral in the last example. Using

$$\text{div (grad } U) = \nabla^2 U = U_{xx} + U_{yy} + U_{zz}$$

(the Laplacian; see (3) in Sec. 9.8), we have by the divergence theorem and (3)

$$\begin{aligned} \iint_S \mathbf{v} \cdot \mathbf{n}\, dA &= -K \iiint_T \text{div (grad } U)\, dx\, dy\, dz \\ &= -K \iiint_T \nabla^2 U\, dx\, dy\, dz. \end{aligned} \tag{4}$$

On the other hand, the total amount of heat H in T is

$$H = \iiint_T \sigma\rho U \, dx\, dy\, dz$$

where the constant σ is the specific heat of the material of the body and ρ is the density (= mass per unit volume) of the material. Hence the time rate of decrease of H is

$$-\frac{\partial H}{\partial t} = -\iiint_T \sigma\rho \frac{\partial U}{\partial t} \, dx\, dy\, dz$$

and this must be equal to the above amount of heat leaving T. From (4) we thus have

$$-\iiint_T \sigma\rho \frac{\partial U}{\partial t} \, dx\, dy\, dz = -K \iiint_T \nabla^2 U \, dx\, dy\, dz$$

or

$$\iiint_T \left(\sigma\rho \frac{\partial U}{\partial t} - K\nabla^2 U\right) dx\, dy\, dz = 0.$$

Since this holds for any region T in the body, the integrand (if continuous) must be zero everywhere; that is,

$$\textbf{(5)} \qquad \frac{\partial U}{\partial t} = c^2 \nabla^2 U \qquad c^2 = \frac{K}{\sigma\rho}$$

where c^2 is called the *thermal diffusivity* of the material. This partial differential equation is called the **heat equation.** It is the fundamental equation for heat conduction. And our derivation is another impressive demonstration of the great importance of the divergence theorem. Methods for solving heat problems will be shown in Chap. 12.

The heat equation is also called the **diffusion equation** because it also models diffusion processes of motions of molecules tending to level off differences in density or pressure in gases or liquids.

If heat flow does not depend on time, it is called **steady-state heat flow.** Then $\partial U/\partial t = 0$, so that (5) reduces to *Laplace's equation* $\nabla^2 U = 0$. We met this equation in Secs. 9.7 and 9.8, and we shall now see that the divergence theorem adds basic insights into the nature of solutions of this equation. ■

Potential Theory. Harmonic Functions

The theory of solutions of **Laplace's equation**

$$\textbf{(6)} \qquad \nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2} = 0$$

is called **potential theory.** A solution of (6) with ***continuous*** second-order partial derivatives is called a **harmonic function.** That continuity is needed for application of the divergence theorem in potential theory, where the theorem plays a key role that we want to explore. Further details of potential theory follow in Chaps. 12 and 18.

EXAMPLE 3 **A Basic Property of Solutions of Laplace's Equation**

The integrands in the divergence theorem are div $\mathbf{F}$ and $\mathbf{F} \cdot \mathbf{n}$ (Sec. 10.7). If $\mathbf{F}$ is the gradient of a scalar function, say, $\mathbf{F} = \text{grad } f$, then div $\mathbf{F} = \text{div (grad } f) = \nabla^2 f$; see (3), Sec. 9.8. Also, $\mathbf{F} \cdot \mathbf{n} = \mathbf{n} \cdot \mathbf{F} = \mathbf{n} \cdot \text{grad } f$. This is the directional derivative of f in the outer normal direction of S, the boundary surface of the region T in the theorem. This derivative is called the (outer) **normal derivative** of f and is denoted by $\partial f/\partial n$. Thus the formula in the divergence theorem becomes

$$\iiint_T \nabla^2 f \, dV = \iint_S \frac{\partial f}{\partial n} \, dA. \tag{7}$$

This is the three-dimensional analog of (9) in Sec. 10.4. Because of the assumptions in the divergence theorem this gives the following result. ■

THEOREM 1

A Basic Property of Harmonic Functions

Let $f(x, y, z)$ be a harmonic function in some domain D is space. Let S be any piecewise smooth closed orientable surface in D whose entire region it encloses belongs to D. Then the integral of the normal derivative of f taken over S is zero. (For "piecewise smooth" see Sec. 10.5.)

EXAMPLE 4 **Green's Theorems**

Let f and g be scalar functions such that $F = f$ grad g satisfies the assumptions of the divergence theorem in some region T. Then

$$\begin{aligned} \operatorname{div} \mathbf{F} &= \operatorname{div} (f \operatorname{grad} g) \\ &= \operatorname{div} \left(\left[f \frac{\partial g}{\partial x}, f \frac{\partial g}{\partial y}, f \frac{\partial g}{\partial z} \right] \right) \\ &= \left(\frac{\partial f}{\partial x} \frac{\partial g}{\partial x} + f \frac{\partial^2 g}{\partial x^2} \right) + \left(\frac{\partial f}{\partial y} \frac{\partial g}{\partial y} + f \frac{\partial^2 g}{\partial y^2} \right) + \left(\frac{\partial f}{\partial z} \frac{\partial g}{\partial z} + f \frac{\partial^2 g}{\partial z^2} \right) \\ &= f \nabla^2 g + \operatorname{grad} f \cdot \operatorname{grad} g. \end{aligned}$$

Also, since f is a scalar function,

$$\begin{aligned} \mathbf{F} \cdot \mathbf{n} &= \mathbf{n} \cdot \mathbf{F} \\ &= \mathbf{n} \cdot (f \operatorname{grad} g) \\ &= (\mathbf{n} \cdot \operatorname{grad} g) f. \end{aligned}$$

Now $\mathbf{n} \cdot \operatorname{grad} g$ is the directional derivative $\partial g / \partial n$ of g in the outer normal direction of S. Hence the formula in the divergence theorem becomes **"Green's first formula"**

$$\iiint_T (f \nabla^2 g + \operatorname{grad} f \cdot \operatorname{grad} g) \, dV = \iint_S f \frac{\partial g}{\partial n} \, dA. \tag{8}$$

Formula (8) together with the assumptions is known as the *first form of Green's theorem.*

Interchanging f and g we obtain a similar formula. Subtracting this formula from (8) we find

$$\iiint_T (f \nabla^2 g - g \nabla^2 f) \, dV = \iint_S \left(f \frac{\partial g}{\partial n} - g \frac{\partial f}{\partial n} \right) dA. \tag{9}$$

This formula is called **Green's second formula** or (together with the assumptions) the *second form of Green's theorem.* ■

EXAMPLE 5 **Uniqueness of Solutions of Laplace's Equation**

Let f be harmonic in a domain D and let f be zero everywhere on a piecewise smooth closed orientable surface S in D whose entire region T it encloses belongs to D. Then $\nabla^2 g$ is zero in T, and the surface integral in (8) is zero, so that (8) with $g = f$ gives

$$\iiint_T \operatorname{grad} f \cdot \operatorname{grad} f \, dV = \iiint_T |\operatorname{grad} f|^2 \, dV = 0.$$

Since f is harmonic, grad f and thus $|\operatorname{grad} f|$ are continuous in T and on S, and since $|\operatorname{grad} f|$ is nonnegative, to make the integral over T zero, grad f must be the zero vector everywhere in T. Hence $f_x = f_y = f_z = 0$, and f is constant in T and, because of continuity, it is equal to its value 0 on S. This proves the following theorem.

THEOREM 2 **Harmonic Functions**

Let $f(x, y, z)$ be harmonic in some domain D and zero at every point of a piecewise smooth closed orientable surface S in D whose entire region T it encloses belongs to D. Then f is identically zero in T.

This theorem has an important consequence. Let f_1 and f_2 be functions that satisfy the assumptions of Theorem 1 and take on the same values on S. Then their difference $f_1 - f_2$ satisfies those assumptions and has the value 0 everywhere on S. Hence, Theorem 2 implies that

$$f_1 - f_2 = 0 \qquad \text{throughout} \qquad T,$$

and we have the following fundamental result.

THEOREM 3 **Uniqueness Theorem for Laplace's Equation**

Let T be a region that satisfies the assumptions of the divergence theorem, and let $f(x, y, z)$ be a harmonic function in a domain D that contains T and its boundary surface S. Then f is uniquely determined in T by its values on S.

The problem of determining a solution u of a partial differential equation in a region T such that u assumes given values on the boundary surface S of T is called the **Dirichlet problem.**[8] We may thus reformulate Theorem 3 as follows.

THEOREM 3* **Uniqueness Theorem for the Dirichlet Problem**

If the assumptions in Theorem 3 are satisfied and the Dirichlet problem for the Laplace equation has a solution in T, then this solution is unique.

These theorems demonstrate the extreme importance of the divergence theorem in potential theory. ■

[8]PETER GUSTAV LEJEUNE DIRICHLET (1805–1859), German mathematician, studied in Paris under Cauchy and others and succeeded Gauss at Göttingen in 1855. He became known by his important research on Fourier series (he knew Fourier personally) and in number theory.

PROBLEM SET 10.8

1. **(Harmonic functions)** Verify Theorem 1 for $f = 2x^2 + 2y^2 - 4z^2$ and S the surface of the cube $0 \leqq x \leqq 1, 0 \leqq y \leqq 1, 0 \leqq z \leqq 1$.
2. **(Harmonic functions)** Verify Theorem 1 for $f = y^2 - x^2$ and the surface of the cylinder $x^2 + y^2 \leqq 1, 0 \leqq z \leqq 5$.
3. **(Green's first formula)** Verify (8) for $f = 3y^2$, $g = x^2$, S the surface of the cube in Prob. 1.
4. **(Green's first formula)** Verify (8) for $f = x$, $g = y^2 + z^2$, S the surface of the box $0 \leqq x \leqq 1$, $0 \leqq y \leqq 2, 0 \leqq z \leqq 3$.
5. **(Green's second formula)** Verify (9) for the data in Prob. 3.
6. **(Green's second formula)** Verify (9) for $f = x^4$, $g = y^2$ and the cube in Prob. 1.
7. **(Volume as a surface integral)** Show that a region T with boundary surface S has the volume

$$V = \frac{1}{3}\iint_S r\cos\phi\, dA$$

where r is the distance of a variable point P: (x, y, z) on S from the origin O and ϕ is the angle between the directed line OP and the outer normal of S at P. (Make a sketch.)

8. Find the volume of a ball of radius a by means of the formula in Prob. 7.
9. Show that a region T with boundary surface S has the volume

$$V = \iint_S x\, dy\, dz$$

$$= \iint_S y\, dz\, dx$$

$$= \iint_S z\, dx\, dy$$

$$= \frac{1}{3}\iint_S (x\, dy\, dz + y\, dz\, dx + z\, dx\, dy).$$

10. **TEAM PROJECT. Divergence Theorem and Potential Theory.** The importance of the divergence theorem in potential theory is obvious from (7)–(9) and Theorems 1–3. To emphasize it further, consider functions f and g that are harmonic in some domain D containing a region T with boundary surface S such that T satisfies the assumptions in the divergence theorem. Prove and illustrate by examples that then:

(a) $$\iint_S g\frac{\partial g}{\partial n}\, dA = \iiint_T |\text{grad } g|^2\, dV.$$

(b) If $\partial g/\partial n = 0$ on S, then g is constant in T.

(c) $$\iint_S \left(f\frac{\partial g}{\partial n} - g\frac{\partial f}{\partial n}\right) dA = 0.$$

(d) If $\partial f/\partial n = \partial g/\partial n$ on S, then $f = g + c$ in T, where c is a constant.

(e) The **Laplacian** can be represented ***independently of coordinate systems*** in the form

$$\nabla^2 f = \lim_{d(T)\to 0} \frac{1}{V(T)} \iint_{S(T)} \frac{\partial f}{\partial n}\, dA$$

where $d(T)$ is the maximum distance of the points of a region T bounded by $S(T)$ from the point at which the Laplacian is evaluated and $V(T)$ is the volume of T.

10.9 Stokes's Theorem

Having seen the great usefulness of Gauss's divergence theorem, we now turn to the second "big" theorem in this chapter, Stokes's theorem. This theorem transforms line integrals into surface integrals and conversely. Hence it generalizes Green's theorem of Sec. 10.4. Stokes's theorem involves the curl

(1) $$\text{curl } \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ F_1 & F_2 & F_3 \end{vmatrix}$$ (see Sec. 9.9).

THEOREM 1

Stokes's Theorem[9]
(Transformation Between Surface and Line Integrals)

Let S be a piecewise smooth[9] oriented surface in space and let the boundary of S be a piecewise smooth simple closed curve C. Let $\mathbf{F}(x, y, z)$ be a continuous vector function that has continuous first partial derivatives in a domain in space containing S. Then

$$\iint_S (\operatorname{curl} \mathbf{F}) \cdot \mathbf{n}\, dA = \oint_C \mathbf{F} \cdot \mathbf{r}'(s)\, ds. \tag{2}$$

Here $\mathbf{n}$ is a unit normal vector of S and, depending on $\mathbf{n}$, the integration around C is taken in the sense shown in Fig. 251. Furthermore, $\mathbf{r}' = d\mathbf{r}/ds$ is the unit tangent vector and s the arc length of C.

In components, formula (2) becomes

$$\iint_R \left[\left(\frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z} \right) N_1 + \left(\frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x} \right) N_2 + \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right) N_3 \right] du\, dv$$
$$= \oint_{\bar{C}} (F_1\, dx + F_2\, dy + F_3\, dz). \tag{2*}$$

Here, $\mathbf{F} = [F_1, F_2, F_3]$, $\mathbf{N} = [N_1, N_2, N_3]$, $\mathbf{n}\, dA = \mathbf{N}\, du\, dv$, $\mathbf{r}'\, ds = [dx, dy, dz]$, and R is the region with boundary curve $\bar{C}$ in the uv-plane corresponding to S represented by $\mathbf{r}(u, v)$.

The proof follows after Example 1.

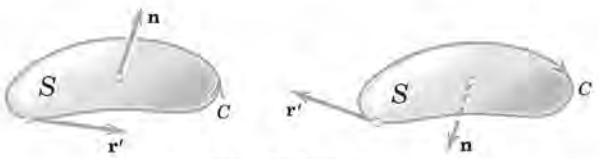

Fig. 251. Stokes's theorem

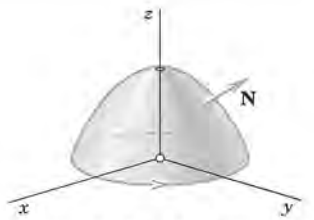

Fig. 252. Surface S in Example 1

EXAMPLE 1 **Verification of Stokes's Theorem**

Before we prove Stokes's theorem, let us first get used to it by verifying it for $\mathbf{F} = [y, z, x]$ and S the paraboloid (Fig. 252)

$$z = f(x, y) = 1 - (x^2 + y^2), \qquad z \geqq 0.$$

Solution. The curve C, oriented as in Fig. 252, is the circle $\mathbf{r}(s) = [\cos s, \sin s, 0]$. Its unit tangent vector is $\mathbf{r}'(s) = [-\sin s, \cos s, 0]$. The function $\mathbf{F} = [y, z, x]$ on C is $\mathbf{F}(\mathbf{r}(s)) = [\sin s, \quad 0, \quad \cos s]$. Hence

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} \mathbf{F}(\mathbf{r}(s)) \cdot \mathbf{r}'(s)\, ds = \int_0^{2\pi} [(\sin s)(-\sin s) + 0 + 0]\, ds = -\pi.$$

---

[9]Sir GEORGE GABRIEL STOKES (1819–1903), Irish mathematician and physicist who became a professor in Cambridge in 1849. He is also known for his important contribution to the theory of infinite series and to viscous flow (Navier–Stokes equations), geodesy, and optics.

"Piecewise smooth" curves and surfaces are defined in Secs. 10.1 and 10.5.

We now consider the surface integral. We have $F_1 = y$, $F_2 = z$, $F_3 = x$, so that in (2*) we obtain

$$\text{curl } \mathbf{F} = \text{curl } [F_1, \quad F_2, \quad F_3] = \text{curl } [y, \quad z, \quad x] = [-1, \quad -1, \quad -1].$$

A normal vector of S is $\mathbf{N} = \text{grad } (z - f(x, y)) = [2x, 2y, 1]$. Hence $(\text{curl } \mathbf{F}) \cdot \mathbf{N} = -2x - 2y - 1$. Now $\mathbf{n}\, dA = \mathbf{N}\, dx\, dy$ (see (3*) in Sec. 10.6 with x, y instead of u, v). Using polar coordinates r, θ defined by $x = r \cos \theta$, $y = r \sin \theta$ and denoting the projection of S into the xy-plane by R, we thus obtain

$$\begin{aligned}
\iint_S (\text{curl } \mathbf{F}) \cdot \mathbf{n}\, dA &= \iint_R (\text{curl } \mathbf{F}) \cdot \mathbf{N}\, dx\, dy = \iint_R (-2x - 2y - 1)\, dx\, dy \\
&= \int_{\theta=0}^{2\pi} \int_{r=0}^{1} (-2r(\cos \theta + \sin \theta) - 1) r\, dr\, d\theta \\
&= \int_{\theta=0}^{2\pi} \left(-\frac{2}{3} (\cos \theta + \sin \theta) - \frac{1}{2} \right) d\theta = 0 + 0 - \frac{1}{2} (2\pi) = -\pi. \qquad \blacksquare
\end{aligned}$$

PROOF We prove Stokes's theorem. Obviously, (2) holds if the integrals of each component on both sides of (2*) are equal; that is,

$$\iint_R \left(\frac{\partial F_1}{\partial z} N_2 - \frac{\partial F_1}{\partial y} N_3 \right) du\, dv = \oint_{\bar{C}} F_1\, dx \tag{3}$$

$$\iint_R \left(-\frac{\partial F_2}{\partial z} N_1 + \frac{\partial F_2}{\partial x} N_3 \right) du\, dv = \oint_{\bar{C}} F_2\, dy \tag{4}$$

$$\iint_R \left(\frac{\partial F_3}{\partial y} N_1 - \frac{\partial F_3}{\partial x} N_2 \right) du\, dv = \oint_{\bar{C}} F_3\, dz. \tag{5}$$

We prove this first for a surface S that can be represented simultaneously in the forms

$$\text{(a)} \quad z = f(x, y), \qquad \text{(b)} \quad y = g(x, z), \qquad \text{(c)} \quad x = h(y, z). \tag{6}$$

We prove (3), using (6a). Setting $u = x$, $v = y$, we have from (6a)

$$\mathbf{r}(u, v) = \mathbf{r}(x, y) = [x, y, f(x, y)] = x\mathbf{i} + y\mathbf{j} + f\mathbf{k}$$

and in (2), Sec. 10.6, by direct calculation

$$\mathbf{N} = \mathbf{r}_u \times \mathbf{r}_v = \mathbf{r}_x \times \mathbf{r}_y = [-f_x, \quad -f_y, \quad 1] = -f_x\mathbf{i} - f_y\mathbf{j} + \mathbf{k}.$$

Note that $\mathbf{N}$ is an *upper* normal vector of S, since it has a *positive* z-component. Also, $R = S^*$, the projection of S into the xy-plane, with boundary curve $\bar{C} = C^*$ (Fig. 253). Hence the left side of (3) is

$$\iint_{S^*} \left[\frac{\partial F_1}{\partial z} (-f_y) - \frac{\partial F_1}{\partial y} \right] dx\, dy. \tag{7}$$

We now consider the right side of (3). We transform this line integral over $\bar{C} = C^*$ into a double integral over S^* by applying Green's theorem [formula (1) in Sec. 10.4 with $F_2 = 0$]. This gives

$$\oint_{C^*} F_1\, dx = \iint_{S^*} -\frac{\partial F_1}{\partial y}\, dx\, dy.$$

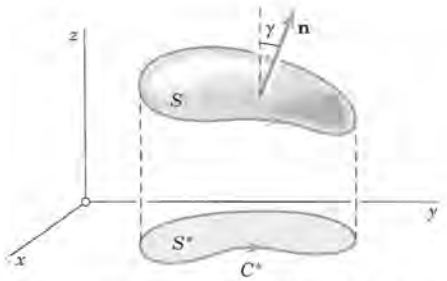

Fig. 253. Proof of Stokes's theorem

Here, $F_1 = F_1(x, y, f(x, y))$. Hence by the chain rule (see also Prob. 10 in Problem Set 9.6),

$$-\frac{\partial F_1(x, y, f(x, y))}{\partial y} = -\frac{\partial F_1(x, y, z)}{\partial y} - \frac{\partial F_1(x, y, z)}{\partial z}\,\frac{\partial f}{\partial y} \qquad [z = f(x, y)].$$

We see that the right side of this equals the integrand in (7). This proves (3). Relations (4) and (5) follow in the same way if we use (6b) and (6c), respectively. By addition we obtain (2*). This proves Stokes's theorem for a surface S that can be represented simultaneously in the forms (6a), (6b), (6c).

As in the proof of the divergence theorem, our result may be immediately extended to a surface S that can be decomposed into finitely many pieces, each of which is of the kind just considered. This covers most of the cases of practical interest. The proof in the case of a most general surface S satisfying the assumptions of the theorem would require a limit process; this is similar to the situation in the case of Green's theorem in Sec. 10.4. ■

EXAMPLE 2 **Green's Theorem in the Plane as a Special Case of Stokes's Theorem**

Let $\mathbf{F} = [F_1, F_2] = F_1\mathbf{i} + F_2\mathbf{j}$ be a vector function that is continuously differentiable in a domain in the xy-plane containing a simply connected bounded closed region S whose boundary C is a piecewise smooth simple closed curve. Then, according to (1),

$$(\operatorname{curl}\mathbf{F})\cdot\mathbf{n} = (\operatorname{curl}\mathbf{F})\cdot\mathbf{k} = \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}.$$

Hence the formula in Stokes's theorem now takes the form

$$\iint_S \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y}\right) dA = \oint_C (F_1\,dx + F_2\,dy).$$

This shows that Green's theorem in the plane (Sec. 10.4) is a special case of Stokes's theorem (which we needed in the proof of the latter!). ■

EXAMPLE 3 **Evaluation of a Line Integral by Stokes's Theorem**

Evaluate $\int_C \mathbf{F}\cdot\mathbf{r}'\,ds$, where C is the circle $x^2 + y^2 = 4$, $z = -3$, oriented counterclockwise as seen by a person standing at the origin, and, with respect to right-handed Cartesian coordinates,

$$\mathbf{F} = [y,\ \ xz^3,\ \ -zy^3] = y\mathbf{i} + xz^3\mathbf{j} - zy^3\mathbf{k}.$$

Solution. As a surface S bounded by C we can take the plane circular disk $x^2 + y^2 \leqq 4$ in the plane $z = -3$. Then $\mathbf{n}$ in Stokes's theorem points in the positive z-direction; thus $\mathbf{n} = \mathbf{k}$. Hence $(\operatorname{curl}\mathbf{F})\cdot\mathbf{n}$ is simply the component of curl $\mathbf{F}$ in the positive z-direction. Since $\mathbf{F}$ with $z = -3$ has the components $F_1 = y$, $F_2 = -27x$, $F_3 = 3y^3$, we thus obtain

$$(\operatorname{curl}\mathbf{F})\cdot\mathbf{n} = \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} = -27 - 1 = -28.$$

Hence the integral over S in Stokes's theorem equals -28 times the area 4π of the disk S. This yields the answer $-28 \cdot 4\pi = -112\pi \approx -352$. Confirm this by direct calculation, which involves somewhat more work. ■

EXAMPLE 4 Physical Meaning of the Curl in Fluid Motion. Circulation

Let S_{r_0} be a circular disk of radius r_0 and center P bounded by the circle C_{r_0} (Fig. 254), and let $\mathbf{F}(Q) \equiv \mathbf{F}(x, y, z)$ be a continuously differentiable vector function in a domain containing S_{r_0}. Then by Stokes's theorem and the mean value theorem for surface integrals (see Sec. 10.6),

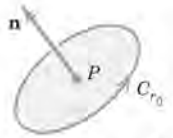

Fig. 254. Example 4

$$\oint_{C_{r_0}} \mathbf{F} \cdot \mathbf{r}' \, ds = \iint_{S_{r_0}} (\operatorname{curl} \mathbf{F}) \cdot \mathbf{n} \, dA = (\operatorname{curl} \mathbf{F}) \cdot \mathbf{n}(P^*) A_{r_0}$$

where A_{r_0} is the area of S_{r_0} and P^* is a suitable point of S_{r_0}. This may be written in the form

$$(\operatorname{curl} \mathbf{F}) \cdot \mathbf{n}(P^*) = \frac{1}{A_{r_0}} \oint_{C_{r_0}} \mathbf{F} \cdot \mathbf{r}' \, ds.$$

In the case of a fluid motion with velocity vector $\mathbf{F} = \mathbf{v}$, the integral

$$\oint_{C_{r_0}} \mathbf{v} \cdot \mathbf{r}' \, ds$$

is called the **circulation** of the flow around C_{r_0}. It measures the extent to which the corresponding fluid motion is a rotation around the circle C_{r_0}. If we now let r_0 approach zero, we find

$$(8) \qquad (\operatorname{curl} \mathbf{v}) \cdot \mathbf{n}(P) = \lim_{r_0 \to 0} \frac{1}{A_{r_0}} \oint_{C_{r_0}} \mathbf{v} \cdot \mathbf{r}' \, ds;$$

that is, the component of the curl in the positive normal direction can be regarded as the **specific circulation** (circulation per unit area) of the flow in the surface at the corresponding point. ■

EXAMPLE 5 Work Done in the Displacement around a Closed Curve

Find the work done by the force $\mathbf{F} = 2xy^3 \sin z \, \mathbf{i} + 3x^2y^2 \sin z \, \mathbf{j} + x^2y^3 \cos z \, \mathbf{k}$ in the displacement around the curve of intersection of the paraboloid $z = x^2 + y^2$ and the cylinder $(x - 1)^2 + y^2 = 1$.

Solution. This work is given by the line integral in Stokes's theorem. Now $\mathbf{F} = \operatorname{grad} f$, where $f = x^2y^3 \sin z$ and $\operatorname{curl}(\operatorname{grad} f) = \mathbf{0}$ (see (2) in Sec. 9.9), so that $(\operatorname{curl} \mathbf{F}) \cdot \mathbf{n} = 0$ and the work is 0 by Stokes's theorem. This agrees with the fact that the present field is conservative (definition in Sec. 9.7). ■

Stokes's Theorem Applied to Path Independence

We emphasized in Sec. 10.2 that the value of a line integral generally depends not only on the function to be integrated and on the two endpoints A and B of the path of integration C, but also on the particular choice of a path from A to B. In Theorem 3 of Sec. 10.2 we proved that if a line integral

$$(9) \qquad \int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_C (F_1 \, dx + F_2 \, dy + F_3 \, dz)$$

(involving continuous F_1, F_2, F_3 that have continuous first partial derivatives) is path independent in a domain D, then $\operatorname{curl} \mathbf{F} = \mathbf{0}$ in D. And we claimed in Sec. 10.2 that, conversely, $\operatorname{curl} \mathbf{F} = \mathbf{0}$ everywhere in D implies path independence of (9) in D provided D is *simply connected.* A proof of this needs Stokes's theorem and can now be given as follows.

Let C be any closed path in D. Since D is simply connected, we can find a surface S in D bounded by C. Stokes's theorem applies and gives

$$\oint_C (F_1 \, dx + F_2 \, dy + F_3 \, dz) = \oint_C \mathbf{F} \cdot \mathbf{r}' \, ds = \iint_S (\operatorname{curl} \mathbf{F}) \cdot \mathbf{n} \, dA$$

for proper direction on C and normal vector $\mathbf{n}$ on S. Since curl $\mathbf{F} = \mathbf{0}$ in D, the surface integral and hence the line integral are zero. This and Theorem 2 of Sec. 10.2 imply that the integral (9) is path independent in D. This completes the proof. ■

PROBLEM SET 10.9

1–8 DIRECT INTEGRATION OF THE SURFACE INTEGRALS

Evaluate the integral $\iint_S (\text{curl } \mathbf{F}) \cdot \mathbf{n}\, dA$ directly for the given $\mathbf{F}$ and S.

1. $\mathbf{F} = [4z^2, \quad 16x, \quad 0]$, S: $z = y$ $(0 \leqq x \leqq 1, 0 \leqq y \leqq 1)$
2. $\mathbf{F} = [0, \quad 0, \quad 5x \cos z]$, S: $x^2 + y^2 = 4$, $y \geqq 0$, $0 \leqq z \leqq \frac{1}{2}\pi$
3. $\mathbf{F} = [-e^y, \quad e^z, \quad e^x]$, S: $z = x + y$ $(0 \leqq x \leqq 1, 0 \leqq y \leqq 1)$
4. $\mathbf{F} = [3 \cos y, \quad \cosh z, \quad x]$, S the square $0 \leqq x \leqq 2$, $0 \leqq y \leqq 2$, $z = 4$
5. $\mathbf{F} = [e^{2z}, \quad e^z \sin y, \quad e^z \cos y]$, S: $z = y^2$ $(0 \leqq x \leqq 4, 0 \leqq y \leqq 1)$
6. $\mathbf{F} = [z^2, \quad x^2, \quad y^2]$, S: $z^2 = x^2 + y^2$, $y \geqq 0$, $0 \leqq z \leqq 2$
7. $\mathbf{F} = [z^2, \quad \frac{3}{2}x, \quad 0]$, S the square $0 \leqq x \leqq a$, $0 \leqq y \leqq a$, $z = 1$
8. $\mathbf{F} = [y^3, \quad -x^3, \quad 0]$, S: $x^2 + y^2 \leqq 1$, $z = 0$
9. Verify Stokes's theorem for $\mathbf{F}$ and S in Prob. 7.
10. Verify Stokes's theorem for $\mathbf{F}$ and S in Prob. 8.

11–18 EVALUATION OF $\oint_C \mathbf{F} \cdot \mathbf{r}'\, ds$

Calculate this line integral by Stokes's theorem, clockwise as seen by a person standing at the origin, for the following F and C. Assume the Cartesian coordinates to be right-handed. (Show the details.)

11. $\mathbf{F} = [-3y, \quad 3x, \quad z]$, C the circle $x^2 + y^2 = 4$, $z = 1$
12. $\mathbf{F} = [4z, \quad -2x, \quad 2x]$, C the intersection of $x^2 + y^2 = 1$ and $z = y + 1$
13. $\mathbf{F} = [y^2, \quad x^2, \quad -x + z]$, around the triangle with vertices (0, 0, 1), (1, 0, 1), (1, 1, 1)
14. $\mathbf{F} = [y, \quad xy^3, \quad -zy^3]$, C the circle $x^2 + y^2 = a^2$, $z = b$ (> 0)
15. $\mathbf{F} = [y, \quad z^2, \quad x^3]$, C as in Prob. 12
16. $\mathbf{F} = [x^2, \quad y^2, \quad z^2]$, C the intersection of $x^2 + y^2 + z^2 = 4$ and $z = y^2$
17. $\mathbf{F} = [\cos \pi y, \quad \sin \pi x, \quad 0]$, around the rectangle with vertices (0, 1, 0), (0, 0, 1), (1, 0, 1), (1, 1, 0)
18. $\mathbf{F} = [z, \quad x, \quad y]$, C as in Prob. 13
19. **(Stokes's theorem not applicable)** Evaluate $\oint_C \mathbf{F} \cdot \mathbf{r}'\, ds$, $\mathbf{F} = (x^2 + y^2)^{-1}[-y, x]$, C: $x^2 + y^2 = 1$, $z = 0$, oriented clockwise. Why can Stokes's theorem not be applied? What (false) result would it give?
20. **WRITING PROJECT. Grad, Div, Curl in Connection with Integrals.** Make a list of ideas and results on this topic in this chapter. See whether you can rearrange or combine parts of your material. Then subdivide the material into 3–5 portions and work out the details of each portion. Include no proofs but simple typical examples of your own that lead to a better understanding of the material.

CHAPTER 10 REVIEW QUESTIONS AND PROBLEMS

1. List the kinds of integrals in this chapter and how the integral theorems relate some of them.
2. How can work of a variable force be expressed by an integral?
3. State from memory how you can evaluate a line integral. A double integral.
4. What do you remember about path independence? Why is it important?
5. How did we use Stokes's theorem in connection with path independence?
6. State the definition of curl. Why is it important in this chapter?
7. How can you transform a double integral or a surface integral into a line integral?
8. What is orientation of a surface? What is its role in connection with surface integrals?
9. State the divergence theorem and its applications from memory.
10. State Laplace's equation. Where in physics is it important? What properties of its solutions did we discuss?

11–20 LINE INTEGRALS $\int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r}$ (WORK INTEGRALS)

Evaluate, with $\mathbf{F}$ and C as given, by the method that seems most suitable. Recall that if $\mathbf{F}$ is a force, the integral gives the work done in a displacement along C. (Show the details.)

11. $\mathbf{F} = [x^2, \quad y^2, \quad z^2]$, C the straight-line segment from (4, 1, 8) to (0, 2, 3)

12. $\mathbf{F} = [\cos z, \quad -\sin z, \quad -x \sin z - y \cos z]$, C the straight-line segment from $(-2, 0, \frac{1}{2}\pi)$ to $(4, 3, 0)$

13. $\mathbf{F} = [x - y, \quad 0, \quad e^z]$,
C: $y = 3x^2$, $z = 2x$ for x from 0 to 2

14. $\mathbf{F} = [yz, \quad 2zx, \quad xy]$,
C the circle $x^2 + y^2 = 9$, $z = 1$, counterclockwise

15. $\mathbf{F} = [-3y^3, \quad 3x^3 + \cos y, \quad 0]$,
C the circle $x^2 + y^2 = 16$, $z = 0$, counterclockwise

16. $\mathbf{F} = [\sin \pi y, \quad \cos \pi x, \quad \sin \pi x]$,
C the boundary of $0 \leqq x \leqq 1/2$, $0 \leqq y \leqq 2$, $z = 2x$

17. $\mathbf{F} = [9z, \quad 5x, \quad 3y]$,
C the ellipse $x^2 + y^2 = 9$, $z = x + 2$

18. $\mathbf{F} = [\cosh x, \quad e^{4y}, \quad \tan z]$, C: $x^2 + y^2 = 4$, $z = x^2$. (Sketch C.)

19. $\mathbf{F} = [z^2, \quad x^3, \quad y^2]$, C: $x^2 + y^2 = 4$, $x + y + z = 0$

20. $\mathbf{F} = [x^2, \quad y^2, \quad y^2x]$, C the helix
$\mathbf{r} = [2 \cos t, \quad 2 \sin t, \quad 6t]$ from $(2, 0, 0)$ to $(0, 2, 3\pi)$

21–25 DOUBLE INTEGRALS, CENTER OF GRAVITY

Find the coordinates $\bar{x}$, $\bar{y}$ of the center of gravity of a mass of density $f(x, y)$ in the region R. (Sketch R. Show the details.)

21. $f = 2xy$, R the triangle with vertices $(0, 0)$, $(1, 0)$, $(1, 1)$

22. $f = 1$, R: $0 \leqq y \leqq 1 - x^2$

23. $f = 1$, R: $x^2 + y^2 \leqq a^2$, $y \geqq 0$

24. $f = x^2 + y^2$, R: $x^2 + y^2 \leqq 1$, $x \geqq 0$, $y \geqq 0$

25. $f = 2x^2$, R the region below $y = x + 2$ and above $y = x^2$

26–35 SURFACE INTEGRALS $\iint_S \mathbf{F} \cdot \mathbf{n}\, dA$

Evaluate this integral directly or, if possible, by the divergence theorem. (Show the details.)

26. $\mathbf{F} = [2x^2, \quad 4y, \quad 0]$,
S: $x + y + z = 1$, $x \geqq 0$, $y \geqq 0$, $z \geqq 0$

27. $\mathbf{F} = [y, \quad -x, \quad 0]$,
S: $3x + 2y + z = 6$, $x \geqq 0$, $y \geqq 0$, $z \geqq 0$

28. $\mathbf{F} = [x - y, \quad y - z, \quad z - x]$,
S the sphere of radius 5 and center 0

29. $\mathbf{F} = [y^2, \quad x^2, \quad z^2]$,
S the surface of $x^2 + y^2 \leqq 4$, $0 \leqq z \leqq 5$

30. $\mathbf{F} = [y^3, \quad x^3, \quad 3z^2]$,
S the portion of the paraboloid $z = x^2 + y^2$, $z \leqq 4$

31. $\mathbf{F} = [\sin^2 x, \quad -y \sin 2x, \quad 5z]$,
S the surface of the box $|x| \leqq a$, $|y| \leqq b$, $|z| \leqq c$

32. $\mathbf{F} = [1, \quad 1, \quad a]$, S: $x^2 + y^2 + 4z^2 = 4$, $z \geqq 0$

33. $\mathbf{F} = [x, \quad xy, \quad z]$, S: $x^2 + y^2 = 1$, $0 \leqq z \leqq h$

34. $\mathbf{F}$ as in Prob. 33, S the complete boundary of $x^2 + y^2 \leqq 1$, $0 \leqq z \leqq h$

35. $\mathbf{F} = [e^y, \quad 0, \quad ze^x]$, S the rectangle with vertices $(0, 0, 0)$, $(1, 2, 0)$, $(0, 0, 5)$, $(1, 2, 5)$

SUMMARY OF CHAPTER 10
Vector Integral Calculus. Integral Theorems

Chapter 9 extended *differential* calculus to vectors, that is, to vector functions $\mathbf{v}(x, y, z)$ or $\mathbf{v}(t)$. Similarly, Chapter 10 extends *integral* calculus to vector functions. This involves *line integrals* (Sec. 10.1), *double integrals* (Sec. 10.3), *surface integrals* (Sec. 10.6), and *triple integrals* (Sec. 10.7) and the three "big" theorems for transforming these integrals into one another, the theorems of Green (Sec. 10.4), Gauss (Sec. 10.7), and Stokes (Sec. 10.9).

The analog of the definite integral of calculus is the **line integral** (Sec. 10.1)

$$(1) \qquad \int_C \mathbf{F}(\mathbf{r}) \cdot d\mathbf{r} = \int_C (F_1\, dx + F_2\, dy + F_3\, dz) = \int_a^b \mathbf{F}(\mathbf{r}(t)) \cdot \frac{d\mathbf{r}}{dt}\, dt$$

where C: $\mathbf{r}(t) = [x(t), y(t), z(t)] = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$ $(a \leqq t \leqq b)$ is a curve in space (or in the plane). Physically, (1) may represent the work done by a (variable) force in a displacement. Other kinds of line integrals and their applications are also discussed in Sec. 10.1.

Independence of path of a line integral in a domain D means that the integral of a given function over any path C with endpoints P and Q has the same value for all paths from P to Q that lie in D; here P and Q are fixed. An integral (1) is independent of path in D if and only if the differential form $F_1\,dx + F_2\,dy + F_3\,dz$ with continuous F_1, F_2, F_3 is **exact** in D (Sec. 10.2). Also, if curl $\mathbf{F} = \mathbf{0}$, where $\mathbf{F} = [F_1, F_2, F_3]$, has continuous first partial derivatives in a *simply connected* domain D, then the integral (1) is independent of path in D (Sec. 10.2).

Integral Theorems. The formula of **Green's theorem in the plane** (Sec. 10.4)

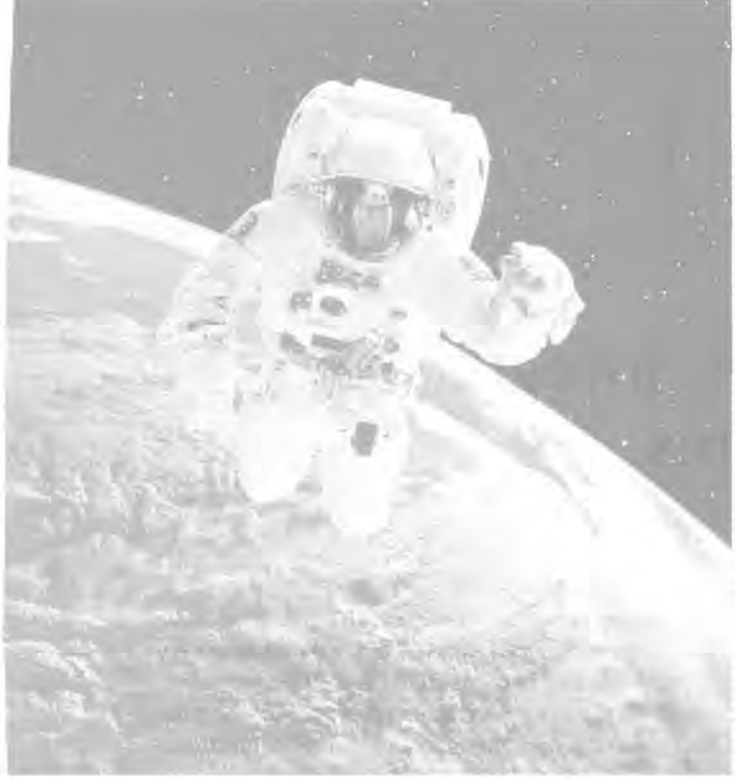
$$\iint_R \left(\frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right) dx\,dy = \oint_C (F_1\,dx + F_2\,dy) \tag{2}$$

transforms **double integrals** over a region R in the xy-plane into line integrals over the boundary curve C of R and conversely. For other forms of (2) see Sec. 10.4.

Similarly, the formula of the **divergence theorem of Gauss** (Sec. 10.7)

$$\iiint_T \operatorname{div} \mathbf{F}\,dV = \iint_S \mathbf{F} \cdot \mathbf{n}\,dA \tag{3}$$

transforms **triple integrals** over a region T in space into surface integrals over the boundary surface S of T, and conversely. Formula (3) implies **Green's formulas**



$$\iiint_T (f \nabla^2 g + \nabla f \cdot \nabla g)\,dV = \iint_S f \frac{\partial g}{\partial n}\,dA, \tag{4}$$

$$\iiint_T (f \nabla^2 g - g \nabla^2 f)\,dV = \iint_S \left(f \frac{\partial g}{\partial n} - g \frac{\partial f}{\partial n} \right) dA. \tag{5}$$

Finally, the formula of **Stokes's theorem** (Sec. 10.9)

$$\iint_S (\operatorname{curl} \mathbf{F}) \cdot \mathbf{n}\,dA = \oint_C \mathbf{F} \cdot \mathbf{r}'(s)\,ds \tag{6}$$

transforms **surface integrals** over a surface S into line integrals over the boundary curve C of S and conversely.

PART C

Fourier Analysis. Partial Differential Equations

CHAPTER 11 Fourier Series, Integrals, and Transforms

CHAPTER 12 Partial Differential Equations (PDEs)

Fourier analysis concerns **periodic phenomena,** as they occur quite frequently in engineering and elsewhere—think of rotating parts of machines, alternating electric currents, or the motion of planets. Related periodic functions may be complicated. This situation poses the important practical task of representing these complicated functions in terms of simple periodic functions, namely, cosines and sines. These representations will be infinite series, called **Fourier series.**[1]

The creation of these series was one of the most path-breaking events in applied mathematics, and we mention that it also had considerable influence on mathematics as a whole, on the concept of a function, on integration theory, on convergence theory for series, and so on (see Ref. [GR7] in App. 1).

Chapter 11 is concerned mainly with Fourier series. However, the underlying ideas can also be extended to *nonperiodic* phenomena. This leads to *Fourier integrals* and *transforms.* A common name for the whole area is **Fourier analysis.**

Chapter 12 deals with the most important **partial differential equations (PDEs)** of physics and engineering. This is the area in which Fourier analysis has its most basic applications, related to boundary and initial value problems of mechanics, heat flow, electrostatics, and other fields.

---

[1]JEAN-BAPTISTE JOSEPH FOURIER (1768–1830), French physicist and mathematician, lived and taught in Paris, accompanied Napoléon in the Egyptian War, and was later made prefect of Grenoble. The beginnings on Fourier series can be found in works by Euler and by Daniel Bernoulli, but it was Fourier who employed them in a systematic and general manner in his main work, *Théorie analytique de la chaleur* (*Analytic Theory of Heat,* Paris, 1822), in which he developed the theory of heat conduction (heat equation; see Sec. 12.5), making these series a most important tool in applied mathematics.

CHAPTER 11

Fourier Series, Integrals, and Transforms

Fourier series (Sec. 11.1) are infinite series designed to represent general periodic functions in terms of simple ones, namely, cosines and sines. They constitute a very important tool, in particular in solving problems that involve ODEs and PDEs.

In this chapter we discuss Fourier series and their engineering use from a practical point of view, in connection with ODEs and with the approximation of periodic functions. Application to PDEs follows in Chap. 12.

The *theory* of Fourier series is complicated, but we shall see that the *application* of these series is rather simple. Fourier series are in a certain sense more universal than the familiar Taylor series in calculus because many *discontinuous* periodic functions of practical interest can be developed in Fourier series but, of course, do not have Taylor series representations.

In the last sections (11.7–11.9) we consider **Fourier integrals** and **Fourier transforms,** which extend the ideas and techniques of Fourier series to nonperiodic functions and have basic applications to PDEs (to be shown in the next chapter).

Prerequisite: Elementary integral calculus (needed for Fourier coefficients)
Sections that may be omitted in a shorter course: 11.4–11.9
References and Answers to Problems: App. 1 Part C, App. 2.

11.1 Fourier Series

Fourier series are the basic tool for representing periodic functions, which play an important role in applications. A function $f(x)$ is called a **periodic function** if $f(x)$ is defined for all real x (perhaps except at some points, such as $x = \pm\pi/2, \pm 3\pi/2, \cdots$ for $\tan x$) and if there is some positive number p, called a **period** of $f(x)$, such that

$$f(x + p) = f(x) \qquad \text{for all } x. \tag{1}$$

The graph of such a function is obtained by periodic repetition of its graph in any interval of length p (Fig. 255).

Familiar periodic functions are the cosine and sine functions. Examples of functions that are not periodic are x, x^2, x^3, e^x, $\cosh x$, and $\ln x$, to mention just a few.

If $f(x)$ has period p, it also has the period $2p$ because (1) implies
$f(x + 2p) = f([x + p] + p) = f(x + p) = f(x)$, etc.; thus for any integer $n = 1, 2, 3, \cdots$,

$$f(x + np) = f(x) \qquad \text{for all } x. \tag{2}$$

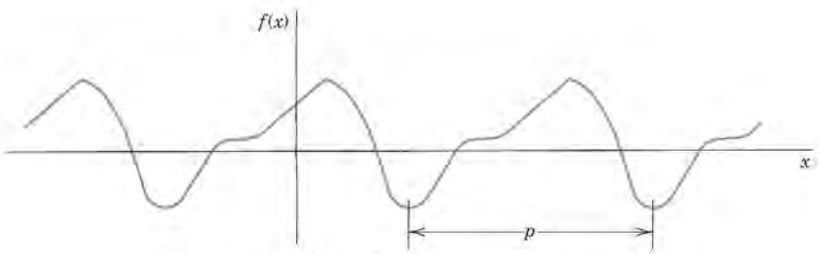


Fig. 255. Periodic function

Furthermore if $f(x)$ and $g(x)$ have period p, then $af(x) + bg(x)$ with any constants a and b also has the period p.

Our problem in the first few sections of this chapter will be the representation of various ***functions f(x) of period 2π*** in terms of the simple functions

$$(3) \quad 1, \quad \cos x, \quad \sin x, \quad \cos 2x, \quad \sin 2x, \cdots, \quad \cos nx, \quad \sin nx, \cdots.$$

All these functions have the period 2π. They form the so-called **trigonometric system.** Figure 256 shows the first few of them (except for the constant 1, which is periodic with any period).

The series to be obtained will be a **trigonometric series,** that is, a series of the form

$$(4) \quad a_0 + a_1 \cos x + b_1 \sin x + a_2 \cos 2x + b_2 \sin 2x + \cdots = a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx).$$

$a_0, a_1, b_1, a_2, b_2, \cdots$ are constants, called the **coefficients** of the series. We see that each term has the period 2π. Hence *if the coefficients are such that the series converges, its sum will be a function of period* 2π.

It can be shown that if the series on the left side of (4) converges, then inserting parentheses on the right gives a series that converges and has the same sum as the series on the left. This justifies the equality in (4).

Now suppose that $f(x)$ is a given function of period 2π and is such that it can be **represented** by a series (4), that is, (4) converges and, moreover, has the sum $f(x)$. Then, using the equality sign, we write

$$\mathbf{(5)} \quad f(x) = a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$$

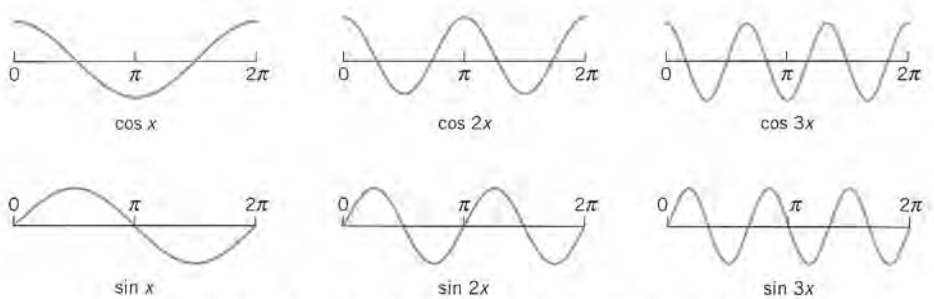

Fig. 256. Cosine and sine functions having the period 2π

and call (5) the **Fourier series** of $f(x)$. We shall prove that in this case the coefficients of (5) are the so-called **Fourier coefficients** of $f(x)$, given by the **Euler formulas**

$$\text{(6)} \qquad \text{(a)} \quad a_0 = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(x)\,dx$$

$$\text{(b)} \quad a_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\cos nx\,dx \qquad n = 1, 2, \cdots$$

$$\text{(c)} \quad b_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\sin nx\,dx \qquad n = 1, 2, \cdots.$$

The name "Fourier series" is sometimes also used in the exceptional case that (5) with coefficients (6) does not converge or does not have the sum $f(x)$—this may happen but is merely of theoretical interest. (For Euler see footnote 4 in Sec. 2.5.)

A Basic Example

Before we derive the Euler formulas (6), let us become familiar with the application of (5) and (6) in the case of an important example. Since your work for other functions will be quite similar, try to fully understand every detail of the integrations, which because of the n involved differ somewhat from what you have practiced in calculus. Do not just routinely use your software, but make observations: How are continuous functions (cosines and sines) able to represent a given discontinuous function? How does the quality of the approximation increase if you take more and more terms of the series? Why are the approximating functions, called the **partial sums** of the series, always zero at 0 and π? Why is the factor $1/n$ (obtained in the integration) important?

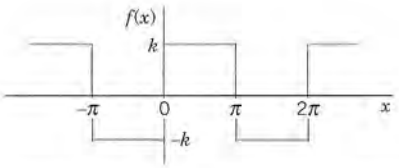
EXAMPLE 1 **Periodic Rectangular Wave (Fig. 257a)**

Find the Fourier coefficients of the periodic function $f(x)$ in Fig. 257a. The formula is

$$\text{(7)} \qquad f(x) = \begin{cases} -k & \text{if} \quad -\pi < x < 0 \\ k & \text{if} \quad 0 < x < \pi \end{cases} \qquad \text{and} \qquad f(x + 2\pi) = f(x).$$

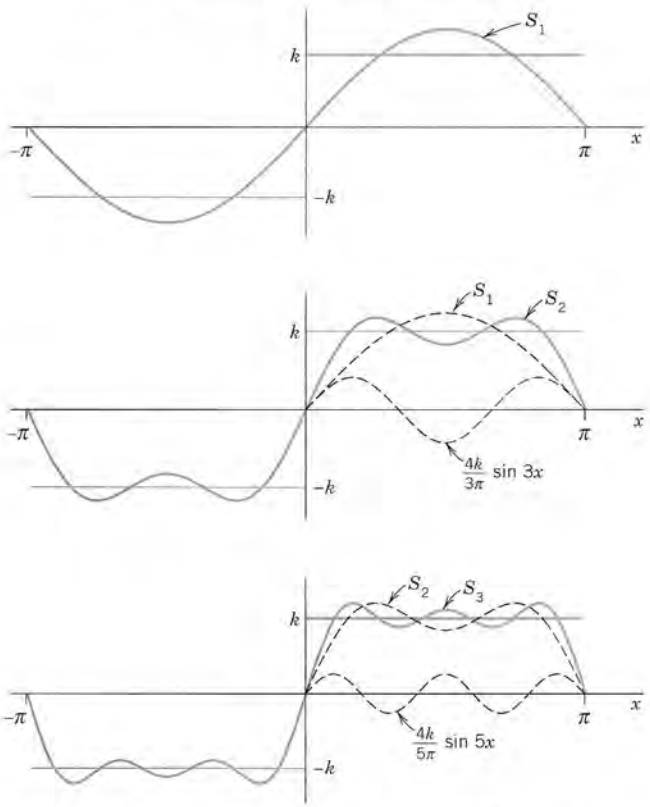
Functions of this kind occur as external forces acting on mechanical systems, electromotive forces in electric circuits, etc. (The value of $f(x)$ at a single point does not affect the integral; hence we can leave $f(x)$ undefined at $x = 0$ and $x = \pm\pi$.)

Solution. From (6a) we obtain $a_0 = 0$. This can also be seen without integration, since the area under the curve of $f(x)$ between $-\pi$ and π is zero. From (6b),



$$a_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\cos nx\,dx = \frac{1}{\pi}\left[\int_{-\pi}^{0}(-k)\cos nx\,dx + \int_{0}^{\pi} k\cos nx\,dx\right]$$

$$= \frac{1}{\pi}\left[-k\,\frac{\sin nx}{n}\Bigg|_{-\pi}^{0} + k\,\frac{\sin nx}{n}\Bigg|_{0}^{\pi}\right] = 0$$



because $\sin nx = 0$ at $-\pi$, 0, and π for all $n = 1, 2, \cdots$. Similarly, from (6c) we obtain

$$b_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\sin nx\,dx = \frac{1}{\pi}\left[\int_{-\pi}^{0}(-k)\sin nx\,dx + \int_{0}^{\pi} k\sin nx\,dx\right]$$

$$= \frac{1}{\pi}\left[k\,\frac{\cos nx}{n}\Bigg|_{-\pi}^{0} - k\,\frac{\cos nx}{n}\Bigg|_{0}^{\pi}\right].$$

(a) The given function $f(x)$ (Periodic rectangular wave)

(b) The first three partial sums of the corresponding Fourier series

Fig. 257. Eample 1

Since $\cos(-\alpha) = \cos\alpha$ and $\cos 0 = 1$, this yields

$$b_n = \frac{k}{n\pi}\left[\cos 0 - \cos(-n\pi) - \cos n\pi + \cos 0\right] = \frac{2k}{n\pi}(1 - \cos n\pi).$$

Now, $\cos\pi = -1$, $\cos 2\pi = 1$, $\cos 3\pi = -1$, etc.; in general,

$$\cos n\pi = \begin{cases} -1 & \text{for odd } n, \\ 1 & \text{for even } n, \end{cases} \qquad \text{and thus} \qquad 1 - \cos n\pi = \begin{cases} 2 & \text{for odd } n, \\ 0 & \text{for even } n. \end{cases}$$

Hence the Fourier coefficients b_n of our function are

$$b_1 = \frac{4k}{\pi}, \qquad b_2 = 0, \qquad b_3 = \frac{4k}{3\pi}, \qquad b_4 = 0, \qquad b_5 = \frac{4k}{5\pi}, \cdots.$$

Since the a_n are zero, the Fourier series of $f(x)$ is

$$\frac{4k}{\pi}\left(\sin x + \frac{1}{3}\sin 3x + \frac{1}{5}\sin 5x + \cdots\right). \tag{8}$$

The partial sums are

$$S_1 = \frac{4k}{\pi}\sin x, \qquad S_2 = \frac{4k}{\pi}\left(\sin x + \frac{1}{3}\sin 3x\right), \qquad \text{etc.}$$

Their graphs in Fig. 257 seem to indicate that the series is convergent and has the sum $f(x)$, the given function. We notice that at $x = 0$ and $x = \pi$, the points of discontinuity of $f(x)$, all partial sums have the value zero, the arithmetic mean of the limits $-k$ and k of our function, at these points.

Furthermore, assuming that $f(x)$ is the sum of the series and setting $x = \pi/2$, we have

$$f\left(\frac{\pi}{2}\right) = k = \frac{4k}{\pi}\left(1 - \frac{1}{3} + \frac{1}{5} - + \cdots\right)$$

thus

$$1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + - \cdots = \frac{\pi}{4}.$$

This is a famous result obtained by Leibniz in 1673 from geometric considerations. It illustrates that the values of various series with constant terms can be obtained by evaluating Fourier series at specific points. ■

Derivation of the Euler Formulas (6)

The key to the Euler formulas (6) is the **orthogonality** of (3), a concept of basic importance, as follows.

THEOREM 1

Orthogonality of the Trigonometric System (3)

The trigonometric system (3) *is orthogonal on the interval* $-\pi \leqq x \leqq \pi$ (hence also on $0 \leqq x \leqq 2\pi$ or any other interval of length 2π because of periodicity); *that is, the integral of the product of any two functions in* (3) *over that interval is* 0, *so that for any integers* n *and* m,

(9)

$$\textbf{(a)} \qquad \int_{-\pi}^{\pi} \cos nx \cos mx\, dx = 0 \qquad (n \neq m)$$

$$\textbf{(b)} \qquad \int_{-\pi}^{\pi} \sin nx \sin mx\, dx = 0 \qquad (n \neq m)$$

$$\textbf{(c)} \qquad \int_{-\pi}^{\pi} \sin nx \cos mx\, dx = 0 \qquad (n \neq m \text{ or } n = m).$$

PROOF This follows simply by transforming the integrands trigonometrically from products into sums. In (9a) and (9b), by (11) in App. A3.1,

$$\int_{-\pi}^{\pi} \cos nx \cos mx\, dx = \frac{1}{2}\int_{-\pi}^{\pi} \cos (n + m)x\, dx + \frac{1}{2}\int_{-\pi}^{\pi} \cos (n - m)x\, dx$$

$$\int_{-\pi}^{\pi} \sin nx \sin mx\, dx = \frac{1}{2}\int_{-\pi}^{\pi} \cos (n - m)x\, dx - \frac{1}{2}\int_{-\pi}^{\pi} \cos (n + m)x\, dx.$$

Since $m \neq n$ (integer!), the integrals on the right are all 0. Similarly, in (9c), for all integer m and n (without exception; do you see why?)

$$\int_{-\pi}^{\pi} \sin nx \cos mx \, dx = \frac{1}{2} \int_{-\pi}^{\pi} \sin (n + m)x \, dx + \frac{1}{2} \int_{-\pi}^{\pi} \sin (n - m)x \, dx = 0 + 0. \quad \blacksquare$$

Application of Theorem 1 to the Fourier Series (5)

We prove (6a). Integrating on both sides of (5) from $-\pi$ to π, we get

$$\int_{-\pi}^{\pi} f(x) \, dx = \int_{-\pi}^{\pi} \left[a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx) \right] dx.$$

We now assume that termwise integration is allowed. (We shall say in the proof of Theorem 2 when this is true.) Then we obtain

$$\int_{-\pi}^{\pi} f(x) \, dx = a_0 \int_{-\pi}^{\pi} dx + \sum_{n=1}^{\infty} \left(a_n \int_{-\pi}^{\pi} \cos nx \, dx + b_n \int_{-\pi}^{\pi} \sin nx \, dx \right).$$

The first term on the right equals $2\pi a_0$. Integration shows that all the other integrals are 0. Hence division by 2π gives (6a).

We prove (6b). Multiplying (5) on both sides by $\cos mx$ with any ***fixed*** positive integer m and integrating from $-\pi$ to π, we have

$$(10) \quad \int_{-\pi}^{\pi} f(x) \cos mx \, dx = \int_{-\pi}^{\pi} \left[a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx) \right] \cos mx \, dx.$$

We now integrate term by term. Then on the right we obtain an integral of $a_0 \cos mx$, which is 0; an integral of $a_n \cos nx \cos mx$, which is $a_m \pi$ for $n = m$ and 0 for $n \neq m$ by (9a); and an integral of $b_n \sin nx \cos mx$, which is 0 for all n and m by (9c). Hence the right side of (10) equals $a_m \pi$. Division by π gives (6b) (with m instead of n).

We finally prove (6c). Multiplying (5) on both sides by $\sin mx$ with any ***fixed*** positive integer m and integrating from $-\pi$ to π, we get

$$(11) \quad \int_{-\pi}^{\pi} f(x) \sin mx \, dx = \int_{-\pi}^{\pi} \left[a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx) \right] \sin mx \, dx.$$

Integrating term by term, we obtain on the right an integral of $a_0 \sin mx$, which is 0; an integral of $a_n \cos nx \sin mx$, which is 0 by (9c); and an integral of $b_n \sin nx \sin mx$, which is $b_m \pi$ if $n = m$ and 0 if $n \neq m$, by (9b). This implies (6c) (with n denoted by m). This completes the proof of the Euler formulas (6) for the Fourier coefficients. ■

Convergence and Sum of a Fourier Series

The class of functions that can be represented by Fourier series is surprisingly large and general. Sufficient conditions valid in most applications are as follows.

THEOREM 2

Representation by a Fourier Series

Let $f(x)$ be periodic with period 2π and piecewise continuous (see Sec. 6.1) *in the interval $-\pi \leqq x \leqq \pi$. Furthermore, let $f(x)$ have a left-hand derivative and a right-hand derivative at each point of that interval. Then the Fourier series* (5) *of $f(x)$* [with coefficients (6)] *converges. Its sum is $f(x)$, except at points x_0 where $f(x)$ is discontinuous. There the sum of the series is the average of the left- and right-hand limits*[2] *of $f(x)$ at x_0.*

PROOF We prove convergence in Theorem 2. We prove convergence for a continuous function $f(x)$ having continuous first and second derivatives. Integrating (6b) by parts, we obtain.

$$a_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\cos nx\,dx = \frac{f(x)\sin nx}{n\pi}\bigg|_{-\pi}^{\pi} - \frac{1}{n\pi}\int_{-\pi}^{\pi} f'(x)\sin nx\,dx.$$

The first term on the right is zero. Another integration by parts gives

$$a_n = \frac{f'(x)\cos nx}{n^2\pi}\bigg|_{-\pi}^{\pi} - \frac{1}{n^2\pi}\int_{-\pi}^{\pi} f''(x)\cos nx\,dx.$$

The first term on the right is zero because of the periodicity and continuity of $f'(x)$. Since f'' is continuous in the interval of integration, we have

$$|f''(x)| < M$$

for an appropriate constant M. Furthermore, $|\cos nx| \leqq 1$. It follows that

$$|a_n| = \frac{1}{n^2\pi}\left|\int_{-\pi}^{\pi} f''(x)\cos nx\,dx\right| < \frac{1}{n^2\pi}\int_{-\pi}^{\pi} M\,dx = \frac{2M}{n^2}.$$

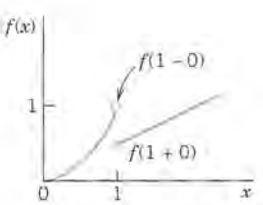


Fig. 258. Left- and right-hand limits

$f(1 - 0) = 1$,

$f(1 + 0) = \frac{1}{2}$

of the function

$$f(x) = \begin{cases} x^2 & \text{if } x < 1 \\ x/2 & \end{cases}$$

[2]The **left-hand limit** of $f(x)$ at x_0 is defined as the limit of $f(x)$ as x approaches x_0 from the left and is commonly denoted by $f(x_0 - 0)$. Thus

$$f(x_0 - 0) = \lim_{h \to 0} f(x_0 - h) \text{ as } h \to 0 \text{ through positive values.}$$

The **right-hand limit** is denoted by $f(x_0 + 0)$ and

$$f(x_0 + 0) = \lim_{h \to 0} f(x_0 + h) \text{ as } h \to 0 \text{ through positive values.}$$

The **left-** and **right-hand derivatives** of $f(x)$ at x_0 are defined as the limits of

$$\frac{f(x_0 - h) - f(x_0 - 0)}{-h} \quad \text{and} \quad \frac{f(x_0 + h) - f(x_0 + 0)}{h},$$

respectively, as $h \to 0$ through positive values. Of course if $f(x)$ is continuous at x_0, the last term in both numerators is simply $f(x_0)$.

Similarly, $|b_n| < 2M/n^2$ for all n. Hence the absolute value of each term of the Fourier series of $f(x)$ is at most equal to the corresponding term of the series

$$|a_0| + 2M\left(1 + 1 + \frac{1}{2^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{3^2} + \cdots\right)$$

which is convergent. Hence that Fourier series converges and the proof is complete. (Readers already familiar with uniform convergence will see that, by the Weierstrass test in Sec. 15.5, under our present assumptions the Fourier series converges uniformly, and our derivation of (6) by integrating term by term is then justified by Theorem 3 of Sec. 15.5.)

The proof of convergence in the case of a piecewise continuous function $f(x)$ and the proof that under the assumptions in the theorem the Fourier series (5) with coefficients (6) represents $f(x)$ are substantially more complicated; see, for instance, Ref. [C12]. ■

EXAMPLE 2 **Convergence at a Jump as Indicated in Theorem 2**

The rectangular wave in Example 1 has a jump at $x = 0$. Its left-hand limit there is $-k$ and its right-hand limit is k (Fig. 257). Hence the average of these limits is 0. The Fourier series (8) of the wave does indeed converge to this value when $x = 0$ because then all its terms are 0. Similarly for the other jumps. This is in agreement with Theorem 2. ■

Summary. A Fourier series of a given function $f(x)$ of period 2π is a series of the form (5) with coefficients given by the Euler formulas (6). Theorem 2 gives conditions that are sufficient for this series to converge and at each x to have the value $f(x)$, except at discontinuities of $f(x)$, where the series equals the arithmetic mean of the left-hand and right-hand limits of $f(x)$ at that point.

PROBLEM SET 11.1

1. **(Calculus review)** Review integration techniques for integrals as they are likely to arise from the Euler formulas, for instance, definite integrals of $x \cos nx$, $x^2 \sin nx$, $e^{-2x} \cos nx$, etc.

2–3 FUNDAMENTAL PERIOD

The *fundamental period* is the smallest positive period. Find it for

2. $\cos x$, $\sin x$, $\cos 2x$, $\sin 2x$, $\cos \pi x$, $\sin \pi x$, $\cos 2\pi x$, $\sin 2\pi x$

3. $\cos nx$, $\sin nx$, $\cos \dfrac{2\pi x}{k}$, $\sin \dfrac{2\pi x}{k}$, $\cos \dfrac{2\pi nx}{k}$, $\sin \dfrac{2\pi nx}{k}$

4. Show that $f = const$ is periodic with any period but has no fundamental period.

5. If $f(x)$ and $g(x)$ have period p, show that $h(x) = af(x) + bg(x)$ (a, b, constant) has the period p. Thus all functions of period p form a **vector space.**

6. **(Change of scale)** If $f(x)$ has period p, show that $f(ax)$, $a \neq 0$, and $f(x/b)$, $b \neq 0$, are periodic functions of x of periods p/a and bp, respectively. Give examples.

7–12 GRAPHS OF 2π-PERIODIC FUNCTIONS

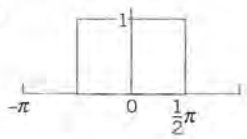
Sketch or graph $f(x)$, of period 2π, which for $-\pi < x < \pi$ is given as follows.

7. $f(x) = x$

8. $f(x) = e^{-|x|}$

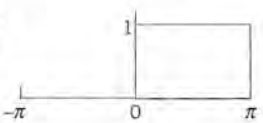
9. $f(x) = \pi - |x|$

10. $f(x) = |\sin 2x|$



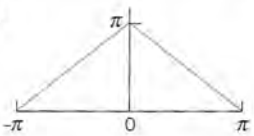
11. $f(x) = \begin{cases} -x^3 & \text{if } -\pi < x < 0 \\ x^3 & \text{if } 0 < x < \pi \end{cases}$

12. $f(x) = \begin{cases} 1 & \text{if } -\pi < x < 0 \\ \cos \frac{1}{2}x & \text{if } 0 < x < \pi \end{cases}$

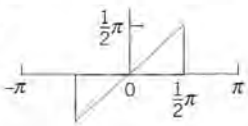


13–24 FOURIER SERIES

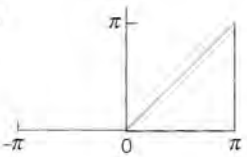
Showing the details of your work, find the Fourier series of the given $f(x)$, which is assumed to have the period 2π. Sketch or graph the partial sums up to that including $\cos 5x$ and $\sin 5x$.



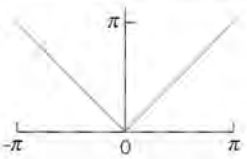
13.



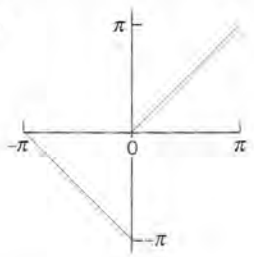
14.



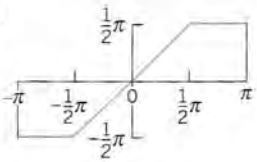
15.



16.



17.



18.

19.

20.

21. $f(x) = x^2 \ (-\pi < x < \pi)$

22. $f(x) = x^2 \ (0 < x < 2\pi)$

23. $f(x) = \begin{cases} x^2 & \text{if } -\frac{1}{2}\pi < x < \frac{1}{2}\pi \\ \frac{1}{4}\pi^2 & \text{if } \frac{1}{2}\pi < x < \frac{3}{2}\pi \end{cases}$

24. $f(x) = \begin{cases} -4x & \text{if } -\pi < x < 0 \\ 4x & \text{if } 0 < x < \pi \end{cases}$

25. (Discontinuities) Verify the last statement in Theorem 2 for the discontinuities of $f(x)$ in Prob. 13.

26. CAS EXPERIMENT. Graphing. Write a program for graphing partial sums of the following series. Guess from the graph what $f(x)$ the series may represent. Confirm or disprove your guess by using the Euler formulas.

(a) $2(\sin x + \frac{1}{3}\sin 3x + \frac{1}{5}\sin 5x + \cdots) - 2(\frac{1}{2}\sin 2x + \frac{1}{4}\sin 4x + \frac{1}{6}\sin 6x \cdots)$

(b) $\frac{1}{2} + \dfrac{4}{\pi^2}(\cos x + \frac{1}{9}\cos 3x + \frac{1}{25}\cos 5x + \cdots)$

(c) $\frac{2}{3}\pi^2 + 4(\cos x - \frac{1}{4}\cos 2x + \frac{1}{9}\cos 3x - \frac{1}{16}\cos 4x + - \cdots)$

27. CAS EXPERIMENT. Order of Fourier Coefficients. The order seems to be $1/n$ if f is discontinous, and $1/n^2$ if f is continuous but $f' = df/dx$ is discontinuous, $1/n^3$ if f and f' are continuous but f'' is discontinuous, etc. Try to verify this for examples. Try to prove it by integrating the Euler formulas by parts. What is the practical significance of this?

28. PROJECT. Euler Formulas in Terms of Jumps Without Integration. Show that for a function whose third derivative is identically zero,

$$a_n = \frac{1}{n\pi}\left[-\sum j_s \sin nx_s - \frac{1}{n}\sum j_s' \cos nx_s + \frac{1}{n^2}\sum j_s'' \sin nx_s\right]$$

$$b_n = \frac{1}{n\pi}\left[\sum j_s \cos nx_s - \frac{1}{n}\sum j_s' \sin nx_s - \frac{1}{n^2}\sum j_s'' \cos nx_s\right]$$

where $n = 1, 2, \cdots$ and we sum over all the jumps j_s, j_s', j_s'' of f, f', f', respectively, located at x_s.

29. Apply the formulas in Project 28 to the function in Prob. 21 and compare the results.

30. CAS EXPERIMENT. Orthogonality. Integrate and graph the integral of the product $\cos mx \cos nx$ (with various integer m and n of your choice) from $-a$ to a as a function of a and conclude orthogonality of $\cos mx$ and $\cos nx$ $(m \neq n)$ for $a = \pi$ from the graph. For what m and n will you get orthogonality for $a = \pi/2$, $\pi/3$, $\pi/4$? Other a? Extend the experiment to $\cos mx \sin nx$ and $\sin mx \sin nx$.

11.2 Functions of Any Period $p = 2L$

The functions considered so far had period 2π, for the simplicity of the formulas. Of course, periodic functions in applications will generally have other periods. However, we now show that the transition from period $p = 2\pi$ to a period $2L$ is quite simple. The notation $p = 2L$ is practical because L will be the length of a violin string (Sec. 12.2) or the length of a rod in heat conduction (Sec. 12.5), and so on.

The idea is simply to find and use a ***change of scale*** that gives from a function $g(v)$ of period 2π a function of period $2L$. Now from (5) and (6) in the last section with $g(v)$ instead of $f(x)$ we have the Fourier series

$$(1) \qquad g(v) = a_0 + \sum_{n=1}^{\infty} (a_n \cos nv + b_n \sin nv)$$

with coefficients

$$a_0 = \frac{1}{2\pi} \int_{-\pi}^{\pi} g(v)\, dv$$

$$(2) \qquad a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} g(v) \cos nv\, dv$$

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} g(v) \sin nv\, dv.$$

We can now write the change of scale as $v = kx$ with k such that the old period $v = 2\pi$ gives for the new variable x the new period $x = 2L$. Thus, $2\pi = k2L$. Hence $k = \pi/L$ and

$$(3) \qquad v = kx = \pi x/L.$$

This implies $dv = (\pi/L)\, dx$, which upon substitution into (2) cancels $1/2\pi$ and $1/\pi$ and gives instead the factors $1/2L$ and $1/L$. Writing

$$(4) \qquad g(v) = f(x),$$

we thus obtain from (1) the **Fourier series** of the function $f(x)$ of period $2L$

$$\mathbf{(5)} \qquad f(x) = a_0 + \sum_{n=1}^{\infty} \left(a_n \cos \frac{n\pi}{L} x + b_n \sin \frac{n\pi}{L} x \right)$$

with the **Fourier coefficients** of $f(x)$ given by the **Euler formulas**

$$\mathbf{(a)} \qquad a_0 = \frac{1}{2L} \int_{-L}^{L} f(x)\, dx$$

$$\mathbf{(6)} \qquad \mathbf{(b)} \qquad a_n = \frac{1}{L} \int_{-L}^{L} f(x) \cos \frac{n\pi x}{L}\, dx \qquad n = 1, 2, \cdots$$

$$\mathbf{(c)} \qquad b_n = \frac{1}{L} \int_{-L}^{L} f(x) \sin \frac{n\pi x}{L}\, dx \qquad n = 1, 2, \cdots.$$

Just as in Sec. 11.1, we continue to call (5) with any coefficients a **trigonometric series.** And we can integrate from 0 to $2L$ or over any other interval of length $p = 2L$.

EXAMPLE 1 Periodic Rectangular Wave

Find the Fourier series of the function (Fig. 259)

$$f(x) = \begin{cases} 0 & \text{if } -2 < x < -1 \\ k & \text{if } -1 < x < 1 \\ 0 & \text{if } 1 < x < 2 \end{cases} \qquad p = 2L = 4, \quad L = 2.$$

Solution. From (6a) we obtain $a_0 = k/2$ (verify!). From (6b) we obtain

$$a_n = \frac{1}{2}\int_{-2}^{2} f(x)\cos\frac{n\pi x}{2}\,dx = \frac{1}{2}\int_{-1}^{1} k\cos\frac{n\pi x}{2}\,dx = \frac{2k}{n\pi}\sin\frac{n\pi}{2}.$$

Thus $a_n = 0$ if n is even and

$$a_n = 2k/n\pi \quad \text{if} \quad n = 1, 5, 9, \cdots, \qquad a_n = -2k/n\pi \quad \text{if} \quad n = 3, 7, 11, \cdots.$$

From (6c) we find that $b_n = 0$ for $n = 1, 2, \cdots$. Hence the Fourier series is

$$f(x) = \frac{k}{2} + \frac{2k}{\pi}\left(\cos\frac{\pi}{2}x - \frac{1}{3}\cos\frac{3\pi}{2}x + \frac{1}{5}\cos\frac{5\pi}{2}x - + \cdots\right). \qquad \blacksquare$$

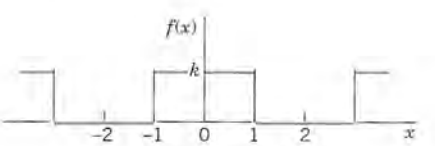


Fig. 259. Example 1

EXAMPLE 2 Periodic Rectangular Wave

Find the Fourier series of the function (Fig. 260)

$$f(x) = \begin{cases} -k & \text{if } -2 < x < 0 \\ k & \text{if } 0 < x < 2 \end{cases} \qquad p = 2L = 4, \qquad L = 2.$$

Solution. $a_0 = 0$ from (6a). From (6b), with $1/L = 1/2$,

$$a_n = \frac{1}{2}\left[\int_{-2}^{0}(-k)\cos\frac{n\pi x}{2}\,dx + \int_{0}^{2} k\cos\frac{n\pi x}{2}\,dx\right]$$

$$= \frac{1}{2}\left[-\frac{2k}{n\pi}\sin\frac{n\pi x}{2}\Big|_{-2}^{0} + \frac{2k}{n\pi}\sin\frac{n\pi x}{2}\Big|_{0}^{2}\right] = 0,$$

so that the Fourier series has no cosine terms. From (6c),

$$b_n = \frac{1}{2}\left[\frac{2k}{n\pi}\cos\frac{n\pi x}{2}\Big|_{-2}^{0} - \frac{2k}{n\pi}\cos\frac{n\pi x}{2}\Big|_{0}^{2}\right]$$

$$= \frac{k}{n\pi}(1 - \cos n\pi - \cos n\pi + 1) = \begin{cases} 4k/n\pi & \text{if } n = 1, 3, \cdots \\ 0 & \text{if } n = 2, 4, \cdots. \end{cases}$$

Hence the Fourier series of $f(x)$ is

$$f(x) = \frac{4k}{\pi}\left(\sin\frac{\pi}{2}x + \frac{1}{3}\sin\frac{3\pi}{2}x + \frac{1}{5}\sin\frac{5\pi}{2}x + \cdots\right).$$

It is interesting that we could have derived this from (8) in Sec. 11.1, namely, by the scale change (3). Indeed, writing v instead of x, we have in (8), Sec. 11.1,

$$\frac{4k}{\pi}\left(\sin v + \frac{1}{3}\sin 3v + \frac{1}{5}\sin 5v + \cdots\right).$$

Since the period 2π in v corresponds to $2L = 4$, we have $k = \pi/L = \pi/2$ and $v = kx = \pi x/2$ in (3); hence we obtain the Fourier series of $f(x)$, as before. ■

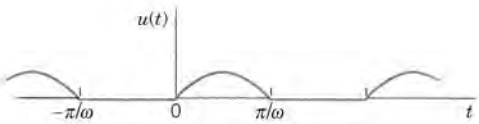

Fig. 261. Half-wave rectifier

EXAMPLE 3 **Half-Wave Rectifier**

A sinusoidal voltage $E \sin \omega t$, where t is time, is passed through a half-wave rectifier that clips the negative portion of the wave (Fig. 261). Find the Fourier series of the resulting periodic function

$$u(t) = \begin{cases} 0 & \text{if } -L < t < 0, \\ E\sin\omega t & \text{if } 0 < t < L \end{cases} \qquad p = 2L = \frac{2\pi}{\omega}, \qquad L = \frac{\pi}{\omega}.$$

Solution. Since $u = 0$ when $-L < t < 0$, we obtain from (6a), with t instead of x,

$$a_0 = \frac{\omega}{2\pi}\int_0^{\pi/\omega} E\sin\omega t\,dt = \frac{E}{\pi}$$

and from (6b), by using formula (11) in App. A3.1 with $x = \omega t$ and $y = n\omega t$,

$$a_n = \frac{\omega}{\pi}\int_0^{\pi/\omega} E\sin\omega t\cos n\omega t\,dt = \frac{\omega E}{2\pi}\int_0^{\pi/\omega}[\sin(1+n)\omega t + \sin(1-n)\omega t]\,dt.$$

If $n = 1$, the integral on the right is zero, and if $n = 2, 3, \cdots$, we readily obtain

$$a_n = \frac{\omega E}{2\pi}\left[-\frac{\cos(1+n)\omega t}{(1+n)\omega} - \frac{\cos(1-n)\omega t}{(1-n)\omega}\right]_0^{\pi/\omega}$$

$$= \frac{E}{2\pi}\left(\frac{-\cos(1+n)\pi + 1}{1+n} + \frac{-\cos(1-n)\pi + 1}{1-n}\right).$$

If n is odd, this is equal to zero, and for even n we have

$$a_n = \frac{E}{2\pi}\left(\frac{2}{1+n} + \frac{2}{1-n}\right) = -\frac{2E}{(n-1)(n+1)\pi} \qquad (n = 2, 4, \cdots).$$

In a similar fashion we find from (6c) that $b_1 = E/2$ and $b_n = 0$ for $n = 2, 3, \cdots$. Consequently,

$$u(t) = \frac{E}{\pi} + \frac{E}{2}\sin\omega t - \frac{2E}{\pi}\left(\frac{1}{1\cdot 3}\cos 2\omega t + \frac{1}{3\cdot 5}\cos 4\omega t + \cdots\right).$$

■

PROBLEM SET 11.2

1–11 FOURIER SERIES FOR PERIOD $p = 2L$

Find the Fourier series of the function $f(x)$, of period $p = 2L$, and sketch or graph the first three partial sums. (Show the details of your work.)

1. $f(x) = -1$ $(-2 < x < 0)$, $f(x) = 1$ $(0 < x < 2)$, $p = 4$
2. $f(x) = 0$ $(-2 < x < 0)$, $f(x) = 4$ $(0 < x < 2)$, $p = 4$
3. $f(x) = x^2 \quad (-1 < x < 1), \quad p = 2$
4. $f(x) = \pi x^3/2 \quad (-1 < x < 1), \quad p = 2$
5. $f(x) = \sin \pi x \quad (0 < x < 1), \quad p = 1$
6. $f(x) = \cos \pi x \quad (-\frac{1}{2} < x < \frac{1}{2}), \quad p = 1$
7. $f(x) = |x| \quad (-1 < x < 1), \quad p = 2$
8. $f(x) = \begin{cases} 1 + x \text{ if } -1 < x < 0 \\ 1 - x \text{ if } \quad 0 < x < 1, \end{cases} \quad p = 2$
9. $f(x) = 1 - x^2 \quad (-1 < x < 1), \quad p = 2$
10. $f(x) = 0$ $(-2 < x < 0)$, $f(x) = x$ $(0 < x < 2)$, $p = 4$
11. $f(x) = -x \quad (-1 < x < 0), \quad f(x) = x \quad (0 < x < 1),$ $f(x) = 1 \quad (1 < x < 3), \quad p = 4$
12. **(Rectifier)** Find the Fourier series of the function obtained by passing the voltage $v(t) = V_0 \cos 100\pi t$ through a half-wave rectifier.
13. Show that the familiar identities $\cos^3 x = \frac{3}{4} \cos x + \frac{1}{4} \cos 3x$ and $\sin^3 x = \frac{3}{4} \sin x - \frac{1}{4} \sin 3x$ can be interpreted as Fourier series expansions. Develop $\cos^4 x$.
14. Obtain the series in Prob. 7 from that in Prob. 8.
15. Obtain the series in Prob. 6 from that in Prob. 5.
16. Obtain the series in Prob. 3 from that in Prob. 21 of Problem Set 11.1.
17. Using Prob. 3, show that $1 - \frac{1}{4} + \frac{1}{9} - \frac{1}{16} + - \cdots = \frac{1}{12}\pi^2$.
18. Show that $1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \cdots = \frac{1}{6}\pi^2$.
19. **CAS PROJECT. Fourier Series of $2L$-Periodic Functions. (a)** Write a program for obtaining partial sums of a Fourier series (1).

    (b) Apply the program to Probs. 2–5, graphing the first few partial sums of each of the four series on common axes. Choose the first five or more partial sums until they approximate the given function reasonably well. Compare and comment.
20. **CAS EXPERIMENT. Gibbs Phenomenon.** The partial sums $s_n(x)$ of a Fourier series show oscillations near a discontinuity point. These oscillations do not disappear as n increases but instead become sharp "spikes." They were explained mathematically by J. W. Gibbs[3]. Graph $s_n(x)$ in Prob. 10. When $n = 50$, say, you will see those oscillations quite distinctly. Consider other Fourier series of your choice in a similar way. Compare.

11.3 Even and Odd Functions. Half-Range Expansions

The function in Example 1, Sec. 11.2, is *even*, and its Fourier series has only *cosine* terms. The function in Example 2, Sec. 11.2, is *odd*, and its Fourier series has only *sine* terms.

Recall that g is **even** if $g(-x) = g(x)$, so that its graph is symmetric with respect to the vertical axis (Fig. 262). A function h is **odd** if $h(-x) = -h(x)$ (Fig. 263).

Now the cosine terms in the Fourier series (5), Sec. 11.2, are even and the sine terms are odd. So it should not be a surprise that an even function is given by a series of cosine terms and an odd function by a series of sine terms. Indeed, the following holds.

[3]JOSIAH WILLARD GIBBS (1839–1903), American mathematician, professor of mathematical physics at Yale from 1871 on, one of the founders of vector calculus [another being O. Heaviside (see Sec. 6.1)], mathematical thermodynamics, and statistical mechanics. His work was of great importance to the development of mathematical physics.

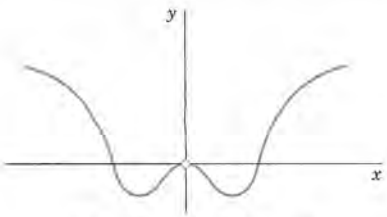

Fig. 262. Even function

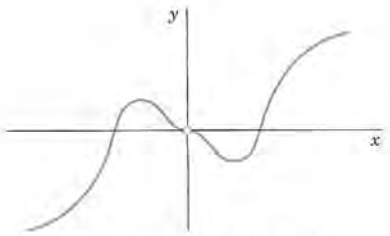

Fig. 263. Odd function

THEOREM 1

Fourier Cosine Series, Fourier Sine Series

The Fourier series of an ***even*** *function of period* $2L$ *is a* **"Fourier cosine series"**

(1) $$f(x) = a_0 + \sum_{n=1}^{\infty} a_n \cos \frac{n\pi}{L} x \qquad (f \text{ even})$$

with coefficients (note: integration from 0 to L only!)

(2) $$a_0 = \frac{1}{L} \int_0^L f(x)\, dx, \qquad a_n = \frac{2}{L} \int_0^L f(x) \cos \frac{n\pi x}{L}\, dx, \qquad n = 1, 2, \cdots.$$

The Fourier series of an ***odd*** *function of period* $2L$ *is a* **"Fourier sine series"**

(3) $$f(x) = \sum_{n=1}^{\infty} b_n \sin \frac{n\pi}{L} x \qquad (f \text{ odd})$$

with coefficients

(4) $$b_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L}\, dx.$$

PROOF Since the definite integral of a function gives the area under the curve of the function between the limits of integration, we have

$$\int_{-L}^{L} g(x)\, dx = 2 \int_0^L g(x)\, dx \qquad \text{for even } g$$

$$\int_{-L}^{L} h(x)\, dx = 0 \qquad \text{for odd } h$$

as is obvious from the graphs of g and h. (Give a formal proof.) Now let f be even. Then (6a), Sec. 11.2, gives a_0 in (2). Also, the integrand in (6b), Sec. 11.2, is even (a product of even functions is even), so that (6b) gives a_n in (2). Furthermore, the integrand in (6c), Sec. 11.2, is the even f times the odd sine, so that the integrand (the product) is odd, the integral is zero, and there are no sine terms in (1).

Similarly, if f is odd, the integrals for a_0 and a_n in (6a) and (6b), Sec. 11.2, are zero, f times the sine in (6c) is even, (6c) implies (4), and there are no cosine terms in (3). ■

The Case of Period 2π. If $L = \pi$, then $f(x) = a_0 + \sum_{n=1}^{\infty} a_n \cos nx$ (f even) with coefficients

$$(2^*) \qquad a_0 = \frac{1}{\pi}\int_0^{\pi} f(x)\,dx, \qquad a_n = \frac{2}{\pi}\int_0^{\pi} f(x)\cos nx\,dx, \qquad n = 1, 2, \cdots$$

and $f(x) = \sum_{n=1}^{\infty} b_n \sin nx$ (f odd) with coefficients

$$(4^*) \qquad b_n = \frac{2}{\pi}\int_0^{\pi} f(x)\sin nx\,dx, \qquad n = 1, 2, \cdots.$$

For instance, $f(x)$ in Example 1, Sec. 11.1, is odd and is represented by a Fourier sine series.

Further simplifications result from the following property, whose very simple proof is left to the student.

THEOREM 2

Sum and Scalar Multiple

The Fourier coefficients of a sum $f_1 + f_2$ are the sums of the corresponding Fourier coefficients of f_1 and f_2.

The Fourier coefficients of cf are c times the corresponding Fourier coefficients of f.

EXAMPLE 1 **Rectangular Pulse**

The function $f^*(x)$ in Fig. 264 is the sum of the function $f(x)$ in Example 1 of Sec 11.1 and the constant k. Hence, from that example and Theorem 2 we conclude that

$$f^*(x) = k + \frac{4k}{\pi}\left(\sin x + \frac{1}{3}\sin 3x + \frac{1}{5}\sin 5x + \cdots\right). \qquad ■$$

EXAMPLE 2 **Half-Wave Rectifier**

The function $u(t)$ in Example 3 of Sec. 11.2 has a Fourier cosine series plus a single term $v(t) = (E/2)\sin \omega t$. We conclude from this and Theorem 2 that $u(t) - v(t)$ must be an even function. Verify this graphically. (See Fig. 265.) ■

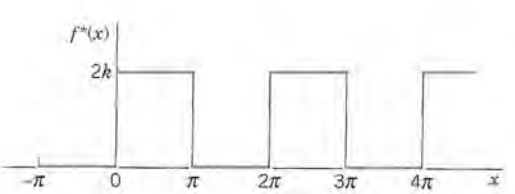

Fig. 264. Example 1

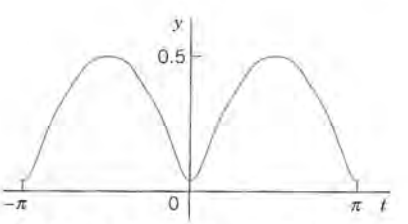

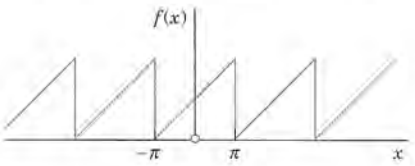

Fig. 265. $u(t) - v(t)$ with $E = 1$, $\omega = 1$

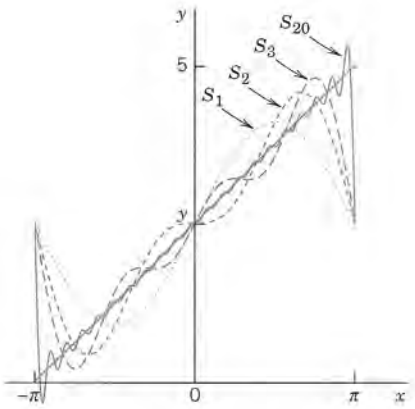


EXAMPLE 3 Sawtooth Wave

Find the Fourier series of the function (Fig. 266)

$$f(x) = x + \pi \quad \text{if} \quad -\pi < x < \pi \qquad \text{and} \qquad f(x + 2\pi) = f(x).$$

(a) The function $f(x)$

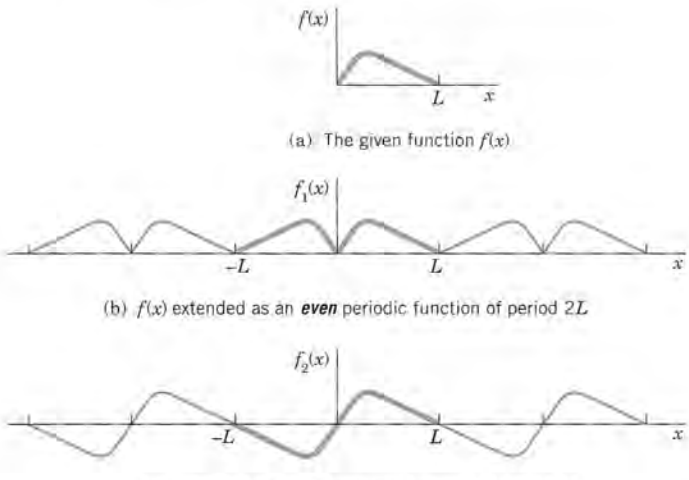
(b) Partial sums S_1, S_2, S_3, S_{20}

Fig. 266. Example 3

Solution. We have $f = f_1 + f_2$, where $f_1 = x$ and $f_2 = \pi$. The Fourier coefficients of f_2 are zero, except for the first one (the constant term), which is π. Hence, by Theorem 2, the Fourier coefficients a_n, b_n are those of f_1, except for a_0, which is π. Since f_1 is odd, $a_n = 0$ for $n = 1, 2, \cdots$, and

$$b_n = \frac{2}{\pi}\int_0^{\pi} f_1(x)\sin nx\,dx = \frac{2}{\pi}\int_0^{\pi} x\sin nx\,dx.$$

Integrating by parts, we obtain



$$b_n = \frac{2}{\pi}\left[\frac{-x\cos nx}{n}\Bigg|_0^{\pi} + \frac{1}{n}\int_0^{\pi}\cos nx\,dx\right] = -\frac{2}{n}\cos n\pi.$$

Hence $b_1 = 2$, $b_2 = -2/2$, $b_3 = 2/3$, $b_4 = -2/4$, $\cdots$, and the Fourier series of $f(x)$ is

$$f(x) = \pi + 2\left(\sin x - \frac{1}{2}\sin 2x + \frac{1}{3}\sin 3x - + \cdots\right). \qquad \blacksquare$$

Half-Range Expansions

Half-range expansions are Fourier series. The idea is simple and useful. Figure 267 explains it. We want to represent $f(x)$ in Fig. 267a by a Fourier series, where $f(x)$ may be the shape of a distorted violin string or the temperature in a metal bar of length L, for example. (Corresponding problems will be discussed in Chap. 12.) Now comes the idea.

(a) The given function $f(x)$

(b) $f(x)$ extended as an ***even*** periodic function of period $2L$

(c) $f(x)$ extended as an ***odd*** periodic function of period $2L$

Fig. 267. (a) Function $f(x)$ given on an interval $0 \leqq x \leqq L$

(b) **Even extension** to the full "range" (interval) $-L \leqq x \leqq L$ (heavy curve) and the periodic extension of period $2L$ to the x-axis

(c) **Odd extension** to $-L \leqq x \leqq L$ (heavy curve) and the periodic extension of period $2L$ to the x-axis

We could extend $f(x)$ as a function of period L and develop the extended function into a Fourier series. But this series would in general contain *both* cosine *and* sine terms. We can do better and get simpler series. Indeed, for our given f we can calculate Fourier coefficients from (2) or from (4) in Theorem 1. And we have a choice and can take what seems more practical. If we use (2), we get (1). This is the **even periodic extension** f_1 of f in Fig. 267b. If we choose (4) instead, we get (3), the **odd periodic extension** f_2 of f in Fig. 267c.

Both extensions have period $2L$. This motivates the name **half-range expansions:** f is given (and of physical interest) only on half the range, half the interval of periodicity of length $2L$.

Let us illustrate these ideas with an example that we shall also need in Chap. 12.

EXAMPLE 4 **"Triangle" and Its Half-Range Expansions**

Find the two half-range expansions of the function (Fig. 268)

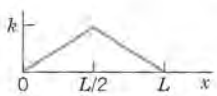


Fig. 268. The given function in Example 4

$$f(x) = \begin{cases} \dfrac{2k}{L}x & \text{if } 0 < x < \dfrac{L}{2} \\ \dfrac{2k}{L}(L - x) & \text{if } \dfrac{L}{2} < x < L. \end{cases}$$

Solution. *(a) Even periodic extension.* From (2) we obtain

$$a_0 = \frac{1}{L}\left[\frac{2k}{L}\int_0^{L/2} x\,dx + \frac{2k}{L}\int_{L/2}^{L}(L - x)\,dx\right] = \frac{k}{2},$$

$$a_n = \frac{2}{L}\left[\frac{2k}{L}\int_0^{L/2} x\cos\frac{n\pi}{L}x\,dx + \frac{2k}{L}\int_{L/2}^{L}(L - x)\cos\frac{n\pi}{L}x\,dx\right].$$

We consider a_n. For the first integral we obtain by integration by parts

$$\int_0^{L/2} x \cos \frac{n\pi}{L} x \, dx = \frac{Lx}{n\pi} \sin \frac{n\pi}{L} x \Big|_0^{L/2} - \frac{L}{n\pi} \int_0^{L/2} \sin \frac{n\pi}{L} x \, dx$$

$$= \frac{L^2}{2n\pi} \sin \frac{n\pi}{2} + \frac{L^2}{n^2\pi^2} \left(\cos \frac{n\pi}{2} - 1 \right).$$

Similarly, for the second integral we obtain

$$\int_{L/2}^{L} (L - x) \cos \frac{n\pi}{L} x \, dx = \frac{L}{n\pi} (L - x) \sin \frac{n\pi}{L} x \Big|_{L/2}^{L} + \frac{L}{n\pi} \int_{L/2}^{L} \sin \frac{n\pi}{L} x \, dx$$

$$= \left(0 - \frac{L}{n\pi} \left(L - \frac{L}{2} \right) \sin \frac{n\pi}{2} \right) - \frac{L^2}{n^2\pi^2} \left(\cos n\pi - \cos \frac{n\pi}{2} \right).$$

We insert these two results into the formula for a_n. The sine terms cancel and so does a factor L^2. This gives

$$a_n = \frac{4k}{n^2\pi^2} \left(2 \cos \frac{n\pi}{2} - \cos n\pi - 1 \right).$$

Thus,

$$a_2 = -16k/(2^2\pi^2), \qquad a_6 = -16k/(6^2\pi^2), \qquad a_{10} = -16k/(10^2\pi^2), \cdots$$

and $a_n = 0$ if $n \neq 2, 6, 10, 14, \cdots$. Hence the first half-range expansion of $f(x)$ is (Fig. 269a)

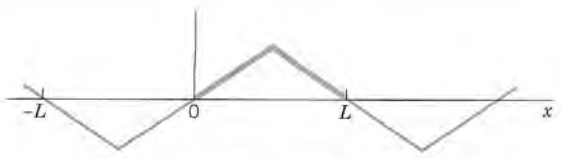
$$f(x) = \frac{k}{2} - \frac{16k}{\pi^2} \left(\frac{1}{2^2} \cos \frac{2\pi}{L} x + \frac{1}{6^2} \cos \frac{6\pi}{L} x + \cdots \right).$$

This Fourier cosine series represents the even periodic extension of the given function $f(x)$, of period $2L$.

(b) ***Odd periodic extension.*** Similarly, from (4) we obtain

$$b_n = \frac{8k}{n^2\pi^2} \sin \frac{n\pi}{2}. \tag{5}$$

Hence the other half-range expansion of $f(x)$ is (Fig. 269b)



$$f(x) = \frac{8k}{\pi^2} \left(\frac{1}{1^2} \sin \frac{\pi}{L} x - \frac{1}{3^2} \sin \frac{3\pi}{L} x + \frac{1}{5^2} \sin \frac{5\pi}{L} x - + \cdots \right).$$

This series represents the odd periodic extension of $f(x)$, of period $2L$.

Basic applications of these results will be shown in Secs. 12.3 and 12.5. ■

(b) Odd extension

Fig. 269. Periodic extensions of $f(x)$ in Example 4

PROBLEM SET 11.3

1–9 EVEN AND ODD FUNCTIONS

Are the following functions even, odd, or neither even nor odd?

1. $|x|$, $x^2 \sin nx$, $x + x^2$, $e^{-|x|}$, $\ln x$, $x \cosh x$

2. $\sin(x^2)$, $\sin^2 x$, $x \sinh x$, $|x^3|$, $e^{\pi x}$, xe^x, $\tan 2x$, $x/(1 + x^2)$

Are the following functions, which are assumed to be periodic of period 2π, even, odd, or neither even nor odd?

3. $f(x) = x^3 \quad (-\pi < x < \pi)$

4. $f(x) = x^2 \quad (-\pi/2 < x < 3\pi/2)$

5. $f(x) = e^{-4x} \quad (-\pi < x < \pi)$

6. $f(x) = x^3 \sin x \quad (-\pi < x < \pi)$

7. $f(x) = x|x| - x^3 \quad (-\pi < x < \pi)$

8. $f(x) = 1 - x + x^3 - x^5 \quad (-\pi < x < \pi)$

9. $f(x) = 1/(1 + x^2)$ if $-\pi < x < 0$, $f(x) = -1/(1 + x^2)$ if $0 < x < \pi$

10. PROJECT. Even and Odd Functions. (a) Are the following expressions even or odd? Sums and products of even functions and of odd functions. Products of even times odd functions. Absolute values of odd functions. $f(x) + f(-x)$ and $f(x) - f(-x)$ for arbitrary $f(x)$.

(b) Write e^{kx}, $1/(1 - x)$, $\sin(x + k)$, $\cosh(x + k)$ as sums of an even and an odd function.

(c) Find all functions that are both even and odd.

(d) Is $\cos^3 x$ even or odd? $\sin^3 x$? Find the Fourier series of these functions. Do you recognize familiar identities?

11–16 FOURIER SERIES OF EVEN AND ODD FUNCTIONS

Is the given function even or odd? Find its Fourier series. Sketch or graph the function and some partial sums. (Show the details of your work.)

11. $f(x) = \pi - |x| \quad (-\pi < x < \pi)$

12. $f(x) = 2x|x| \quad (-1 < x < 1)$

13. $f(x) = \begin{cases} x & \text{if } -\pi/2 < x < \pi/2 \\ \pi - x & \text{if } \pi/2 < x < 3\pi/2 \end{cases}$

14. $f(x) = \begin{cases} \pi e^{-x} & \text{if } -\pi < x < 0 \\ \pi e^{x} & \text{if } 0 < x < \pi \end{cases}$

15. $f(x) = \begin{cases} 2 & \text{if } -2 < x < 0 \\ 0 & \text{if } 0 < x < 2 \end{cases}$

16. $f(x) = \begin{cases} 1 - \frac{1}{2}|x| & \text{if } -2 < x < 2 \\ 0 & \text{if } 2 < x < 6 \end{cases} \quad (p = 8)$

17–25 HALF-RANGE EXPANSIONS

Find (a) the Fourier cosine series, (b) the Fourier sine series. Sketch $f(x)$ and its two periodic extensions. (Show the details of your work.)

17. $f(x) = 1 \quad (0 < x < 2)$

18. $f(x) = x \quad (0 < x < \frac{1}{2})$

19. $f(x) = 2 - x \quad (0 < x < 2)$

20. $f(x) = \begin{cases} 0 & (0 < x < 2) \\ 1 & (2 < x < 4) \end{cases}$

21. $f(x) = \begin{cases} 1 & (0 < x < 1) \\ 2 & (1 < x < 2) \end{cases}$

22. $f(x) = \begin{cases} x & (0 < x < \pi/2) \\ \pi/2 & (\pi/2 < x < \pi) \end{cases}$

23. $f(x) = x \quad (0 < x < L)$

24. $f(x) = x^2 \quad (0 < x < L)$

25. $f(x) = \pi - x \quad (0 < x < \pi)$

26. Illustrate the formulas in the proof of Theorem 1 with examples. Prove the formulas.

11.4 Complex Fourier Series. *Optional*

In this optional section we show that the Fourier series

$$(1) \qquad f(x) = a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$$

can be written in complex form, which sometimes simplifies calculations (see Example 1, on page 498). This complex form can be obtained because in complex, the exponential function e^{it} and $\cos t$ and $\sin t$ are related by the basic **Euler formula** (see (11) in Sec. 2.2)

$$(2) \qquad e^{it} = \cos t + i \sin t. \qquad \text{Thus} \qquad e^{-it} = \cos t - i \sin t.$$

Conversely, by adding and subtracting these two formulas, we obtain

$$(3) \qquad \text{(a)} \quad \cos t = \frac{1}{2}(e^{it} + e^{-it}), \qquad \text{(b)} \quad \sin t = \frac{1}{2i}(e^{it} - e^{-it}).$$

From (3), using $1/i = -i$ in $\sin t$ and setting $t = nx$ in both formulas, we get

$$a_n \cos nx + b_n \sin nx = \frac{1}{2}\, a_n(e^{inx} + e^{-inx}) + \frac{1}{2i}\, b_n(e^{inx} - e^{-inx})$$

$$= \frac{1}{2}\, (a_n - ib_n)e^{inx} + \frac{1}{2}\, (a_n + ib_n)e^{-inx}.$$

We insert this into (1). Writing $a_0 = c_0$, $\frac{1}{2}(a_n - ib_n) = c_n$, and $\frac{1}{2}(a_n + ib_n) = k_n$, we get from (1)

$$\textbf{(4)} \qquad f(x) = c_0 + \sum_{n=1}^{\infty} (c_n e^{inx} + k_n e^{-inx}).$$

The coefficients $c_1, c_2, \cdots$, and $k_1, k_2, \cdots$ are obtained from (6b), (6c) in Sec. 11.1 and then (2) above with $t = nx$,

$$\textbf{(5)} \qquad c_n = \frac{1}{2}\, (a_n - ib_n) = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x)(\cos nx - i \sin nx)\, dx = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-inx}\, dx$$

$$k_n = \frac{1}{2}\, (a_n + ib_n) = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x)(\cos nx + i \sin nx)\, dx = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{inx}\, dx.$$

Finally, we can combine (5) into a single formula by the trick of writing $k_n = c_{-n}$. Then (4), (5), and $c_0 = a_0$ in (6a) of Sec. 11.1 give (summation from $-\infty$!)

$$\textbf{(6)} \qquad f(x) = \sum_{n=-\infty}^{\infty} c_n e^{inx},$$

$$c_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-inx}\, dx, \qquad n = 0, \pm 1, \pm 2, \cdots.$$

This is the so-called *complex form of the Fourier series* or, more briefly, the **complex Fourier series,** of $f(x)$. The c_n are called the **complex Fourier coefficients** of $f(x)$.

For a function of period $2L$ our reasoning gives the **complex Fourier series**

$$\textbf{(7)} \qquad f(x) = \sum_{n=-\infty}^{\infty} c_n e^{in\pi x/L},$$

$$c_n = \frac{1}{2L} \int_{-L}^{L} f(x) e^{-in\pi x/L}\, dx, \qquad n = 0, \pm 1, \pm 2, \cdots.$$

EXAMPLE 1 **Complex Fourier Series**

Find the complex Fourier series of $f(x) = e^x$ if $-\pi < x < \pi$ and $f(x + 2\pi) = f(x)$ and obtain from it the usual Fourier series.

Solution. Since $\sin n\pi = 0$ for integer n, we have

$$e^{\pm in\pi} = \cos n\pi \pm i \sin n\pi = \cos n\pi = (-1)^n.$$

With this we obtain from (6) by integration

$$c_n = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^x e^{-inx}\,dx = \frac{1}{2\pi}\,\frac{1}{1-in}\,e^{x-inx}\Big|_{x=-\pi}^{\pi} = \frac{1}{2\pi}\,\frac{1}{1-in}\,(e^{\pi} - e^{-\pi})(-1)^n.$$

On the right,

$$\frac{1}{1-in} = \frac{1+in}{(1-in)(1+in)} = \frac{1+in}{1+n^2} \qquad \text{and} \qquad e^{\pi} - e^{-\pi} = 2\sinh \pi.$$

Hence the complex Fourier series is

$$e^x = \frac{\sinh \pi}{\pi}\sum_{n=-\infty}^{\infty}(-1)^n\,\frac{1+in}{1+n^2}\,e^{inx} \qquad (-\pi < x < \pi). \tag{8}$$

From this let us derive the real Fourier series. Using (2) with $t = nx$ and $i^2 = -1$, we have in (8)

$$(1 + in)e^{inx} = (1 + in)(\cos nx + i \sin nx) = (\cos nx - n \sin nx) + i(n \cos nx + \sin nx).$$

Now (8) also has a corresponding term with $-n$ instead of n. Since $\cos(-nx) = \cos nx$ and $\sin(-nx) = -\sin nx$, we obtain in this term

$$(1 - in)e^{-inx} = (1 - in)(\cos nx - i \sin nx) = (\cos nx - n \sin nx) - i(n \cos nx + \sin nx).$$

If we add these two expressions, the imaginary parts cancel. Hence their sum is

$$2(\cos nx - n \sin nx), \qquad n = 1, 2, \cdots.$$

For $n = 0$ we get 1 (not 2) because there is only one term. Hence the real Fourier series is

$$e^x = \frac{2\sinh \pi}{\pi}\left[\frac{1}{2} - \frac{1}{1+1^2}(\cos x - \sin x) + \frac{1}{1+2^2}(\cos 2x - 2\sin 2x) - + \cdots\right]. \tag{9}$$

In Fig. 270 the poor approximation near the jumps at $\pm\pi$ is a case of the Gibbs phenomenon (see CAS Experiment 20 in Problem Set 11.2). ■

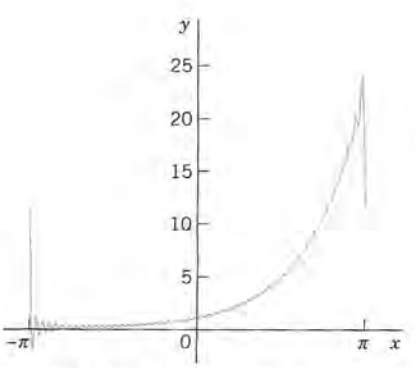

Fig. 270. Partial sum of (9), terms from $n = 0$ to 50

PROBLEM SET 11.4

1. **(Calculus review)** Review complex numbers.
2. **(Even and odd functions)** Show that the complex Fourier coefficients of an even function are real and those of an odd function are pure imaginary.
3. **(Fourier coefficients)** Show that $a_0 = c_0$, $a_n = c_n + c_{-n}$, $b_n = i(c_n - c_{-n})$.
4. Verify the calculations in Example 1.
5. Find further terms in (9) and graph partial sums with your CAS.
6. Obtain the real series in Example 1 directly from the Euler formulas in Sec. 11.

7–13 COMPLEX FOURIER SERIES

Find the complex Fourier series of the following functions. (Show the details of your work.)

7. $f(x) = -1$ if $-\pi < x < 0$, $f(x) = 1$ if $0 < x < \pi$
8. Convert the series in Prob. 7 to real form.
9. $f(x) = x \quad (-\pi < x < \pi)$
10. Convert the series in Prob. 9 to real form.
11. $f(x) = x^2 \quad (-\pi < x < \pi)$
12. Convert the series in Prob. 11 to real form.
13. $f(x) = x \quad (0 < x < 2\pi)$
14. **PROJECT. Complex Fourier Coefficients.** It is very interesting that the c_n in (6) can be derived directly by a method similar to that for a_n and b_n in Sec. 11.1. For this, multiply the series in (6) by e^{-imx} with fixed integer m, and integrate termwise from $-\pi$ to π on both sides (allowed, for instance, in the case of uniform convergence) to get

$$\int_{-\pi}^{\pi} f(x)e^{-imx}\,dx = \sum_{n=-\infty}^{\infty} c_n \int_{-\pi}^{\pi} e^{i(n-m)x}\,dx.$$

Show that the integral on the right equals 2π when $n = m$ and 0 when $n \neq m$ [use (3b)], so that you get the coefficient formula in (6).

11.5 Forced Oscillations

Fourier series have important applications in connection with ODEs and PDEs. We show this for a basic problem modeled by an ODE. Various applications to PDEs will follow in Chap. 12. This will show the enormous usefulness of Euler's and Fourier's ingenious idea of splitting up periodic functions into the simplest ones possible.

From Sec. 2.8 we know that forced oscillations of a body of mass m on a spring of modulus k are governed by the ODE

$$\textbf{(1)} \qquad my'' + cy' + ky = r(t)$$

where $y = y(t)$ is the displacement from rest, c the damping constant, k the spring constant (spring modulus), and $r(t)$ the external force depending on time t. Figure 271 shows the model and Fig. 272 its electrical analog, an *RLC*-circuit governed by

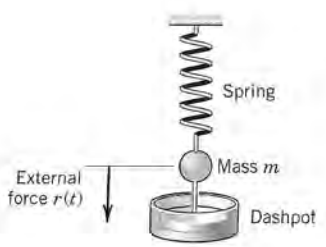

Fig. 271. Vibrating system under consideration

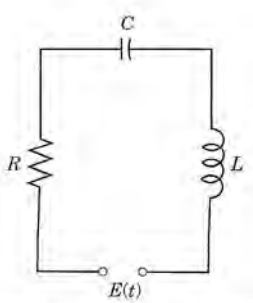

Fig. 272. Electrical analog of the system in Fig. 271 (*RLC*-circuit)

(1*) $$LI'' + RI' + \frac{1}{C}I = E'(t) \qquad \text{(Sec. 2.9).}$$

We consider (1). If $r(t)$ is a sine or cosine function and if there is damping ($c > 0$), then the steady-state solution is a harmonic oscillation with frequency equal to that of $r(t)$. However, if $r(t)$ is not a pure sine or cosine function but is any other periodic function, then the steady-state solution will be a superposition of harmonic oscillations with frequencies equal to that of $r(t)$ and integer multiples of the latter. And if one of these frequencies is close to the (practical) resonant frequency of the vibrating system (see Sec. 2.8), then the corresponding oscillation may be the dominant part of the response of the system to the external force. This is what the use of Fourier series will show us. Of course, this is quite surprising to an observer unfamiliar with Fourier series, which are highly important in the study of vibrating systems and resonance. Let us discuss the entire situation in terms of a typical example.

EXAMPLE 1 **Forced Oscillations under a Nonsinusoidal Periodic Driving Force**

In (1), let $m = 1$ (gm), $c = 0.05$ (gm/sec), and $k = 25$ (gm/sec^2), so that (1) becomes

(2) $$y'' + 0.05y' + 25y = r(t)$$

where $r(t)$ is measured in gm · cm/sec^2. Let (Fig. 273)

$$r(t) = \begin{cases} t + \dfrac{\pi}{2} & \text{if } -\pi < t < 0, \\ -t + \dfrac{\pi}{2} & \text{if } 0 < t < \pi, \end{cases} \qquad r(t + 2\pi) = r(t).$$

Find the steady-state solution $y(t)$.

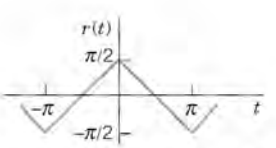

Fig. 273. Force in Example 1

Solution. We represent $r(t)$ by a Fourier series, finding

(3) $$r(t) = \frac{4}{\pi}\left(\cos t + \frac{1}{3^2}\cos 3t + \frac{1}{5^2}\cos 5t + \cdots\right)$$

(take the answer to Prob. 11 in Problem Set 11.3 minus $\frac{1}{2}\pi$ and write t for x). Then we consider the ODE

(4) $$y'' + 0.05y' + 25y = \frac{4}{n^2\pi}\cos nt \qquad (n = 1, 3, \cdots)$$

whose right side is a single term of the series (3). From Sec. 2.8 we know that the steady-state solution $y_n(t)$ of (4) is of the form

(5) $$y_n = A_n \cos nt + B_n \sin nt.$$

By substituting this into (4) we find that

$$(6) \qquad A_n = \frac{4(25 - n^2)}{n^2 \pi D_n}, \qquad B_n = \frac{0.2}{n \pi D_n}, \qquad \text{where} \qquad D_n = (25 - n^2)^2 + (0.05n)^2.$$

Since the ODE (2) is linear, we may expect the steady-state solution to be

$$(7) \qquad y = y_1 + y_3 + y_5 + \cdots$$

where y_n is given by (5) and (6). In fact, this follows readily by substituting (7) into (2) and using the Fourier series of $r(t)$, provided that termwise differentiation of (7) is permissible. (Readers already familiar with the notion of uniform convergence [Sec. 15.5] may prove that (7) may be differentiated term by term.)

From (6) we find that the amplitude of (5) is (a factor $\sqrt{D_n}$ cancels out)

$$C_n = \sqrt{A_n^2 + B_n^2} = \frac{4}{n^2 \pi \sqrt{D_n}}.$$

Numeric values are

$$C_1 = 0.0531$$

$$C_3 = 0.0088$$

$$C_5 = 0.2037$$

$$C_7 = 0.0011$$

$$C_9 = 0.0003.$$

Figure 274 shows the input (multiplied by 0.1) and the output. For $n = 5$ the quantity D_n is very small, the denominator of C_5 is small, and C_5 is so large that y_5 is the dominating term in (7). Hence the output is almost a harmonic oscillation of five times the frequency of the driving force, a little distorted due to the term y_1, whose amplitude is about 25% of that of y_5. You could make the situation still more extreme by decreasing the damping constant c. Try it. ■

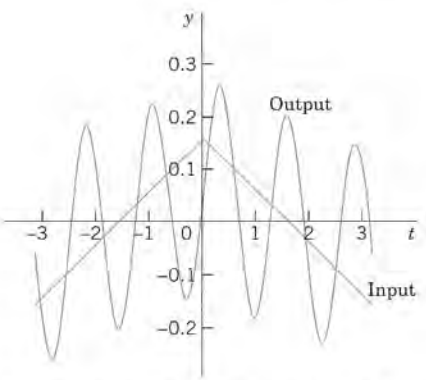

Fig. 274. Input and steady-state output in Example 1

PROBLEM SET 11.5

1. **(Coefficients)** Derive the formula for C_n from A_n and B_n.
2. **(Spring constant)** What would happen to the amplitudes C_n in Example 1 (and thus to the form of the vibration) if we changed the spring constant to the value 9? If we took a stiffer spring with $k = 81$? First guess.
3. **(Damping)** In Example 1 change c to 0.02 and discuss how this changes the output.
4. **(Input)** What would happen in Example 1 if we replaced $r(t)$ with its derivative (the rectangular wave)? What is the ratio of the new C_n to the old ones?

5–11 GENERAL SOLUTION

Find a general solution of the ODE $y'' + \omega^2 y = r(t)$ with $r(t)$ as given. (Show the details of your work.)

5. $r(t) = \cos \omega t$, $\omega = 0.5, 0.8, 1.1, 1.5, 5.0, 10.0$

6. $r(t) = \cos \omega_1 t + \cos \omega_2 t \quad (\omega^2 \neq \omega_1^2, \omega_2^2)$

7. $r(t) = \sum_{n=1}^{N} a_n \cos nt, \quad |\omega| \neq 1, 2, \cdots, N$

8. $r(t) = \sin t + \frac{1}{3} \sin 3t + \frac{1}{5} \sin 5t + \frac{1}{7} \sin 7t$

9. $r(t) = \begin{cases} t + \pi & \text{if } -\pi < t < 0 \\ -t + \pi & \text{if } 0 < t < \pi \end{cases}$

and $r(t + 2\pi) = r(t)$, $|\omega| \neq 0, 1, 3, \cdots$

10. $r(t) = \begin{cases} t & \text{if } -\pi/2 < t < \pi/2 \\ \pi - t & \text{if } \pi/2 < t < 3\pi/2 \end{cases}$

and $r(t + 2\pi) = r(t)$, $|\omega| \neq 1, 3, 5, \cdots$

11. $r(t) = \frac{\pi}{4} |\sin t|$ if $-\pi < t < \pi$ and $r(t + 2\pi) = r(t)$, $|\omega| \neq 0, 2, 4, \cdots$

12. (CAS Program) Write a program for solving the ODE just considered and for jointly graphing input and output of an initial value problem involving that ODE. Apply the program to Probs. 5 and 9 with initial values of your choice.

13. (Sign of coefficients) Some A_n in Example 1 are positive and some negative. Is this physically understandable?

14–17 STEADY-STATE DAMPED OSCILLATIONS

Find the steady-state oscillation of $y'' + cy' + y = r(t)$ with $c > 0$ and $r(t)$ as given. (Show the details of your work.)

14. $r(t) = a_n \cos nt$

15. $r(t) = \sin 3t$

16. $r(t) = \begin{cases} \pi t & \text{if } -\pi/2 < t < \pi/2 \\ \pi(\pi - t) & \text{if } \pi/2 < t < 3\pi/2 \end{cases}$

and $r(t + 2\pi) = r(t)$

17. $r(t) = \sum_{n=1}^{N} b_n \sin nt$

18. CAS EXPERIMENT. Maximum Output Term. Graph and discuss outputs of $y'' + cy' + ky = r(t)$ with $r(t)$ as in Example 1 for various c and k with emphasis on the maximum C_n and its ratio to the second largest $|C_n|$.

19–20 RLC-CIRCUIT

Find the steady-state current $I(t)$ in the RLC-circuit in Fig. 272, where $R = 100\ \Omega$, $L = 10$ H, $C = 10^{-2}$ F and $E(t)$ V as follows and periodic with period 2π. Sketch or graph the first four partial sums. Note that the coefficients of the solution decrease rapidly.

19. $E(t) = 200t(\pi^2 - t^2) \quad (-\pi < t < \pi)$

20. $E(t) = \begin{cases} 100(\pi t + t^2) & \text{if } -\pi < t < 0 \\ 100(\pi t - t^2) & \text{if } 0 < t < \pi \end{cases}$

11.6 Approximation by Trigonometric Polynomials

Fourier series play a prominent role in differential equations. Another field in which they have major applications is **approximation theory,** which concerns the approximation of functions by other (usually simpler) functions. In connection with Fourier series the idea is as follows.

Let $f(x)$ be a function on the interval $-\pi \leqq x \leqq \pi$ that can be represented on this interval by a Fourier series. Then the ***N*th partial sum** of the series

$$f(x) \approx a_0 + \sum_{n=1}^{N} (a_n \cos nx + b_n \sin nx) \tag{1}$$

is an approximation of the given $f(x)$. It is natural to ask whether (1) is the "best" approximation of f by a **trigonometric polynomial of degree *N*,** that is, by a function of the form

$$F(x) = A_0 + \sum_{n=1}^{N} (A_n \cos nx + B_n \sin nx) \qquad (N \text{ fixed}) \tag{2}$$

where "best" means that the "error" of the approximation is as small as possible.

Of course, we must first define what we mean by the **error** E of such an approximation. We could choose the maximum of $|f - F|$. But in connection with Fourier series it is better to choose a definition that measures the goodness of agreement between f and F *on the whole interval* $-\pi \leqq x \leqq \pi$. This seems preferable, in particular if f has jumps: F in Fig. 275 is a good overall approximation of f, but the maximum of $|f - F|$ (more precisely, the *supremum*) is large (it equals at least half the jump of f at x_0). We choose

$$E = \int_{-\pi}^{\pi} (f - F)^2 \, dx \,. \tag{3}$$

This is called the **square error** of F relative to the function f on the interval $-\pi \leqq x \leqq \pi$. Clearly, $E \geqq 0$.

N being fixed, we want to determine the coefficients in (2) such that E is minimum. Since $(f - F)^2 = f^2 - 2fF + F^2$, we have

$$E = \int_{-\pi}^{\pi} f^2 \, dx - 2 \int_{-\pi}^{\pi} fF \, dx + \int_{-\pi}^{\pi} F^2 \, dx. \tag{4}$$

We square (2), insert it into the last integral in (4), and evaluate the occurring integrals. This gives integrals of $\cos^2 nx$ and $\sin^2 nx$ ($n \geqq 1$), which equal π, and integrals of $\cos nx$, $\sin nx$, and $(\cos nx)(\sin mx)$, which are zero (just as in Sec. 11.1). Thus

$$\int_{-\pi}^{\pi} F^2 \, dx = \int_{-\pi}^{\pi} \left[A_0 + \sum_{n=1}^{N} (A_n \cos nx + B_n \sin nx) \right]^2 dx$$

$$= \pi(2A_0^2 + A_1^2 + \cdots + A_N^2 + B_1^2 + \cdots + B_N^2).$$

We now insert (2) into the integral of fF in (4). This gives integrals of $f \cos nx$ as well as $f \sin nx$, just as in Euler's formulas, Sec. 11.1, for a_n and b_n (each multiplied by A_n or B_n). Hence

$$\int_{-\pi}^{\pi} fF \, dx = \pi(2A_0 a_0 + A_1 a_1 + \cdots + A_N a_N + B_1 b_1 + \cdots + B_N b_N).$$

With these expressions, (4) becomes

$$E = \int_{-\pi}^{\pi} f^2 \, dx - 2\pi \left[2A_0 a_0 + \sum_{n=1}^{N} (A_n a_n + B_n b_n) \right] + \pi \left[2A_0^2 + \sum_{n=1}^{N} (A_n^2 + B_n^2) \right]. \tag{5}$$

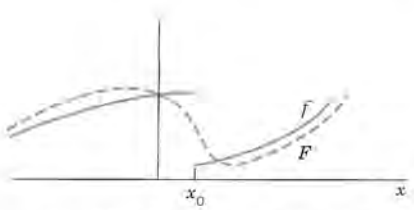

Fig. 275. Error of approximation

We now take $A_n = a_n$ and $B_n = b_n$ in (2). Then in (5) the second line cancels half of the integral-free expression in the first line. Hence for this choice of the coefficients of F the square error, call it E^*, is

$$\textbf{(6)} \qquad E^* = \int_{-\pi}^{\pi} f^2\,dx - \pi\left[2a_0^2 + \sum_{n=1}^{N}(a_n^2 + b_n^2)\right].$$

We finally subtract (6) from (5). Then the integrals drop out and we get terms $A_n^2 - 2A_na_n + a_n^2 = (A_n - a_n)^2$ and similar terms $(B_n - b_n)^2$:

$$E - E^* = \pi\left\{2(A_0 - a_0)^2 + \sum_{n=1}^{N}\left[(A_n - a_n)^2 + (B_n - b_n)^2\right]\right\}.$$

Since the sum of squares of real numbers on the right cannot be negative,

$$E - E^* \geqq 0, \qquad \text{thus} \qquad E \geqq E^*,$$

and $E = E^*$ if and only if $A_0 = a_0, \cdots, B_N = b_N$. This proves the following fundamental minimum property of the partial sums of Fourier series.

THEOREM 1

Minimum Square Error

The square error of F in (2) *(with fixed N) relative to f on the interval $-\pi \leqq x \leqq \pi$ is minimum if and only if the coefficients of F in* (2) *are the Fourier coefficients of f. This minimum value E^* is given by* (6).

From (6) we see that E^* cannot increase as N increases, but may decrease. Hence *with increasing N the partial sums of the Fourier series of f yield better and better approximations to f*, considered from the viewpoint of the square error.

Since $E^* \geqq 0$ and (6) holds for every N, we obtain from (6) the important **Bessel's inequality**

$$\textbf{(7)} \qquad 2a_0^2 + \sum_{n=1}^{\infty}(a_n^2 + b_n^2) \leqq \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)^2\,dx$$

for the Fourier coefficients of any function f for which integral on the right exists. (For F. W. Bessel see Sec. 5.5.)

It can be shown (see [C12] in App. 1) that for such a function f, **Parseval's theorem** holds; that is, formula (7) holds with the equality sign, so that it becomes **Parseval's identity**[4]

$$\textbf{(8)} \qquad 2a_0^2 + \sum_{n=1}^{\infty}(a_n^2 + b_n^2) = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)^2\,dx.$$

[4]MARC ANTOINE PARSEVAL (1755–1836), French mathematician. A physical interpretation of the identity follows in the next section.

EXAMPLE 1 **Minimum Square Error for the Sawtooth Wave**

Compute the minimum square error E^* of $F(x)$ with $N = 1, 2, \cdots, 10, 20, \cdots, 100$ and 1000 relative to

$$f(x) = x + \pi \qquad (-\pi < x < \pi)$$

on the interval $-\pi \leqq x \leqq \pi$.

Solution. $F(x) = \pi + 2(\sin x - \frac{1}{2}\sin 2x + \frac{1}{3}\sin 3x - + \cdots + \frac{(-1)^{N+1}}{N}\sin Nx)$ by Example 3 in Sec. 11.3. From this and (6),

$$E^* = \int_{-\pi}^{\pi} (x + \pi)^2\,dx - \pi\left(2\pi^2 + 4\sum_{n=1}^{N}\frac{1}{n^2}\right).$$

Numeric values are:

N	E^*	N	E^*	N	E^*	N	E^*
1	8.1045	6	1.9295	20	0.6129	70	0.1782
2	4.9629	7	1.6730	30	0.4120	80	0.1561
3	3.5666	8	1.4767	40	0.3103	90	0.1389
4	2.7812	9	1.3216	50	0.2488	100	0.1250
5	2.2786	10	1.1959	60	0.2077	1000	0.0126

Fig. 276. F with $N = 20$ in Example 1

$F = S_1$, S_2, S_3 are shown in Fig. 266 in Sec. 11.3, and $F = S_{20}$ is shown in Fig. 276. Although $|f(x) - F(x)|$ is large at $\pm\pi$ (how large?), where f is discontinuous, F approximates f quite well on the whole interval, except near $\pm\pi$, where "waves" remain owing to the Gibbs phenomenon (see CAS Experiment 20 in Problem Set 11.2).

Can you think of functions f for which E^* decreases more quickly with increasing N? ■

This is the end of our discussion of Fourier series, which has emphasized the practical aspects of these series, as needed in applications. In the last three sections of this chapter we show how ideas and techniques in Fourier series can be extended to ***nonperiodic*** functions.

PROBLEM SET 11.6

1–9 MINIMUM SQUARE ERROR

Find the trigonometric polynomial $F(x)$ of the form (2) for which the square error with respect to the given $f(x)$ on the interval $-\pi \leqq x \leqq \pi$ is minimum, and compute the minimum value for $N = 1, 2, \cdots, 5$ (or also for larger values if you have a CAS).

1. $f(x) = x \ (-\pi < x < \pi)$
2. $f(x) = x^2 \ (-\pi < x < \pi)$
3. $f(x) = |x| \ (-\pi < x < \pi)$
4. $f(x) = x^3 \ (-\pi < x < \pi)$
5. $f(x) = |\sin x| \ (-\pi < x < \pi)$
6. $f(x) = e^{-|x|} \ (-\pi < x < \pi)$
7. $f(x) = \begin{cases} -1 & \text{if } -\pi < x < 0 \\ 1 & \text{if } 0 < x < \pi \end{cases}$
8. $f(x) = \begin{cases} x & \text{if } -\frac{1}{2}\pi < x < \frac{1}{2}\pi \\ 0 & \text{if } \frac{1}{2}\pi < x < \frac{3}{2}\pi \end{cases}$
9. $f(x) = x(x + \pi)$ if $-\pi < x < 0$, $f(x) = x(-x + \pi)$ if $0 < x < \pi$
10. **CAS EXPERIMENT. Size and Decrease of E^*.** Compare the size of the minimum square error E^* for functions of your choice. Find experimentally the factors on which the decrease of E^* with N depends. For each function considered find the smallest N such that $E^* < 0.1$.
11. **(Monotonicity)** Show that the minimum square error (6) is a monotone decreasing function of N. How can you use this in practice?

12–16 PARSEVAL'S IDENTITY

Using Parseval's identity, prove that the series have the indicated sums. Compute the first few partial sums to see that the convergence is rapid.

12. $1 + \frac{1}{3^4} + \frac{1}{5^4} + \frac{1}{7^4} + \cdots = \frac{\pi^4}{96} = 1.01467\ 8032$

(Use Prob. 15 in Sec. 11.1.)

13. $1 + \frac{1}{3^2} + \frac{1}{5^2} + \cdots = \frac{\pi^2}{8} = 1.23370\ 0550$

(Use Prob. 13 in Sec. 11.1.)

14. $\frac{1}{1^2 \cdot 3^2} + \frac{1}{3^2 \cdot 5^2} + \frac{1}{5^2 \cdot 7^2} + \cdots$

$= \frac{\pi^2}{16} - \frac{1}{2} = 0.11685\ 0275$

(Use Prob. 5, this set.)

15. $1 + \frac{1}{2^4} + \frac{1}{3^4} + \cdots = \frac{\pi^4}{90} = 1.08232\ 3234$

(Use Prob. 21 in Sec. 11.1.)

16. $1 + \frac{1}{3^6} + \frac{1}{5^6} + \frac{1}{7^6} + \cdots = \frac{\pi^6}{960} = 1.00144\ 7078$

(Use Prob. 9, this set.)

11.7 Fourier Integral

Fourier series are powerful tools for problems involving functions that are periodic or are of interest on a finite interval only. Sections 11.3 and 11.5 first illustrated this, and various further applications follow in Chap. 12. Since, of course, many problems involve functions that are **nonperiodic** *and are of interest on the whole x-axis,* we ask what can be done to extend the method of Fourier series to such functions. This idea will lead to "Fourier integrals."

In Example 1 we start from a special function f_L of period $2L$ and see what happens to its Fourier series if we let $L \to \infty$. Then we do the same for an *arbitrary* function f_L of period $2L$. This will motivate and suggest the main result of this section, which is an integral representation given in Theorem 1 (below).

EXAMPLE 1 Rectangular Wave

Consider the periodic rectangular wave $f_L(x)$ of period $2L > 2$ given by

$$f_L(x) = \begin{cases} 0 & \text{if} \quad -L < x < -1 \\ 1 & \text{if} \quad -1 < x < 1 \\ 0 & \text{if} \quad 1 < x < L. \end{cases}$$

The left part of Fig. 277 shows this function for $2L = 4, 8, 16$ as well as the nonperiodic function $f(x)$, which we obtain from f_L if we let $L \to \infty$,

$$f(x) = \lim_{L \to \infty} f_L(x) = \begin{cases} 1 & \text{if } -1 < x < 1 \\ 0 & \text{otherwise.} \end{cases}$$

We now explore what happens to the Fourier coefficients of f_L as L increases. Since f_L is even, $b_n = 0$ for all n. For a_n the Euler formulas (6), Sec. 11.2, give

$$a_0 = \frac{1}{2L} \int_{-1}^{1} dx = \frac{1}{L}, \qquad a_n = \frac{1}{L} \int_{-1}^{1} \cos \frac{n\pi x}{L}\, dx = \frac{2}{L} \int_{0}^{1} \cos \frac{n\pi x}{L}\, dx = \frac{2}{L} \frac{\sin (n\pi/L)}{n\pi/L}.$$

This sequence of Fourier coefficients is called the **amplitude spectrum** of f_L because $|a_n|$ is the maximum amplitude of the wave $a_n \cos (n\pi x/L)$. Figure 277 shows this spectrum for the periods $2L = 4, 8, 16$. We see that for increasing L these amplitudes become more and more dense on the positive w_n-axis, where $w_n = n\pi/L$. Indeed, for $2L = 4, 8, 16$ we have 1, 3, 7 amplitudes per "half-wave" of the function $(2 \sin w_n)/(Lw_n)$ (dashed in the figure). Hence for $2L = 2^k$ we have $2^{k-1} - 1$ amplitudes per half-wave, so that these amplitudes will eventually be everywhere dense on the positive w_n-axis (and will decrease to zero).

The outcome of this example gives an intuitive impression of what about to expect if we turn from our special function to an arbitrary one, as we shall do next. ■

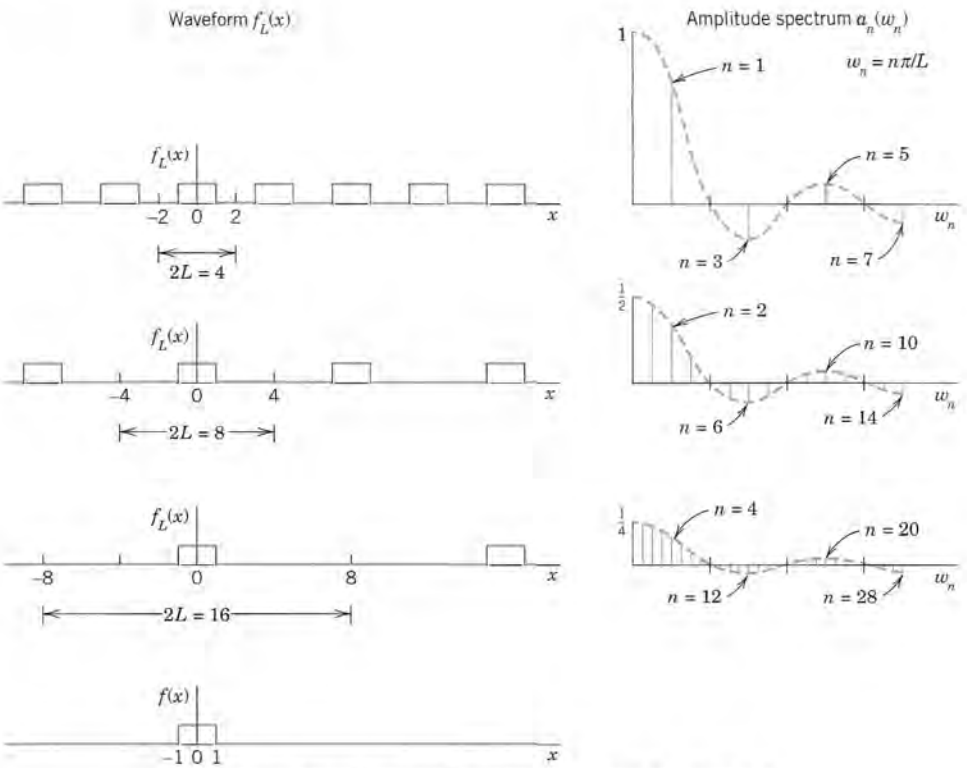

Fig. 277. Waveforms and amplitude spectra in Example 1

From Fourier Series to Fourier Integral

We now consider any periodic function $f_L(x)$ of period $2L$ that can be represented by a Fourier series

$$f_L(x) = a_0 + \sum_{n=1}^{\infty} (a_n \cos w_n x + b_n \sin w_n x), \qquad w_n = \frac{n\pi}{L}$$

and find out what happens if we let $L \to \infty$. Together with Example 1 the present calculation will suggest that we should expect an integral (instead of a series) involving $\cos wx$ and $\sin wx$ with w no longer restricted to integer multiples $w = w_n = n\pi/L$ of π/L but taking *all* values. We shall also see what form such an integral might have.

If we insert a_n and b_n from the Euler formulas (6), Sec. 11.2, and denote the variable of integration by v, the Fourier series of $f_L(x)$ becomes

$$f_L(x) = \frac{1}{2L} \int_{-L}^{L} f_L(v)\, dv + \frac{1}{L} \sum_{n=1}^{\infty} \left[\cos w_n x \int_{-L}^{L} f_L(v) \cos w_n v\, dv + \sin w_n x \int_{-L}^{L} f_L(v) \sin w_n v\, dv \right].$$

We now set

$$\Delta w = w_{n+1} - w_n = \frac{(n+1)\pi}{L} - \frac{n\pi}{L} = \frac{\pi}{L}.$$

Then $1/L = \Delta w/\pi$, and we may write the Fourier series in the form

$$(1) \quad f_L(x) = \frac{1}{2L}\int_{-L}^{L} f_L(v)\,dv + \frac{1}{\pi}\sum_{n=1}^{\infty}\left[(\cos w_n x)\,\Delta w \int_{-L}^{L} f_L(v)\cos w_n v\,dv + (\sin w_n x)\,\Delta w \int_{-L}^{L} f_L(v)\sin w_n v\,dv\right].$$

This representation is valid for any fixed L, arbitrarily large, but finite.

We now let $L \to \infty$ and assume that the resulting nonperiodic function

$$f(x) = \lim_{L\to\infty} f_L(x)$$

is **absolutely integrable** on the x-axis; that is, the following (finite!) limits exist:

$$(2) \qquad \lim_{a\to-\infty}\int_{a}^{0}|f(x)|\,dx + \lim_{b\to\infty}\int_{0}^{b}|f(x)|\,dx \quad \left(\text{written } \int_{-\infty}^{\infty}|f(x)|\,dx\right).$$

Then $1/L \to 0$, and the value of the first term on the right side of (1) approaches zero. Also $\Delta w = \pi/L \to 0$ and it seems ***plausible*** that the infinite series in (1) becomes an integral from 0 to ∞, which represents $f(x)$, namely,

$$(3) \quad f(x) = \frac{1}{\pi}\int_{0}^{\infty}\left[\cos wx\int_{-\infty}^{\infty} f(v)\cos wv\,dv + \sin wx\int_{-\infty}^{\infty} f(v)\sin wv\,dv\right]dw.$$

If we introduce the notations

$$\mathbf{(4)} \qquad A(w) = \frac{1}{\pi}\int_{-\infty}^{\infty} f(v)\cos wv\,dv, \qquad B(w) = \frac{1}{\pi}\int_{-\infty}^{\infty} f(v)\sin wv\,dv$$

we can write this in the form

$$\mathbf{(5)} \qquad f(x) = \int_{0}^{\infty}[A(w)\cos wx + B(w)\sin wx]\,dw.$$

This is called a representation of $f(x)$ by a **Fourier integral.**

It is clear that our naive approach merely ***suggests*** the representation (5), but by no means establishes it; in fact, the limit of the series in (1) as Δw approaches zero is not the definition of the integral (3). Sufficient conditions for the validity of (5) are as follows.

THEOREM 1

Fourier Integral

If $f(x)$ is piecewise continuous (see Sec. 6.1) *in every finite interval and has a right-hand derivative and a left-hand derivative at every point* (see Sec 11.1) *and if the integral* (2) *exists, then $f(x)$ can be represented by a Fourier integral* (5) *with A and B given by* (4). *At a point where $f(x)$ is discontinuous the value of the Fourier integral equals the average of the left- and right-hand limits of $f(x)$ at that point* (see Sec. 11.1). (Proof in Ref. [C12]; see App. 1.)

Applications of Fourier Integrals

The main application of Fourier integrals is in solving ODEs and PDEs, as we shall see for PDEs in Sec. 12.6. However, we can also use Fourier integrals in integration and in discussing functions defined by integrals, as the next examples (2 and 3) illustrate.

EXAMPLE 2 **Single Pulse, Sine Integral**

Find the Fourier integral representation of the function

$$f(x) = \begin{cases} 1 & \text{if} \quad |x| < 1 \\ 0 & \text{if} \quad |x| > 1 \end{cases} \qquad \text{(Fig. 278).}$$

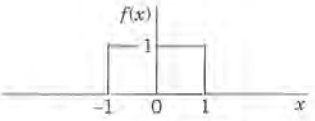

Fig. 278. Example 2

Solution. From (4) we obtain

$$A(w) = \frac{1}{\pi}\int_{-\infty}^{\infty} f(v)\cos wv\, dv = \frac{1}{\pi}\int_{-1}^{1}\cos wv\, dv = \frac{\sin wv}{\pi w}\bigg|_{-1}^{1} = \frac{2\sin w}{\pi w}$$

$$B(w) = \frac{1}{\pi}\int_{-1}^{1}\sin wv\, dv = 0$$

and (5) gives the answer

$$f(x) = \frac{2}{\pi}\int_0^{\infty}\frac{\cos wx \sin w}{w}\, dw. \tag{6}$$

The average of the left- and right-hand limits of $f(x)$ at $x = 1$ is equal to $(1 + 0)/2$, that is, $1/2$.

Furthermore, from (6) and Theorem 1 we obtain (multiply by $\pi/2$)

$$\int_0^{\infty}\frac{\cos wx \sin w}{w}\, dw = \begin{cases} \pi/2 & \text{if} \quad 0 \leqq x < 1, \\ \pi/4 & \text{if} \quad x = 1, \\ 0 & \text{if} \quad x > 1. \end{cases} \tag{7}$$

We mention that this integral is called **Dirichlet's discontinous factor.** (For P. L. Dirichlet see Sec. 10.8.)

The case $x = 0$ is of particular interest. If $x = 0$, then (7) gives

$$\int_0^{\infty}\frac{\sin w}{w}\, dw = \frac{\pi}{2}. \tag{8*}$$

We see that this integral is the limit of the so-called **sine integral**

$$\mathrm{Si}(u) = \int_0^{u}\frac{\sin w}{w}\, dw \tag{8}$$

as $u \to \infty$. The graphs of $\mathrm{Si}(u)$ and of the integrand are shown in Fig. 279.

In the case of a Fourier series the graphs of the partial sums are approximation curves of the curve of the periodic function represented by the series. Similarly, in the case of the Fourier integral (5), approximations are obtained by replacing ∞ by numbers a. Hence the integral

$$\frac{2}{\pi}\int_0^{a}\frac{\cos wx \sin w}{w}\, dw \tag{9}$$

approximates the right side in (6) and therefore $f(x)$.

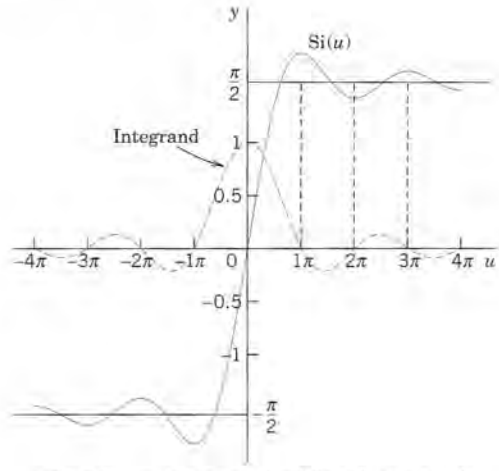

Fig. 279. Sine integral Si(u) and integrand

Figure 280 shows oscillations near the points of discontinuity of $f(x)$. We might expect that these oscillations disappear as a approaches infinity. But this is not true; with increasing a, they are shifted closer to the points $x = \pm 1$. This unexpected behavior, which also occurs in connection with Fourier series, is known as the **Gibbs phenomenon.** (See also Problem Set 11.2.) We can explain it by representing (9) in terms of sine integrals as follows. Using (11) in App. A3.1, we have

$$\frac{2}{\pi}\int_0^a \frac{\cos wx \sin w}{w}\,dw = \frac{1}{\pi}\int_0^a \frac{\sin(w + wx)}{w}\,dw + \frac{1}{\pi}\int_0^a \frac{\sin(w - wx)}{w}\,dw.$$

In the first integral on the right we set $w + wx = t$. Then $dw/w = dt/t$, and $0 \leqq w \leqq a$ corresponds to $0 \leqq t \leqq (x + 1)a$. In the last integral we set $w - wx = -t$. Then $dw/w = dt/t$, and $0 \leqq w \leqq a$ corresponds to $0 \leqq t \leqq (x - 1)a$. Since $\sin(-t) = -\sin t$, we thus obtain

$$\frac{2}{\pi}\int_0^a \frac{\cos wx \sin w}{w}\,dw = \frac{1}{\pi}\int_0^{(x+1)a} \frac{\sin t}{t}\,dt - \frac{1}{\pi}\int_0^{(x-1)a} \frac{\sin t}{t}\,dt.$$

From this and (8) we see that our integral (9) equals

$$\frac{1}{\pi}\,\mathrm{Si}(a[x + 1]) - \frac{1}{\pi}\,\mathrm{Si}(a[x - 1])$$

and the oscillations in Fig. 280 result from those in Fig. 279. The increase of a amounts to a transformation of the scale on the axis and causes the shift of the oscillations (the waves) toward the points of discontinuity -1 and 1. ■

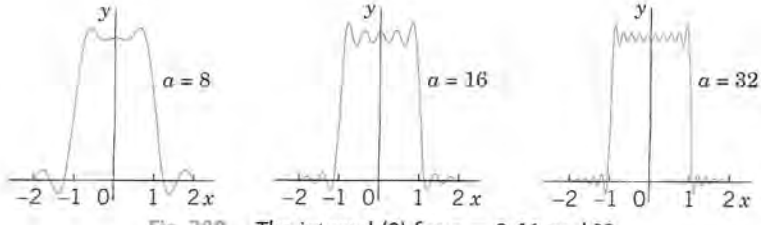

Fig. 280. The integral (9) for $a = 8$, 16, and 32

Fourier Cosine Integral and Fourier Sine Integral

For an even or odd function the Fourier integral becomes simpler. Just as in the case of Fourier series (Sec. 11.3), this is of practical interest in saving work and avoiding errors. The simplifications follow immediately from the formulas just obtained.

Indeed, if $f(x)$ is an ***even*** function, then $B(w) = 0$ in (4) and

$$\textbf{(10)} \qquad A(w) = \frac{2}{\pi} \int_0^\infty f(v) \cos wv \, dv.$$

The Fourier integral (5) then reduces to the **Fourier cosine integral**

$$\textbf{(11)} \qquad f(x) = \int_0^\infty A(w) \cos wx \, dw \qquad (f \text{ even}).$$

Similarly, if $f(x)$ is ***odd,*** then in (4) we have $A(w) = 0$ and

$$\textbf{(12)} \qquad B(w) = \frac{2}{\pi} \int_0^\infty f(v) \sin wv \, dv.$$

The Fourier integral (5) then reduces to the **Fourier sine integral**

$$\textbf{(13)} \qquad f(x) = \int_0^\infty B(w) \sin wx \, dw \qquad (f \text{ odd}).$$

Evaluation of Integrals

Earlier in this section we pointed out that the main application of the Fourier integral is in differential equations but that Fourier integral representations also help in evaluating certain integrals. To see this, we show the method for an important case, the Laplace integrals.

EXAMPLE 3 **Laplace Integrals**

We shall derive the Fourier cosine and Fourier sine integrals of $f(x) = e^{-kx}$, where $x > 0$ and $k > 0$ (Fig. 281). The result will be used to evaluate the so-called Laplace integrals.

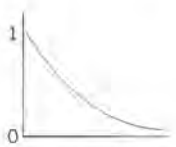

Fig. 281. $f(x)$ in Example 3

Solution. (a) From (10) we have $A(w) = \frac{2}{\pi} \int_0^\infty e^{-kv} \cos wv \, dv$. Now, by integration by parts,

$$\int e^{-kv} \cos wv \, dv = -\frac{k}{k^2 + w^2} e^{-kv} \left(-\frac{w}{k} \sin wv + \cos wv \right).$$

If $v = 0$, the expression on the right equals $-k/(k^2 + w^2)$. If v approaches infinity, that expression approaches zero because of the exponential factor. Thus

$$(14) \qquad A(w) = \frac{2k/\pi}{k^2 + w^2}.$$

By substituting this into (11) we thus obtain the Fourier cosine integral representation

$$f(x) = e^{-kx} = \frac{2k}{\pi} \int_0^\infty \frac{\cos wx}{k^2 + w^2} \, dw \qquad (x > 0, \quad k > 0).$$

From this representation we see that

$$\textbf{(15)} \qquad \int_0^\infty \frac{\cos wx}{k^2 + w^2}\, dw = \frac{\pi}{2k}\, e^{-kx} \qquad (x > 0, \quad k > 0).$$

(b) Similarly, from (12) we have $B(w) = \dfrac{2}{\pi} \displaystyle\int_0^\infty e^{-kv} \sin wv\, dv$. By integration by parts,

$$\int e^{-kv} \sin wv\, dv = -\frac{w}{k^2 + w^2}\, e^{-kv} \left(\frac{k}{w} \sin wv + \cos wv \right).$$

This equals $-w/(k^2 + w^2)$ if $v = 0$, and approaches 0 as $v \to \infty$. Thus

$$(16) \qquad B(w) = \frac{2w/\pi}{k^2 + w^2}.$$

From (13) we thus obtain the Fourier sine integral representation

$$f(x) = e^{-kx} = \frac{2}{\pi} \int_0^\infty \frac{w \sin wx}{k^2 + w^2}\, dw.$$

From this we see that

$$\textbf{(17)} \qquad \int_0^\infty \frac{w \sin wx}{k^2 + w^2}\, dw = \frac{\pi}{2}\, e^{-kx} \qquad (x > 0, \quad k > 0).$$

The integrals (15) and (17) are called the **Laplace integrals.**

PROBLEM SET 11.7

1–6 EVALUATION OF INTEGRALS

Show that the given integral represents the indicated function. *Hint.* Use (5), (11), or (13); the integral tells you which one, and its value tells you what function to consider. (Show the details of your work.)

1. $$\int_0^\infty \frac{\cos xw + w \sin xw}{1 + w^2}\, dw = \begin{cases} 0 & \text{if } x < 0 \\ \pi/2 & \text{if } x = 0 \\ \pi e^{-x} & \text{if } x > 0 \end{cases}$$

2. $$\int_0^\infty \frac{\sin w - w \cos w}{w^2} \sin xw\, dw = \begin{cases} \pi x/2 & \text{if } 0 < x < 1 \\ \pi/4 & \text{if } x = 1 \\ 0 & \text{if } x > 1 \end{cases}$$

3. $$\int_0^\infty \frac{\cos xw}{1 + w^2}\, dw = \frac{\pi}{2} e^{-x} \text{ if } x > 0$$

4. $$\int_0^\infty \frac{\sin w}{w} \cos xw\, dw = \begin{cases} \pi/2 & \text{if } 0 \leqq x < 1 \\ \pi/4 & \text{if } x = 1 \\ 0 & \text{if } x > 1 \end{cases}$$

5. $$\int_0^\infty \frac{\cos(\pi w/2)}{1 - w^2} \cos xw\, dw = \begin{cases} \frac{\pi}{2} \cos x & \text{if } 0 < |x| < \pi/2 \\ 0 & \text{if } |x| \geqq \pi/2 \end{cases}$$

6. $$\int_0^\infty \frac{\sin \pi w \sin xw}{1 - w^2}\, dw = \begin{cases} \frac{\pi}{2} \sin x & \text{if } 0 \leqq x \leqq \pi \\ 0 & \text{if } x > \pi \end{cases}$$

7–12 FOURIER COSINE INTEGRAL REPRESENTATIONS

Represent $f(x)$ as an integral (11).

7. $$f(x) = \begin{cases} 1 & \text{if } 0 < x < a \\ 0 & \text{if } x > a \end{cases}$$

8. $f(x) = \begin{cases} x^2 & \text{if } 0 < x < a \\ 0 & \text{if } x > a \end{cases}$

9. $f(x) = \begin{cases} x & \text{if } 0 < x < 1 \\ 0 & \text{if } x > 1 \end{cases}$

10. $f(x) = \begin{cases} x/2 & \text{if } 0 < x < 1 \\ 1 - x/2 & \text{if } 1 < x < 2 \\ 0 & \text{if } x > 2 \end{cases}$

11. $f(x) = \begin{cases} \sin x & \text{if } 0 < x < \pi \\ 0 & \text{if } x > \pi \end{cases}$

12. $f(x) = \begin{cases} e^{-x} & \text{if } 0 < x < a \\ 0 & \text{if } x > a \end{cases}$

13. CAS EXPERIMENT. Approximate Fourier Cosine Integrals. Graph the integrals in Prob. 7, 9, and 11 as functions of x. Graph approximations obtained by replacing ∞ with finite upper limits of your choice. Compare the quality of the approximations. Write a short report on your empirical results and observations.

14–19 FOURIER SINE INTEGRAL REPRESENTATIONS

Represent $f(x)$ as an integral (13).

14. $f(x) = \begin{cases} 1 & \text{if } 0 < x < a \\ 0 & \text{if } x > a \end{cases}$

15. $f(x) = \begin{cases} \sin x & \text{if } 0 < x < \pi \\ 0 & \text{if } x > \pi \end{cases}$

16. $f(x) = \begin{cases} 1 - x^2 & \text{if } 0 < x < 1 \\ 0 & \text{if } x > 1 \end{cases}$

17. $f(x) = \begin{cases} \pi - x & \text{if } 0 < x < \pi \\ 0 & \text{if } x > \pi \end{cases}$

18. $f(x) = \begin{cases} \cos x & \text{if } 0 < x < \pi \\ 0 & \text{if } x > \pi \end{cases}$

19. $f(x) = \begin{cases} a - x & \text{if } 0 < x < a \\ 0 & \text{if } x > a \end{cases}$

20. PROJECT. Properties of Fourier Integrals

(a) Fourier cosine integral. Show that (11) implies

$$\text{(a1)} \quad f(ax) = \frac{1}{a} \int_0^\infty A\left(\frac{w}{a}\right) \cos xw \, dw \qquad (a > 0) \quad \textit{(Scale change)}$$

$$\text{(a2)} \quad xf(x) = \int_0^\infty B^*(w) \sin xw \, dw, \qquad B^* = -\frac{dA}{dw}, \quad A \text{ as in (10)}$$

$$\text{(a3)} \quad x^2 f(x) = \int_0^\infty A^*(w) \cos xw \, dw, \qquad A^* = -\frac{d^2A}{dw^2}.$$

(b) Solve Prob. 8 by applying (a3) to the result of Prob. 7.

(c) Verify (a2) for $f(x) = 1$ if $0 < x < a$ and $f(x) = 0$ if $x > a$.

(d) Fourier sine integral. Find formulas for the Fourier sine integral similar to those in (a).

11.8 Fourier Cosine and Sine Transforms

An **integral transform** is a transformation in the form of an integral that produces from given functions new functions depending on a different variable. These transformations are of interest mainly as tools for solving ODEs, PDEs, and integral equations, and they often also help in handling and applying special functions. The **Laplace transform** (Chap. 6) is of this kind and is by far the most important integral transform in engineering.

The next in order of importance are Fourier transforms. We shall see that these transforms can be obtained from the Fourier integral in Sec. 11.7 in a rather simple fashion. In this section we consider two of them, which are real, and in the next section a third one that is complex.

Fourier Cosine Transform

For an ***even*** function $f(x)$, the Fourier integral is the Fourier cosine integral

$$(1)\quad (a)\quad f(x) = \int_0^\infty A(w)\cos wx\,dw, \qquad \text{where} \qquad (b)\quad A(w) = \frac{2}{\pi}\int_0^\infty f(v)\cos wv\,dv$$

[see (10), (11), Sec. 11.7]. We now set $A(w) = \sqrt{2/\pi}\,\hat{f}_c(w)$, where c suggests "cosine." Then from (1b), writing $v = x$, we have

$$\textbf{(2)}\qquad \hat{f}_c(w) = \sqrt{\frac{2}{\pi}}\int_0^\infty f(x)\cos wx\,dx$$

and from (1a),

$$\textbf{(3)}\qquad f(x) = \sqrt{\frac{2}{\pi}}\int_0^\infty \hat{f}_c(w)\cos wx\,dw.$$

ATTENTION! In (2) we integrate with respect to x and in (3) with respect to w. Formula (2) gives from $f(x)$ a new function $\hat{f}_c(w)$, called the **Fourier cosine transform** of $f(x)$. Formula (3) gives us back $f(x)$ from $\hat{f}_c(w)$, and we therefore call $f(x)$ the **inverse Fourier cosine transform** of $\hat{f}_c(w)$.

The process of obtaining the transform $\hat{f}_c$ from a given f is also called the **Fourier cosine transform** or the *Fourier cosine transform method.*

Fourier Sine Transform

Similarly, for an ***odd*** function $f(x)$, the Fourier integral is the Fourier sine integral [see (12), (13), Sec. 11.7]

$$(4)\quad (a)\quad f(x) = \int_0^\infty B(w)\sin wx\,dw, \qquad \text{where} \qquad (b)\quad B(w) = \frac{2}{\pi}\int_0^\infty f(v)\sin wv\,dv.$$

We now set $B(w) = \sqrt{2/\pi}\,\hat{f}_s(w)$, where s suggests "sine." Then from (4b), writing $v = x$, we have

$$\textbf{(5)}\qquad \hat{f}_s(w) = \sqrt{\frac{2}{\pi}}\int_0^\infty f(x)\sin wx\,dx.$$

This is called the **Fourier sine transform** of $f(x)$. Similarly, from (4a) we have

$$\textbf{(6)}\qquad f(x) = \sqrt{\frac{2}{\pi}}\int_0^\infty \hat{f}_s(w)\sin wx\,dw.$$

This is called the **inverse Fourier sine transform** of $\hat{f}_s(w)$. The process of obtaining $\hat{f}_s(w)$ from $f(x)$ is also called the **Fourier sine transform** or the *Fourier sine transform method.*

Other notations are

$$\mathcal{F}_c(f) = \hat{f}_c, \qquad \mathcal{F}_s(f) = \hat{f}_s$$

and $\mathcal{F}_c^{-1}$ and $\mathcal{F}_s^{-1}$ for the inverses of $\mathcal{F}_c$ and $\mathcal{F}_s$, respectively.

EXAMPLE 1 Fourier Cosine and Fourier Sine Transforms

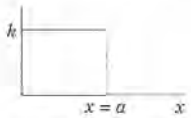

Fig. 282. $f(x)$ in Example 1

Find the Fourier cosine and Fourier sine transforms of the function

$$f(x) = \begin{cases} k & \text{if } 0 < x < a \\ 0 & \text{if } x > a \end{cases} \qquad \text{(Fig. 282).}$$

Solution. From the definitions (2) and (5) we obtain by integration

$$\hat{f}_c(w) = \sqrt{\frac{2}{\pi}}\, k \int_0^a \cos wx\, dx = \sqrt{\frac{2}{\pi}}\, k \left(\frac{\sin aw}{w}\right)$$

$$\hat{f}_s(w) = \sqrt{\frac{2}{\pi}}\, k \int_0^a \sin wx\, dx = \sqrt{\frac{2}{\pi}}\, k \left(\frac{1 - \cos aw}{w}\right).$$

This agrees with formulas 1 in the first two tables in Sec. 11.10 (where $k = 1$).

Note that for $f(x) = k = const$ $(0 < x < \infty)$, these transforms do not exist. (Why?) ■

EXAMPLE 2 Fourier Cosine Transform of the Exponential Function

Find $\mathcal{F}_c(e^{-x})$.

Solution. By integration by parts and recursion,

$$\mathcal{F}_c(e^{-x}) = \sqrt{\frac{2}{\pi}} \int_0^\infty e^{-x} \cos wx\, dx = \sqrt{\frac{2}{\pi}}\, \frac{e^{-x}}{1 + w^2}\, (-\cos wx + w \sin wx) \Big|_0^\infty = \frac{\sqrt{2/\pi}}{1 + w^2}.$$

This agrees with formula 3 in Table I, Sec. 11.10, with $a = 1$. See also the next example. ■

What did we do to introduce the two integral transforms under consideration? Actually not much: We changed the notations A and B to get a "symmetric" distribution of the constant $2/\pi$ in the original formulas (10)–(13), Sec. 11.7. This redistribution is a standard convenience, but it is not essential. One could do without it.

What have we gained? We show next that these transforms have operational properties that permit them to convert differentiations into algebraic operations (just as the Laplace transform does). This is the key to their application in solving differential equations.

Linearity, Transforms of Derivatives

If $f(x)$ is absolutely integrable (see Sec. 11.7) on the positive x-axis and piecewise continuous (see Sec. 6.1) on every finite interval, then the Fourier cosine and sine transforms of f exist.

Furthermore, if f and g have Fourier cosine and sine transforms, so does $af + bg$ for any constants a and b, and by (2),

$$\mathcal{F}_c(af + bg) = \sqrt{\frac{2}{\pi}} \int_0^\infty [af(x) + bg(x)] \cos wx\, dx$$

$$= a\sqrt{\frac{2}{\pi}} \int_0^\infty f(x) \cos wx\, dx + b\sqrt{\frac{2}{\pi}} \int_0^\infty g(x) \cos wx\, dx.$$

The right side is $a\mathcal{F}_c(f) + b\mathcal{F}_c(g)$. Similarly for $\mathcal{F}_s$, by (5). This shows that the Fourier cosine and sine transforms are **linear operations,**

(7)
$$\text{(a)} \quad \mathcal{F}_c(af + bg) = a\mathcal{F}_c(f) + b\mathcal{F}_c(g),$$
$$\text{(b)} \quad \mathcal{F}_s(af + bg) = a\mathcal{F}_s(f) + b\mathcal{F}_s(g).$$

THEOREM 1

Cosine and Sine Transforms of Derivatives

Let $f(x)$ be continuous and absolutely integrable on the x-axis, let $f'(x)$ be piecewise continuous on every finite interval, and let let $f(x) \to 0$ *as* $x \to \infty$. *Then*

$$\textbf{(8)} \qquad \textbf{(a)} \qquad \mathcal{F}_c\{f'(x)\} = w\mathcal{F}_s\{f(x)\} - \sqrt{\frac{2}{\pi}}\, f(0),$$

$$\textbf{(b)} \qquad \mathcal{F}_s\{f'(x)\} = -w\mathcal{F}_c\{f(x)\}.$$

PROOF This follows from the definitions by integration by parts, namely,

$$\begin{aligned}\mathcal{F}_c\{f'(x)\} &= \sqrt{\frac{2}{\pi}} \int_0^\infty f'(x) \cos wx\, dx \\ &= \sqrt{\frac{2}{\pi}} \left[f(x) \cos wx \,\Big|_0^\infty + w \int_0^\infty f(x) \sin wx\, dx \right] \\ &= -\sqrt{\frac{2}{\pi}}\, f(0) + w\mathcal{F}_s\{f(x)\};\end{aligned}$$

and similarly,

$$\begin{aligned}\mathcal{F}_s\{f'(x)\} &= \sqrt{\frac{2}{\pi}} \int_0^\infty f'(x) \sin wx\, dx \\ &= \sqrt{\frac{2}{\pi}} \left[f(x) \sin wx \,\Big|_0^\infty - w \int_0^\infty f(x) \cos wx\, dx \right] \\ &= 0 - w\mathcal{F}_c\{f(x)\}.\end{aligned}$$

■

Formula (8a) with f' instead of f gives (when f', f'' satisfy the respective assumptions for f, f' in Theorem 1)

$$\mathcal{F}_c\{f''(x)\} = w\mathcal{F}_s\{f'(x)\} - \sqrt{\frac{2}{\pi}}\, f'(0);$$

hence by (8b)

$$\textbf{(9a)} \qquad \mathcal{F}_c\{f''(x)\} = -w^2\mathcal{F}_c\{f(x)\} - \sqrt{\frac{2}{\pi}}\, f'(0).$$

Similarly,

$$\textbf{(9b)} \qquad \mathcal{F}_s\{f''(x)\} = -w^2\mathcal{F}_s\{f(x)\} + \sqrt{\frac{2}{\pi}}\, wf(0).$$

A basic application of (9) to PDEs will be given in Sec. 12.6. For the time being we show how (9) can be used for deriving transforms.

EXAMPLE 3 **An Application of the Operational Formula (9)**

Find the Fourier cosine transform $\mathcal{F}_c(e^{-ax})$ of $f(x) = e^{-ax}$, where $a > 0$.

Solution. By differentiation, $(e^{-ax})'' = a^2e^{-ax}$; thus

$$a^2f(x) = f''(x).$$

From this, (9a), and the linearity (7a),

$$\begin{aligned} a^2\mathcal{F}_c(f) &= \mathcal{F}_c(f'') \\ &= -w^2\mathcal{F}_c(f) - \sqrt{\frac{2}{\pi}}\, f'(0) \\ &= -w^2\mathcal{F}_c(f) + a\sqrt{\frac{2}{\pi}}. \end{aligned}$$

Hence

$$(a^2 + w^2)\mathcal{F}_c(f) = a\sqrt{2/\pi}.$$

The *answer* is (see Table I, Sec. 11.10)

$$\mathcal{F}_c(e^{-ax}) = \sqrt{\frac{2}{\pi}}\left(\frac{a}{a^2 + w^2}\right) \qquad (a > 0).$$

Tables of Fourier cosine and sine transforms are included in Sec. 11.10.

PROBLEM SET 11.8

1–10 FOURIER COSINE TRANSFORM

1. Let $f(x) = -1$ if $0 < x < 1$, $f(x) = 1$ if $1 < x < 2$, $f(x) = 0$ if $x > 2$. Find $\hat{f}_c(w)$.
2. Let $f(x) = x$ if $0 < x < k$, $f(x) = 0$ if $x > k$. Find $\hat{f}_c(w)$.
3. Derive formula 3 in Table 1 of Sec. 11.10 by integration.
4. Find the inverse Fourier cosine transform $f(x)$ from the answer to Prob. 1. *Hint.* Use Prob. 4 in Sec. 11.7.
5. Obtain $\mathcal{F}_c^{-1}(1/(1 + w^2))$ from Prob. 3 in Sec. 11.7.
6. Obtain $\mathcal{F}_c^{-1}(e^{-w})$ by integration.
7. Find $\mathcal{F}_c((1 - x^2)^{-1} \cos(\pi x/2))$. *Hint.* Use Prob. 5 in Sec. 11.7.
8. Let $f(x) = x^2$ if $0 < x < 1$ and 0 if $x > 1$. Find $\mathcal{F}_c(f)$.
9. Does the Fourier cosine transform of $x^{-1} \sin x$ exist? Of $x^{-1} \cos x$? Give reasons.
10. $f(x) = 1$ $(0 < x < \infty)$ has no Fourier cosine or sine transform. Give reasons.

11–20 FOURIER SINE TRANSFORM

11. Find $\mathcal{F}_s(e^{-\pi x})$ by integration.
12. Find the answer to Prob. 11 from (9b).
13. Obtain formula 8 in Table II of Sec. 11.11 from (8b) and a suitable formula in Table I.
14. Let $f(x) = \sin x$ if $0 < x < \pi$ and 0 if $x > \pi$. Find $\mathcal{F}_s(f)$. Compare with Prob. 6 in Sec. 11.7. Comment.
15. In Table II of Sec. 11.10 obtain formula 2 from formula 4, using $\Gamma(\frac{1}{2}) = \sqrt{\pi}$ [(30) in App. 3.1].
16. Show that $\mathcal{F}_s(x^{-1/2}) = w^{-1/2}$ by setting $wx = t^2$ and using $S(\infty) = \sqrt{\pi/8}$ in (38) of App. 3.1.
17. Obtain $\mathcal{F}_s(e^{-ax})$ from (8a) and formula 3 in Table I of Sec. 11.10.
18. Show that $\mathcal{F}_s(x^{-3/2}) = 2w^{1/2}$. *Hint.* Set $wx = t^2$, integrate by parts, and use $C(\infty) = \sqrt{\pi/8}$ in (38) of App. 3.1.
19. **(Scale change)** Using the notation of (5), show that $f(ax)$ has the Fourier sine transform $(1/a)\hat{f}_s(w/a)$.
20. **WRITING PROJECT. Obtaining Fourier Cosine and Sine Transforms.** Write a short report on ways of obtaining these transforms, giving illustrations with examples of your own.

11.9 Fourier Transform. Discrete and Fast Fourier Transforms

The two transforms in the last section are real. We now consider a third one, called the **Fourier transform,** which is complex. We shall obtain this transform from the complex Fourier integral, which we explain first.

Complex Form of the Fourier Integral

The (real) Fourier integral is [see (4), (5), Sec. 11.7]

$$f(x) = \int_0^\infty [A(w) \cos wx + B(w) \sin wx]\, dw$$

where

$$A(w) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(v) \cos wv\, dv, \qquad B(w) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(v) \sin wv\, dv.$$

Substituting A and B into the integral for f, we have

$$f(x) = \frac{1}{\pi} \int_0^\infty \int_{-\infty}^{\infty} f(v)\, [\cos wv \cos wx + \sin wv \sin wx]\, dv\, dw.$$

By the addition formula for the cosine [(6) in App. A3.1] the expression in the brackets $[\cdots]$ equals $\cos(wv - wx)$ or, since the cosine is even, $\cos(wx - wv)$. We thus obtain

$$(1^*) \qquad f(x) = \frac{1}{\pi} \int_0^\infty \left[\int_{-\infty}^{\infty} f(v) \cos(wx - wv)\, dv \right] dw.$$

The integral in brackets is an *even* function of w, call it $F(w)$, because $\cos(wx - wv)$ is an even function of w, the function f does not depend on w, and we integrate with respect to v (not w). Hence the integral of $F(w)$ from $w = 0$ to ∞ is 1/2 times the integral of $F(w)$ from $-\infty$ to ∞. Thus (note the change of the integration limit!)

$$(1) \qquad f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(v) \cos(wx - wv)\, dv \right] dw.$$

We claim that the integral of the form (1) with sin instead of cos is zero:

$$(2) \qquad \frac{1}{2\pi} \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(v) \sin(wx - wv)\, dv \right] dw = 0.$$

This is true since $\sin(wx - wv)$ is an odd function of w, which makes the integral in brackets an odd function of w, call it $G(w)$. Hence the integral of $G(w)$ from $-\infty$ to ∞ is zero, as claimed.

We now take the integrand of (1) plus i $(= \sqrt{-1})$ times the integrand of (2) and use the **Euler formula** [(11) in Sec. 2.2]

$$(3) \qquad e^{ix} = \cos x + i \sin x.$$

Taking $wx - wv$ instead of x in (3) and multiplying by $f(v)$ gives

$$f(v)\cos(wx - wv) + if(v)\sin(wx - wv) = f(v)e^{i(wx-wv)}.$$

Hence the result of adding (1) plus i times (2), called the **complex Fourier integral,** is

$$\textbf{(4)} \qquad f(x) = \frac{1}{2\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(v)e^{iw(x-v)}\,dv\,dw \qquad (i = \sqrt{-1}).$$

It is now only a very short step to our present goal, the Fourier transform.

Fourier Transform and Its Inverse

Writing the exponential function in (4) as a product of exponential functions, we have

$$\textbf{(5)} \qquad f(x) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\left[\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} f(v)e^{-iwv}\,dv\right]e^{iwx}\,dw.$$

The expression in brackets is a function of w, is denoted by $\hat{f}(w)$, and is called the **Fourier transform** of f; writing $v = x$, we have

$$\textbf{(6)} \qquad \hat{f}(w) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} f(x)e^{-iwx}\,dx.$$

With this, (5) becomes

$$\textbf{(7)} \qquad f(x) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \hat{f}(w)e^{iwx}\,dw$$

and is called the **inverse Fourier transform** of $\hat{f}(w)$.

Another notation for the Fourier transform is

$$\hat{f} = \mathcal{F}(f),$$

so that

$$f = \mathcal{F}^{-1}(\hat{f}).$$

The process of obtaining the Fourier transform $\mathcal{F}(f) = \hat{f}$ from a given f is also called the **Fourier transform** or the *Fourier transform method.*

Conditions sufficient for the existence of the Fourier transform (involving concepts defined in Secs. 6.1 and 11.7) are as follows, as we state without proof.

THEOREM 1

Existence of the Fourier Transform

If $f(x)$ is absolutely integrable on the x-axis and piecewise continuous on every finite interval, then the Fourier transform $\hat{f}(w)$ of $f(x)$ given by (6) *exists.*

EXAMPLE 1 Fourier Transform

Find the Fourier transform of $f(x) = 1$ if $|x| < 1$ and $f(x) = 0$ otherwise.

Solution. Using (6) and integrating, we obtain

$$\hat{f}(w) = \frac{1}{\sqrt{2\pi}} \int_{-1}^{1} e^{-iwx}\, dx = \frac{1}{\sqrt{2\pi}} \cdot \frac{e^{-iwx}}{-iw} \Bigg|_{-1}^{1} = \frac{1}{-iw\sqrt{2\pi}} (e^{-iw} - e^{iw}).$$

As in (3) we have $e^{iw} = \cos w + i \sin w$, $e^{-iw} = \cos w - i \sin w$, and by subtraction

$$e^{iw} - e^{-iw} = 2i \sin w.$$

Substituting this in the previous formula on the right, we see that i drops out and we obtain the answer

$$\hat{f}(w) = \sqrt{\frac{\pi}{2}}\, \frac{\sin w}{w}. \qquad \blacksquare$$

EXAMPLE 2 Fourier Transform

Find the Fourier transform $\mathcal{F}(e^{-ax})$ of $f(x) = e^{-ax}$ if $x > 0$ and $f(x) = 0$ if $x < 0$; here $a > 0$.

Solution. From the definition (6) we obtain by integration

$$\mathcal{F}(e^{-ax}) = \frac{1}{\sqrt{2\pi}} \int_{0}^{\infty} e^{-ax} e^{-iwx}\, dx$$

$$= \frac{1}{\sqrt{2\pi}}\, \frac{e^{-(a+iw)x}}{-(a+iw)} \Bigg|_{x=0}^{\infty} = \frac{1}{\sqrt{2\pi}\,(a+iw)}.$$

This proves formula 5 of Table III in Sec. 11.10. $\blacksquare$

Physical Interpretation: Spectrum

The nature of the representation (7) of $f(x)$ becomes clear if we think of it as a superposition of sinusoidal oscillations of all possible frequencies, called a **spectral representation.** This name is suggested by optics, where light is such a superposition of colors (frequencies). In (7), the **"spectral density"** $\hat{f}(w)$ measures the intensity of $f(x)$ in the frequency interval between w and $w + \Delta w$ (Δw small, fixed). We claim that in connection with vibrations, the integral

$$\int_{-\infty}^{\infty} |\hat{f}(w)|^2\, dw$$

can be interpreted as the **total energy** of the physical system. Hence an integral of $|\hat{f}(w)|^2$ from a to b gives the contribution of the frequencies w between a and b to the total energy.

To make this plausible, we begin with a mechanical system giving a single frequency, namely, the harmonic oscillator (mass on a spring, Sec. 2.4)

$$my'' + ky = 0.$$

Here we denote time t by x. Multiplication by y' gives $my'y'' + ky'y = 0$. By integration,

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}ky^2 = E_0 = const$$

where $v = y'$ is the velocity. The first term is the kinetic energy, the second the potential energy, and E_0 the total energy of the system. Now a general solution is (use (3) in Sec. 11.4 with $t = x$)

$$y = a_1 \cos w_0 x + b_1 \sin w_0 x = c_1 e^{iw_0 x} + c_{-1} e^{-iw_0 x}, \qquad w_0^2 = k/m$$

where $c_1 = (a_1 - ib_1)/2$, $c_{-1} = \bar{c}_1 = (a_1 + ib_1)/2$. We write simply $A = c_1 e^{iw_0 x}$, $B = c_{-1} e^{-iw_0 x}$. Then $y = A + B$. By differentiation, $v = y' = A' + B' = iw_0(A - B)$. Substitution of v and y on the left side of the equation for E_0 gives

$$E_0 = \tfrac{1}{2}mv^2 + \tfrac{1}{2}ky^2 = \tfrac{1}{2}m(iw_0)^2(A - B)^2 + \tfrac{1}{2}k(A + B)^2.$$

Here $w_0^2 = k/m$, as just stated; hence $mw_0^2 = k$. Also $i^2 = -1$, so that

$$E_0 = \tfrac{1}{2}k[-(A - B)^2 + (A + B)^2] = 2kAB = 2kc_1 e^{iw_0 x} c_{-1} e^{-iw_0 x} = 2kc_1 c_{-1} = 2k|c_1|^2.$$

Hence *the energy is proportional to the square of the amplitude* $|c_1|$.

As the next step, if a more complicated system leads to a periodic solution $y = f(x)$ that can be represented by a Fourier series, then instead of the single energy term $|c_1|^2$ we get a series of squares $|c_n|^2$ of Fourier coefficients c_n given by (6), Sec. 11.4. In this case we have a **"discrete spectrum"** (or **"point spectrum"**) consisting of countably many isolated frequencies (infinitely many, in general), the corresponding $|c_n|^2$ being the contributions to the total energy.

Finally, a system whose solution can be represented by an integral (7) leads to the above integral for the energy, as is plausible from the cases just discussed.

Linearity. Fourier Transform of Derivatives

New transforms can be obtained from given ones by

THEOREM 1

Linearity of the Fourier Transform

The Fourier transform is a ***linear operation;*** *that is, for any functions $f(x)$ and $g(x)$ whose Fourier transforms exist and any constants a and b, the Fourier transform of $af + bg$ exists, and*

(8) $$\mathcal{F}(af + bg) = a\mathcal{F}(f) + b\mathcal{F}(g).$$

PROOF This is true because integration is a linear operation, so that (6) gives

$$\begin{aligned}\mathcal{F}\{af(x) + bg(x)\} &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} [af(x) + bg(x)] e^{-iwx}\, dx \\ &= a \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) e^{-iwx}\, dx + b \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} g(x) e^{-iwx}\, dx \\ &= a\mathcal{F}\{f(x)\} + b\mathcal{F}\{g(x)\}.\end{aligned}$$

■

In applying the Fourier transform to differential equations, the key property is that differentiation of functions corresponds to multiplication of transforms by iw:

THEOREM 3

Fourier Transform of the Derivative of $f(x)$

Let $f(x)$ be continuous on the x-axis and $f(x) \to 0$ as $|x| \to \infty$. Furthermore, let $f'(x)$ be absolutely integrable on the x-axis. Then

$$\mathcal{F}\{f'(x)\} = iw\mathcal{F}\{f(x)\}. \tag{9}$$

PROOF From the definition of the Fourier transform we have

$$\mathcal{F}\{f'(x)\} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f'(x)e^{-iwx}\,dx.$$

Integrating by parts, we obtain

$$\mathcal{F}\{f'(x)\} = \frac{1}{\sqrt{2\pi}} \left[f(x)e^{-iwx} \Big|_{-\infty}^{\infty} - (-iw) \int_{-\infty}^{\infty} f(x)e^{-iwx}\,dx \right].$$

Since $f(x) \to 0$ as $|x| \to \infty$, the desired result follows, namely,

$$\mathcal{F}\{f'(x)\} = 0 + iw\mathcal{F}\{f(x)\}.$$

Two successive applications of (9) give

$$\mathcal{F}(f'') = iw\mathcal{F}(f') = (iw)^2\mathcal{F}(f).$$

Since $(iw)^2 = -w^2$, we have for the transform of the second derivative of f

$$\mathcal{F}\{f''(x)\} = -w^2\mathcal{F}\{f(x)\}. \tag{10}$$

Similarly for higher derivatives.

An application of (10) to differential equations will be given in Sec. 12.6. For the time being we show how (9) can be used to derive transforms.

EXAMPLE 3 **Application of the Operational Formula (9)**

Find the Fourier transform of xe^{-x^2} from Table III, Sec 11.10.

Solution. We use (9). By formula 9 in Table III.

$$\begin{aligned}
\mathcal{F}(xe^{-x^2}) &= \mathcal{F}\left\{-\frac{1}{2}\left(e^{-x^2}\right)'\right\} \\
&= -\frac{1}{2}\,\mathcal{F}\left\{\left(e^{-x^2}\right)'\right\} \\
&= -\frac{1}{2}\,iw\mathcal{F}(e^{-x^2}) \\
&= -\frac{1}{2}\,iw\,\frac{1}{\sqrt{2}}\,e^{-w^2/4} \\
&= -\frac{iw}{2\sqrt{2}}\,e^{-w^2/4}.
\end{aligned}$$

Convolution

The **convolution** $f * g$ of functions f and g is defined by

$$\textbf{(11)} \qquad h(x) = (f * g)(x) = \int_{-\infty}^{\infty} f(p)g(x - p)\, dp = \int_{-\infty}^{\infty} f(x - p)g(p)\, dp.$$

The purpose is the same as in the case of Laplace transforms (Sec. 6.5): taking the convolution of two functions and then taking the transform of the convolution is the same as multiplying the transforms of these functions (and multiplying them by $\sqrt{2\pi}$):

THEOREM 4

Convolution Theorem

Suppose that $f(x)$ and $g(x)$ are piecewise continuous, bounded, and absolutely integrable on the x-axis. Then

$$\textbf{(12)} \qquad \mathcal{F}(f * g) = \sqrt{2\pi}\, \mathcal{F}(f)\mathcal{F}(g).$$

PROOF By the definition,

$$\mathcal{F}(f * g) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(p)g(x - p)\, dp\, e^{-iwx}\, dx.$$

An interchange of the order of integration gives

$$\mathcal{F}(f * g) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(p)g(x - p)e^{-iwx}\, dx\, dp.$$

Instead of x we now take $x - p = q$ as a new variable of integration. Then $x = p + q$ and

$$\mathcal{F}(f * g) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(p)g(q)e^{-iw(p+q)}\, dq\, dp.$$

This double integral can be written as a product of two integrals and gives the desired result

$$\mathcal{F}(f * g) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(p)e^{-iwp}\, dp \int_{-\infty}^{\infty} g(q)e^{-iwq}\, dq$$

$$= \frac{1}{\sqrt{2\pi}} \left[\sqrt{2\pi}\, \mathcal{F}(f)\right]\left[\sqrt{2\pi}\, \mathcal{F}(g)\right] = \sqrt{2\pi}\, \mathcal{F}(f)\mathcal{F}(g). \qquad \blacksquare$$

By taking the inverse Fourier transform on both sides of (12), writing $\hat{f} = \mathcal{F}(f)$ and $\hat{g} = \mathcal{F}(g)$ as before, and noting that $\sqrt{2\pi}$ and $1/\sqrt{2\pi}$ in (12) and (7) cancel each other, we obtain

$$\textbf{(13)} \qquad (f * g)(x) = \int_{-\infty}^{\infty} \hat{f}(w)\hat{g}(w)e^{iwx}\, dw,$$

a formula that will help us in solving partial differential equations (Sec. 12.6).

Discrete Fourier Transform (DFT), Fast Fourier Transform (FFT)

In using Fourier series, Fourier transforms, and trigonometric approximations (Sec. 11.6) we have to assume that a function $f(x)$, to be developed or transformed, is given on some interval, over which we integrate in the Euler formulas, etc. Now very often a function $f(x)$ is given only in terms of values at finitely many points, and one is interested in extending Fourier analysis to this case. The main application of such a "discrete Fourier analysis" concerns large amounts of equally spaced data, as they occur in telecommunication, time series analysis, and various simulation problems. In these situations, dealing with sampled values rather than with functions, we can replace the Fourier transform by the so-called **discrete Fourier transform (DFT)** as follows.

Let $f(x)$ be periodic, for simplicity of period 2π. We assume that N measurements of $f(x)$ are taken over the interval $0 \leqq x \leqq 2\pi$ at regularly spaced points

$$x_k = \frac{2\pi k}{N}, \qquad k = 0, 1, \cdots, N-1. \tag{14}$$

We also say that $f(x)$ is being **sampled** at these points. We now want to determine a **complex trigonometric polynomial**

$$q(x) = \sum_{n=0}^{N-1} c_n e^{inx_k} \tag{15}$$

that **interpolates** $f(x)$ at the nodes (14), that is, $q(x_k) = f(x_k)$, written out, with f_k denoting $f(x_k)$,

$$f_k = f(x_k) = q(x_k) = \sum_{n=0}^{N-1} c_n e^{inx_k}, \qquad k = 0, 1, \cdots, N-1. \tag{16}$$

Hence we must determine the coefficients $c_0, \cdots, c_{N-1}$ such that (16) holds. We do this by an idea similar to that in Sec. 11.1 for deriving the Fourier coefficients by using the orthogonality of the trigonometric system. Instead of integrals we now take sums. Namely, we multiply (16) by e^{-imx_k} (note the minus!) and sum over k from 0 to $N-1$. Then we interchange the order of the two summations and insert x_k from (14). This gives

$$\sum_{k=0}^{N-1} f_k e^{-imx_k} = \sum_{k=0}^{N-1} \sum_{n=0}^{N-1} c_n e^{i(n-m)x_k} = \sum_{n=0}^{N-1} c_n \sum_{k=0}^{N-1} e^{i(n-m)2\pi k/N}. \tag{17}$$

Now

$$e^{i(n-m)2\pi k/N} = \left[e^{i(n-m)2\pi/N}\right]^k.$$

We denote $[\cdots]$ by r. For $n = m$ we have $r = e^0 = 1$. The sum of *these* terms over k equals N, the number of these terms. For $n \neq m$ we have $r \neq 1$ and by the formula for a geometric sum [(6) in Sec. 15.1 with $q = r$ and $n = N - 1$]

$$\sum_{k=0}^{N-1} r^k = \frac{1 - r^N}{1 - r} = 0$$

because $r^N = 1$; indeed, since k, m, and n are integers,

$$r^N = e^{i(n-m)2\pi k} = \cos 2\pi k(n-m) + i \sin 2\pi k(n-m) = 1 + 0 = 1.$$

This shows that the right side of (17) equals $c_m N$. Writing n for m and dividing by N, we thus obtain the desired coefficient formula

$$\textbf{(18*)} \qquad c_n = \frac{1}{N} \sum_{k=0}^{N-1} f_k e^{-inx_k} \qquad f_k = f(x_k), \quad n = 0, 1, \cdots, N-1.$$

Since computation of the c_n (by the fast Fourier transform, below) involves successive halfing of the problem size N, it is practical to drop the factor $1/N$ from c_n and define the **discrete Fourier transform** of the given signal $\mathbf{f} = [f_0 \quad \cdots \quad f_{N-1}]^\mathsf{T}$ to be the vector $\hat{\mathbf{f}} = [\hat{f}_0 \quad \cdots \quad \hat{f}_{N-1}]$ with components

$$\textbf{(18)} \qquad \hat{f}_n = Nc_n = \sum_{k=0}^{N-1} f_k e^{-inx_k}, \qquad f_k = f(x_k), \quad n = 0, \cdots, N-1.$$

This is the frequency spectrum of the signal.

In vector notation, $\hat{\mathbf{f}} = \mathbf{F}_N \mathbf{f}$, where the $N \times N$ **Fourier matrix** $\mathbf{F}_N = [e_{nk}]$ has the entries [given in (18)]

$$(19) \qquad e_{nk} = e^{-inx_k} = e^{-2\pi ink/N} = w^{nk}, \qquad w = w_N = e^{-2\pi i/N},$$

where $n, k = 0, \cdots, N-1$.

EXAMPLE 4 **Discrete Fourier Transform (DFT). Sample of $N = 4$ Values**

Let $N = 4$ measurements (sample values) be given. Then $w = e^{-2\pi i/N} = e^{-\pi i/2} = -i$ and thus $w^{nk} = (-i)^{nk}$. Let the sample values be, say $\mathbf{f} = [0 \quad 1 \quad 4 \quad 9]^\mathsf{T}$. Then by (18) and (19),

$$(20) \qquad \hat{\mathbf{f}} = \mathbf{F}_4 \mathbf{f} = \begin{bmatrix} w^0 & w^0 & w^0 & w^0 \\ w^0 & w^1 & w^2 & w^3 \\ w^0 & w^2 & w^4 & w^6 \\ w^0 & w^3 & w^6 & w^9 \end{bmatrix} \mathbf{f} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -i & -1 & i \\ 1 & -1 & 1 & -1 \\ 1 & i & -1 & -i \end{bmatrix} \begin{bmatrix} 0 \\ 1 \\ 4 \\ 9 \end{bmatrix} = \begin{bmatrix} 14 \\ -4 + 8i \\ -6 \\ -4 - 8i \end{bmatrix}.$$

From the first matrix in (20) it is easy to infer what $\mathbf{F}_N$ looks like for arbitrary N, which in practice may be 1000 or more, for reasons given below. ■

From the DFT (the frequency spectrum) $\hat{\mathbf{f}} = \mathbf{F}_N \mathbf{f}$ we can recreate the given signal $\mathbf{f} = \mathbf{F}_N^{-1} \mathbf{f}$, as we shall now prove. Here $\mathbf{F}_N$ and its complex conjugate $\overline{\mathbf{F}}_N = \frac{1}{N} [\overline{w}^{nk}]$ satisfy

$$(21a) \qquad \overline{\mathbf{F}}_N \mathbf{F}_N = \mathbf{F}_N \overline{\mathbf{F}}_N = N\mathbf{I}$$

where $\mathbf{I}$ is the $N \times N$ unit matrix; hence $\mathbf{F}_N$ has the inverse

$$(21b) \qquad \mathbf{F}_N^{-1} = \frac{1}{N} \overline{\mathbf{F}}_N.$$

PROOF We prove (21). By the multiplication rule (row times column) the product matrix $\mathbf{G}_N = \overline{\mathbf{F}}_N\mathbf{F}_N = [g_{jk}]$ in (21a) has the entries $g_{jk} = \textit{Row } j \textit{ of } \overline{\mathbf{F}}_N \textit{ times Column } k \textit{ of } \mathbf{F}_N$. That is, writing $W = \overline{w}^j w^k$, we prove that

$$g_{jk} = (\overline{w}^j w^k)^0 + (\overline{w}^j w^k)^1 + \cdots + (\overline{w}^j w^k)^{N-1}$$

$$= W^0 + W^1 + \cdots + W^{N-1} = \begin{cases} 0 & \text{if} \quad j \neq k \\ N & \text{if} \quad j = k. \end{cases}$$

Indeed, when $j = k$, then $\overline{w}^k w^k = (\overline{w}w)^k = (e^{2\pi i/N}e^{-2\pi i/N})^k = 1^k = 1$, so that the sum of *these* N terms equals N; these are the diagonal entries of $\mathbf{G}_N$. Also, when $j \neq k$, then $W \neq 1$ and we have a geometric sum (whose value is given by (6) in Sec. 15.1 with $q = W$ and $n = N - 1$)

$$W^0 + W^1 + \cdots + W^{N-1} = \frac{1 - W^N}{1 - W} = 0$$

because $W^N = (\overline{w}^j w^k)^N = (e^{2\pi i})^j(e^{-2\pi i})^k = 1^j \cdot 1^k = 1$. ∎

We have seen that $\hat{\mathbf{f}}$ is the frequency spectrum of the signal $f(x)$. Thus the components $\hat{f}_n$ of $\hat{\mathbf{f}}$ give a resolution of the 2π-periodic function $f(x)$ into simple (complex) harmonics. Here one should use only n's that are much smaller than $N/2$, to avoid **aliasing.** By this we mean the effect caused by sampling at too few (equally spaced) points, so that, for instance, in a motion picture, rotating wheels appear as rotating too slowly or even in the wrong sense. Hence in applications, N is usually large. But this poses a problem. Eq. (18) requires $O(N)$ operations for any particular n, hence $O(N^2)$ operations for, say, all $n < N/2$. Thus, already for 1000 sample points the straightforward calculation would involve millions of operations. However, this difficulty can be overcome by the so called **fast Fourier transform (FFT),** for which codes are readily available (e.g. in Maple). The FFT is a computational method for the DFT that needs only $O(N)\log_2 N$ operations instead of $O(N^2)$. It makes the DFT a practical tool for large N. Here one chooses $N = 2^p$ (p integer) and uses the special form of the Fourier matrix to break down the given problem into smaller problems. For instance, when $N = 1000$, those operations are reduced by a factor $1000/\log_2 1000 \approx 100$.

The breakdown produces two problems of size $M = N/2$. This breakdown is possible because for $N = 2M$ we have in (19)

$$w_N^2 = w_{2M}^2 = (e^{-2\pi i/N})^2 = e^{-4\pi i/(2M)} = e^{-2\pi i/M} = w_M.$$

The given vector $\mathbf{f} = [f_0 \quad \cdots \quad f_{N-1}]^\mathsf{T}$ is split into two vectors with M components each, namely, $\mathbf{f}_{\text{ev}} = [f_0 \quad f_2 \quad \cdots \quad f_{N-2}]^\mathsf{T}$ containing the even components of $\mathbf{f}$, and $\mathbf{f}_{\text{od}} = [f_1 \quad f_3 \quad \cdots \quad f_{N-1}]^\mathsf{T}$ containing the odd components of $\mathbf{f}$. For $\mathbf{f}_{\text{ev}}$ and $\mathbf{f}_{\text{od}}$ we determine the DFTs

$$\hat{\mathbf{f}}_{\text{ev}} = \left[\hat{f}_{\text{ev},0} \quad \hat{f}_{\text{ev},2} \quad \cdots \quad \hat{f}_{\text{ev},N-2}\right]^\mathsf{T} = \mathbf{F}_M\mathbf{f}_{\text{ev}}$$

and

$$\hat{\mathbf{f}}_{\text{od}} = \left[\hat{f}_{\text{od},1} \quad \hat{f}_{\text{od},3} \quad \cdots \quad \hat{f}_{\text{od},N-1}\right]^\mathsf{T} = \mathbf{F}_M\mathbf{f}_{\text{od}}$$

involving the same $M \times M$ matrix $\mathbf{F}_M$. From these vectors we obtain the components of the DFT of the given vector $\mathbf{f}$ by the formulas

(22)

$$\text{(a)} \quad \hat{f}_n = \hat{f}_{\text{ev},n} + w_N^n\hat{f}_{\text{od},n} \qquad n = 0, \cdots, M-1$$

$$\text{(b)} \quad \hat{f}_{n+M} = \hat{f}_{\text{ev},n} - w_N^n\hat{f}_{\text{od},n} \qquad n = 0, \cdots, M-1.$$

For $N = 2^p$ this breakdown can be repeated $p - 1$ times in order to finally arrive at $N/2$ problems of size 2 each, so that the number of multiplications is reduced as indicated above.

We show the reduction from $N = 4$ to $M = N/2 = 2$ and then prove (22).

EXAMPLE 5 **Fast Fourier Transform (FFT). Sample of $N = 4$ Values**

When $N = 4$, then $w = w_N = -i$ as in Example 4 and $M = N/2 = 2$, hence $w = w_M = e^{-2\pi i/2} = e^{-\pi i} = -1$. Consequently,

$$\hat{\mathbf{f}}_{ev} = \begin{bmatrix} \hat{f}_0 \\ \hat{f}_2 \end{bmatrix} = \mathbf{F}_2\mathbf{f}_{ev} = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}\begin{bmatrix} f_0 \\ f_2 \end{bmatrix} = \begin{bmatrix} f_0 + f_2 \\ f_0 - f_2 \end{bmatrix}$$

$$\hat{\mathbf{f}}_{od} = \begin{bmatrix} \hat{f}_1 \\ \hat{f}_3 \end{bmatrix} = \mathbf{F}_2\mathbf{f}_{od} = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}\begin{bmatrix} f_1 \\ f_3 \end{bmatrix} = \begin{bmatrix} f_1 + f_3 \\ f_1 - f_3 \end{bmatrix}.$$

From this and (22a) we obtain

$$\hat{f}_0 = \hat{f}_{ev,0} + w_N{}^0\hat{f}_{od,0} = (f_0 + f_2) + (f_1 + f_3) = f_0 + f_1 + f_2 + f_3$$
$$\hat{f}_1 = \hat{f}_{ev,1} + w_N{}^1\hat{f}_{od,1} = (f_0 - f_2) - i(f_1 + f_3) = f_0 - if_1 - f_2 + if_3.$$

Similarly, by (22b),

$$\hat{f}_2 = \hat{f}_{ev,0} - w_N{}^0\hat{f}_{od,0} = (f_0 + f_2) - (f_1 + f_3) \qquad = f_0 - f_1 + f_2 - f_3$$
$$\hat{f}_3 = \hat{f}_{ev,1} - w_N{}^1\hat{f}_{od,1} = (f_0 - f_2) - (-i)(f_1 - f_3) = f_0 + if_1 - f_2 - if_3.$$

This agrees with Example 4, as can be seen by replacing 0, 1, 4, 9 with f_0, f_1, f_2, f_3. ■

We prove (22). From (18) and (19) we have for the components of the DFT

$$\hat{f}_n = \sum_{k=0}^{N-1} w_N{}^{kn} f_k.$$

Splitting into two sums of $M = N/2$ terms each gives

$$\hat{f}_n = \sum_{k=0}^{M-1} w_N{}^{2kn} f_{2k} + \sum_{k=0}^{M-1} w_N{}^{(2k+1)n} f_{2k+1}.$$

We now use $w_N{}^2 = w_M$ and pull out $w_N{}^n$ from under the second sum, obtaining

$$\hat{f}_n = \sum_{k=0}^{M-1} w_M{}^{kn} f_{ev,k} + w_N{}^n \sum_{k=0}^{M-1} w_M{}^{kn} f_{od,k}. \tag{23}$$

The two sums are $f_{ev,n}$ and $f_{od,n}$, the components of the "half-size" transforms $\mathbf{F}\,\mathbf{f}_{ev}$ and $\mathbf{F}\,\mathbf{f}_{od}$.

Formula (22a) is the same as (23). In (22b) we have $n + M$ instead of n. This causes a sign change in (23), namely $-w_N{}^n$ before the second sum because

$$w_N{}^M = e^{-2\pi iM/N} = e^{-2\pi i/2} = e^{-\pi i} = -1,$$

This gives the minus in (22b) and completes the proof. ■

PROBLEM SET 11.9

1. (Review) Show that $1/i = -i$, $e^{ix} + e^{-ix} = 2\cos x$, $e^{ix} - e^{-ix} = 2i \sin x$.

2–9 FOURIER TRANSFORMS BY INTEGRATION

Find the Fourier transform of $f(x)$ (without using Table III in Sec. 11.10). Show the details.

2. $f(x) = \begin{cases} e^{kx} & \text{if } x < 0 \quad (k > 0) \\ 0 & \text{if } x > 0 \end{cases}$

3. $f(x) = \begin{cases} k & \text{if } 0 < x < b \\ 0 & \text{otherwise} \end{cases}$

4. $f(x) = \begin{cases} e^{2ix} & \text{if } -1 < x < 1 \\ 0 & \text{otherwise} \end{cases}$

5. $f(x) = \begin{cases} k & \text{if } -1 < x < 1 \\ 0 & \text{otherwise} \end{cases}$

6. $f(x) = \begin{cases} x & \text{if } -1 < x < 1 \\ 0 & \text{otherwise} \end{cases}$

7. $f(x) = \begin{cases} x & \text{if } 0 < x < 1 \\ 0 & \text{otherwise} \end{cases}$

8. $f(x) = \begin{cases} xe^{-x} & \text{if } -1 < x < 0 \\ 0 & \text{otherwise} \end{cases}$

9. $f(x) = \begin{cases} -1 & \text{if } -1 < x < 0 \\ 1 & \text{if } 0 < x < 1 \\ 0 & \text{otherwise} \end{cases}$

OTHER METHODS

10. Find the Fourier transform of $f(x) = xe^{-x}$ if $x > 0$ and 0 if $x < 0$ from formula 5 in Table III and (9) in the text. *Hint:* Consider xe^{-x} and e^{-x}.

11. Obtain $\mathcal{F}(e^{-x^2/2})$ from formula 9 in Table III.

12. Obtain formula 7 in Table III from formula 8.

13. Obtain formula 1 in Table III from formula 2.

14. TEAM PROJECT. Shifting. (a) Show that if $f(x)$ has a Fourier transform, so does $f(x - a)$, and $\mathcal{F}\{f(x - a)\} = e^{-iwa}\mathcal{F}\{f(x)\}$.

(b) Using (a), obtain formula 1 in Table III, Sec. 11.10, from formula 2.

(c) Shifting on the w-Axis. Show that if $\hat{f}(w)$ is the Fourier transform of $f(x)$, then $\hat{f}(w - a)$ is the Fourier transform of $e^{iax}f(x)$.

(d) Using (c), obtain formula 7 in Table III from 1 and formula 8 from 2.

11.10 Tables of Transforms

Table I. Fourier Cosine Transforms

See (2) in Sec. 11.8.

	$f(x)$	$\hat{f}_c(w) = \mathcal{F}_c(f)$
1	$\begin{cases} 1 & \text{if } 0 < x < a \\ 0 & \text{otherwise} \end{cases}$	$\sqrt{\frac{2}{\pi}}\,\frac{\sin aw}{w}$
2	$x^{a-1} \quad (0 < a < 1)$	$\sqrt{\frac{2}{\pi}}\,\frac{\Gamma(a)}{w^a}\cos\frac{a\pi}{2}$ ($\Gamma(a)$ see App. A3.1.)
3	$e^{-ax} \quad (a > 0)$	$\sqrt{\frac{2}{\pi}}\left(\frac{a}{a^2 + w^2}\right)$
4	$e^{-x^2/2}$	$e^{-w^2/2}$
5	$e^{-ax^2} \quad (a > 0)$	$\frac{1}{\sqrt{2a}}\,e^{-w^2/(4a)}$
6	$x^n e^{-ax} \quad (a > 0)$	$\sqrt{\frac{2}{\pi}}\,\frac{n!}{(a^2 + w^2)^{n+1}}\,\mathrm{Re}\,(a + iw)^{n+1}$ Re = Real part
7	$\begin{cases} \cos x & \text{if } 0 < x < a \\ 0 & \text{otherwise} \end{cases}$	$\frac{1}{\sqrt{2\pi}}\left[\frac{\sin a(1 - w)}{1 - w} + \frac{\sin a(1 + w)}{1 + w}\right]$
8	$\cos(ax^2) \quad (a > 0)$	$\frac{1}{\sqrt{2a}}\cos\left(\frac{w^2}{4a} - \frac{\pi}{4}\right)$
9	$\sin(ax^2) \quad (a > 0)$	$\frac{1}{\sqrt{2a}}\cos\left(\frac{w^2}{4a} + \frac{\pi}{4}\right)$
10	$\frac{\sin ax}{x} \quad (a > 0)$	$\sqrt{\frac{\pi}{2}}\,(1 - u(w - a))$ (See Sec. 6.3.)
11	$\frac{e^{-x}\sin x}{x}$	$\frac{1}{\sqrt{2\pi}}\arctan\frac{2}{w^2}$
12	$J_0(ax) \quad (a > 0)$	$\sqrt{\frac{2}{\pi}}\,\frac{1}{\sqrt{a^2 - w^2}}\,(1 - u(w - a))$ (See Secs. 5.5, 6.3.)

Table II. Fourier Sine Transforms

See (5) in Sec. 11.8.

	$f(x)$	$\hat{f}_s(w) = \mathcal{F}_s(f)$
1	$\begin{cases} 1 & \text{if } 0 < x < a \\ 0 & \text{otherwise} \end{cases}$	$\sqrt{\frac{2}{\pi}} \left[\frac{1 - \cos aw}{w} \right]$

8	$xe^{-x^2/2}$	$we^{-w^2/2}$
9	xe^{-ax^2} $(a > 0)$	$\frac{w}{(2a)^{3/2}} e^{-w^2/4a}$
10	$\begin{cases} \sin x & \text{if } 0 < x < a \\ 0 & \text{otherwise} \end{cases}$	$\frac{1}{\sqrt{2\pi}} \left[\frac{\sin a(1 - w)}{1 - w} - \frac{\sin a(1 + w)}{1 + w} \right]$
11	$\frac{\cos ax}{x}$ $(a > 0)$	$\sqrt{\frac{\pi}{2}}\, u(w - a)$ (See Sec. 6.3.)
12	$\arctan \frac{2a}{x}$ $(a > 0)$	$\sqrt{2\pi} \frac{\sinh aw}{w} e^{-aw}$

Table III. Fourier Transforms

See (6) in Sec. 11.9.

	$f(x)$	$\hat{f}(w) = \mathcal{F}(f)$
1	$\begin{cases} 1 & \text{if } -b < x < b \\ 0 & \text{otherwise} \end{cases}$	$\sqrt{\frac{2}{\pi}}\,\frac{\sin bw}{w}$
2	$\begin{cases} 1 & \text{if } b < x < c \\ 0 & \text{otherwise} \end{cases}$	$\frac{e^{-ibw} - e^{-icw}}{iw\sqrt{2\pi}}$
3	$\frac{1}{x^2 + a^2} \quad (a > 0)$	$\sqrt{\frac{\pi}{2}}\,\frac{e^{-a\lvert w\rvert}}{a}$
4	$\begin{cases} x & \text{if } 0 < x < b \\ 2x - b & \text{if } b < x < 2b \\ 0 & \text{otherwise} \end{cases}$	$\frac{-1 + 2e^{ibw} - e^{-2ibw}}{\sqrt{2\pi}\,w^2}$
5	$\begin{cases} e^{-ax} & \text{if } x > 0 \\ 0 & \text{otherwise} \end{cases} \quad (a > 0)$	$\frac{1}{\sqrt{2\pi}(a + iw)}$
6	$\begin{cases} e^{ax} & \text{if } b < x < c \\ 0 & \text{otherwise} \end{cases}$	$\frac{e^{(a-iw)c} - e^{(a-iw)b}}{\sqrt{2\pi}(a - iw)}$
7	$\begin{cases} e^{iax} & \text{if } -b < x < b \\ 0 & \text{otherwise} \end{cases}$	$\sqrt{\frac{2}{\pi}}\,\frac{\sin b(w - a)}{w - a}$
8	$\begin{cases} e^{iax} & \text{if } b < x < c \\ 0 & \text{otherwise} \end{cases}$	$\frac{i}{\sqrt{2\pi}}\,\frac{e^{ib(a-w)} - e^{ic(a-w)}}{a - w}$
9	$e^{-ax^2} \quad (a > 0)$	$\frac{1}{\sqrt{2a}}\,e^{-w^2/4a}$
10	$\frac{\sin ax}{x} \quad (a > 0)$	$\sqrt{\frac{\pi}{2}}$ if $\lvert w\rvert < a$; 0 if $\lvert w\rvert > a$

CHAPTER 11 REVIEW QUESTIONS AND PROBLEMS

1. What is a Fourier series? A Fourier sine series? A half-range expansion?
2. Can a discontinuous function have a Fourier series? A Taylor series? Explain.
3. Why did we start with period 2π? How did we proceed to functions of any period p?
4. What is the trigonometric system? Its main property by which we obtained the Euler formulas?
5. What do you know about the convergence of a Fourier series?
6. What is the Gibbs phenomenon?
7. What is approximation by trigonometric polynomials? The minimum square error?
8. What is remarkable about the response of a vibrating system to an *arbitrary* periodic force?
9. What do you know about the Fourier integral? Its applications?
10. What is the Fourier sine transform? Give examples.

11–20 FOURIER SERIES

Find the Fourier series of $f(x)$ as given over one period. Sketch $f(x)$. (Show the details of your work.)

11. $f(x) = \begin{cases} -k & \text{if } -1 < x < 0 \\ k & \text{if } 0 < x < 1 \end{cases}$

12. $f(x) = \begin{cases} 0 & \text{if } -\pi/2 < x < \pi/2 \\ 1 & \text{if } \pi/2 < x < 3\pi/2 \end{cases}$

13. $f(x) = x \quad (-2\pi < x < 2\pi)$

14. $f(x) = |x| \quad (-2 < x < 2)$

15. $f(x) = \begin{cases} x & \text{if } -1 < x < 1 \\ 2 - x & \text{if } 1 < x < 3 \end{cases}$

16. $f(x) = \begin{cases} -1 - x & \text{if } -1 < x < 0 \\ 1 - x & \text{if } 0 < x < 1 \end{cases}$

17. $f(x) = |\sin 8\pi x| \ (-1/8 < x < 1/8)$

18. $f(x) = e^x \ (-\pi < x < \pi)$

19. $f(x) = x^2 \ (-\pi/2 < x < \pi/2)$

20. $f(x) = x \ (0 < x < 2\pi)$

21–23 Using the answers to suitable odd-numbered problems, find the sum of

21. $1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + - \cdots$

22. $\frac{1}{1 \cdot 3} + \frac{1}{3 \cdot 5} + \frac{1}{5 \cdot 7} + \cdots$

23. $1 + \frac{1}{9} + \frac{1}{25} + \cdots$

24. (Parseval's identity) Obtain the result of Prob. 23 by applying Parseval's identity to Prob. 12.

25. What are the sum of the cosine terms and the sum of the sine terms in a Fourier series whose sum is $f(x)$? Give two examples.

26. (Half-range expansion) Find the half-range sine series of $f(x) = 0$ if $0 < x < \pi/2$, $f(x) = 1$ if $\pi/2 < x < \pi$. Compare with Prob. 12.

27. (Half-range cosine series) Find the half-range cosine series of $f(x) = x$ $(0 < x < 2\pi)$. Compare with Prob. 20.

28–29 MINIMUM SQUARE ERROR

Compute the minimum square errors for the trigonometric polynomials of degree $N = 1, \cdots, 8$:

28. For $f(x)$ in Prob. 12.

29. For $f(x) = x$ $(-\pi < x < \pi)$.

30–31 GENERAL SOLUTION

Solve $y'' + \omega^2 y = r(t)$, where $|\omega| \neq 0, 1, 2, \cdots$, $r(t)$ is 2π-periodic and:

30. $r(t) = t(\pi^2 - t^2) \quad (-\pi < t < \pi)$

31. $r(t) = t^2 \quad (-\pi < t < \pi)$

32–37 FOURIER INTEGRALS AND TRANSFORMS

Sketch the given function and represent it as indicated. If you have a CAS, graph approximate curves obtained by replacing ∞ with finite limits; also look for Gibbs phenomena.

32. $f(x) = 1$ if $1 < x < 2$ and 0 otherwise, by a Fourier integral

33. $f(x) = x$ if $0 < x < 1$ and 0 otherwise, by a Fourier integral

34. $f(x) = 1 + x/2$ if $-2 < x < 0$, $f(x) = 1 - x/2$ if $0 < x < 2$, $f(x) = 0$ otherwise, by a Fourier cosine integral

35. $f(x) = -1 - x/2$ if $-2 < x < 0$, $f(x) = 1 - x/2$ if $0 < x < 2$, $f(x) = 0$ otherwise, by a Fourier sine integral

36. $f(x) = -4 + x^2$ if $-2 < x < 0$, $f(x) = 4 - x^2$ if $0 < x < 2$, $f(x) = 0$ otherwise, by a Fourier sine integral

37. $f(x) = 4 - x^2$ if $-2 < x < 2$, $f(x) = 0$ otherwise, by a Fourier cosine integral

38. Find the Fourier transform of $f(x) = k$ if $a < x < b$, $f(x) = 0$ otherwise.

39. Find the Fourier cosine transform of $f(x) = e^{-2x}$ if $x > 0$, $f(x) = 0$ if $x < 0$.

40. Find $\mathcal{F}_c(e^{-2x})$ and $\mathcal{F}_s(e^{-2x})$ by formulas involving second derivatives.

SUMMARY OF CHAPTER 11
Fourier Series, Integrals, Transforms

Fourier series concern **periodic functions** $f(x)$ of period $p = 2L$, that is, by definition $f(x + p) = f(x)$ for all x and some fixed $p > 0$; thus, $f(x + np) = f(x)$ for any integer n. These series are of the form

$$(1) \qquad f(x) = a_0 + \sum_{n=1}^{\infty} \left(a_n \cos \frac{n\pi}{L} x + b_n \sin \frac{n\pi}{L} x \right) \qquad \text{(Sec. 11.2)}$$

with coefficients, called the **Fourier coefficients** of $f(x)$, given by the Euler formulas (Sec. 11.2)

$$(2) \qquad a_0 = \frac{1}{2L} \int_{-L}^{L} f(x)\, dx, \qquad a_n = \frac{1}{L} \int_{-L}^{L} f(x) \cos \frac{n\pi x}{L}\, dx$$
$$b_n = \frac{1}{L} \int_{-L}^{L} f(x) \sin \frac{n\pi x}{L}\, dx$$

where $n = 1, 2, \cdots$. For period 2π we simply have (Sec. 11.1)

$$(1^*) \qquad f(x) = a_0 + \sum_{n=1}^{\infty} (a_n \cos nx + b_n \sin nx)$$

with the *Fourier coefficients* of $f(x)$ (Sec. 11.1)

$$a_0 = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x)\, dx, \quad a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx\, dx, \quad b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx\, dx.$$

Fourier series are fundamental in connection with periodic phenomena, particularly in models involving differential equations (Sec. 11.5, Chap. 12). If $f(x)$ is even $[f(-x) = f(x)]$ or odd $[f(-x) = -f(x)]$, they reduce to **Fourier cosine** or **Fourier sine series,** respectively (Sec. 11.3). If $f(x)$ is given for $0 \leqq x \leqq L$ only, it has two **half-range expansions** of period $2L$, namely, a cosine and a sine series (Sec. 11.3).

The set of cosine and sine functions in (1) is called the **trigonometric system.** Its most basic property is its **orthogonality** on an interval of length $2L$; that is, for all integers m and $n \neq m$ we have

$$\int_{-L}^{L} \cos \frac{m\pi x}{L} \cos \frac{n\pi x}{L}\, dx = 0, \qquad \int_{-L}^{L} \sin \frac{m\pi x}{L} \sin \frac{n\pi x}{L}\, dx = 0$$

and for all integers m and n,

$$\int_{-L}^{L} \cos \frac{m\pi x}{L} \sin \frac{n\pi x}{L}\, dx = 0.$$

This orthogonality was crucial in deriving the Euler formulas (2).

Partial sums of Fourier series minimize the **square error** (Sec. 11.6).

Ideas and techniques of Fourier series extend to nonperiodic functions $f(x)$ defined on the entire real line; this leads to the **Fourier integral**

$$(3) \qquad f(x) = \int_0^{\infty} [A(w) \cos wx + B(w) \sin wx]\, dw \qquad \text{(Sec. 11.7)}$$

where

$$(4) \qquad A(w) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(v) \cos wv\, dv, \qquad B(w) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(v) \sin wv\, dv$$

or, in complex form (Sec. 11.9),

$$(5) \qquad f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \hat{f}(w) e^{iwx}\, dw \qquad (i = \sqrt{-1})$$

where

$$(6) \qquad \hat{f}(w) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) e^{-iwx}\, dx.$$

Formula (6) transforms $f(x)$ into its **Fourier transform** $\hat{f}(w)$, and (5) is the inverse transform.

Related to this are the **Fourier cosine transform** (Sec. 11.8)

$$(7) \qquad \hat{f}_c(w) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(x) \cos wx\, dx$$

and the **Fourier sine transform** (Sec. 11.8)

$$(8) \qquad \hat{f}_s(w) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(x) \sin wx\, dx.$$

The **discrete Fourier transform (DFT)** and a practical method of computing it, called the **fast Fourier transform (FFT),** are discussed in Sec. 11.9.

CHAPTER 12

Partial Differential Equations (PDEs)

PDEs are models of various physical and geometrical problems, arising when the unknown functions (the solutions) depend on two or more variables, usually on time t and one or several space variables. It is fair to say that only the simplest physical systems can be modeled by ODEs, whereas most problems in dynamics, elasticity, heat transfer, electromagnetic theory, and quantum mechanics require PDEs. Indeed, the range of applications of PDEs is enormous, compared to that of ODEs.

In this chapter we concentrate on the most important PDEs of applied mathematics, the wave equations governing the vibrating string (Sec. 12.2) and the vibrating membrane (Sec. 12.7), the heat equation (Sec. 12.5), and the Laplace equation (Secs. 12.5, 12.10). We derive these PDEs from physics and consider methods for solving **initial and boundary value problems,** that is, methods of obtaining solutions satisfying conditions that are given by the physical situation.

In Secs. 12.6 and 12.11 we show that PDEs can also be solved by Fourier and Laplace transform methods.

COMMENT. ***Numerics for PDEs*** is explained in Secs. 21.4–21.7.

Prerequisites: Linear ODEs (Chap. 2), Fourier series (Chap. 11)
Sections that may be omitted in a shorter course: 12.6, 12.9–12.11

12.1 Basic Concepts

A **partial differential equation (PDE)** is an equation involving one or more partial derivatives of an (unknown) function, call it u, that depends on two or more variables, often time t and one or several variables in space. The order of the highest derivative is called the **order** of the PDE. As for ODEs, second-order PDEs will be the most important ones in applications.

Just as for ordinary differential equations (ODEs) we say that a PDE is **linear** if it is of the first degree in the unknown function u and its partial derivatives. Otherwise we call it **nonlinear.** Thus, all the equations in Example 1 on p. 536 are linear. We call a *linear* PDE **homogeneous** if each of its terms contains either u or one of its partial derivatives. Otherwise we call the equation **nonhomogeneous.** Thus, (4) in Example 1 (with f not identically zero) is nonhomogeneous, whereas the other equations are homogeneous.

EXAMPLE 1 **Important Second-Order PDEs**

(1) $$\frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2}$$ ***One-dimensional wave equation***

(2) $$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$$ ***One-dimensional heat equation***

(3) $$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$ ***Two-dimensional Laplace equation***

(4) $$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = f(x, y)$$ ***Two-dimensional Poisson equation***

(5) $$\frac{\partial^2 u}{\partial t^2} = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$ ***Two-dimensional wave equation***

(6) $$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$ ***Three-dimensional Laplace equation***

Here c is a positive constant, t is time, x, y, z are Cartesian coordinates, and *dimension* is the number of these coordinates in the equation. ■

A **solution** of a PDE in some region R of the space of the independent variables is a function that has all the partial derivatives appearing in the PDE in some domain D (definition in Sec. 9.6) containing R, and satisfies the PDE everywhere in R.

Often one merely requires that the function is continuous on the boundary of R, has those derivatives in the interior of R, and satisfies the PDE in the interior of R. Letting R lie in D simplifies the situation regarding derivatives on the boundary of R, which is then the same on the boundary as it is in the interior of R.

In general, the totality of solutions of a PDE is very large. For example, the functions

(7) $$u = x^2 - y^2, \qquad u = e^x \cos y, \qquad u = \sin x \cosh y, \qquad u = \ln (x^2 + y^2)$$

which are entirely different from each other, are solutions of (3), as you may verify. We shall see later that the unique solution of a PDE corresponding to a given physical problem will be obtained by the use of **additional conditions** arising from the problem. For instance, this may be the condition that the solution u assume given values on the boundary of the region R (**"boundary conditions"**). Or, when time t is one of the variables, u (or $u_t = \partial u/\partial t$ or both) may be prescribed at $t = 0$ (**"initial conditions"**).

We know that if an ODE is linear and homogeneous, then from known solutions we can obtain further solutions by superposition. For PDEs the situation is quite similar:

THEOREM 1 **Fundamental Theorem on Superposition**

If u_1 and u_2 are solutions of a ***homogeneous linear*** *PDE in some region R, then*

$$u = c_1 u_1 + c_2 u_2$$

with any constants c_1 and c_2 is also a solution of that PDE in the region R.

The simple proof of this important theorem is quite similar to that of Theorem 1 in Sec. 2.1 and is left to the student.

Verification of solutions in Probs. 14–25 proceeds as for ODEs. Problems 1–12 concern PDEs solvable like ODEs. To help the student with them, we consider two typical examples.

EXAMPLE 2 Solving $u_{xx} - u = 0$ Like an ODE

Find solutions u of the PDE $u_{xx} - u = 0$ depending on x and y.

Solution. Since no y-derivatives occur, we can solve this PDE like $u'' - u = 0$. In Sec. 2.2 we would have obtained $u = Ae^x + Be^{-x}$ with constant A and B. Here A and B may be functions of y, so that the answer is

$$u(x, y) = A(y)e^x + B(y)e^{-x}$$

with arbitrary functions A and B. We thus have a great variety of solutions. Check the result by differentiation. ■

EXAMPLE 3 Solving $u_{xy} = -u_x$ Like an ODE

Find solutions $u = u(x, y)$ of this PDE.

Solution. Setting $u_x = p$, we have $p_y = -p$, $p_y/p = -1$, $\ln p = -y + \tilde{c}(x)$, $p = c(x)e^{-y}$ and by integration with respect to x,

$$u(x, y) = f(x)e^{-y} + g(y) \qquad \text{where} \qquad f(x) = \int c(x)\,dx;$$

here, $f(x)$ and $g(y)$ are arbitrary. ■

PROBLEM SET 12.1

1–12 PDEs SOLVABLE AS ODEs

This happens if a PDE involves derivatives with respect to one variable only (or can be transformed to such a form), so that the other variable(s) can be treated as parameter(s). Solve for $u = u(x, y)$:

1. $u_{yy} + 16u = 0$
2. $u_{xx} = u$
3. $u_{yy} = 0$
4. $u_y + 2yu = 0$
5. $u_y + u = e^{xy}$
6. $u_{xx} = 4y^2u$
7. $u_y = (\cosh x)yu$
8. $u_y = 2xyu$
9. $y^2u_{yy} + 2yu_y - 2u = 0$
10. $u_{yy} = 4xu_y$
11. $u_{xy} = u_x$
12. $u_{yy} + 10u_y + 25u = e^{-5y}$

13. **(Fundamental Theorem)** Prove Fundamental Theorem 1 for second-order PDEs in two and three independent variables.

14–25 VERIFICATION OF SOLUTIONS

Verify (by substitution) that the given function is a solution of the indicated PDE. Sketch or graph the solution as a surface in space.

14–17 Wave Equation (1) with suitable c

14. $u = 4x^2 + t^2$
15. $u = \sin 8x \cos 2t$
16. $u = \sin 3x \sin 18t$
17. $u = \sin kx \cos kct$

18–21 Heat Equation (2) with suitable c

18. $u = e^{-2kt} \cos 8x$
19. $u = e^{-\pi^2 t} \sin 4x$
20. $u = e^{-4\omega^2 t} \sin \omega x$
21. $u = e^{-\omega^2 c^2 t} \cos \omega x$

22–25 Laplace Equation (3)

22. u in (7) in the text
23. $u = \cos 2y \sinh 2x$
24. $u = \arctan(y/x)$
25. $u = e^{x^2 - y^2} \sin 2xy$

26. **TEAM PROJECT. Verification of Solutions**
(a) Wave equation. Verify that $u(x, t) = v(x + ct) + w(x - ct)$ with any twice differentiable functions v and w satisfies (1).
(b) Poisson equation. Verify that each u satisfies (4) with $f(x, y)$ as indicated.

$u = x^4 + y^4$ $\qquad f = 12(x^2 + y^2)$

$u = \cos x \sin y$ $\qquad f = -2 \cos x \sin y$

$u = y/x$ $\qquad f = 2y/x^3$

(c) Laplace equation. Verify that $u = 1/\sqrt{x^2 + y^2 + z^2}$ satisfies (6) and $u = \ln(x^2 + y^2)$ satisfies (3). Is $u = 1/\sqrt{x^2 + y^2}$ a solution of (3)? Of what Poisson equation?

(d) Verify that u with any (sufficiently often differentiable) v and w satisfies the given PDE.

$u = v(x) + w(y)$ $\qquad u_{xy} = 0$

$u = v(x)w(y)$ $\qquad uu_{xy} = u_x u_y$

$u = v(x + 3t) + w(x - 3t)$ $\qquad u_{tt} = 9u_{xx}$

27. (Boundary value problem) Verify that the function $u(x, y) = a \ln (x^2 + y^2) + b$ satisfies Laplace's equation (3) and determine a and b so that u satisfies the boundary conditions $u = 110$ on the circle $x^2 + y^2 = 1$ and $u = 0$ on the circle $x^2 + y^2 = 100$.

28–30 SYSTEMS OF PDEs

Solve

28. $u_x = 0$, $u_y = 0$

29. $u_{xx} = 0$, $u_{xy} = 0$

30. $u_{xx} = 0$, $u_{yy} = 0$

12.2 Modeling: Vibrating String, Wave Equation

As a first important PDE let us derive the equation modeling small transverse vibrations of an elastic string, such as a violin string. We place the string along the x-axis, stretch it to length L, and fasten it at the ends $x = 0$ and $x = L$. We then distort the string, and at some instant, call it $t = 0$, we release it and allow it to vibrate. The problem is to determine the vibrations of the string, that is, to find its deflection $u(x, t)$ at any point x and at any time $t > 0$; see Fig. 283.

$u(x, t)$ will be the solution of a PDE that is the model of our physical system to be derived. This PDE should not be too complicated, so that we can solve it. Reasonable simplifying assumptions (just as for ODEs modeling vibrations in Chap. 2) are as follows.

Physical Assumptions

1. The mass of the string per unit length is constant ("homogeneous string"). The string is perfectly elastic and does not offer any resistance to bending.
2. The tension caused by stretching the string before fastening it at the ends is so large that the action of the gravitational force on the string (trying to pull the string down a little) can be neglected.
3. The string performs small transverse motions in a vertical plane; that is, every particle of the string moves strictly vertically and so that the deflection and the slope at every point of the string always remain small in absolute value.

Under these assumptions we may expect solutions $u(x, t)$ that describe the physical reality sufficiently well.

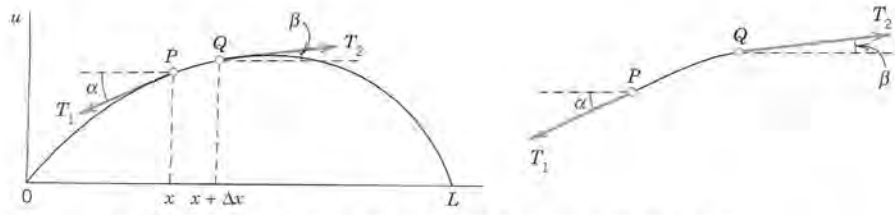

Fig. 283. Deflected string at fixed time t. Explanation on p. 539

Derivation of the PDE of the Model ("Wave Equation") from Forces

The model of the vibrating string will consist of a PDE ("wave equation") and additional conditions. To obtain the PDE, we consider the ***forces acting on a small portion of the string*** (Fig. 283). This method is typical of modeling in mechanics and elsewhere.

Since the string offers no resistance to bending, the tension is tangential to the curve of the string at each point. Let T_1 and T_2 be the tension at the endpoints P and Q of that portion. Since the points of the string move vertically, there is no motion in the horizontal direction. Hence the horizontal components of the tension must be constant. Using the notation shown in Fig. 283, we thus obtain

$$T_1 \cos \alpha = T_2 \cos \beta = T = const. \tag{1}$$

In the vertical direction we have two forces, namely, the vertical components $-T_1 \sin \alpha$ and $T_2 \sin \beta$ of T_1 and T_2; here the minus sign appears because the component at P is directed downward. By **Newton's second law** the resultant of these two forces is equal to the mass $\rho \Delta x$ of the portion times the acceleration $\partial^2 u/\partial t^2$, evaluated at some point between x and $x + \Delta x$; here ρ is the mass of the undeflected string per unit length, and Δx is the length of the portion of the undeflected string. (Δ is generally used to denote small quantities; this has nothing to do with the Laplacian ∇^2, which is sometimes also denoted by Δ.) Hence

$$T_2 \sin \beta - T_1 \sin \alpha = \rho \Delta x \frac{\partial^2 u}{\partial t^2}.$$

Using (1), we can divide this by $T_2 \cos \beta = T_1 \cos \alpha = T$, obtaining

$$\frac{T_2 \sin \beta}{T_2 \cos \beta} - \frac{T_1 \sin \alpha}{T_1 \cos \alpha} = \tan \beta - \tan \alpha = \frac{\rho \Delta x}{T} \frac{\partial^2 u}{\partial t^2}. \tag{2}$$

Now $\tan \alpha$ and $\tan \beta$ are the slopes of the string at x and $x + \Delta x$:

$$\tan \alpha = \left(\frac{\partial u}{\partial x}\right)\Big|_x \qquad \text{and} \qquad \tan \beta = \left(\frac{\partial u}{\partial x}\right)\Big|_{x+\Delta x}.$$

Here we have to write *partial* derivatives because u depends also on time t. Dividing (2) by Δx, we thus have

$$\frac{1}{\Delta x}\left[\left(\frac{\partial u}{\partial x}\right)\Big|_{x+\Delta x} - \left(\frac{\partial u}{\partial x}\right)\Big|_x\right] = \frac{\rho}{T} \frac{\partial^2 u}{\partial t^2}.$$

If we let Δx approach zero, we obtain the linear PDE

$$\frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2}, \qquad c^2 = \frac{T}{\rho}. \tag{3}$$

This is called the **one-dimensional wave equation.** We see that it is homogeneous and of the second order. The physical constant T/ρ is denoted by c^2 (instead of c) to indicate

that this constant is *positive*, a fact that will be essential to the form of the solutions. "One-dimensional" means that the equation involves only one space variable, x. In the next section we shall complete setting up the model and then show how to solve it by a general method that is probably the most important one for PDEs in engineering mathematics.

12.3 Solution by Separating Variables. Use of Fourier Series

The model of a vibrating elastic string (a violin string, for instance) consists of the **one-dimensional wave equation**

$$\textbf{(1)} \qquad \frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2} \qquad c^2 = \frac{T}{\rho}$$

for the unknown deflection $u(x, t)$ of the string, a PDE that we have just obtained, and some ***additional conditions,*** which we shall now derive.

Since the string is fastened at the ends $x = 0$ and $x = L$ (see Sec. 12.2), we have the two **boundary conditions**

$$\textbf{(2)} \qquad \text{(a)} \quad u(0, t) = 0, \qquad \text{(b)} \quad u(L, t) = 0 \qquad \text{for all } t.$$

Furthermore, the form of the motion of the string will depend on its *initial deflection* (deflection at time $t = 0$), call it $f(x)$, and on its *initial velocity* (velocity at $t = 0$), call it $g(x)$. We thus have the two **initial conditions**

$$\textbf{(3)} \qquad \text{(a)} \quad u(x, 0) = f(x), \qquad \text{(b)} \quad u_t(x, 0) = g(x) \qquad (0 \leqq x \leqq L)$$

where $u_t = \partial u/\partial t$. We now have to find a solution of the PDE (1) satisfying the conditions (2) and (3). This will be the solution of our problem. We shall do this in three steps, as follows.

Step 1. By the **"method of separating variables"** or *product method,* setting $u(x, t) = F(x)G(t)$, we obtain from (1) two ODEs, one for $F(x)$ and the other one for $G(t)$.

Step 2. We determine solutions of these ODEs that satisfy the boundary conditions (2).

Step 3. Finally, using **Fourier series,** we compose the solutions gained in Step 2 to obtain a solution of (1) satisfying both (2) and (3), that is, the solution of our model of the vibrating string.

Step 1. Two ODEs from the Wave Equation (1)

In the **method of separating variables,** or *product method,* we determine solutions of the wave equation (1) of the form

$$\textbf{(4)} \qquad u(x, t) = F(x)G(t)$$

which are a product of two functions, each depending only on one of the variables x and t. This is a powerful general method that has various applications in engineering mathematics, as we shall see in this chapter. Differentiating (4), we obtain

$$\frac{\partial^2 u}{\partial t^2} = F\ddot{G} \qquad \text{and} \qquad \frac{\partial^2 u}{\partial x^2} = F''G$$

where dots denote derivatives with respect to t and primes derivatives with respect to x. By inserting this into the wave equation (1) we have

$$F\ddot{G} = c^2 F''G.$$

Dividing by c^2FG and simplifying gives

$$\frac{\ddot{G}}{c^2 G} = \frac{F''}{F}.$$

The variables are now separated, the left side depending only on t and the right side only on x. Hence both sides must be constant because if they were variable, then changing t or x would affect only one side, leaving the other unaltered. Thus, say,

$$\frac{\ddot{G}}{c^2 G} = \frac{F''}{F} = k.$$

Multiplying by the denominators gives immediately two ***ordinary*** DEs

(5) $$F'' - kF = 0$$

and

(6) $$\ddot{G} - c^2 kG = 0.$$

Here, the **separation constant** k is still arbitrary.

Step 2. Satisfying the Boundary Conditions (2)

We now determine solutions F and G of (5) and (6) so that $u = FG$ satisfies the boundary conditions (2), that is,

(7) $$u(0, t) = F(0)G(t) = 0, \qquad u(L, t) = F(L)G(t) = 0 \qquad \text{for all } t.$$

We first solve (5). If $G \equiv 0$, then $u = FG \equiv 0$, which is of no interest. Hence $G \not\equiv 0$ and then by (7),

(8) $$\text{(a)} \quad F(0) = 0, \qquad \text{(b)} \quad F(L) = 0.$$

We show that k must be negative. For $k = 0$ the general solution of (5) is $F = ax + b$, and from (8) we obtain $a = b = 0$, so that $F \equiv 0$ and $u = FG \equiv 0$, which is of no interest. For positive $k = \mu^2$ a general solution of (5) is

$$F = Ae^{\mu x} + Be^{-\mu x}$$

and from (8) we obtain $F \equiv 0$ as before (verify!). Hence we are left with the possibility of choosing k negative, say, $k = -p^2$. Then (5) becomes $F'' + p^2F = 0$ and has as a general solution

$$F(x) = A \cos px + B \sin px.$$

From this and (8) we have

$$F(0) = A = 0 \qquad \text{and then} \qquad F(L) = B \sin pL = 0.$$

We must take $B \neq 0$ since otherwise $F \equiv 0$. Hence $\sin pL = 0$. Thus

$$pL = n\pi, \qquad \text{so that} \qquad p = \frac{n\pi}{L} \qquad (n \text{ integer}). \tag{9}$$

Setting $B = 1$, we thus obtain infinitely many solutions $F(x) = F_n(x)$, where

$$F_n(x) = \sin \frac{n\pi}{L} x \qquad (n = 1, 2, \cdots). \tag{10}$$

These solutions satisfy (8). [For negative integer n we obtain essentially the same solutions, except for a minus sign, because $\sin(-\alpha) = -\sin \alpha$.]

We now solve (6) with $k = -p^2 = -(n\pi/L)^2$ resulting from (9), that is,

$$\ddot{G} + \lambda_n^2 G = 0 \qquad \text{where} \qquad \lambda_n = cp = \frac{cn\pi}{L}. \tag{11*}$$

A general solution is

$$G_n(t) = B_n \cos \lambda_n t + B_n^* \sin \lambda_n t.$$

Hence solutions of (1) satisfying (2) are $u_n(x, t) = F_n(x)G_n(t) = G_n(t)F_n(x)$, written out

$$u_n(x, t) = (B_n \cos \lambda_n t + B_n^* \sin \lambda_n t) \sin \frac{n\pi}{L} x \qquad (n = 1, 2, \cdots). \tag{11}$$

These functions are called the **eigenfunctions,** or *characteristic functions,* and the values $\lambda_n = cn\pi/L$ are called the **eigenvalues,** or *characteristic values,* of the vibrating string. The set $\{\lambda_1, \lambda_2, \cdots\}$ is called the **spectrum.**

Discussion of Eigenfunctions. We see that each u_n represents a harmonic motion having the **frequency** $\lambda_n/2\pi = cn/2L$ cycles per unit time. This motion is called the nth **normal mode** of the string. The first normal mode is known as the *fundamental mode* ($n = 1$), and the others are known as *overtones;* musically they give the octave, octave plus fifth, etc. Since in (11)

$$\sin \frac{n\pi x}{L} = 0 \qquad \text{at} \qquad x = \frac{L}{n}, \frac{2L}{n}, \cdots, \frac{n-1}{n} L,$$

the nth normal mode has $n - 1$ **nodes,** that is, points of the string that do not move (in addition to the fixed endpoints); see Fig. 284.

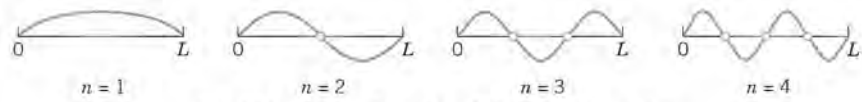

Fig. 284. Normal modes of the vibrating string

Figure 285 shows the second normal mode for various values of t. At any instant the string has the form of a sine wave. When the left part of the string is moving down, the other half is moving up, and conversely. For the other modes the situation is similar.

Tuning is done by changing the tension T. Our formula for the frequency $\lambda_n/2\pi = cn/2L$ of u_n with $c = \sqrt{T/\rho}$ [see (3), Sec. 12.2] confirms that effect because it shows that the frequency is proportional to the tension. T cannot be increased indefinitely, but can you see what to do to get a string with a high fundamental mode? (Think of both L and ρ.) Why is a violin smaller than a double-bass?

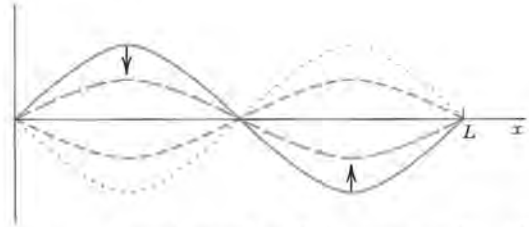

Fig. 285. Second normal mode for various values of t

Step 3. Solution of the Entire Problem. Fourier Series

The eigenfunctions (11) satisfy the wave equation (1) and the boundary conditions (2) (string fixed at the ends). A single u_n will generally not satisfy the initial conditions (3). But since the wave equation (1) is linear and homogeneous, it follows from Fundamental Theorem 1 in Sec. 12.1 that the sum of finitely many solutions u_n is a solution of (1). To obtain a solution that also satisfies the initial conditions (3), we consider the infinite series (with $\lambda_n = cn\pi/L$ as before)

$$\textbf{(12)} \qquad u(x, t) = \sum_{n=1}^{\infty} u_n(x, t) = \sum_{n=1}^{\infty} (B_n \cos \lambda_n t + B_n^* \sin \lambda_n t) \sin \frac{n\pi}{L} x.$$

Satisfying Initial Condition (3a) (Given Initial Displacement). From (12) and (3a) we obtain

$$(13) \qquad u(x, 0) = \sum_{n=1}^{\infty} B_n \sin \frac{n\pi}{L} x = f(x).$$

Hence we must choose the B_n's so that $u(x, 0)$ becomes the **Fourier sine series** of $f(x)$. Thus, by (4) in Sec. 11.3,

$$\textbf{(14)} \qquad B_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} dx, \qquad n = 1, 2, \cdots.$$

Satisfying Initial Condition (3b) (Given Initial Velocity). Similarly, by differentiating (12) with respect to t and using (3b), we obtain

$$\left.\frac{\partial u}{\partial t}\right|_{t=0} = \left[\sum_{n=1}^{\infty} (-B_n\lambda_n \sin \lambda_n t + B_n^*\lambda_n \cos \lambda_n t) \sin \frac{n\pi x}{L}\right]_{t=0}$$

$$= \sum_{n=1}^{\infty} B_n^*\lambda_n \sin \frac{n\pi x}{L} = g(x).$$

Hence we must choose the B_n^*'s so that for $t = 0$ the derivative $\partial u/\partial t$ becomes the Fourier sine series of $g(x)$. Thus, again by (4) in Sec. 11.3,

$$B_n^*\lambda_n = \frac{2}{L}\int_0^L g(x) \sin \frac{n\pi x}{L}\, dx.$$

Since $\lambda_n = cn\pi/L$, we obtain by division

(15)
$$B_n^* = \frac{2}{cn\pi}\int_0^L g(x) \sin \frac{n\pi x}{L}\, dx, \qquad n = 1, 2, \cdots.$$

Result. Our discussion shows that $u(x, t)$ given by (12) with coefficients (14) and (15) is a solution of (1) that satisfies all the conditions in (2) and (3), provided the series (12) converges and so do the series obtained by differentiating (12) twice termwise with respect to x and t and have the sums $\partial^2 u/\partial x^2$ and $\partial^2 u/\partial t^2$, respectively, which are continuous.

Solution (12) Established. According to our derivation the solution (12) is at first a purely formal expression, but we shall now establish it. For the sake of simplicity we consider only the case when the initial velocity $g(x)$ is identically zero. Then the B_n^* are zero, and (12) reduces to

(16)
$$u(x, t) = \sum_{n=1}^{\infty} B_n \cos \lambda_n t \sin \frac{n\pi x}{L}, \qquad \lambda_n = \frac{cn\pi}{L}.$$

It is possible to ***sum this series,*** that is, to write the result in a closed or finite form. For this purpose we use the formula [see (11), App. A3.1]

$$\cos \frac{cn\pi}{L} t \sin \frac{n\pi}{L} x = \frac{1}{2}\left[\sin\left\{\frac{n\pi}{L}(x - ct)\right\} + \sin\left\{\frac{n\pi}{L}(x + ct)\right\}\right].$$

Consequently, we may write (16) in the form

$$u(x, t) = \frac{1}{2}\sum_{n=1}^{\infty} B_n \sin\left\{\frac{n\pi}{L}(x - ct)\right\} + \frac{1}{2}\sum_{n=1}^{\infty} B_n \sin\left\{\frac{n\pi}{L}(x + ct)\right\}.$$

These two series are those obtained by substituting $x - ct$ and $x + ct$, respectively, for the variable x in the Fourier sine series (13) for $f(x)$. Thus

(17)
$$u(x, t) = \tfrac{1}{2}[f^*(x - ct) + f^*(x + ct)]$$

where f^* is the odd periodic extension of f with the period $2L$ (Fig. 286). Since the initial deflection $f(x)$ is continuous on the interval $0 \leqq x \leqq L$ and zero at the endpoints, it follows from (17) that $u(x, t)$ is a continuous function of both variables x and t for all values of the variables. By differentiating (17) we see that $u(x, t)$ is a solution of (1), provided $f(x)$ is twice differentiable on the interval $0 < x < L$, and has one-sided second derivatives at $x = 0$ and $x = L$, which are zero. Under these conditions $u(x, t)$ is established as a solution of (1), satisfying (2) and (3) with $g(x) \equiv 0$. ■

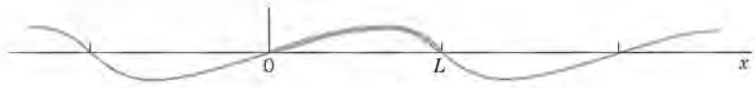

Fig. 286. Odd periodic extension of $f(x)$

Generalized Solution. If $f'(x)$ and $f''(x)$ are merely piecewise continuous (see Sec. 6.1), or if those one-sided derivatives are not zero, then for each t there will be finitely many values of x at which the second derivatives of u appearing in (1) do not exist. Except at these points the wave equation will still be satisfied. We may then regard $u(x, t)$ as a **"generalized solution,"** as it is called, that is, as a solution in a broader sense. For instance, a triangular initial deflection as in Example 1 (below) leads to a generalized solution.

Physical Interpretation of the Solution (17). The graph of $f^*(x - ct)$ is obtained from the graph of $f^*(x)$ by shifting the latter ct units to the right (Fig. 287). This means that $f^*(x - ct)$ $(c > 0)$ represents a wave that is traveling to the right as t increases. Similarly, $f^*(x + ct)$ represents a wave that is traveling to the left, and $u(x, t)$ is the superposition of these two waves.

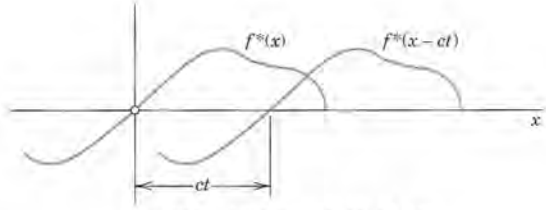

Fig. 287. Interpretation of (17)

EXAMPLE 1 **Vibrating String if the Initial Deflection Is Triangular**

Find the solution of the wave equation (1) corresponding to the triangular initial deflection

$$f(x) = \begin{cases} \dfrac{2k}{L}x & \text{if} \quad 0 < x < \dfrac{L}{2} \\ \dfrac{2k}{L}(L - x) & \text{if} \quad \dfrac{L}{2} < x < L \end{cases}$$

and initial velocity zero. (Figure 288 shows $f(x) = u(x, 0)$ at the top.)

Solution. Since $g(x) \equiv 0$, we have $B_n^* = 0$ in (12), and from Example 4 in Sec. 11.3 we see that the B_n are given by (5), Sec. 11.3. Thus (12) takes the form

$$u(x, t) = \frac{8k}{\pi^2}\left[\frac{1}{1^2}\sin\frac{\pi}{L}x\cos\frac{\pi c}{L}t - \frac{1}{3^2}\sin\frac{3\pi}{L}x\cos\frac{3\pi c}{L}t + - \cdots\right].$$

For graphing the solution we may use $u(x, 0) = f(x)$ and the above interpretation of the two functions in the representation (17). This leads to the graph shown in Fig. 288. ■

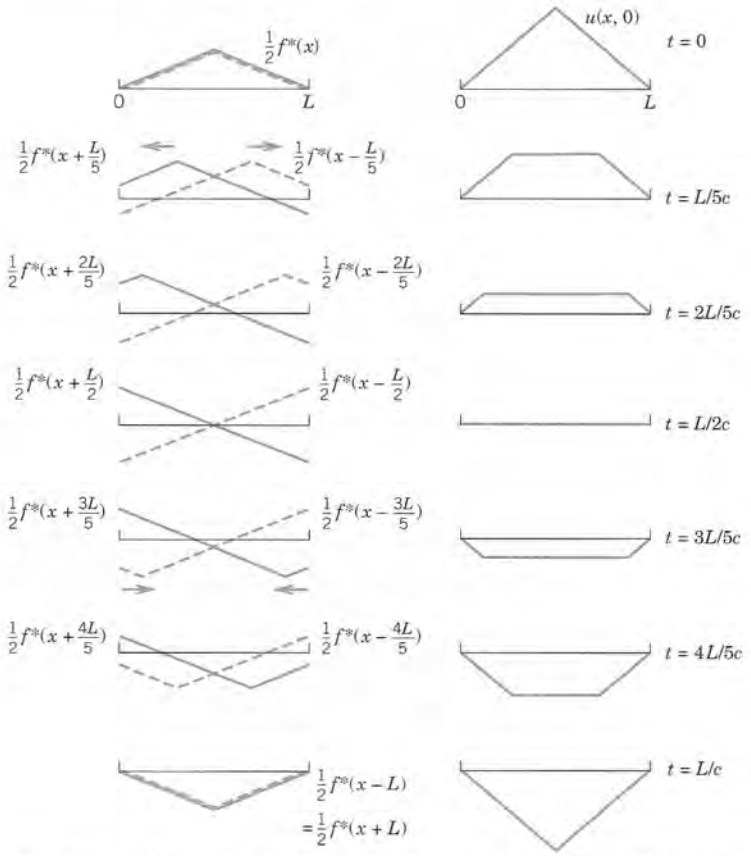

Fig. 288. Solution $u(x, t)$ in Example 1 for various values of t (right part of the figure) obtained as the superposition of a wave traveling to the right (dashed) and a wave traveling to the left (left part of the figure)

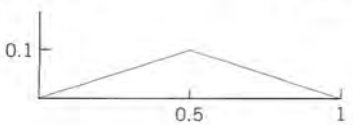
PROBLEM SET 12.3

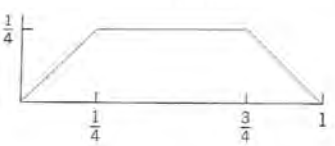
1–10 DEFLECTION OF THE STRING

Find $u(x, t)$ for the string of length $L = 1$ and $c^2 = 1$ when the initial velocity is zero and the initial deflection with small k (say, 0.01) is as follows. Sketch or graph $u(x, t)$ as in Fig. 288.



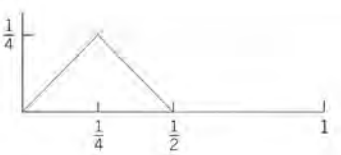
1. $k \sin 2\pi x$

2. $k(\sin \pi x - \frac{1}{3} \sin 3\pi x)$

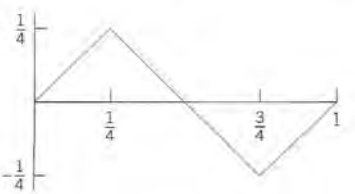


3. $kx(1 - x)$

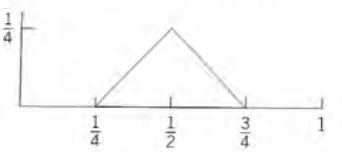
4. $kx(1 - x^2)$



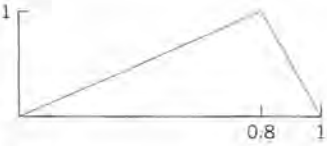
5.



6.



7.



8.

9.

10.

11. (Frequency) How does the frequency of the fundamental mode of the vibrating string depend on the length of the string? On the mass per unit length? What happens to the string if we double the tension? Why is a contrabass larger than a violin?

12. (Nonzero initial velocity) Find the deflection $u(x, t)$ of the string of length $L = \pi$ and $c^2 = 1$ for zero initial displacement and "triangular" initial velocity $u_t(x, 0) = 0.01x$ if $0 \leqq x \leqq \frac{1}{2}\pi$, $u_t(x, 0) = 0.01(\pi - x)$ if $\frac{1}{2}\pi \leqq x \leqq \pi$. (Initial conditions with $u_t(x, 0) \neq 0$ are hard to realize experimentally.)

13. CAS PROJECT. Graphing Normal Modes. Write a program for graphing u_n with $L = \pi$ and c^2 of your choice similarly as in Fig. 284. Apply the program to u_2, u_3, u_4. Also graph these solutions as surfaces over the xt-plane. Explain the connection between these two kinds of graphs.

14. TEAM PROJECT. Forced Vibrations of an Elastic String. Show the following.

(a) Substitution of

$$(17) \qquad u(x, t) = \sum_{n=1}^{\infty} G_n(t) \sin \frac{n\pi x}{L}$$

(L = length of the string) into the wave equation (1) governing free vibrations leads to [see (10*)]

$$(18) \quad \ddot{G}_n + \lambda_n^2 G = 0, \qquad \lambda_n = \frac{cn\pi}{L}.$$

(b) Forced vibrations of the string under an external force $P(x, t)$ per unit length acting normal to the string are governed by the PDE

$$\textbf{(19)} \qquad u_{tt} = c^2 u_{xx} + \frac{P}{\rho}.$$

(c) For a sinusoidal force $P = A\rho \sin \omega t$ we obtain

$$\frac{P}{\rho} = A \sin \omega t = \sum_{n=1}^{\infty} k_n(t) \sin \frac{n\pi x}{L},$$

$$(20) \qquad k_n(t) = \begin{cases} (4A/n\pi) \sin \omega t & (n \text{ odd}) \\ 0 & (n \text{ even}). \end{cases}$$

Substituting (17) and (20) into (19) gives

$$\ddot{G}_n + \lambda_n^2 G_n = \frac{2A}{n\pi}(1 - \cos n\pi) \sin \omega t.$$

If $\lambda_n^2 \neq \omega^2$, the solution is

$$G_n(t) = B_n \cos \lambda_n t + B_n^* \sin \lambda_n t + \frac{2A(1 - \cos n\pi)}{n\pi(\lambda_n^2 - \omega^2)} \sin \omega t.$$

Determine B_n and B_n^* so that u satisfies the initial conditions $u(x, 0) = f(x)$, $u_t(x, 0) = 0$.

(d) (Resonance) Show that if $\lambda_n = \omega$, then

$$G_n(t) = B_n \cos \omega t + B_n^* \sin \omega t - \frac{A}{n\pi\omega}(1 - \cos n\pi) t \cos \omega t.$$

(e) (Reduction of boundary conditions) Show that a problem (1)–(3) with more complicated boundary conditions $u(0, t) = 0$, $u(L, t) = h(t)$, can be reduced to a problem for a new function v satisfying conditions $v(0, t) = v(L, t) = 0$, $v(x, 0) = f_1(x)$, $v_t(x, 0) = g_1(x)$ but a nonhomogeneous wave equation. *Hint:* Set $u = v + w$ and determine w suitably.

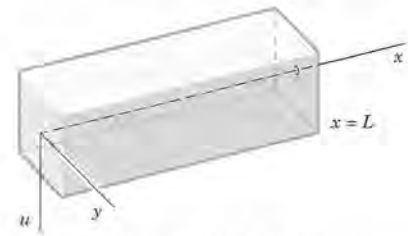


Fig. 289. Elastic beam

15–20 SEPARATION OF A FOURTH-ORDER PDE. VIBRATING BEAM

By the principles used in modeling the string it can be shown that small free vertical vibrations of a uniform elastic beam (Fig. 289) are modeled by the fourth-order PDE

$$\textbf{(21)} \qquad \frac{\partial^2 u}{\partial t^2} = -c^2 \frac{\partial^4 u}{\partial x^4} \qquad \text{(Ref. [C11])}$$

where $c^2 = EI/\rho A$ (E = Young's modulus of elasticity, I = moment of intertia of the cross section with respect to the y-axis in the figure, ρ = density, A = cross-sectional area). (*Bending* of a beam under a load is discussed in Sec. 3.3.)

15. Substituting $u = F(x)G(t)$ into (21), show that

$$F^{(4)}/F = -\ddot{G}/c^2 G = \beta^4 = const,$$

$$F(x) = A \cos \beta x + B \sin \beta x + C \cosh \beta x + D \sinh \beta x,$$

$$G(t) = a \cos c\beta^2 t + b \sin c\beta^2 t.$$

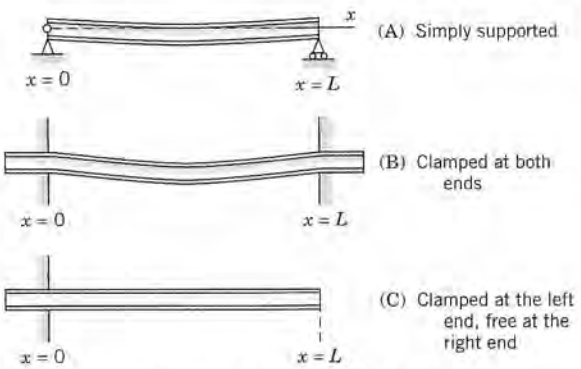

Fig. 290. Supports of a beam

16. (Simply supported beam in Fig. 290A) Find solutions $u_n = F_n(x)G_n(t)$ of (21) corresponding to zero initial velocity and satisfying the boundary conditions (see Fig. 290A)

$$u(0, t) = 0, \quad u(L, t) = 0$$

(ends simply supported for all times t),

$$u_{xx}(0, t) = 0, \quad u_{xx}(L, t) = 0$$

(zero moments, hence zero curvature, at the ends).

17. Find the solution of (21) that satisfies the conditions in Prob. 16 as well as the initial condition

$$u(x, 0) = f(x) = x(L - x).$$

18. Compare the results of Probs. 17 and 3. What is the basic difference between the frequencies of the normal modes of the vibrating string and the vibrating beam?

19. (Clamped beam in Fig. 290B) What are the boundary conditions for the clamped beam in Fig. 290B? Show that F in Prob. 15 satisfies these conditions if βL is a solution of the equation

$$\cosh \beta L \cos \beta L = 1. \tag{22}$$

Determine approximate solutions of (22), for instance, graphically from the intersections of the curves of $\cos \beta L$ and $1/\cosh \beta L$.

20. (Clamped-free beam in Fig. 290C) If the beam is clamped at the left and free at the right (Fig. 290C), the boundary conditions are

$$u(0, t) = 0, \qquad u_x(0, t) = 0,$$
$$u_{xx}(L, t) = 0, \qquad u_{xxx}(L, t) = 0.$$

Show that F in Prob. 15 satisfies these conditions if βL is a solution of the equation

$$\cosh \beta L \cos \beta L = -1. \tag{23}$$

Find approximate solutions of (18).

12.4 D'Alembert's Solution of the Wave Equation. Characteristics

It is interesting that the solution (17), Sec. 12.3, of the wave equation

$$\frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2}, \qquad c^2 = \frac{T}{\rho}, \tag{1}$$

can be immediately obtained by transforming (1) in a suitable way, namely, by introducing the new independent variables

$$v = x + ct, \qquad w = x - ct. \tag{2}$$

Then u becomes a function of v and w. The derivatives in (1) can now be expressed in terms of derivatives with respect to v and w by the use of the chain rule in Sec. 9.6. Denoting partial derivatives by subscripts, we see from (2) that $v_x = 1$ and $w_x = 1$. For simplicity let us denote $u(x, t)$, as a function of v and w, by the same letter u. Then

$$u_x = u_v v_x + u_w w_x = u_v + u_w.$$

We now apply the chain rule to the right side of this equation. We assume that all the partial derivatives involved are continuous, so that $u_{wv} = u_{vw}$. Since $v_x = 1$ and $w_x = 1$, we obtain

$$u_{xx} = (u_v + u_w)_x = (u_v + u_w)_v v_x + (u_v + u_w)_w w_x = u_{vv} + 2u_{vw} + u_{ww}.$$

Transforming the other derivative in (1) by the same procedure, we find

$$u_{tt} = c^2(u_{vv} - 2u_{vw} + u_{ww}).$$

By inserting these two results in (1) we get (see footnote 2 in App. A3.2)

$$u_{vw} \equiv \frac{\partial^2 u}{\partial w\, \partial v} = 0. \tag{3}$$

The point of the present method is that (3) can be readily solved by two successive integrations, first with respect to w and then with respect to v. This gives

$$\frac{\partial u}{\partial v} = h(v) \qquad \text{and} \qquad u = \int h(v)\, dv + \psi(w).$$

Here $h(v)$ and $\psi(w)$ are arbitrary functions of v and w, respectively. Since the integral is a function of v, say, $\phi(v)$, the solution is of the form $u = \phi(v) + \psi(w)$. In terms of x and t, by (2), we thus have

$$u(x, t) = \phi(x + ct) + \psi(x - ct). \tag{4}$$

This is known as **d'Alembert's solution**[1] of the wave equation (1).

Its derivation was much more elegant than the method in Sec. 12.3, but d'Alembert's method is special, whereas the use of Fourier series applies to various equations, as we shall see.

D'Alembert's Solution Satisfying the Initial Conditions

$$\text{(a)}\quad u(x, 0) = f(x), \qquad \text{(b)}\quad u_t(x, 0) = g(x). \tag{5}$$

These are the same as (3) in Sec. 12.3. By differentiating (4) we have

$$u_t(x, t) = c\phi'(x + ct) - c\psi'(x - ct) \tag{6}$$

---

[1]JEAN LE ROND D'ALEMBERT (1717–1783), French mathematician, also known for his important work in mechanics.

We mention that the general theory of PDEs provides a systematic way for finding the transformation (2) that simplifies (1). See Ref. [C8] in App. 1.

where primes denote derivatives with respect to the *entire* arguments $x + ct$ and $x - ct$, respectively, and the minus sign comes from the chain rule. From (4)–(6) we have

$$u(x, 0) = \phi(x) + \psi(x) = f(x), \tag{7}$$

$$u_t(x, 0) = c\phi'(x) - c\psi'(x) = g(x). \tag{8}$$

Dividing (8) by c and integrating with respect to x, we obtain

$$\phi(x) - \psi(x) = k(x_0) + \frac{1}{c}\int_{x_0}^{x} g(s)\,ds, \qquad k(x_0) = \phi(x_0) - \psi(x_0). \tag{9}$$

If we add this to (7), then ψ drops out and division by 2 gives

$$\phi(x) = \frac{1}{2}\,f(x) + \frac{1}{2c}\int_{x_0}^{x} g(s)\,ds + \frac{1}{2}\,k(x_0). \tag{10}$$

Similarly, subtraction of (9) from (7) and division by 2 gives

$$\psi(x) = \frac{1}{2}\,f(x) - \frac{1}{2c}\int_{x_0}^{x} g(s)\,ds - \frac{1}{2}\,k(x_0). \tag{11}$$

In (10) we replace x by $x + ct$; we then get an integral from x_0 to $x + ct$. In (11) we replace x by $x - ct$ and get minus an integral from x_0 to $x - ct$ or plus an integral from $x - ct$ to x_0. Hence addition of $\phi(x + ct)$ and $\psi(x - ct)$ gives $u(x, t)$ [see (4)] in the form

$$\mathbf{u(x, t) = \frac{1}{2}\,[f(x + ct) + f(x - ct)] + \frac{1}{2c}\int_{x-ct}^{x+ct} g(s)\,ds.} \tag{12}$$

If the initial velocity is zero, we see that this reduces to

$$u(x, t) = \tfrac{1}{2}[f(x + ct) + f(x - ct)], \tag{13}$$

in agreement with (17) in Sec. 12.3. You may show that because of the boundary conditions (2) in that section the function f must be odd and must have the period $2L$.

Our result shows that the two initial conditions [the functions $f(x)$ and $g(x)$ in (5)] determine the solution uniquely.

The solution of the wave equation by the Laplace transform method will be shown in Sec. 12.11.

Characteristics. Types and Normal Forms of PDEs

The idea of d'Alembert's solution is just a special instance of the **method of characteristics.** This concerns PDEs of the form

$$\mathbf{Au_{xx} + 2Bu_{xy} + Cu_{yy} = F(x, y, u, u_x, u_y)} \tag{14}$$

(as well as PDEs in more than two variables). Equation (14) is called **quasilinear** because it is linear in the highest derivatives (but may be arbitrary otherwise). There are three types of PDEs (14), depending on the discriminant $AC - B^2$, as follows.

Type	Defining Condition	Example in Sec. 12.1
Hyperbolic	$AC - B^2 < 0$	Wave equation (1)
Parabolic	$AC - B^2 = 0$	Heat equation (2)
Elliptic	$AC - B^2 > 0$	Laplace equation (3)

Note that (1) and (2) in Sec. 12.1 involve t, but to have y as in (14), we set $y = ct$ in (1), obtaining $u_{tt} - c^2u_{xx} = c^2(u_{yy} - u_{xx}) = 0$. And in (2) we set $y = c^2t$, so that $u_t - c^2u_{xx} = c^2(u_y - u_{xx})$.

A, B, C may be functions of x, y, so that a PDE may be **of mixed type,** that is, of different type in different regions of the xy-plane. An important mixed-type PDE is the **Tricomi equation** (see Prob. 10).

Transformation of (14) to Normal Form. The normal forms of (14) and the corresponding transformations depend on the type of the PDE. They are obtained by solving the **characteristic equation** of (14), which is the ODE

$$\textbf{(15)} \qquad Ay'^2 - 2By' + C = 0$$

where $y' = dy/dx$ (note $-2B$, not $+2B$). The solutions of (15) are called the **characteristics** of (14), and we write them in the form $\Phi(x, y) = const$ and $\Psi(x, y) = const$. Then the transformations giving new variables v, w instead of x, y and the normal forms of (14) are as follows.

Type	New Variables		Normal Form
Hyperbolic	$v = \Phi$	$w = \Psi$	$u_{vv} = F_1$
Parabolic	$v = x$	$w = \Phi = \Psi$	$u_{ww} = F_2$
Elliptic	$v = \frac{1}{2}(\Phi + \Psi)$	$w = \dfrac{1}{2i}(\Phi - \Psi)$	$u_{vv} + u_{ww} = F_3$

Here, $\Phi = \Phi(x, y)$, $\Psi = \Psi(x, y)$, $F_1 = F_1(v, w, u, u_v, u_w)$, etc., and we denote u as function of v, w again by u, for simplicity. We see that the normal form of a hyperbolic PDE is as in d'Alembert's solution. In the parabolic case we get just one family of solutions $\Phi = \Psi$. In the elliptic case, $i = \sqrt{-1}$, and the characteristics are complex and are of minor interest. For derivation, see Ref. [GR3] in App. 1.

EXAMPLE 1 **D'Alembert's Solution Obtained Systematically**

The theory of characteristics gives d'Alembert's solution in a systematic fashion. To see this, we write the wave equation $u_{tt} - c^2u_{xx} = 0$ in the form (14) by setting $y = ct$. By the chain rule, $u_t = u_y y_t = cu_y$ and $u_{tt} = c^2u_{yy}$. Division by c^2 gives $u_{xx} - u_{yy} = 0$, as stated before. Hence the characteristic equation is $y'^2 - 1 = (y' + 1)(y' - 1) = 0$. The two families of solutions (characteristics) are $\Phi(x, y) = y + x = const$ and $\Psi(x, y) = y - x = const$. This gives the new variables $v = \Phi = y + x = ct + x$ and $w = \Psi = y - x = ct - x$ and d'Alembert's solution $u = f_1(x + ct) + f_2(x - ct)$. ■

PROBLEM SET 12.4

1. Show that c is the speed of each of the two waves given by (4).
2. Show that because of the boundary conditions (2), Sec. 12.3, the function f in (13) of this section must be odd and of period $2L$.
3. If a steel wire 2 m in length weighs 0.9 nt (about 0.20 lb) and is stretched by a tensile force of 300 nt (about 67.4 lb), what is the corresponding speed of transverse waves?
4. What are the frequencies of the eigenfunctions in Prob. 3?
5. **Longitudinal Vibrations of an Elastic Bar or Rod.** These vibrations in the direction of the x-axis are modeled by the wave equation $u_{tt} = c^2 u_{xx}$, $c^2 = E/\rho$ (see Tolstov [C9], p. 275). If the rod is fastened at one end, $x = 0$, and free at the other, $x = L$, we have $u(0, t) = 0$ and $u_x(L, t) = 0$. Show that the motion corresponding to initial displacement $u(x, 0) = f(x)$ and initial velocity zero is

$$u = \sum_{n=0}^{\infty} A_n \sin p_n x \cos p_n c t,$$

$$A_n = \frac{2}{L}\int_0^L f(x) \sin p_n x \, dx, \qquad p_n = \frac{(2n + 1)\pi}{2L}.$$

6–9 **GRAPHING SOLUTIONS**

Using (13), sketch or graph a figure (similar to Fig. 288 in Sec. 12.3) of the deflection $u(x, t)$ of a vibrating string (length $L = 1$, ends fixed, $c = 1$) starting with initial velocity 0 and initial deflection (k small, say, $k = 0.01$).

6. $f(x) = k \sin \pi x$
7. $f(x) = k(1 - \cos 2\pi x)$
8. $f(x) = kx(1 - x)$
9. $f(x) = k(x - x^3)$

10. **(Tricomi and Airy equations[2])** Show that the *Tricomi equation* $yu_{xx} + u_{yy} = 0$ is of mixed type. Obtain the **Airy equation** $G'' - yG = 0$ from the Tricomi equation by separation. (For solutions, see p. 446 of Ref. [GR1] listed in App. 1.)

11–20 **NORMAL FORMS**

Find the type, transform to normal form, and solve. (Show the details of your work.)

11. $u_{xy} - u_{yy} = 0$
12. $u_{xx} - 2u_{xy} + u_{yy} = 0$
13. $u_{xx} + 9u_{yy} = 0$
14. $u_{xx} + u_{xy} - 2u_{yy} = 0$
15. $u_{xx} + 2u_{xy} + u_{yy} = 0$
16. $xu_{xy} - yu_{yy} = 0$
17. $u_{xx} - 4u_{xy} + 4u_{yy} = 0$
18. $u_{xx} + 2u_{xy} + 5u_{yy} = 0$
19. $xu_{xx} - yu_{xy} = 0$
20. $u_{xx} - 4u_{xy} + 3u_{yy} = 0$

12.5 Heat Equation: Solution by Fourier Series

From the wave equation we now turn to the next "big" PDE, the **heat equation**

$$\frac{\partial u}{\partial t} = c^2 \nabla^2 u, \qquad c^2 = \frac{K}{\sigma\rho},$$

which gives the temperature $u(x, y, z, t)$ in a body of homogeneous material. Here c^2 is the thermal diffusivity, K the thermal conductivity, σ the specific heat, and ρ the density of the material of the body. $\nabla^2 u$ is the Laplacian of u, and with respect to Cartesian coordinates x, y, z,

$$\nabla^2 u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2}.$$

The heat equation was derived in Sec. 10.8. It is also called the **diffusion equation.**

As an important application, let us first consider the temperature in a long thin metal bar or wire of constant cross section and homogeneous material, which is oriented along the x-axis (Fig. 291) and is perfectly insulated laterally, so that heat flows in the x-direction

[2]SIR GEORGE BIDELL AIRY (1801–1892), English mathematician, known for his work in elasticity. FRANCESCO TRICOMI (1897–1978), Italian mathematician, who worked in integral equations.

Fig. 291. Bar under consideration

only. Then u depends only on x and time t, and the heat equation becomes the **one-dimensional heat equation**

$$\textbf{(1)} \qquad \frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}.$$

This seems to differ only very little from the wave equation, which has a term u_{tt} instead of u_t, but we shall see that this will make the solutions of (1) behave quite differently from those of the wave equation.

We shall solve (1) for some important types of boundary and initial conditions. We begin with the case in which the ends $x = 0$ and $x = L$ of the bar are kept at temperature zero, so that we have the **boundary conditions**

$$\textbf{(2)} \qquad u(0, t) = 0, \qquad u(L, t) = 0 \qquad \text{for all } t.$$

Furthermore, the initial temperature in the bar at time $t = 0$ is given, say, $f(x)$, so that we have the **initial condition**

$$\textbf{(3)} \qquad u(x, 0) = f(x) \qquad [f(x) \text{ given}].$$

Here we must have $f(0) = 0$ and $f(L) = 0$ because of (2).

We shall determine a solution $u(x, t)$ of (1) satisfying (2) and (3)—one initial condition will be enough, as opposed to two initial conditions for the wave equation. Technically, our method will parallel that for the wave equation in Sec. 12.3: a separation of variables, followed by the use of Fourier series. You may find a step-by-step comparison worthwhile.

Step 1. **Two ODEs from the heat equation (1).** Substitution of a product $u(x, t) = F(x)G(t)$ into (1) gives $F\dot{G} = c^2F''G$ with $\dot{G} = dG/dt$ and $F'' = d^2F/dx^2$. To separate the variables, we divide by c^2FG, obtaining

$$(4) \qquad \frac{\dot{G}}{c^2G} = \frac{F''}{F}.$$

The left side depends only on t and the right side only on x, so that both sides must equal a constant k (as in Sec. 12.3). You may show that for $k = 0$ or $k > 0$ the only solution $u = FG$ satisfying (2) is $u \equiv 0$. For negative $k = -p^2$ we have from (4)

$$\frac{\dot{G}}{c^2G} = \frac{F''}{F} = -p^2.$$

Multiplication by the denominators gives immediately the two ODEs

$$\textbf{(5)} \qquad F'' + p^2F = 0$$

and

$$\dot{G} + c^2p^2G = 0. \tag{6}$$

Step 2. **Satisfying the boundary conditions (2).** We first solve (5). A general solution is

$$F(x) = A \cos px + B \sin px. \tag{7}$$

From the boundary conditions (2) it follows that

$$u(0, t) = F(0)G(t) = 0 \qquad \text{and} \qquad u(L, t) = F(L)G(t) = 0.$$

Since $G \equiv 0$ would give $u \equiv 0$, we require $F(0) = 0$, $F(L) = 0$ and get $F(0) = A = 0$ by (7) and then $F(L) = B \sin pL = 0$, with $B \neq 0$ (to avoid $F \equiv 0$); thus,

$$\sin pL = 0, \qquad \text{hence} \qquad p = \frac{n\pi}{L}, \qquad n = 1, 2, \cdots.$$

Setting $B = 1$, we thus obtain the following solutions of (5) satisfying (2):

$$F_n(x) = \sin \frac{n\pi x}{L}, \qquad n = 1, 2, \cdots.$$

(As in Sec. 12.3, we need not consider *negative* integral values of n.)

All this was literally the same as in Sec. 12.3. From now on it differs since (6) differs from (6) in Sec. 12.3. We now solve (6). For $p = n\pi/L$, as just obtained, (6) becomes

$$\dot{G} + \lambda_n^2 G = 0 \qquad \text{where} \qquad \lambda_n = \frac{cn\pi}{L}.$$

It has the general solution

$$G_n(t) = B_n e^{-\lambda_n^2 t}, \qquad n = 1, 2, \cdots$$

where B_n is a constant. Hence the functions

$$u_n(x, t) = F_n(x)G_n(t) = B_n \sin \frac{n\pi x}{L} e^{-\lambda_n^2 t} \qquad (n = 1, 2, \cdots) \tag{8}$$

are solutions of the heat equation (1), satisfying (2). These are the **eigenfunctions** of the problem, corresponding to the **eigenvalues** $\lambda_n = cn\pi/L$.

Step 3. **Solution of the entire problem. Fourier series.** So far we have solutions (8) satisfying the boundary conditions (2). To obtain a solution that also satisfies the initial condition (3), we consider a series of these eigenfunctions,

$$u(x, t) = \sum_{n=1}^{\infty} u_n(x, t) = \sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{L} e^{-\lambda_n^2 t} \qquad \left(\lambda_n = \frac{cn\pi}{L}\right). \tag{9}$$

From this and (3) we have

$$u(x, 0) = \sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{L} = f(x).$$

Hence for (9) to satisfy (3), the B_n's must be the coefficients of the **Fourier sine series,** as given by (4) in Sec. 11.3; thus

(10)
$$B_n = \frac{2}{L} \int_0^L f(x) \sin \frac{n\pi x}{L} \, dx \qquad (n = 1, 2, \cdots).$$

The solution of our problem can be established, assuming that $f(x)$ is piecewise continuous (see Sec. 6.1) on the interval $0 \leqq x \leqq L$ and has one-sided derivatives (see Sec. 11.1) at all interior points of that interval; that is, under these assumptions the series (9) with coefficients (10) is the solution of our physical problem. A proof requires knowledge of uniform convergence and will be given at a later occasion (Probs. 19, 20 in Problem Set 15.5).

Because of the exponential factor, all the terms in (9) approach zero as t approaches infinity. The rate of decay increases with n.

EXAMPLE 1 **Sinusoidal Initial Temperature**

Find the temperature $u(x, t)$ in a laterally insulated copper bar 80 cm long if the initial temperature is $100 \sin (\pi x/80)$ °C and the ends are kept at 0°C. How long will it take for the maximum temperature in the bar to drop to 50°C? First guess, then calculate. *Physical data for copper:* density 8.92 gm/cm^3, specific heat 0.092 cal/(gm °C), thermal conductivity 0.95 cal/(cm sec °C).

Solution. The initial condition gives

$$u(x, 0) = \sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{80} = f(x) = 100 \sin \frac{\pi x}{80}.$$

Hence, by inspection or from (9) we get $B_1 = 100$, $B_2 = B_3 = \cdots = 0$. In (9) we need $\lambda_1^2 = c^2\pi^2/L^2$, where $c^2 = K/(\sigma\rho) = 0.95/(0.092 \cdot 8.92) = 1.158$ [cm^2/sec]. Hence we obtain

$$\lambda_1^2 = 1.158 \cdot 9.870/80^2 = 0.001785 \ [\text{sec}^{-1}].$$

The solution (9) is

$$u(x, t) = 100 \sin \frac{\pi x}{80} \, e^{-0.001785t}.$$

Also, $100e^{-0.001785t} = 50$ when $t = (\ln 0.5)/(-0.001785) = 388$ [sec] ≈ 6.5 [min]. Does your guess, or at least its order of magnitude, agree with this result? ■

EXAMPLE 2 **Speed of Decay**

Solve the problem in Example 1 when the initial temperature is $100 \sin (3\pi x/80)$ °C and the other data are as before.

Solution. In (9), instead of $n = 1$ we now have $n = 3$, and $\lambda_3^2 = 3^2\lambda_1^2 = 9 \cdot 0.001785 = 0.01607$, so that the solution now is

$$u(x, t) = 100 \sin \frac{3\pi x}{80} \, e^{-0.01607t}.$$

Hence the maximum temperature drops to 50°C in $t = (\ln 0.5)/(-0.01607) \approx 43$ [seconds], which is much faster (9 times as fast as in Example 1; why?).

Had we chosen a bigger n, the decay would have been still faster, and in a sum or series of such terms, each term has its own rate of decay, and terms with large n are practically 0 after a very short time. Our next example is of this type, and the curve in Fig. 292 corresponding to $t = 0.5$ looks almost like a sine curve; that is, it is practically the graph of the first term of the solution. ■

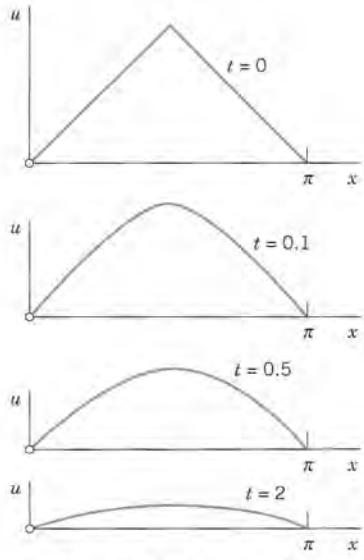

Fig. 292. Example 3. Decrease of temperature with time t for $L = \pi$ and $c = 1$

EXAMPLE 3 **"Triangular" Initial Temperature in a Bar**

Find the temperature in a laterally insulated bar of length L whose ends are kept at temperature 0, assuming that the initial temperature is

$$f(x) = \begin{cases} x & \text{if} \quad 0 < x < L/2, \\ L - x & \text{if} \quad L/2 < x < L. \end{cases}$$

(The uppermost part of Fig. 292 shows this function for the special $L = \pi$.)

Solution. From (10) we get

$$(10^*) \qquad B_n = \frac{2}{L}\left(\int_0^{L/2} x \sin\frac{n\pi x}{L}\,dx + \int_{L/2}^{L} (L - x)\sin\frac{n\pi x}{L}\,dx\right).$$

Integration gives $B_n = 0$ if n is even,

$$B_n = \frac{4L}{n^2\pi^2} \quad (n = 1, 5, 9, \cdots) \qquad \text{and} \qquad B_n = -\frac{4L}{n^2\pi^2} \quad (n = 3, 7, 11, \cdots).$$

(see also Example 4 in Sec. 11.3 with $k = L/2$). Hence the solution is

$$u(x, t) = \frac{4L}{\pi^2}\left[\sin\frac{\pi x}{L}\exp\left[-\left(\frac{c\pi}{L}\right)^2 t\right] - \frac{1}{9}\sin\frac{3\pi x}{L}\exp\left[-\left(\frac{3c\pi}{L}\right)^2 t\right] + - \cdots\right].$$

Figure 292 shows that the temperature decreases with increasing t, because of the heat loss due to the cooling of the ends.

Compare Fig. 292 and Fig. 288 in Sec. 12.3 and comment. ■

EXAMPLE 4 Bar with Insulated Ends. Eigenvalue 0

Find a solution formula of (1), (3) with (2) replaced by the condition that both ends of the bar are insulated.

Solution. Physical experiments show that the rate of heat flow is proportional to the gradient of the temperature. Hence if the ends $x = 0$ and $x = L$ of the bar are insulated, so that no heat can flow through the ends, we have grad $u = u_x = \partial u/\partial x$ and the boundary conditions

$$(2^*) \qquad u_x(0, t) = 0, \qquad u_x(L, t) = 0 \qquad \text{for all } t.$$

Since $u(x, t) = F(x)G(t)$, this gives $u_x(0, t) = F'(0)G(t) = 0$ and $u_x(L, t) = F'(L)G(t) = 0$. Differentiating (7), we have $F'(x) = -Ap \sin px + Bp \cos px$, so that

$$F'(0) = Bp = 0 \qquad \text{and then} \qquad F'(L) = -Ap \sin pL = 0.$$

The second of these conditions gives $p = p_n = n\pi/L$, $(n = 0, 1, 2, \cdots)$. From this and (7) with $A = 1$ and $B = 0$ we get $F_n(x) = \cos(n\pi x/L)$, $(n = 0, 1, 2, \cdots)$. With G_n as before, this yields the eigenfunctions

$$(11) \qquad u_n(x, t) = F_n(x)G_n(t) = A_n \cos \frac{n\pi x}{L} e^{-\lambda_n^2 t} \qquad (n = 0, 1, \cdots)$$

corresponding to the eigenvalues $\lambda_n = cn\pi/L$. The latter are as before, but we now have the additional eigenvalue $\lambda_0 = 0$ and eigenfunction $u_0 = const$, which is the solution of the problem if the initial temperature $f(x)$ is constant. This shows the remarkable fact that ***a separation constant can very well be zero, and zero can be an eigenvalue.***

Furthermore, whereas (8) gave a Fourier sine series, we now get from (11) a Fourier cosine series

$$\textbf{(12)} \qquad u(x, t) = \sum_{n=0}^{\infty} u_n(x, t) = \sum_{n=0}^{\infty} A_n \cos \frac{n\pi x}{L} e^{-\lambda_n^2 t} \qquad \left(\lambda_n = \frac{cn\pi}{L}\right).$$

Its coefficients result from the initial condition (3),

$$u(x, 0) = \sum_{n=0}^{\infty} A_n \cos \frac{n\pi x}{L} = f(x),$$

in the form (2), Sec. 11.3, that is,

$$(13) \qquad A_0 = \frac{1}{L} \int_0^L f(x)\, dx, \qquad A_n = \frac{2}{L} \int_0^L f(x) \cos \frac{n\pi x}{L}\, dx, \qquad n = 1, 2, \cdots.$$

■

EXAMPLE 5 "Triangular" Initial Temperature in a Bar with Insulated Ends

Find the temperature in the bar in Example 3, assuming that the ends are insulated (instead of being kept at temperature 0).

Solution. For the triangular initial temperature, (13) gives $A_0 = L/4$ and (see also Example 4 in Sec. 11.3 with $k = L/2$)

$$A_n = \frac{2}{L}\left[\int_0^{L/2} x \cos \frac{n\pi x}{L}\, dx + \int_{L/2}^{L} (L - x) \cos \frac{n\pi x}{L}\, dx\right] = \frac{2L}{n^2\pi^2}\left(2 \cos \frac{n\pi}{2} - \cos n\pi - 1\right).$$

Hence the solution (12) is

$$u(x, t) = \frac{L}{4} - \frac{8L}{\pi^2}\left\{\frac{1}{2^2} \cos \frac{2\pi x}{L} \exp\left[-\left(\frac{2c\pi}{L}\right)^2 t\right] + \frac{1}{6^2} \cos \frac{6\pi x}{L} \exp\left[-\left(\frac{6c\pi}{L}\right)^2 t\right] + \cdots\right\}.$$

We see that the terms decrease with increasing t, and $u \to L/4$ as $t \to \infty$; this is the mean value of the initial temperature. This is plausible because no heat can escape from this totally insulated bar. In contrast, the cooling of the ends in Example 3 led to heat loss and $u \to 0$, the temperature at which the ends were kept. ■

Steady Two-Dimensional Heat Problems. Laplace's Equation

We shall now extend our discussion from one to two space dimensions and consider the two-dimensional heat equation

$$\frac{\partial u}{\partial t} = c^2 \nabla^2 u = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$

for **steady** (that is, *time-independent*) problems. Then $\partial u/\partial t = 0$ and the heat equation reduces to **Laplace's equation**

$$\nabla^2 u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \tag{14}$$

(which has already occurred in Sec. 10.8 and will be considered further in Secs. 12.7–12.10). A heat problem then consists of this PDE to be considered in some region R of the xy-plane and a given boundary condition on the boundary curve C of R. This is a **boundary value problem (BVP).** One calls it:

First BVP or **Dirichlet Problem** if u is prescribed on C **("Dirichlet boundary condition")**

Second BVP or **Neumann Problem** if the normal derivative $u_n = \partial u/\partial n$ is prescribed on C **("Neumann boundary condition")**

Third BVP, Mixed BVP, or **Robin Problem** if u is prescribed on a portion of C and u_n on the rest of C **("Mixed boundary condition").**

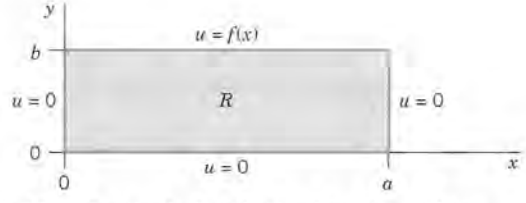

Fig. 293. Rectangle R and given boundary values

Dirichlet Problem in a Rectangle R (Fig. 293). We consider a Dirichlet problem for Laplace's equation (14) in a rectangle R, assuming that the temperature $u(x, y)$ equals a given function $f(x)$ on the upper side and 0 on the other three sides of the rectangle.

We solve this problem by separating variables. Substituting $u(x, y) = F(x)G(y)$ into (14) written as $u_{xx} = -u_{yy}$, dividing by FG, and equating both sides to a negative constant, we obtain

$$\frac{1}{F} \cdot \frac{d^2F}{dx^2} = -\frac{1}{G} \cdot \frac{d^2G}{dy^2} = -k.$$

From this we get

$$\frac{d^2F}{dx^2} + kF = 0,$$

and the left and right boundary conditions imply

$$F(0) = 0, \qquad \text{and} \qquad F(a) = 0.$$

This gives $k = (n\pi/a)^2$ and corresponding nonzero solutions

$$F(x) = F_n(x) = \sin \frac{n\pi}{a} x, \qquad n = 1, 2, \cdots. \tag{15}$$

The ODE for G with $k = (n\pi/a)^2$ then becomes

$$\frac{d^2G}{dy^2} - \left(\frac{n\pi}{a}\right)^2 G = 0.$$

Solutions are

$$G(y) = G_n(y) = A_n e^{n\pi y/a} + B_n e^{-n\pi y/a}.$$

Now the boundary condition $u = 0$ on the lower side of R implies that $G_n(0) = 0$; that is, $G_n(0) = A_n + B_n = 0$ or $B_n = -A_n$. This gives

$$G_n(y) = A_n(e^{n\pi y/a} - e^{-n\pi y/a}) = 2A_n \sinh \frac{n\pi y}{a}.$$

From this and (15), writing $2A_n = A_n^*$, we obtain as the **eigenfunctions** of our problem

$$u_n(x, y) = F_n(x)G_n(y) = A_n^* \sin \frac{n\pi x}{a} \sinh \frac{n\pi y}{a}. \tag{16}$$

These solutions satisfy the boundary condition $u = 0$ on the left, right, and lower sides.

To get a solution also satisfying the boundary condition $u(x, b) = f(x)$ on the upper side, we consider the infinite series

$$u(x, y) = \sum_{n=1}^{\infty} u_n(x, y).$$

From this and (16) with $y = b$ we obtain

$$u(x, b) = f(x) = \sum_{n=1}^{\infty} A_n^* \sin \frac{n\pi x}{a} \sinh \frac{n\pi b}{a}.$$

We can write this in the form

$$u(x, b) = \sum_{n=1}^{\infty} \left(A_n^* \sinh \frac{n\pi b}{a}\right) \sin \frac{n\pi x}{a}$$

This shows that the expressions in the parentheses must be the Fourier coefficients b_n of $f(x)$; that is, by (4) in Sec. 11.3,

$$b_n = A_n^* \sinh \frac{n\pi b}{a} = \frac{2}{a} \int_0^a f(x) \sin \frac{n\pi x}{a}\, dx.$$

From this and (16) we see that the solution of our problem is

$$\textbf{(17)} \qquad u(x, y) = \sum_{n=1}^{\infty} u_n(x, y) = \sum_{n=1}^{\infty} A_n^* \sin \frac{n\pi x}{a} \sinh \frac{n\pi y}{a}$$

where

$$\textbf{(18)} \qquad A_n^* = \frac{2}{a \sinh (n\pi b/a)} \int_0^a f(x) \sin \frac{n\pi x}{a}\, dx.$$

We have obtained this solution formally, neither considering convergence nor showing that the series for u, u_{xx}, and u_{yy} have the right sums. This can be proved if one assumes that f and f' are continuous and f'' is piecewise continuous on the interval $0 \leqq x \leqq a$. The proof is somewhat involved and relies on uniform convergence. It can be found in [C4] listed in App. 1.

Unifying Power of Methods. Electrostatics, Elasticity

The Laplace equation (14) also governs the electrostatic potential of electrical charges in any region that is free of these charges. Thus our steady-state heat problem can also be interpreted as an electrostatic potential problem. Then (17), (18) is the potential in the rectangle R when the upper side of R is at potential $f(x)$ and the other three sides are grounded.

Actually, in the steady-state case, the two-dimensional wave equation (to be considered in Secs. 12.7, 12.8) also reduces to (14). Then (17), (18) is the displacement of a rectangular elastic membrane (rubber sheet, drumhead) that is fixed along its boundary, with three sides lying in the xy-plane and the fourth side given the displacement $f(x)$.

This is another impressive demonstration of the ***unifying power*** of mathematics. It illustrates that ***entirely different physical systems may have the same mathematical model*** and can thus be treated by the same mathematical methods.

PROBLEM SET 12.5

1. **WRITING PROJECT. Wave and Heat Equations.** Compare the two PDEs with respect to type, general behavior of eigenfunctions, and kind of boundary and initial conditions and resulting practical problems. Also discuss the difference between Figs. 288 in Sec. 12.3 and 292.

2. **(Eigenfunctions)** Sketch (or graph) and compare the first three eigenfunctions (8) with $B_n = 1$, $c = 1$, $L = \pi$ for $t = 0, 0.2, 0.4, 0.6, 0.8, 1.0$.

3. **(Decay)** How does the rate of decay of (8) with fixed n depend on the specific heat, the density, and the thermal conductivity of the material?

4. If the first eigenfunction (8) of the bar decreases to half its value within 10 sec, what is the value of the diffusivity?

5–9 LATERALLY INSULATED BAR

A laterally insulated bar of length 10 cm and constant cross-sectional area 1 cm^2, of density 10.6 gm/cm^3, thermal conductivity 1.04 cal/(cm sec °C), and specific heat 0.056 cal/(gm °C) (this corresponds to silver, a good heat conductor) has initial temperature $f(x)$ and is kept at 0°C at the ends $x = 0$ and $x = 10$. Find the temperature $u(x, t)$ at later times. Here, $f(x)$ equals:

5. $f(x) = \sin 0.4\pi x$
6. $f(x) = \sin 0.1\pi x + \frac{1}{2} \sin 0.2\pi x$
7. $f(x) = 0.2x$ if $0 < x < 5$ and 0 otherwise
8. $f(x) = 1 - 0.2|x - 5|$
9. $f(x) = x$ if $0 < x < 2.5$, $f(x) = 2.5$ if $2.5 < x < 7.5$, $f(x) = 10 - x$ if $7.5 < x < 10$

10. **(Arbitrary temperatures at ends)** If the ends $x = 0$ and $x = L$ of the bar in the text are kept at constant temperatures U_1 and U_2, respectively, what is the temperature $u_1(x)$ in the bar after a long time (theoretically, as $t \to \infty$)? First guess, then calculate.
11. In Prob. 10 find the temperature at any time.
12. **(Changing end temperatures)** Assume that the ends of the bar in Probs. 5–9 have been kept at 100°C for a long time. Then at some instant, call it $t = 0$, the temperature at $x = L$ is suddenly changed to 0°C and kept at 0°C, whereas the temperature at $x = 0$ is kept at 100°C. Find the temperature in the middle of the bar at $t = 1, 2, 3, 10, 50$ sec. First guess, then calculate.

BAR UNDER ADIABATIC CONDITIONS

"Adiabatic" means no heat exchange with the neighborhood, because the bar is completely insulated, also at the ends. *Physical Information:* The heat flux at the ends is proportional to the value of $\partial u/\partial x$ there.

13. Show that for the completely insulated bar, $u_x(0, t) = 0$, $u_x(L, t) = 0$, $u(x, t) = f(x)$ and separation of variables gives the following solution, with A_n given by (2) in Sec. 11.3.

$$u(x, t) = A_0 + \sum_{n=1}^{\infty} A_n \cos \frac{n\pi x}{L} e^{-(cn\pi/L)^2 t}$$

14–19 Find the temperature in Prob. 13 with $L = \pi$, $c = 1$, and

14. $f(x) = x$
15. $f(x) = 1$
16. $f(x) = 0.5 \cos 4x$
17. $f(x) = \pi^2 - x^2$
18. $f(x) = \frac{1}{2}\pi - |x - \frac{1}{2}\pi|$
19. $f(x) = (x - \frac{1}{2}\pi)^2$

20. Find the temperature of the bar in Prob. 13 if the left end is kept at 0°C, the right end is insulated, and the initial temperature is $U_0 = const$.

21. The **boundary condition of heat transfer**

$$(19) \qquad -u_x(\pi, t) = k[u(\pi, t) - u_0]$$

applies when a bar of length π with $c = 1$ is laterally insulated, the left end $x = 0$ is kept at 0°C, and at the right end heat is flowing into air of constant temperature u_0. Let $k = 1$ for simplicity, and $u_0 = 0$. Show that a solution is $u(x, t) = \sin px\, e^{-p^2 t}$, where p is a solution of $\tan p\pi = -p$. Show graphically that this equation has infinitely many positive solutions $p_1, p_2, p_3, \cdots$, where $p_n > n - \frac{1}{2}$ and $\lim_{n\to\infty} (p_n - n + \frac{1}{2}) = 0$. (Formula (19) is also known as **radiation boundary condition,** but this is misleading; see Ref. [C3], p. 19.)

22. **(Discontinuous f)** Solve (1), (2), (3) with $L = \pi$ and $f(x) = U_0 = const$ $(\neq 0)$ if $0 < x < \pi/2$, $f(x) = 0$ if $\pi/2 < x < \pi$.
23. **(Heat flux)** The *heat flux* of a solution $u(x, t)$ across $x = 0$ is defined by $\phi(t) = -Ku_x(0, t)$. Find $\phi(t)$ for the solution (9). Explain the name. Is it physically understandable that ϕ goes to 0 as $t \to \infty$?

OTHER HEAT EQUATIONS

24. **(Bar with heat generation)** If heat is generated at a constant rate throughout a bar of length $L = \pi$ with initial temperature $f(x)$ and the ends at $x = 0$ and π are kept at temperature 0, the heat equation is $u_t = c^2 u_{xx} + H$ with constant $H > 0$. Solve this problem. *Hint.* Set $u = v - Hx(x - \pi)/(2c^2)$.
25. **(Convection)** If heat in the bar in the text is free to flow through an end into the surrounding medium kept at 0°C, the PDE becomes $v_t = c^2 v_{xx} - \beta v$. Show that it can be reduced to the form (1) by setting $v(x, t) = u(x, t)w(t)$.
26. Consider $v_t = c^2 v_{xx} - v$ $(0 < x < L, t > 0)$, $v(0, t) = 0$, $v(L, t) = 0$, $v(x, 0) = f(x)$, where the term $-v$ models heat transfer to the surrounding medium kept at temperature 0. Reduce this PDE by setting $v(x, t) = u(x, t)w(t)$ with w such that u is given by (9), (10).
27. **(Nonhomogeneous heat equation)** Show that the problem modeled by

$$u_t - c^2 u_{xx} = Ne^{-\alpha x}$$

and (2), (3) can be reduced to a problem for the homogeneous heat equation by setting

$$u(x, t) = v(x, t) + w(x)$$

and determining w so that v satisfies the homogeneous PDE and the conditions $v(0, t) = v(L, t) = 0$, $v(x, 0) = f(x) - w(x)$. (The term $Ne^{-\alpha x}$ may represent heat loss due to radioactive decay in the bar.)

28–35 TWO-DIMENSIONAL PROBLEMS

28. (Laplace equation) Find the potential in the rectangle $0 \leqq x \leqq 20$, $0 \leqq y \leqq 40$ whose upper side is kept at potential 220 V and whose other sides are grounded.

29. Find the potential in the square $0 \leqq x \leqq 2$, $0 \leqq y \leqq 2$ if the upper side is kept at the potential $\sin \frac{1}{2}\pi x$ and the other sides are grounded.

30. CAS PROJECT. Isotherms. Find the steady-state solutions (temperatures) in the square plate in Fig. 294 with $a = 2$ satisfying the following boundary conditions. Graph isotherms.

(a) $u = \sin \pi x$ on the upper side, 0 on the others.

(b) $u = 0$ on the vertical sides, assuming that the other sides are perfectly insulated.

(c) Boundary conditions of your choice (such that the solution is not identically zero).

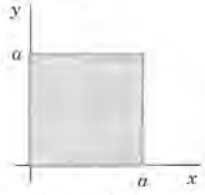

Fig. 294. Square plate

31. (Heat flow in a plate) The faces of the thin square plate in Fig. 294 with side $a = 24$ are perfectly insulated. The upper side is kept at 20°C and the other sides are kept at 0°C. Find the steady-state temperature $u(x, y)$ in the plate.

32. Find the steady-state temperature in the plate in Prob. 31 if the lower side is kept at U_0°C, the upper side at U_1°C, and the other sides are kept at 0°C. *Hint:* Split into two problems in which the boundary temperature is 0 on three sides for each problem.

33. (Mixed boundary value problem) Find the steady-state temperature in the plate in Prob. 31 with the upper and lower sides perfectly insulated, the left side kept at 0°C, and the right side kept at $f(y)$°C.

34. (Radiation) Find steady-state temperatures in the rectangle in Fig. 293 with the upper and left sides perfectly insulated and the right side radiating into a medium at 0°C according to $u_x(a, y) + hu(a, y) = 0$, $h > 0$ constant. (You will get many solutions since no condition on the lower side is given.)

35. Find formulas similar to (17), (18) for the temperature in the rectangle R of the text when the lower side of R is kept at temperature $f(x)$ and the other sides are kept at 0°C.

12.6 Heat Equation: Solution by Fourier Integrals and Transforms

Our discussion of the heat equation

$$\textbf{(1)} \qquad \frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$$

in the last section extends to bars of infinite length, which are good models of very long bars or wires (such as a wire of length, say, 300 ft). Then the role of Fourier series in the solution process will be taken by **Fourier integrals** (Sec. 11.7).

Let us illustrate the method by solving (1) for a bar that extends to infinity on both sides (and is laterally insulated as before). Then we do not have boundary conditions, but only the **initial condition**

$$(2) \qquad u(x, 0) = f(x) \qquad (-\infty < x < \infty)$$

where $f(x)$ is the given initial temperature of the bar.

To solve this problem, we start as in the last section, substituting $u(x, t) = F(x)G(t)$ into (1). This gives the two ODEs

$$(3) \qquad F'' + p^2 F = 0 \qquad \text{[see (5), Sec. 12.5]}$$

and

$$\dot{G} + c^2p^2G = 0 \qquad \text{[see (6), Sec. 12.5].} \tag{4}$$

Solutions are

$$F(x) = A\cos px + B\sin px \qquad \text{and} \qquad G(t) = e^{-c^2p^2t},$$

respectively, where A and B are any constants. Hence a solution of (1) is

$$u(x, t; p) = FG = (A\cos px + B\sin px)e^{-c^2p^2t}. \tag{5}$$

Here we had to choose the separation constant k negative, $k = -p^2$, because positive values of k would lead to an increasing exponential function in (5), which has no physical meaning.

Use of Fourier Integrals

Any series of functions (5), found in the usual manner by taking p as multiples of a fixed number, would lead to a function that is periodic in x when $t = 0$. However, since $f(x)$ in (2) is not assumed to be periodic, it is natural to use **Fourier integrals** instead of Fourier series. Also, A and B in (5) are arbitrary and we may regard them as functions of p, writing $A = A(p)$ and $B = B(p)$. Now, since the heat equation (1) is linear and homogeneous, the function

$$\textbf{(6)} \qquad u(x, t) = \int_0^\infty u(x, t; p)\,dp = \int_0^\infty [A(p)\cos px + B(p)\sin px]\,e^{-c^2p^2t}\,dp$$

is then a solution of (1), provided this integral exists and can be differentiated twice with respect to x and once with respect to t.

Determination of $A(p)$ and $B(p)$ from the Initial Condition. From (6) and (2) we get

$$u(x, 0) = \int_0^\infty [A(p)\cos px + B(p)\sin px]\,dp = f(x). \tag{7}$$

This gives $A(p)$ and $B(p)$ in terms of $f(x)$; indeed, from (4) in Sec. 11.7 we have

$$\textbf{(8)} \qquad A(p) = \frac{1}{\pi}\int_{-\infty}^{\infty} f(v)\cos pv\,dv, \qquad B(p) = \frac{1}{\pi}\int_{-\infty}^{\infty} f(v)\sin pv\,dv.$$

According to (1*), Sec. 11.9, our Fourier integral (7) with these $A(p)$ and $B(p)$ can be written

$$u(x, 0) = \frac{1}{\pi}\int_0^\infty \left[\int_{-\infty}^{\infty} f(v)\cos(px - pv)\,dv\right] dp.$$

Similarly, (6) in this section becomes

$$u(x, t) = \frac{1}{\pi}\int_0^\infty \left[\int_{-\infty}^{\infty} f(v)\cos(px - pv)\,e^{-c^2p^2t}\,dv\right] dp.$$

Assuming that we may reverse the order of integration, we obtain

$$\textbf{(9)} \qquad u(x, t) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(v) \left[\int_0^{\infty} e^{-c^2p^2t} \cos(px - pv)\, dp \right] dv.$$

Then we can evaluate the inner integral by using the formula

$$(10) \qquad \int_0^{\infty} e^{-s^2} \cos 2bs\, ds = \frac{\sqrt{\pi}}{2} e^{-b^2}.$$

[A derivation of (10) is given in Problem Set 16.4 (Team Project 28).] This takes the form of our inner integral if we choose $p = s/(c\sqrt{t})$ as a new variable of integration and set

$$b = \frac{x - v}{2c\sqrt{t}}.$$

Then $2bs = (x - v)p$ and $ds = c\sqrt{t}\, dp$, so that (10) becomes

$$\int_0^{\infty} e^{-c^2p^2t} \cos(px - pv)\, dp = \frac{\sqrt{\pi}}{2c\sqrt{t}} \exp\left\{ -\frac{(x - v)^2}{4c^2t} \right\}.$$

By inserting this result into (9) we obtain the representation

$$\textbf{(11)} \qquad u(x, t) = \frac{1}{2c\sqrt{\pi t}} \int_{-\infty}^{\infty} f(v) \exp\left\{ -\frac{(x - v)^2}{4c^2t} \right\} dv.$$

Taking $z = (v - x)/(2c\sqrt{t})$ as a variable of integration, we get the alternative form

$$\textbf{(12)} \qquad u(x, t) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} f(x + 2cz\sqrt{t})\, e^{-z^2}\, dz.$$

If $f(x)$ is bounded for all values of x and integrable in every finite interval, it can be shown (see Ref. [C10]) that the function (11) or (12) satisfies (1) and (2). Hence this function is the required solution in the present case.

EXAMPLE 1 **Temperature in an Infinite Bar**

Find the temperature in the infinite bar if the initial temperature is (Fig. 295)

$$f(x) = \begin{cases} U_0 = const & \text{if } |x| < 1, \\ 0 & \text{if } |x| > 1. \end{cases}$$

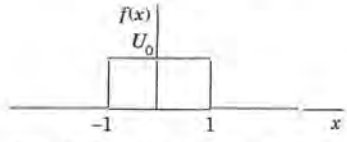

Fig. 295. Initial temperature in Example 1

Solution. From (11) we have

$$u(x, t) = \frac{U_0}{2c\sqrt{\pi t}} \int_{-1}^{1} \exp\left\{-\frac{(x - v)^2}{4c^2 t}\right\} dv.$$

If we introduce the above variable of integration z, then the integration over v from -1 to 1 corresponds to the integration over z from $(-1 - x)/(2c\sqrt{t})$ to $(1 - x)/(2c\sqrt{t})$, and

$$u(x, t) = \frac{U_0}{\sqrt{\pi}} \int_{-(1+x)/(2c\sqrt{t})}^{(1-x)/(2c\sqrt{t})} e^{-z^2} dz \qquad (t > 0). \tag{13}$$

We mention that this integral is not an elementary function, but can be expressed in terms of the error function, whose values have been tabulated. (Table A4 in App. 5 contains a few values; larger tables are listed in Ref. [GR1] in App. 1. See also CAS Project 10, p. 568.) Figure 296 shows $u(x, t)$ for $U_0 = 100°C$, $c^2 = 1\ \text{cm}^2/\text{sec}$, and several values of t. ■

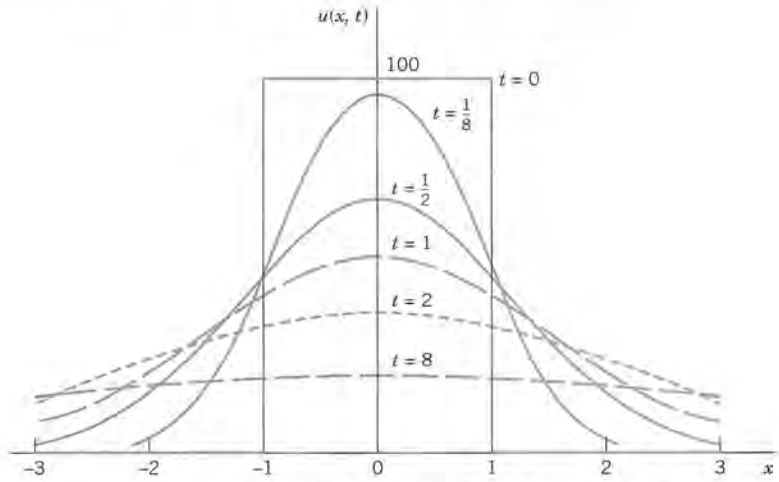

Fig. 296. Solution $u(x, t)$ in Example 1 for $U_0 = 100°C$, $c^2 = 1\ \text{cm}^2/\text{sec}$, and several values of t

Use of Fourier Transforms

The Fourier transform is closely related to the Fourier integral, from which we obtained the transform in Sec. 11.9. And the transition to the Fourier cosine and sine transform in Sec. 11.8 was even simpler. (You may perhaps wish to review this before going on.) Hence it should not surprise you that we can use these transforms for solving our present or similar problems. The Fourier transform applies to problems concerning the entire axis, and the Fourier cosine and sine transforms to problems involving the positive half-axis. Let us explain these transform methods by typical applications that fit our present discussion.

EXAMPLE 2 **Temperature in the Infinite Bar in Example 1**

Solve Example 1 using the Fourier transform.

Solution. The problem consists of the heat equation (1) and the initial condition (2), which in this example is

$$f(x) = U_0 = const \quad \text{if } |x| < 1 \qquad \text{and 0 otherwise.}$$

Our strategy is to take the Fourier transform with respect to x and then to solve the resulting ***ordinary*** DE in t. The details are as follows.

Let $\hat{u} = \mathcal{F}(u)$ denote the Fourier transform of u, ***regarded as a function of x.*** From (10) in Sec. 11.9 we see that the heat equation (1) gives

$$\mathcal{F}(u_t) = c^2\mathcal{F}(u_{xx}) = c^2(-w^2)\mathcal{F}(u) = -c^2w^2\hat{u}.$$

On the left, assuming that we may interchange the order of differentiation and integration, we have

$$\mathcal{F}(u_t) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} u_t e^{-iwx}\,dx = \frac{1}{\sqrt{2\pi}}\frac{\partial}{\partial t}\int_{-\infty}^{\infty} u e^{-iwx}\,dx = \frac{\partial \hat{u}}{\partial t}.$$

Thus

$$\frac{\partial \hat{u}}{\partial t} = -c^2w^2\hat{u}.$$

Since this equation involves only a derivative with respect to t but none with respect to w, this is a first-order ***ordinary DE,*** with t as the independent variable and w as a parameter. By separating variables (Sec. 1.3) we get the general solution

$$\hat{u}(w, t) = C(w)e^{-c^2w^2t}$$

with the arbitrary "constant" $C(w)$ depending on the parameter w. The initial condition (2) yields the relationship $\hat{u}(w, 0) = C(w) = \hat{f}(w) = \mathcal{F}(f)$. Our intermediate result is

$$\hat{u}(w, t) = \hat{f}(w)e^{-c^2w^2t}.$$

The inversion formula (7), Sec. 11.9, now gives the solution

$$u(x, t) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \hat{f}(w)e^{-c^2w^2t}e^{iwx}\,dw. \tag{14}$$

In this solution we may insert the Fourier transform

$$\hat{f}(w) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} f(v)e^{-ivw}\,dv.$$

Assuming that we may invert the order of integration, we then obtain

$$u(x, t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} f(v)\left[\int_{-\infty}^{\infty} e^{-c^2w^2t}e^{i(wx-wv)}\,dw\right]dv.$$

By the Euler formula (3), Sec. 11.9, the integrand of the inner integral equals

$$e^{-c^2w^2t}\cos(wx - wv) + ie^{-c^2w^2t}\sin(wx - wv).$$

We see that its imaginary part is an odd function of w, so that its integral is 0. (More precisely, this is the principal part of the integral; see Sec. 16.4.) The real part is an even function of w, so that its integral from $-\infty$ to ∞ equals twice the integral from 0 to ∞:

$$u(x, t) = \frac{1}{\pi}\int_{-\infty}^{\infty} f(v)\left[\int_{0}^{\infty} e^{-c^2w^2t}\cos(wx - wv)\,dw\right]dv.$$

This agrees with (9) (with $p = w$) and leads to the further formulas (11) and (13). ■

EXAMPLE 3 Solution in Example 1 by the Method of Convolution

Solve the heat problem in Example 1 by the method of convolution.

Solution. The beginning is as in Example 2 and leads to (14), that is,

$$u(x, t) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \hat{f}(w)e^{-c^2w^2t}e^{iwx}\,dw. \tag{15}$$

Now comes the crucial idea. We recognize that this is of the form (13) in Sec. 11.9, that is,

$$u(x, t) = (f * g)(x) = \int_{-\infty}^{\infty} \hat{f}(w)\hat{g}(w)e^{iwx}\, dw \tag{16}$$

where

$$\hat{g}(w) = \frac{1}{\sqrt{2\pi}}\, e^{-c^2w^2t}. \tag{17}$$

Since, by the definition of convolution [(11), Sec. 11.9],

$$(f * g)(x) = \int_{-\infty}^{\infty} f(p)g(x - p)\, dp, \tag{18}$$

as our next and last step we must determine the inverse Fourier transform g of $\hat{g}$. For this we can use formula 9 in Table III of Sec. 11.10,

$$\mathcal{F}(e^{-ax^2}) = \frac{1}{\sqrt{2a}}\, e^{-w^2/(4a)}$$

with a suitable a. With $c^2t = 1/(4a)$ or $a = 1/(4c^2t)$, using (17) we obtain

$$\mathcal{F}(e^{-x^2/(4c^2t)}) = \sqrt{2c^2t}\, e^{-c^2w^2t} = \sqrt{2c^2t}\,\sqrt{2\pi}\,\hat{g}(w).$$

Hence $\hat{g}$ has the inverse

$$\frac{1}{\sqrt{2c^2t}\,\sqrt{2\pi}}\, e^{-x^2/(4c^2t)}.$$

Replacing x with $x - p$ and substituting this into (18) we finally have

$$u(x, t) = (f * g)(x) = \frac{1}{2c\sqrt{\pi t}} \int_{-\infty}^{\infty} f(p) \exp\left\{-\frac{(x - p)^2}{4c^2t}\right\} dp. \tag{19}$$

This solution formula of our problem agrees with (11). We wrote $(f * g)(x)$, without indicating the parameter t with respect to which we did not integrate. ■

EXAMPLE 4 Fourier Sine Transform Applied to the Heat Equation

If a laterally insulated bar extends from $x = 0$ to infinity, we can use the Fourier sine transform. We let the initial temperature be $u(x, 0) = f(x)$ and impose the boundary condition $u(0, t) = 0$. Then from the heat equation and (9b) in Sec. 11.8, since $f(0) = u(0, 0) = 0$, we obtain

$$\mathcal{F}_s(u_t) = \frac{\partial \hat{u}_s}{\partial t} = c^2\mathcal{F}_s(u_{xx}) = -c^2w^2\mathcal{F}_s(u) = -c^2w^2\hat{u}_s(w, t).$$

This is a first-order ODE $\partial\hat{u}_s/\partial t + c^2w^2\hat{u}_s = 0$. Its solution is

$$\hat{u}_s(w, t) = C(w)e^{-c^2w^2t}.$$

From the initial condition $u(x, 0) = f(x)$ we have $\hat{u}_s(w, 0) = \hat{f}_s(w) = C(w)$. Hence

$$\hat{u}_s(w, t) = \hat{f}_s(w)e^{-c^2w^2t}.$$

Taking the inverse Fourier sine transform and substituting

$$\hat{f}_s(w) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(p) \sin wp\, dp$$

on the right, we obtain the solution formula

$$u(x, t) = \frac{2}{\pi} \int_0^\infty \int_0^\infty f(p) \sin wp \, e^{-c^2 w^2 t} \sin wx \, dp \, dw. \tag{20}$$

Figure 297 shows (20) with $c = 1$ for $f(x) = 1$ if $0 \leqq x \leqq 1$ and 0 otherwise, graphed over the xt-plane for $0 \leqq x \leqq 2$, $0.01 \leqq t \leqq 1.5$. Note that the curves of $u(x, t)$ for constant t resemble those in Fig. 296 on p. 565. ■

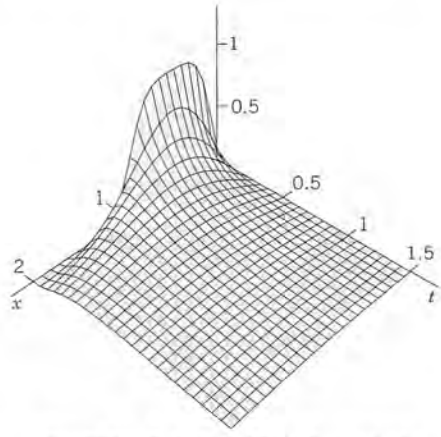

Fig. 297. Solution (20) in Example 4

PROBLEM SET 12.6

1–7 SOLUTION IN INTEGRAL FORM

Using (6), obtain the solution of (1) in integral form satisfying the initial condition $u(x, 0) = f(x)$, where

1. $f(x) = 1$ if $|x| < a$ and 0 otherwise
2. $f(x) = e^{-k|x|}$ $(k > 0)$
3. $f(x) = 1/(1 + x^2)$. [Use (15) in Sec. 11.7.]
4. $f(x) = (\sin x)/x$. [Use Prob. 4 in Sec. 11.7.]
5. $f(x) = (\sin \pi x)/x$. [Use Prob. 4 in Sec. 11.7.]
6. $f(x) = x$ if $|x| < 1$ and 0 otherwise
7. $f(x) = |x|$ if $|x| < 1$ and 0 otherwise.

8. Verify that u in Prob. 5 satisfies the initial condition.
9. **CAS PROJECT. Heat Flow.** **(a)** Graph the basic Fig. 296.

   (b) In (a) apply animation to "see" the heat flow in terms of the decrease of temperature.

   (c) Graph $u(x, t)$ with $c = 1$ as a surface over the upper xt-half-plane.
10. **CAS PROJECT. Error Function**

$$\text{erf } x = \frac{2}{\sqrt{\pi}} \int_0^x e^{-w^2} \, dw \tag{21}$$

This function is important in applied mathematics and physics (probability theory and statistics, thermodynamics, etc.) and fits our present discussion. Regarding it as a typical case of a special function defined by an integral that cannot be evaluated as in elementary calculus, do the following.

(a) Sketch or graph the **bell-shaped curve** [the curve of the integrand in (21)]. Show that erf x is odd. Show that

$$\int_a^b e^{-w^2} \, dw = \frac{\sqrt{\pi}}{2} (\text{erf } b - \text{erf } a),$$

$$\int_{-b}^b e^{-w^2} \, dw = \sqrt{\pi} \, \text{erf } b.$$

(b) Obtain the Maclaurin series of erf x from that of the integrand. Use that series to compute a table of erf x for $x = 0(0.01)3$ (meaning $x = 0, 0.01, 0.02, \cdots, 3$).

(c) Obtain the values required in (b) by an integration command of your CAS. Compare accuracy.

(d) It can be shown that erf $(\infty) = 1$. Confirm this experimentally by computing erf x for large x.

(e) Let $f(x) = 1$ when $x > 0$ and 0 when $x < 0$. Using $\operatorname{erf}(\infty) = 1$, show that (12) then gives

$$u(x, t) = \frac{1}{\sqrt{\pi}} \int_{-x/(2c\sqrt{t})}^{\infty} e^{-z^2}\, dz = \frac{1}{2} - \frac{1}{2} \operatorname{erf}\left(-\frac{x}{2c\sqrt{t}}\right) \qquad (t > 0).$$

(f) Express the temperature (13) in terms of the error function.

(g) Show that $\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-s^2/2}\, ds = \frac{1}{2} + \frac{1}{2} \operatorname{erf}\left(\frac{x}{\sqrt{2}}\right)$.

Here, the integral is the definition of the "distribution function of the normal distribution" to be discussed in Sec. 24.8.

12.7 Modeling: Membrane, Two-Dimensional Wave Equation

The vibrating string in Sec. 12.2 is a basic one-dimensional vibrational problem. Equally important is its two-dimensional analog, namely, the motion of an elastic membrane, such as a drumhead, that is stretched and then fixed along its edge. Indeed, setting up the model will proceed almost as in Sec. 12.2.

Physical Assumptions

1. The mass of the membrane per unit area is constant ("homogeneous membrane"). The membrane is perfectly flexible and offers no resistance to bending.
2. The membrane is stretched and then fixed along its entire boundary in the xy-plane. The tension per unit length T caused by stretching the membrane is the same at all points and in all directions and does not change during the motion.
3. The deflection $u(x, y, t)$ of the membrane during the motion is small compared to the size of the membrane, and all angles of inclination are small.

Although these assumptions cannot be realized exactly, they hold relatively accurately for small transverse vibrations of a thin elastic membrane, so that we shall obtain a good model, for instance, of a drumhead.

Derivation of the PDE of the Model ("Two-Dimensional Wave Equation") from Forces. As in Sec. 12.2 the model will consist of a PDE and additional conditions. The PDE will be obtained by the same method as in Sec. 12.2, namely, by considering the forces acting on a small portion of the physical system, the membrane in Fig. 298 on the next page, as it is moving up and down.

Since the deflections of the membrane and the angles of inclination are small, the sides of the portion are approximately equal to Δx and Δy. The tension T is the force per unit length. Hence the forces acting on the sides of the portion are approximately $T\,\Delta x$ and $T\,\Delta y$. Since the membrane is perfectly flexible, these forces are tangent to the moving membrane at every instant.

Horizontal Components of the Forces. We first consider the horizontal components of the forces. These components are obtained by multiplying the forces by the cosines of the angles of inclination. Since these angles are small, their cosines are close to 1. Hence

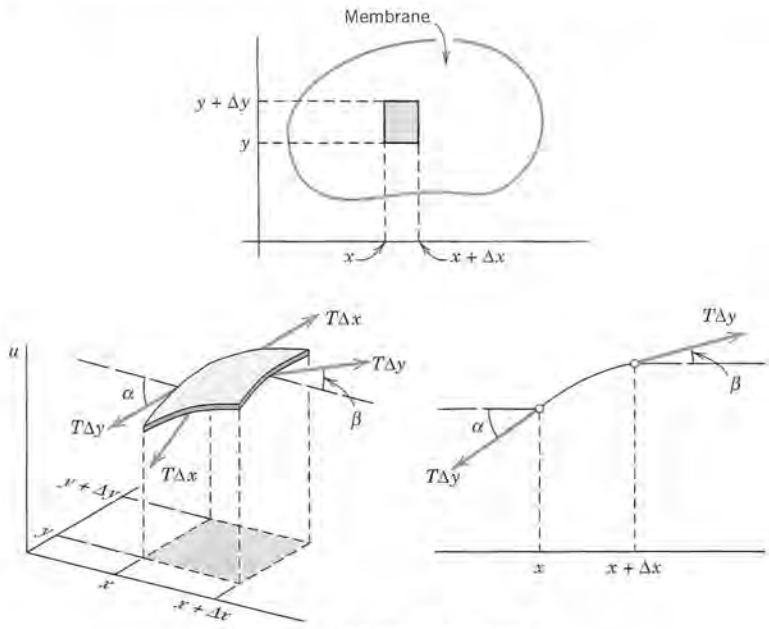

Fig. 298. Vibrating membrane

the horizontal components of the forces at opposite sides are approximately equal. Therefore, the motion of the particles of the membrane in a horizontal direction will be negligibly small. From this we conclude that we may regard the motion of the membrane as transversal; that is, each particle moves vertically.

Vertical Components of the Forces. These components along the right side and the left side are (Fig. 298), respectively,

$$T\,\Delta y \sin \beta \qquad \text{and} \qquad -T\,\Delta y \sin \alpha.$$

Here α and β are the values of the angle of inclination (which varies slightly along the edges) in the middle of the edges, and the minus sign appears because the force on the left side is directed downward. Since the angles are small, we may replace their sines by their tangents. Hence the resultant of those two vertical components is

$$\begin{aligned} T\,\Delta y\,(\sin \beta - \sin \alpha) &\approx T\,\Delta y\,(\tan \beta - \tan \alpha) \\ &= T\,\Delta y\,[u_x(x + \Delta x, y_1) - u_x(x, y_2)] \end{aligned} \tag{1}$$

where subscripts x denote partial derivatives and y_1 and y_2 are values between y and $y + \Delta y$. Similarly, the resultant of the vertical components of the forces acting on the other two sides of the portion is

$$T\,\Delta x\,[u_y(x_1, y + \Delta y) - u_y(x_2, y)] \tag{2}$$

where x_1 and x_2 are values between x and $x + \Delta x$.

Newton's Second Law Gives the PDE of the Model. By Newton's second law (see Sec. 2.4) the sum of the forces given by (1) and (2) is equal to the mass $\rho \Delta A$ of that small

portion times the acceleration $\partial^2 u/\partial t^2$; here ρ is the mass of the undeflected membrane per unit area, and $\Delta A = \Delta x\, \Delta y$ is the area of that portion when it is undeflected. Thus

$$\rho\, \Delta x\, \Delta y\, \frac{\partial^2 u}{\partial t^2} = T\, \Delta y\, [u_x(x + \Delta x, y_1) - u_x(x, y_2)] + T\, \Delta x\, [u_y(x_1, y + \Delta y) - u_y(x_2, y)]$$

where the derivative on the left is evaluated at some suitable point $(\tilde{x}, \tilde{y})$ corresponding to that portion. Division by $\rho\, \Delta x\, \Delta y$ gives

$$\frac{\partial^2 u}{\partial t^2} = \frac{T}{\rho} \left[\frac{u_x(x + \Delta x, y_1) - u_x(x, y_2)}{\Delta x} + \frac{u_y(x_1, y + \Delta y) - u_y(x_2, y)}{\Delta y} \right].$$

If we let Δx and Δy approach zero, we obtain the PDE of the model

$$\textbf{(3)} \qquad \frac{\partial^2 u}{\partial t^2} = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) \qquad c^2 = \frac{T}{\rho}.$$

This PDE is called the **two-dimensional wave equation.** The expression in parentheses is the Laplacian $\nabla^2 u$ of u (Sec. 10.8). Hence (3) can be written

$$\textbf{(3')} \qquad \frac{\partial^2 u}{\partial t^2} = c^2 \nabla^2 u.$$

Solutions of the wave equation (3) will be obtained and discussed in the next section.

12.8 Rectangular Membrane. Double Fourier Series

The model of the vibrating membrane for obtaining the displacement $u(x, y, t)$ of a point (x, y) of the membrane from rest ($u = 0$) at time t is

$$\textbf{(1)} \qquad \frac{\partial^2 u}{\partial t^2} = c^2 \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$

$$\textbf{(2)} \qquad u = 0 \text{ on the boundary}$$

$$\textbf{(3a)} \qquad u(x, y, 0) = f(x, y)$$

$$\textbf{(3b)} \qquad u_t(x, y, 0) = g(x, y).$$

Here (1) is the **two-dimensional wave equation** with $c^2 = T/\rho$ just derived, (2) is the **boundary condition** (membrane fixed along the boundary in the xy-plane for all times $t \geqq 0$), and (3) are the **initial conditions** at $t = 0$, consisting of the given *initial displacement* (initial shape) $f(x, y)$ and the given *initial velocity* $g(x, y)$, where $u_t = \partial u/\partial t$. We see that these conditions are quite similar to those for the string in Sec. 12.2.

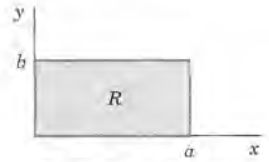

Fig. 299. Rectangular membrane

As a first important model, let us consider the **rectangular membrane** R in Fig. 299, which is simpler than the circular drumhead to follow. Then the boundary in (2) is the rectangle in Fig. 299. We shall solve this problem in three steps:

Step 1. By separating variables, setting $u(x, y, t) = F(x, y)G(t)$ and later $F(x, y) = H(x)Q(y)$ we obtain from (1) an ODE (4) for G and later from a PDE (5) for F two ODEs (6) and (7) for H and Q.

Step 2. From the solutions of those ODEs we determine solutions (13) of (1) ("**eigenfunctions**" u_{mn}) that satisfy the boundary condition (2).

Step 3. We compose the u_{mn} into a double series (14) solving the whole model (1), (2), (3).

Step 1. Three ODEs From the Wave Equation (1)

To obtain ODEs from (1), we apply two successive separations of variables. In the first separation we set $u(x, y, t) = F(x, y)G(t)$. Substitution into (1) gives

$$F\ddot{G} = c^2(F_{xx}G + F_{yy}G)$$

where subscripts denote partial derivatives and dots denote derivatives with respect to t. To separate the variables, we divide both sides by c^2FG:

$$\frac{\ddot{G}}{c^2G} = \frac{1}{F}(F_{xx} + F_{yy}).$$

Since the left side depends only on t, whereas the right side is independent of t, both sides must equal a constant. By a simple investigation we see that only negative values of that constant will lead to solutions that satisfy (2) without being identically zero; this is similar to Sec. 12.3. Denoting that negative constant by $-\nu^2$, we have

$$\frac{\ddot{G}}{c^2G} = \frac{1}{F}(F_{xx} + F_{yy}) = -\nu^2.$$

This gives two equations: for the **"time function"** $G(t)$ we have the ODE

$$\ddot{G} + \lambda^2 G = 0 \qquad \text{where } \lambda = c\nu, \tag{4}$$

and for the **"amplitude function"** $F(x, y)$ a PDE, called the *two-dimensional* **Helmholtz**[3] **equation**

$$F_{xx} + F_{yy} + \nu^2 F = 0. \tag{5}$$

[3]HERMANN VON HELMHOLTZ (1821–1894), German physicist, known for his basic work in thermodynamics, fluid flow, and acoustics.

Separation of the Helmholtz equation is achieved if we set $F(x, y) = H(x)Q(y)$. By substitution of this into (5) we obtain

$$\frac{d^2H}{dx^2}\,Q = -\left(H\,\frac{d^2Q}{dy^2} + \nu^2 HQ\right).$$

To separate the variables, we divide both sides by HQ, finding

$$\frac{1}{H}\,\frac{d^2H}{dx^2} = -\frac{1}{Q}\left(\frac{d^2Q}{dy^2} + \nu^2 Q\right).$$

Both sides must equal a constant, by the usual argument. This constant must be negative, say, $-k^2$, because only negative values will lead to solutions that satisfy (2) without being identically zero. Thus

$$\frac{1}{H}\,\frac{d^2H}{dx^2} = -\frac{1}{Q}\left(\frac{d^2Q}{dy^2} + \nu^2 Q\right) = -k^2.$$

This yields two ODEs for H and Q, namely,

$$\frac{d^2H}{dx^2} + k^2 H = 0 \tag{6}$$

and

$$\frac{d^2Q}{dy^2} + p^2 Q = 0 \qquad \text{where } p^2 = \nu^2 - k^2. \tag{7}$$

Step 2. Satisfying the Boundary Condition

General solutions of (6) and (7) are

$$H(x) = A\cos kx + B\sin kx \qquad \text{and} \qquad Q(y) = C\cos py + D\sin py$$

with constant A, B, C, D. From $u = FG$ and (2) it follows that $F = HQ$ must be zero on the boundary, that is, on the edges $x = 0$, $x = a$, $y = 0$, $y = b$; see Fig. 299. This gives the conditions

$$H(0) = 0, \qquad H(a) = 0, \qquad Q(0) = 0, \qquad Q(b) = 0.$$

Hence $H(0) = A = 0$ and then $H(a) = B\sin ka = 0$. Here we must take $B \neq 0$ since otherwise $H(x) \equiv 0$ and $F(x, y) \equiv 0$. Hence $\sin ka = 0$ or $ka = m\pi$, that is,

$$k = \frac{m\pi}{a} \quad (m \text{ integer}).$$

In precisely the same fashion we conclude that $C = 0$ and p must be restricted to the values $p = n\pi/b$ where n is an integer. We thus obtain the solutions $H = H_m$, $Q = Q_n$, where

$$H_m(x) = \sin \frac{m\pi x}{a} \qquad \text{and} \qquad Q_n(y) = \sin \frac{n\pi y}{b}, \qquad \begin{matrix} m = 1, 2, \cdots, \\ n = 1, 2, \cdots. \end{matrix}$$

As in the case of the vibrating string, it is not necessary to consider $m, n = -1, -2, \cdots$ since the corresponding solutions are essentially the same as for positive m and n, except for a factor -1. Hence the functions

$$\textbf{(8)} \qquad F_{mn}(x, y) = H_m(x)Q_n(y) = \sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b}, \qquad \begin{matrix} m = 1, 2, \cdots, \\ n = 1, 2, \cdots, \end{matrix}$$

are solutions of the Helmholtz equation (5) that are zero on the boundary of our membrane.

Eigenfunctions and Eigenvalues. Having taken care of (5), we turn to (4). Since $p^2 = \nu^2 - k^2$ in (7) and $\lambda = c\nu$ in (4), we have

$$\lambda = c\sqrt{k^2 + p^2}.$$

Hence to $k = m\pi/a$ and $p = n\pi/b$ there corresponds the value

$$\textbf{(9)} \qquad \lambda = \lambda_{mn} = c\pi \sqrt{\frac{m^2}{a^2} + \frac{n^2}{b^2}}, \qquad \begin{matrix} m = 1, 2, \cdots, \\ n = 1, 2, \cdots, \end{matrix}$$

in the ODE (4). A corresponding general solution of (4) is

$$G_{mn}(t) = B_{mn} \cos \lambda_{mn} t + B_{mn}^* \sin \lambda_{mn} t.$$

It follows that the functions $u_{mn}(x, y, t) = F_{mn}(x, y)G_{mn}(t)$, written out

$$\textbf{(10)} \qquad u_{mn}(x, y, t) = (B_{mn} \cos \lambda_{mn} t + B_{mn}^* \sin \lambda_{mn} t) \sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b}$$

with λ_{mn} according to (9), are solutions of the wave equation (1) that are zero on the boundary of the rectangular membrane in Fig. 299. These functions are called the **eigenfunctions** or *characteristic functions*, and the numbers λ_{mn} are called the **eigenvalues** or *characteristic values* of the vibrating membrane. The frequency of u_{mn} is $\lambda_{mn}/2\pi$.

Discussion of Eigenfunctions. It is very interesting that, depending on a and b, several functions F_{mn} may correspond to the same eigenvalue. Physically this means that there may exist vibrations having the same frequency but entirely different **nodal lines** (curves of points on the membrane that do not move). Let us illustrate this with the following example.

EXAMPLE 1 Eigenvalues and Eigenfunctions of the Square Membrane

Consider the square membrane with $a = b = 1$. From (9) we obtain its eigenvalues

$$\lambda_{mn} = c\pi\sqrt{m^2 + n^2}. \tag{11}$$

Hence $\lambda_{mn} = \lambda_{nm}$, but for $m \neq n$ the corresponding functions

$$F_{mn} = \sin m\pi x \sin n\pi y \qquad \text{and} \qquad F_{nm} = \sin n\pi x \sin m\pi y$$

are certainly different. For example, to $\lambda_{12} = \lambda_{21} = c\pi\sqrt{5}$ there correspond the two functions

$$F_{12} = \sin \pi x \sin 2\pi y \qquad \text{and} \qquad F_{21} = \sin 2\pi x \sin \pi y.$$

Hence the corresponding solutions

$$u_{12} = (B_{12} \cos c\pi\sqrt{5}t + B_{12}^* \sin c\pi\sqrt{5}t)F_{12} \qquad \text{and} \qquad u_{21} = (B_{21} \cos c\pi\sqrt{5}t + B_{21}^* \sin c\pi\sqrt{5}t)F_{21}$$

have the nodal lines $y = \frac{1}{2}$ and $x = \frac{1}{2}$, respectively (see Fig. 300). Taking $B_{12} = 1$ and $B_{12}^* = B_{21}^* = 0$, we obtain

$$u_{12} + u_{21} = \cos c\pi\sqrt{5}t\,(F_{12} + B_{21}F_{21}) \tag{12}$$

which represents another vibration corresponding to the eigenvalue $c\pi\sqrt{5}$. The nodal line of this function is the solution of the equation

$$F_{12} + B_{21}F_{21} = \sin \pi x \sin 2\pi y + B_{21} \sin 2\pi x \sin \pi y = 0$$

or, since $\sin 2\alpha = 2 \sin \alpha \cos \alpha$,

$$\sin \pi x \sin \pi y\,(\cos \pi y + B_{21} \cos \pi x) = 0. \tag{13}$$

This solution depends on the value of B_{21} (see Fig. 301).

From (11) we see that even more than two functions may correspond to the same numerical value of λ_{mn}. For example, the four functions F_{18}, F_{81}, F_{47}, and F_{74} correspond to the value

$$\lambda_{18} = \lambda_{81} = \lambda_{47} = \lambda_{74} = c\pi\sqrt{65}, \qquad \text{because} \qquad 1^1 + 8^2 = 4^2 + 7^2 = 65.$$

This happens because 65 can be expressed as the sum of two squares of positive integers in several ways. According to a theorem by Gauss, this is the case for every sum of two squares among whose prime factors there are at least two different ones of the form $4n + 1$ where n is a positive integer. In our case we have $65 = 5 \cdot 13 = (4 + 1)(12 + 1)$. ■

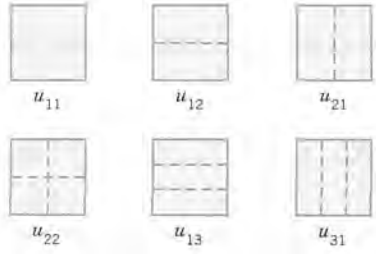

Fig. 300. Nodal lines of the solutions u_{11}, u_{12}, u_{21}, u_{22}, u_{13}, u_{31} in the case of the square membrane

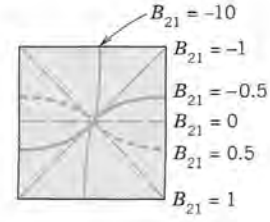

Fig. 301. Nodal lines of the solution (12) for some values of B_{21}

Step 3. Solution of the Model (1), (2), (3). Double Fourier Series

So far we have solutions (10) satisfying (1) and (2) only. To obtain the solution that also satisfies (3), we proceed as in Sec. 12.3. We consider the double series

$$\begin{aligned} u(x, y, t) &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} u_{mn}(x, y, t) \\ &= \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} (B_{mn} \cos \lambda_{mn} t + B_{mn}^{*} \sin \lambda_{mn} t) \sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b} \end{aligned} \tag{14}$$

(without discussing convergence and uniqueness). From (14) and (3a), setting $t = 0$, we have

$$u(x, y, 0) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} B_{mn} \sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b} = f(x, y). \tag{15}$$

Suppose that $f(x, y)$ can be represented by (15). (Sufficient for this is the continuity of f, $\partial f/\partial x$, $\partial f/\partial y$, $\partial^2 f/\partial x \partial y$ in R.) Then (15) is called the **double Fourier series** of $f(x, y)$. Its coefficients can be determined as follows. Setting

$$K_m(y) = \sum_{n=1}^{\infty} B_{mn} \sin \frac{n\pi y}{b} \tag{16}$$

we can write (15) in the form

$$f(x, y) = \sum_{m=1}^{\infty} K_m(y) \sin \frac{m\pi x}{a}.$$

For fixed y this is the Fourier sine series of $f(x, y)$, considered as a function of x. From (4) in Sec. 11.3 we see that the coefficients of this expansion are

$$K_m(y) = \frac{2}{a} \int_0^a f(x, y) \sin \frac{m\pi x}{a} \, dx. \tag{17}$$

Furthermore, (16) is the Fourier sine series of $K_m(y)$, and from (4) in Sec. 11.3 it follows that the coefficients are

$$B_{mn} = \frac{2}{b} \int_0^b K_m(y) \sin \frac{n\pi y}{b} \, dy.$$

From this and (17) we obtain the **generalized Euler formula**

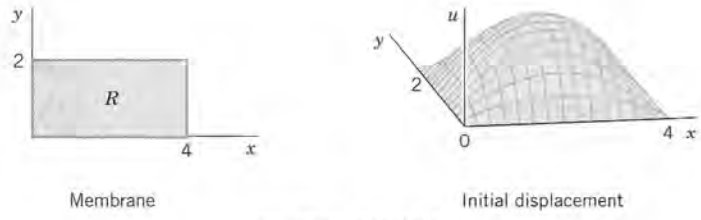
$$B_{mn} = \frac{4}{ab} \int_0^b \int_0^a f(x, y) \sin \frac{m\pi x}{a} \sin \frac{n\pi y}{b} \, dx \, dy \qquad \begin{matrix} m = 1, 2, \cdots \\ n = 1, 2, \cdots \end{matrix} \tag{18}$$

for the **Fourier coefficients** of $f(x, y)$ in the double Fourier series (15).

The B_{mn} in (14) are now determined in terms of $f(x, y)$. To determine the B^*_{mn}, we differentiate (14) termwise with respect to t; using (3b), we obtain

$$\left.\frac{\partial u}{\partial t}\right|_{t=0} = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} B^*_{mn}\lambda_{mn} \sin\frac{m\pi x}{a} \sin\frac{n\pi y}{b} = g(x, y).$$

Suppose that $g(x, y)$ can be developed in this double Fourier series. Then, proceeding as before, we find that the coefficients are



(19)
$$B^*_{mn} = \frac{4}{ab\lambda_{mn}} \int_0^b\int_0^a g(x, y) \sin\frac{m\pi x}{a} \sin\frac{n\pi y}{b}\, dx\, dy \qquad \begin{matrix} m = 1, 2, \cdots \\ n = 1, 2, \cdots. \end{matrix}$$

Result. *If f and g in* (3) *are such that u can be represented by* (14), *then* (14) *with coefficients* (18) *and* (19) *is the solution of the model* (1), (2), (3).

EXAMPLE 2 **Vibration of a Rectangular Membrane**

Find the vibrations of a rectangular membrane of sides $a = 4$ ft and $b = 2$ ft (Fig. 302) if the tension is 12.5 lb/ft, the density is 2.5 slugs/ft^2 (as for light rubber), the initial velocity is 0, and the initial displacement is

(20)
$$f(x, y) = 0.1(4x - x^2)(2y - y^2) \text{ ft}.$$

Membrane Initial displacement

Fig. 302. Example 2

Solution. $c^2 = T/\rho = 12.5/2.5 = 5$ [ft^2/sec^2]. Also, $B^*_{mn} = 0$ from (19). From (18) and (20),

$$B_{mn} = \frac{4}{4 \cdot 2}\int_0^2\int_0^4 0.1(4x - x^2)(2y - y^2) \sin\frac{m\pi x}{4} \sin\frac{n\pi y}{2}\, dx\, dy$$

$$= \frac{1}{20}\int_0^4 (4x - x^2) \sin\frac{m\pi x}{4}\, dx \int_0^2 (2y - y^2) \sin\frac{n\pi y}{2}\, dy.$$

Two integrations by parts give for the first integral on the right

$$\frac{128}{m^3\pi^3}\left[1 - (-1)^m\right] = \frac{256}{m^3\pi^3} \qquad (m \text{ odd})$$

and for the second integral

$$\frac{16}{n^3\pi^3}\left[1 - (-1)^n\right] = \frac{32}{n^3\pi^3} \qquad (n \text{ odd}).$$

For even m or n we get 0. Together with the factor 1/20 we thus have $B_{mn} = 0$ if m or n is even and

$$B_{mn} = \frac{256 \cdot 32}{20m^3n^3\pi^6} \approx \frac{0.426\,050}{m^3n^3} \qquad (m \text{ and } n \text{ both odd}).$$

From this, (9), and (14) we obtain the answer

$$u(x, y, t) = 0.426\,050 \sum_{m,n \text{ odd}} \sum \frac{1}{m^3 n^3} \cos\left(\frac{\sqrt{5}\pi}{4}\sqrt{m^2 + 4n^2}\right) t \sin\frac{m\pi x}{4} \sin\frac{n\pi y}{2}$$

$$(21) \quad = 0.426\,050 \left(\cos\frac{\sqrt{5}\pi\sqrt{5}}{4} t \sin\frac{\pi x}{4} \sin\frac{\pi y}{2} + \frac{1}{27} \cos\frac{\sqrt{5}\pi\sqrt{37}}{4} t \sin\frac{\pi x}{4} \sin\frac{3\pi y}{2}\right.$$

$$\left. + \frac{1}{27} \cos\frac{\sqrt{5}\pi\sqrt{13}}{4} t \sin\frac{3\pi x}{4} \sin\frac{\pi y}{2} + \frac{1}{729} \cos\frac{\sqrt{5}\pi\sqrt{45}}{4} t \sin\frac{3\pi x}{4} \sin\frac{3\pi y}{2} + \cdots\right).$$

To discuss this solution, we note that the first term is very similar to the initial shape of the membrane, has no nodal lines, and is by far the dominating term because the coefficients of the next terms are much smaller. The second term has two horizontal nodal lines ($y = 2/3, 4/3$), the third term two vertical ones ($x = 4/3, 8/3$), the fourth term two horizontal and two vertical ones, and so on. ■

PROBLEM SET 12.8

1. (Frequency) How does the frequency of the eigenfunctions of the rectangular membrane change if (a) we double the tension, (b) we take a membrane of half the mass of the original one, (c) we double the sides of the membrane? (Give reason.)

SQUARE MEMBRANE

2. Determine and sketch the nodal lines of the eigenfunctions of the square membrane for $m = 1, 2, 3, 4$ and $n = 1, 2, 3, 4$.

3–8 **Double Fourier Series.** Represent $f(x, y)$ by a series (15), where $0 < x < 1$, $0 < y < 1$.

3. $f(x, y) = 1$

4. $f(x, y) = x$

5. $f(x, y) = y$

6. $f(x, y) = x + y$

7. $f(x, y) = xy$

8. $f(x, y) = xy(1 - x)(1 - y)$

9. CAS PROJECT. Double Fourier Series. (a) Write a program that gives and graphs partial sums of (15). Apply it to Probs. 4 and 5. Do the graphs show that those partial sums satisfy the boundary condition (3a)? Explain why. Why is the convergence rapid?

(b) Do the tasks in (a) for Prob. 3. Graph a portion, say, $0 < x < \frac{1}{2}$, $0 < y < \frac{1}{2}$, of several partial sums on common axes, so that you can see how they differ. (See Fig. 303.)

(c) Do the tasks in (b) for functions of your choice.

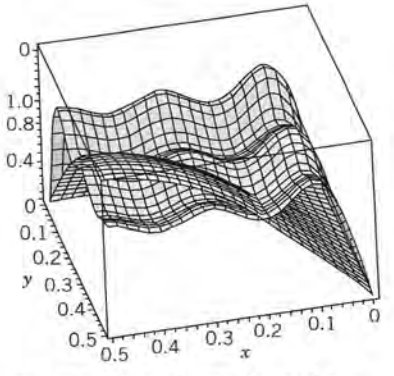


Fig. 303. Partial sums $S_{2,2}$ and $S_{10,10}$ in CAS Project 9b

10. CAS EXPERIMENT. Quadruples of F_{mn}. Write a program that gives you four numerically equal λ_{mn} in Example 1, so that four different F_{mn} correspond to it. Sketch the nodal lines of F_{18}, F_{81}, F_{47}, F_{74} in Example 1 and similarly for further F_{mn} that you will find.

11–13 **Deflection.** Find the deflection $u(x, y, t)$ of the square membrane of side π and $c^2 = 1$ if the initial velocity is 0 and the initial deflection is

11. $k \sin 2x \sin 5y$

12. $0.1 \sin x \sin y$

13. $0.1xy(\pi - x)(\pi - y)$

RECTANGULAR MEMBRANE

14. Verify the discussion of the terms of (21) in Example 2.

15. Repeat the task of Prob. 2 when $a = 4$ and $b = 1$.

16. Verify the calculation of B_{mn} in Example 2 by integration by parts.

17. Find eigenvalues of the rectangular membrane of sides $a = 2$ and $b = 1$ to which there correspond two or more different (independent) eigenfunctions.

18. (Minimum property) Show that among all rectangular membranes of the same area $A = ab$ and the same c the square membrane is that for which u_{11} [see (10)] has the lowest frequency.

19–22 **Double Fourier Series.** Represent $f(x, y)$ $(0 < x < a, 0 < y < b)$ by a double Fourier series (15).

19. $f(x, y) = k$

20. $f(x, y) = 0.25xy$

21. $f(x, y) = xy(a^2 - x^2)(b^2 - y^2)$

22. $f(x, y) = xy(a - x)(b - y)$

23. (Deflection) Find the deflection of the membrane of sides a and b with $c^2 = 1$ for the initial deflection

$$f(x, y) = \sin \frac{3\pi x}{a} \sin \frac{4\pi y}{b}$$ and initial velocity 0.

24. Repeat the task in Prob. 23 with $c^2 = 1$, for $f(x, y)$ as in Prob. 22 and initial velocity 0.

25. (Forced vibrations) Show that forced vibrations of a membrane are modeled by the PDE $u_{tt} = c^2\nabla^2 u + P/\rho$, where $P(x, y, t)$ is the external force per unit area acting perpendicular to the xy-plane.

12.9 Laplacian in Polar Coordinates. Circular Membrane. Fourier–Bessel Series

In boundary value problems for PDEs it is a ***general principle*** to use coordinates in which the formula for the boundary is as simple as possible. Since we want to discuss circular membranes (drumheads), we first transform the Laplacian in the wave equation (1), Sec. 12.8,

$$u_{tt} = c^2\nabla^2 u = c^2(u_{xx} + u_{yy}) \tag{1}$$

(subscripts denoting partial derivatives) into **polar coordinates**

$$r = \sqrt{x^2 + y^2}, \qquad \theta = \arctan \frac{y}{x}.$$

Hence $x = r\cos\theta$, $y = r\sin\theta$. By the chain rule (Sec. 9.6) we obtain

$$u_x = u_r r_x + u_\theta \theta_x.$$

Differentiating once more with respect to x and using the product rule and then again the chain rule gives

$$\begin{aligned} u_{xx} &= (u_r r_x)_x + (u_\theta \theta_x)_x \\ &= (u_r)_x r_x + u_r r_{xx} + (u_\theta)_x \theta_x + u_\theta \theta_{xx} \\ &= (u_{rr} r_x + u_{r\theta}\theta_x) r_x + u_r r_{xx} + (u_{\theta r} r_x + u_{\theta\theta}\theta_x)\theta_x + u_\theta \theta_{xx}. \end{aligned} \tag{2}$$

Also, by differentiation of r and θ we find

$$r_x = \frac{x}{\sqrt{x^2 + y^2}} = \frac{x}{r}, \qquad \theta_x = \frac{1}{1 + (y/x)^2}\left(-\frac{y}{x^2}\right) = -\frac{y}{r^2}.$$

Differentiating these two formulas again, we obtain

$$r_{xx} = \frac{r - xr_x}{r^2} = \frac{1}{r} - \frac{x^2}{r^3} = \frac{y^2}{r^3}, \qquad \theta_{xx} = -y\left(-\frac{2}{r^3}\right) r_x = \frac{2xy}{r^4}.$$

We substitute all these expressions into (2). Assuming continuity of the first and second partial derivatives, we have $u_{r\theta} = u_{\theta r}$, and by simplifying,

$$u_{xx} = \frac{x^2}{r^2}\, u_{rr} - 2\,\frac{xy}{r^3}\, u_{r\theta} + \frac{y^2}{r^4}\, u_{\theta\theta} + \frac{y^2}{r^3}\, u_r + 2\,\frac{xy}{r^4}\, u_\theta. \tag{3}$$

In a similar fashion it follows that

$$u_{yy} = \frac{y^2}{r^2}\, u_{rr} + 2\,\frac{xy}{r^3}\, u_{r\theta} + \frac{x^2}{r^4}\, u_{\theta\theta} + \frac{x^2}{r^3}\, u_r - 2\,\frac{xy}{r^4}\, u_\theta. \tag{4}$$

By adding (3) and (4) we see that the **Laplacian of u in polar coordinates** is

$$\nabla^2 u = \frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\,\frac{\partial u}{\partial r} + \frac{1}{r^2}\,\frac{\partial^2 u}{\partial \theta^2}. \tag{5}$$

Circular Membrane

Circular membranes occur in drums, pumps, microphones, telephones, and so on. This accounts for their great importance in engineering. Whenever a circular membrane is plane and its material is elastic, but offers no resistance to bending (this excludes thin metallic membranes!), its vibrations are modeled by the **two-dimensional wave equation in polar coordinates** obtained from (1) with $\nabla^2 u$ given by (5), that is,

$$\frac{\partial^2 u}{\partial t^2} = c^2\left(\frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\,\frac{\partial u}{\partial r} + \frac{1}{r^2}\,\frac{\partial^2 u}{\partial \theta^2}\right) \qquad c^2 = \frac{T}{\rho}. \tag{6}$$

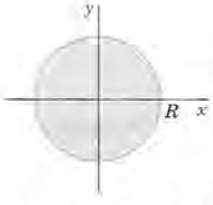

Fig. 304. Circular membrane

We shall consider a membrane of radius R (Fig. 304) and determine solutions $u(r, t)$ that are radially symmetric. (Solutions also depending on the angle θ will be discussed in the problem set.) Then $u_{\theta\theta} = 0$ in (6) and the model of the problem (the analog of (1), (2), (3) in Sec. 12.8) is

$$\frac{\partial^2 u}{\partial t^2} = c^2\left(\frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\,\frac{\partial u}{\partial r}\right) \tag{7}$$

$$u(R, t) = 0 \text{ for all } t \geqq 0 \tag{8}$$

$$u(r, 0) = f(r) \tag{9a}$$

$$u_t(r, 0) = g(r). \tag{9b}$$

Here (8) means that the membrane is fixed along the boundary circle $r = R$. The initial deflection $f(r)$ and the initial velocity $g(r)$ depend only on r, not on θ, so that we can expect radially symmetric solutions $u(r, t)$.

Step 1. Two ODEs From the Wave Equation (7). Bessel's Equation

Using the **method of separation of variables,** we first determine solutions $u(r, t) = W(r)G(t)$. (We write W, not F because W depends on r, whereas F, used before, depended on x.) Substituting $u = WG$ and its derivatives into (7) and dividing the result by c^2WG, we get

$$\frac{\ddot{G}}{c^2G} = \frac{1}{W}\left(W'' + \frac{1}{r}\,W'\right)$$

where dots denote derivatives with respect to t and primes denote derivatives with respect to r. The expressions on both sides must equal a constant. This constant must be negative, say, $-k^2$, in order to obtain solutions that satisfy the boundary condition without being identically zero. Thus,

$$\frac{\ddot{G}}{c^2G} = \frac{1}{W}\left(W'' + \frac{1}{r}\,W'\right) = -k^2.$$

This gives the two linear ODEs

(10) $$\ddot{G} + \lambda^2 G = 0 \qquad \text{where } \lambda = ck$$

and

(11) $$W'' + \frac{1}{r}\,W' + k^2W = 0.$$

We can reduce (11) to Bessel's equation (Sec. 5.5) if we set $s = kr$. Then $1/r = k/s$ and, retaining the notation W for simplicity, we obtain by the chain rule

$$W' = \frac{dW}{dr} = \frac{dW}{ds}\,\frac{ds}{dr} = \frac{dW}{ds}\,k \qquad \text{and} \qquad W'' = \frac{d^2W}{ds^2}\,k^2.$$

By substituting this into (11) and omitting the common factor k^2 we have

(12) $$\frac{d^2W}{ds^2} + \frac{1}{s}\,\frac{dW}{ds} + W = 0.$$

This is **Bessel's equation** (1), Sec. 5.5, with parameter $\nu = 0$.

Step 2. Satisfying the Boundary Condition (8)

Solutions of (12) are the Bessel functions J_0 and Y_0 of the first and second kind (see Secs. 5.5, 5.6). But Y_0 becomes infinite at 0, so that we cannot use it because the deflection of the membrane must always remain finite. This leaves us with

(13) $$W(r) = J_0(s) = J_0(kr) \qquad (s = kr).$$

On the boundary $r = R$ we get $W(R) = J_0(kR) = 0$ from (8) (because $G \equiv 0$ would imply $u \equiv 0$). We can satisfy this condition because J_0 has (infinitely many) positive zeros, $s = \alpha_1, \alpha_2, \cdots$ (see Fig. 305), with numerical values

$$\alpha_1 = 2.4048, \quad \alpha_2 = 5.5201, \quad \alpha_3 = 8.6537, \quad \alpha_4 = 11.7915, \quad \alpha_5 = 14.9309$$

and so on. (For further values, consult your CAS or Ref. [GR1] in App. 1.) These zeros are slightly irregularly spaced, as we see. Equation (13) now implies

$$(14) \qquad kR = \alpha_m \qquad \text{thus} \qquad k = k_m = \frac{\alpha_m}{R}, \qquad m = 1, 2, \cdots.$$

Hence the functions

$$(15) \qquad W_m(r) = J_0(k_m r) = J_0\left(\frac{\alpha_m}{R} r\right), \qquad m = 1, 2, \cdots$$

are solutions of (11) that are zero on the boundary circle $r = R$.

Eigenfunctions and Eigenvalues. For W_m in (15), a corresponding general solution of (10) with $\lambda = \lambda_m = ck_m = c\alpha_m/R$ is

$$G_m(t) = A_m \cos \lambda_m t + B_m \sin \lambda_m t.$$

Hence the functions

$$\mathbf{(16)} \qquad u_m(r, t) = W_m(r)G_m(t) = (A_m \cos \lambda_m t + B_m \sin \lambda_m t)J_0(k_m r)$$

with $m = 1, 2, \cdots$ are solutions of the wave equation (7) satisfying the boundary condition (8). These are the **eigenfunctions** of our problem. The corresponding **eigenvalues** are λ_m.

The vibration of the membrane corresponding to u_m is called the mth **normal mode;** it has the frequency $\lambda_m/2\pi$ cycles per unit time. Since the zeros of the Bessel function J_0 are not regularly spaced on the axis (in contrast to the zeros of the sine functions appearing in the case of the vibrating string), the sound of a drum is entirely different from that of a violin. The forms of the normal modes can easily be obtained from Fig. 305 and are shown in Fig. 306. For $m = 1$, all the points of the membrane move up (or down) at the same time. For $m = 2$, the situation is as follows. The function $W_2(r) = J_0(\alpha_2 r/R)$ is zero for $\alpha_2 r/R = \alpha_1$, thus $r = \alpha_1 R/\alpha_2$. The circle $r = \alpha_1 R/\alpha_2$ is, therefore, **nodal line,** and when at some instant the central part of the membrane moves up, the outer part ($r > \alpha_1 R/\alpha_2$) moves down, and conversely. The solution $u_m(r, t)$ has $m - 1$ nodal lines, which are circles (Fig. 306).

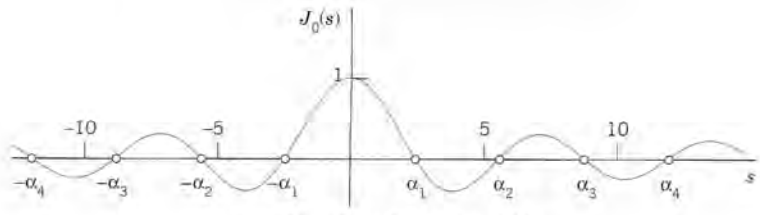

Fig. 305. Bessel function $J_0(s)$

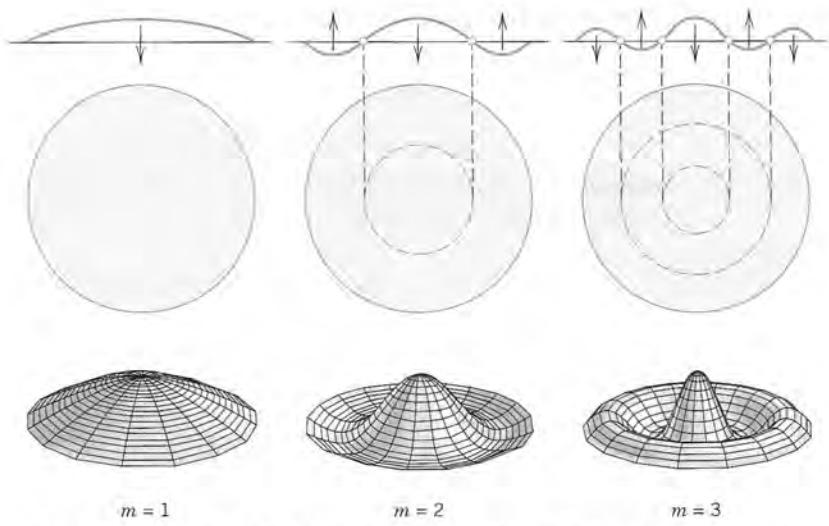

Fig. 306. Normal modes of the circular membrane in the case of vibrations independent of the angle

Step 3. Solution of the Entire Problem

To obtain a solution $u(r, t)$ that also satisfies the initial conditions (9), we may proceed as in the case of the string. That is, we consider the series

$$(17) \qquad u(r, t) = \sum_{m=1}^{\infty} W_m(r)G_m(t) = \sum_{m=1}^{\infty} (A_m \cos \lambda_m t + B_m \sin \lambda_m t)\, J_0\left(\frac{\alpha_m}{R} r\right)$$

(leaving aside the problems of convergence and uniqueness). Setting $t = 0$ and using (9a), we obtain

$$\textbf{(18)} \qquad u(r, 0) = \sum_{m=1}^{\infty} A_m J_0\left(\frac{\alpha_m}{R} r\right) = f(r).$$

Thus for the series (17) to satisfy the condition (9a), the constants A_m must be the coefficients of the **Fourier–Bessel series** (18) that represents $f(r)$ in terms of $J_0(\alpha_m r/R)$; that is [see (10) in Sec. 5.8 with $n = 0$, $\alpha_{0,m} = \alpha_m$, and $x = r$],

$$\textbf{(19)} \qquad A_m = \frac{2}{R^2 J_1^2(\alpha_m)} \int_0^R r f(r) J_0\left(\frac{\alpha_m}{R} r\right) dr \qquad (m = 1, 2, \cdots).$$

Differentiability of $f(r)$ in the interval $0 \leqq r \leqq R$ is sufficient for the existence of the development (18); see Ref. [A13]. The coefficients B_m in (17) can be determined from (9b) in a similar fashion. Numeric values of A_m and B_m may be obtained from a CAS or by a numeric integration method, using tables of J_0 and J_1. However, numeric integration can sometimes be ***avoided,*** as the following example shows.

EXAMPLE 1 Vibrations of a Circular Membrane

Find the vibrations of a circular drumhead of radius 1 ft and density 2 slugs/ft^2 if the tension is 8 lb/ft, the initial velocity is 0, and the initial displacement is

$$f(r) = 1 - r^2 \text{ [ft]}.$$

Solution. $c^2 = T/\rho = 8/2 = 4$ [ft^2/sec^2]. Also $B_m = 0$, since the initial velocity is 0. From (19) and Example 3 in Sec. 5.8, since $R = 1$, we obtain

$$\begin{aligned} A_m &= \frac{2}{J_1^2(\alpha_m)} \int_0^1 r(1 - r^2)\, J_0(\alpha_m r)\, dr \\ &= \frac{4J_2(\alpha_m)}{\alpha_m^2 J_1^2(\alpha_m)} \\ &= \frac{8}{\alpha_m^3 J_1(\alpha_m)} \end{aligned}$$

where the last equality follows from (24c), Sec. 5.5, with $\nu = 1$, that is,

$$J_2(\alpha_m) = \frac{2}{\alpha_m} J_1(\alpha_m) - J_0(\alpha_m) = \frac{2}{\alpha_m} J_1(\alpha_m).$$

Table 9.5 on p. 409 of [GR1] gives α_m and $J_0'(\alpha_m)$. From this we get $J_1(\alpha_m) = -J_0'(\alpha_m)$ by (24b), Sec. 5.5, with $\nu = 0$, and compute the coefficients A_m:

m	α_m	$J_1(\alpha_m)$	$J_2(\alpha_m)$	A_m
1	2.40483	0.51915	0.43176	1.10801
2	5.52008	−0.34026	−0.12328	−0.13978
3	8.65373	0.27145	0.06274	0.04548
4	11.79153	−0.23246	−0.03943	−0.02099
5	14.93092	0.20655	0.02767	0.01164
6	18.07106	−0.18773	−0.02078	−0.00722
7	21.21164	0.17327	0.01634	0.00484
8	24.35247	−0.16170	−0.01328	−0.00343
9	27.49348	0.15218	0.01107	0.00253
10	30.63461	−0.14417	−0.00941	−0.00193

Thus

$$f(r) = 1.108J_0(2.4048r) - 0.140J_0(5.5201r) + 0.045J_0(8.6537r) - \cdots.$$

We see that the coefficients decrease relatively slowly. The sum of the explicitly given coefficients in the table is 0.99915. The sum of *all* the coefficients should be 1. (Why?) Hence by the Leibniz test in App. A3.3 the partial sum of those terms gives about three correct decimals of the amplitude $f(r)$.

Since

$$\lambda_m = ck_m = c\alpha_m/R = 2\alpha_m,$$

from (17) we thus obtain the solution (with r measured in feet and t in seconds)

$$u(r, t) = 1.108J_0(2.4048r)\cos 4.8097t - 0.140J_0(5.5201r)\cos 11.0402t + 0.045J_0(8.6537r)\cos 17.3075t - \cdots.$$

In Fig. 306, $m = 1$ gives an idea of the motion of the first term of our series, $m = 2$ of the second term, and $m = 3$ of the third term, so that we can "see" our result about as well as for a violin string in Sec. 12.3. ■

PROBLEM SET 12.9

1. Why did we use polar coordinates in this section?
2. Work out the details of the calculation leading to the Laplacian in polar coordinates.
3. If u is independent of θ, then (5) reduces to $\nabla^2 u = u_{rr} + u_r/r$. Derive this directly from the Laplacian in Cartesian coordinates.
4. An **alternative form** of (5) is $\nabla^2 u = \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial u}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2}$. Derive this from (5).
5. **(Radial solution)** Show that the only solution of $\nabla^2 u = 0$ depending only on $r = \sqrt{x^2 + y^2}$ is $u = a \ln r + b$ with constant a and b.
6. **TEAM PROJECT. Series for Dirichlet and Neumann Problems**

   (a) Show that $u_n = r^n \cos n\theta$, $u_n = r^n \sin n\theta$, $n = 0, 1, \cdots$, are solutions of Laplace's equation $\nabla^2 u = 0$ with $\nabla^2 u$ given by (5). (What would u_n be in Cartesian coordinates? Experiment with small n.)

   (b) Dirichlet problem (See Sec. 12.5) Assuming that termwise differentiation is permissible, show that a solution of the Laplace equation in the disk $r < R$ satisfying the boundary condition $u(R, \theta) = f(\theta)$ (f given) is

$$u(r, \theta) = a_0 + \sum_{n=1}^{\infty}\left[a_n\left(\frac{r}{R}\right)^n \cos n\theta + b_n\left(\frac{r}{R}\right)^n \sin n\theta\right] \tag{20}$$

   where a_n, b_n are the Fourier coefficients of f (see Sec. 11.1).

   (c) Dirichlet problem Solve the Dirichlet problem using (20) if $R = 1$ and the boundary values are $u(\theta) = -100$ volts if $-\pi < \theta < 0$, $u(\theta) = 100$ volts if $0 < \theta < \pi$. (Sketch this disk, indicate the boundary values.)

   (d) Neumann problem Show that the solution of the Neumann problem $\nabla^2 u = 0$ if $r < R$, $u_N(R, \theta) = f(\theta)$ (where $u_N = \partial u/\partial N$ is the directional derivative in the direction of the outer normal) is

$$u(r, \theta) = A_0 + \sum_{n=1}^{\infty} r^n (A_n \cos n\theta + B_n \sin n\theta)$$

   with arbitrary A_0 and

$$A_n = \frac{1}{\pi n R^{n-1}}\int_{-\pi}^{\pi} f(\theta)\cos n\theta \, d\theta,$$

$$B_n = \frac{1}{\pi n R^{n-1}}\int_{-\pi}^{\pi} f(\theta)\sin n\theta \, d\theta.$$

   (e) Compatibility condition Show that (9), Sec. 10.4, imposes on $f(\theta)$ in (d) the *"compatibility condition"*

$$\int_{-\pi}^{\pi} f(\theta)\, d\theta = 0.$$

   (f) Neumann problem Solve $\nabla^2 u = 0$ in the annulus $1 < r < 3$ if $u_r(1, \theta) = \sin\theta$, $u_r(3, \theta) = 0$.

7–12 ELECTROSTATIC POTENTIAL. STEADY-STATE HEAT PROBLEMS

The electrostatic potential satisfies Laplace's equation $\nabla^2 u = 0$ in any region free of charges. Also the heat equation $u_t = c^2\nabla^2 u$ (Sec. 12.5) reduces to Laplace's equation if the temperature u is time-independent **("steady-state case").** Using (20), find the potential (equivalently: the steady-state temperature) in the disk $r < 1$ if the boundary values are (sketch them, to see what is going on).

7. $u(1, \theta) = 40\cos^3\theta$
8. $u(1, \theta) = 800\sin^3\theta$
9. $u(1, \theta) = 110$ if $-\frac{1}{2}\pi < \theta < \frac{1}{2}\pi$ and 0 otherwise
10. $u(1, \theta) = \theta$ if $-\frac{1}{2}\pi < \theta < \frac{1}{2}\pi$ and 0 otherwise
11. $u(1, \theta) = |\theta|$ if $-\pi < \theta < \pi$
12. $u(1, \theta) = \theta^2$ if $-\pi < \theta < \pi$
13. **CAS EXPERIMENT. Equipotential Lines.** Guess what the equipotential lines $u(r, \theta) = const$ in Probs. 9 and 11 may look like. Then graph some of them, using partial sums of the series.
14. **(Semidisk)** Find the electrostatic potential in the semidisk $r < 1$, $0 < \theta < \pi$ which equals $110\,\theta(\pi - \theta)$ on the semicircle $r = 1$ and 0 on the segment $-1 < x < 1$.
15. **(Semidisk)** Find the steady-state temperature in a semicircular thin plate $r < a$, $0 < \theta < \pi$ with the semicircle $r = a$ kept at constant temperature u_0 and the segment $-a < x < a$ at 0.
16. **(Invariance)** Show that $\nabla^2 u$ is invariant under translations $x^* = x + a$, $y^* = y + b$ and under rotations $x^* = x\cos\alpha - y\sin\alpha$, $y^* = x\sin\alpha + y\cos\alpha$.

CIRCULAR MEMBRANE

17. (Frequency) What happens to the frequency of an eigenfunction of a drum if you double the tension?

18. (Size of a drum) A small drum should have a higher fundamental frequency than a large one, tension and density being the same. How does this follow from our formulas?

19. (Tension) Find a formula for the tension required to produce a desired fundamental frequency f_1 of a drum.

20. CAS PROJECT. Normal Modes. (a) Graph the normal modes u_4, u_5, u_6 as in Fig. 306.

(b) Write a program for calculating the A_m's in Example 1 and extend the table to $m = 15$. Verify numerically that $\alpha_m \approx (m - \frac{1}{4})\pi$ and compute the error for $m = 1, \cdots, 10$.

(c) Graph the initial deflection $f(r)$ in Example 1 as well as the first three partial sums of the series. Comment on accuracy.

(d) Compute the radii of the nodal lines of u_2, u_3, u_4 when $R = 1$. How do these values compare to those of the nodes of the vibrating string of length 1? Can you establish any empirical laws by experimentation with further u_m?

21. (Nodal lines) Is it possible that for fixed c and R two or more u_m [see (16)] with different nodal lines correspond to the same eigenvalue? (Give a reason.)

22. Why is $A_1 + A_2 + \cdots = 1$ in Example 1? Compute the first few partial sums until you get 3-digit accuracy. What does this problem mean in the field of music?

23. (Nonzero initial velocity) Show that for (17) to satisfy (9b) we must have

$$B_m = \frac{2}{c\alpha_m R J_1^{\,2}(\alpha_m)} \times \times \int_0^R r g(r) J_0(\alpha_m r/R)\, dr. \tag{21}$$

VIBRATIONS OF A CIRCULAR MEMBRANE DEPENDING ON BOTH r AND θ

24. (Separations) Show that substitution of $u = F(r, \theta)G(t)$ into the wave equation (6), that is,

$$u_{tt} = c^2 \left(u_{rr} + \frac{1}{r} u_r + \frac{1}{r^2} u_{\theta\theta} \right) \tag{22}$$

gives an ODE and a PDE

$$\ddot{G} + \lambda^2 G = 0, \qquad \text{where } \lambda = ck, \tag{23}$$

$$F_{rr} + \frac{1}{r} F_r + \frac{1}{r^2} F_{\theta\theta} + k^2 F = 0. \tag{24}$$

Show that the PDE can now be separated by substituting $F = W(r)Q(\theta)$, giving

$$Q'' + n^2 Q = 0, \tag{25}$$

$$r^2 W'' + rW' + (k^2 r^2 - n^2) W = 0. \tag{26}$$

25. (Periodicity) Show that $Q(\theta)$ must be periodic with period 2π and, therefore, $n = 0, 1, 2, \cdots$ in (25) and (26). Show that this yields the solutions $Q_n = \cos n\theta$, $Q_n^* = \sin n\theta$, $W_n = J_n(kr)$, $n = 0, 1, \cdots$.

26. (Boundary condition) Show that the boundary condition

$$u(R, \theta, t) = 0 \tag{27}$$

leads to $k = k_{mn} = \alpha_{mn}/R$, where $s = \alpha_{mn}$ is the mth positive zero of $J_n(s)$.

27. (Solutions depending on both r and θ) Show that solutions of (22) satisfying (27) are (see Fig. 307)

$$\begin{aligned} u_{mn} &= (A_{mn} \cos ck_{mn}t + B_{mn} \sin ck_{mn}t) \times \\ &\quad \times J_n(k_{mn}r) \cos n\theta \\ u_{mn}^* &= (A_{mn}^* \cos ck_{mn}t + B_{mn}^* \sin ck_{mn}t) \times \\ &\quad \times J_n(k_{mn}r) \sin n\theta \end{aligned} \tag{28}$$

Fig. 307. Nodal lines of some of the solutions (28)

28. (Initial condition) Show that $u_t(r, \theta, 0) = 0$ gives $B_{mn} = 0$, $B_{mn}^* = 0$ in (28).

29. Show that $u_{m0}^* = 0$ and u_{m0} is identical with (16) in the current section.

30. (Semicircular membrane) Show that u_{11} represents the fundamental mode of a semicircular membrane and find the corresponding frequency when $c^2 = 1$ and $R = 1$.

12.10 Laplace's Equation in Cylindrical and Spherical Coordinates. Potential

Laplace's equation

$$\nabla^2 u = u_{xx} + u_{yy} + u_{zz} = 0 \tag{1}$$

is one of the most important PDEs in physics and its engineering applications. Here, x, y, z are Cartesian coordinates in space (Fig. 165 in Sec. 9.1), $u_{xx} = \partial^2 u/\partial x^2$, etc. The expression $\nabla^2 u$ is called the **Laplacian** of u. The theory of the solutions of (1) is called **potential theory.** Solutions of (1) that have ***continuous*** second partial derivatives are known as **harmonic functions.**

Laplace's equation occurs mainly in **gravitation, electrostatics** (see Theorem 3, Sec. 9.7). steady-state **heat flow** (Sec. 12.5), and **fluid flow** (to be discussed in Chap. 18.4).

Recall from Sec. 9.7 that the gravitational **potential** $u(x, y, z)$ at a point (x, y, z) resulting from a single mass located at a point (X, Y, Z) is

$$u(x, y, z) = \frac{c}{r} = \frac{c}{\sqrt{(x - X)^2 + (y - Y)^2 + (z - Z)^2}} \qquad (r > 0) \tag{2}$$

and u satisfies (1). Similarly, if mass is distributed in a region T in space with density $\rho(X, Y, Z)$, its potential at a point (x, y, z) not occupied by mass is

$$u(x, y, z) = k \iiint_T \frac{\rho(X, Y, Z)}{r}\, dX\, dY\, dZ. \tag{3}$$

It satisfies (1) because $\nabla^2(1/r) = 0$ (Sec. 9.7) and ρ is not a function of x, y, z.

Practical problems involving Laplace's equation are boundary value problems in a region T in space with boundary surface S. Such a problem is called (see also Sec. 12.5 for the two-dimensional case):

(I) First boundary value problem or **Dirichlet problem** if u is prescribed on S.

(II) Second boundary value problem or **Neumann problem** if the normal derivative $u_n = \partial u/\partial n$ is prescribed on S.

(III) Third or **mixed boundary value problem** or **Robin problem** if u is prescribed on a portion of S and u_n on the remaining portion of S.

Laplacian in Cylindrical Coordinates

The first step in solving a boundary value problem is generally the introduction of coordinates in which the boundary surface S has a simple representation. Cylindrical symmetry (a cylinder as a region T) calls for cylindrical coordinates r, θ, z related to x, y, z by

$$x = r\cos\theta, \qquad y = r\sin\theta, \qquad z = z \tag{4}$$

(Fig. 308, p. 588).

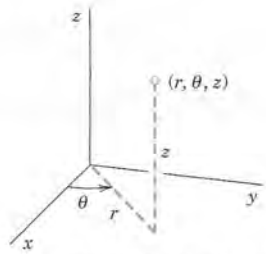

Fig. 308. Cylindrical coordinates

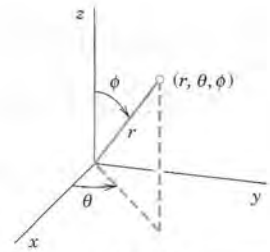

Fig. 309. Spherical coordinates

For these we get $\nabla^2 u$ immediately by adding u_{zz} to (5) in Sec. 12.9; thus,

$$\textbf{(5)} \qquad \nabla^2 u = \frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} + \frac{\partial^2 u}{\partial z^2}.$$

Laplacian in Spherical Coordinates

Spherical symmetry (a ball as region T bounded by a sphere S) requires **spherical coordinates** r, θ, ϕ related to x, y, z by

$$\textbf{(6)} \qquad x = r\cos\theta\sin\phi, \qquad y = r\sin\theta\sin\phi, \qquad z = r\cos\phi \qquad \text{(Fig. 309)}.$$

Using the chain rule (as in Sec. 12.9), we obtain $\nabla^2 u$ in spherical coordinates

$$\textbf{(7)} \qquad \nabla^2 u = \frac{\partial^2 u}{\partial r^2} + \frac{2}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \phi^2} + \frac{\cot\phi}{r^2}\frac{\partial u}{\partial \phi} + \frac{1}{r^2\sin^2\phi}\frac{\partial^2 u}{\partial \theta^2}.$$

We leave the details as an exercise. It is sometimes practical to write (7) in the form

$$(7') \qquad \nabla^2 u = \frac{1}{r^2}\left[\frac{\partial}{\partial r}\left(r^2\frac{\partial u}{\partial r}\right) + \frac{1}{\sin\phi}\frac{\partial}{\partial \phi}\left(\sin\phi\frac{\partial u}{\partial \phi}\right) + \frac{1}{\sin^2\phi}\frac{\partial^2 u}{\partial \theta^2}\right].$$

Remark on Notation. Equation (6) is used in calculus and extends the familiar notation for polar coordinates. Unfortunately, some books use θ and ϕ interchanged, an extension of the notation $x = r\cos\phi$, $y = r\sin\phi$ for polar coordinates (used in some European countries).

Boundary Value Problem in Spherical Coordinates

We shall solve the following **Dirichlet problem** in spherical coordinates:

$$\textbf{(8)} \qquad \nabla^2 u = \frac{1}{r^2}\left[\frac{\partial}{\partial r}\left(r^2\frac{\partial u}{\partial r}\right) + \frac{1}{\sin\phi}\frac{\partial}{\partial \phi}\left(\sin\phi\frac{\partial u}{\partial \phi}\right)\right] = 0.$$

$$\textbf{(9)} \qquad u(R, \phi) = f(\phi)$$

$$\textbf{(10)} \qquad \lim_{r\to\infty} u(r, \phi) = 0.$$

The PDE (8) follows from (7) by assuming that the solution u will not depend on θ because the Dirichlet condition (9) is independent of θ. This may be an electrostatic potential (or a temperature) $f(\phi)$ at which the sphere S: $r = R$ is kept. Condition (10) means that the potential at infinity will be zero.

Separating Variables by substituting $u(r, \phi) = G(r)H(\phi)$ into (8). Multiplying (8) by r^2, making the substitution and then dividing by GH, we obtain

$$\frac{1}{G}\frac{d}{dr}\left(r^2\frac{dG}{dr}\right) = -\frac{1}{H\sin\phi}\frac{d}{d\phi}\left(\sin\phi\frac{dH}{d\phi}\right).$$

By the usual argument both sides must be equal to a constant k. Thus we get the two ODEs

$$\frac{1}{G}\frac{d}{dr}\left(r^2\frac{dG}{dr}\right) = k \qquad \text{or} \qquad r^2\frac{d^2G}{dr^2} + 2r\frac{dG}{dr} = kG \tag{11}$$

and

$$\frac{1}{\sin\phi}\frac{d}{d\phi}\left(\sin\phi\frac{dH}{d\phi}\right) + kH = 0. \tag{12}$$

The solutions of (11) will take a simple form if we set $k = n(n + 1)$. Then, writing $G' = dG/dr$, etc., we obtain

$$r^2G'' + 2rG' - n(n + 1)G = 0. \tag{13}$$

This is an **Euler–Cauchy equation.** From Sec. 2.5 we know that it has solutions $G = r^a$. Substituting this and dropping the common factor r^a gives

$$a(a - 1) + 2a - n(n + 1) = 0. \qquad \text{The roots are} \qquad a = n \quad \text{and} \quad -n - 1.$$

Hence solutions are

$$G_n(r) = r^n \qquad \text{and} \qquad G_n^*(r) = \frac{1}{r^{n+1}}. \tag{14}$$

We now solve (12). Setting $\cos\phi = w$, we have $\sin^2\phi = 1 - w^2$ and

$$\frac{d}{d\phi} = \frac{d}{dw}\frac{dw}{d\phi} = -\sin\phi\frac{d}{dw}.$$

Consequently, (12) with $k = n(n + 1)$ takes the form

$$\frac{d}{dw}\left[(1 - w^2)\frac{dH}{dw}\right] + n(n + 1)H = 0. \tag{15}$$

This is **Legendre's equation** (see Sec. 5.3), written out

$$(15') \qquad (1 - w^2)\frac{d^2H}{dw^2} - 2w\frac{dH}{dw} + n(n+1)H = 0.$$

For integer $n = 0, 1, \cdots$ the Legendre polynomials

$$H = P_n(w) = P_n(\cos\phi) \qquad n = 0, 1, \cdots,$$

are solutions of Legendre's equation (15). We thus obtain the following two sequences of solution $u = GH$ of Laplace's equation (8), with constant A_n and B_n, where $n = 0, 1, \cdots$,

$$(16) \quad \text{(a)} \quad u_n(r, \phi) = A_n r^n P_n(\cos\phi), \qquad \text{(b)} \quad u_n^*(r, \phi) = \frac{B_n}{r^{n+1}} P_n(\cos\phi)$$

Use of Fourier–Legendre Series

Interior Problem: Potential Within the Sphere S. We consider a series of terms from (16a),

$$(17) \qquad u(r, \phi) = \sum_{n=0}^{\infty} A_n r^n P_n(\cos\phi) \qquad (r \leqq R).$$

Since S is given by $r = R$, for (17) to satisfy the Dirichlet condition (9) on the sphere S, we must have

$$(18) \qquad u(R, \phi) = \sum_{n=0}^{\infty} A_n R^n P_n(\cos\phi) = f(\phi);$$

that is, (18) must be the **Fourier–Legendre series** of $f(\phi)$. From (7) in Sec. 5.8 we get the coefficients

$$(19^*) \qquad A_n R^n = \frac{2n+1}{2}\int_{-1}^{1} \tilde{f}(w) P_n(w)\, dw$$

where $\tilde{f}(w)$ denotes $f(\phi)$ as a function of $w = \cos\phi$. Since $dw = -\sin\phi\, d\phi$, and the limits of integration -1 and 1 correspond to $\phi = \pi$ and $\phi = 0$, respectively, we also obtain

$$(19) \qquad A_n = \frac{2n+1}{2R^n}\int_0^{\pi} f(\phi) P_n(\cos\phi)\sin\phi\, d\phi, \qquad n = 0, 1, \cdots.$$

If $f(\phi)$ and $f'(\phi)$ are piecewise continuous on the interval $0 \leqq \phi \leqq \pi$, then the series (17) with coefficients (19) solves our problem for points inside the sphere because it can be shown that under these continuity assumptions the series (17) with coefficients (19) gives the derivatives occurring in (8) by termwise differentiation, thus justifying our derivation.

Exterior Problem: Potential Outside the Sphere S. Outside the sphere we cannot use the functions u_n in (16a) because they do not satisfy (10). But we can use the u_n^* in (16b), which do satisfy (10) (but could not be used inside S; why?). Proceeding as before leads to the solution of the exterior problem

$$\textbf{(20)} \qquad u(r, \phi) = \sum_{n=0}^{\infty} \frac{B_n}{r^{n+1}} P_n(\cos \phi) \qquad (r \geqq R)$$

satisfying (8), (9), (10), with coefficients

$$\textbf{(21)} \qquad B_n = \frac{2n + 1}{2} R^{n+1} \int_0^{\pi} f(\phi) P_n(\cos \phi) \sin \phi \, d\phi.$$

The next example illustrates all this for a sphere of radius 1 consisting of two hemispheres that are separated by a small strip of insulating material along the equator, so that these hemispheres can be kept at different potentials (110 V and 0 V).

EXAMPLE 1 **Spherical Capacitor**

Find the potential inside and outside a spherical capacitor consisting of two metallic hemispheres of radius 1 ft separated by a small slit for reasons of insulation, if the upper hemisphere is kept at 110 V and the lower is grounded (Fig. 310).

Solution. The given boundary condition is (recall Fig. 309)

$$f(\phi) = \begin{cases} 110 & \text{if} \quad 0 \leqq \phi < \pi/2 \\ 0 & \text{if} \quad \pi/2 < \phi \leqq \pi. \end{cases}$$

Since $R = 1$, we thus obtain from (19)

$$A_n = \frac{2n + 1}{2} \cdot 110 \int_0^{\pi/2} P_n(\cos \phi) \sin \phi \, d\phi$$

$$= \frac{2n + 1}{2} \cdot 110 \int_0^1 P_n(w) \, dw$$

where $w = \cos \phi$. Hence $P_n(\cos \phi) \sin \phi \, d\phi = -P_n(w) \, dw$, we integrate from 1 to 0, and we finally get rid of the minus by integrating from 0 to 1. You can evaluate this integral by your CAS or continue by using (11) in Sec. 5.3, obtaining

$$A_n = 55(2n + 1) \sum_{m=0}^{M} (-1)^m \frac{(2n - 2m)!}{2^n m!(n - m)!(n - 2m)!} \int_0^1 w^{n-2m} \, dw$$

where $M = n/2$ for even n and $M = (n - 1)/2$ for odd n. The integral equals $1/(n - 2m + 1)$. Thus

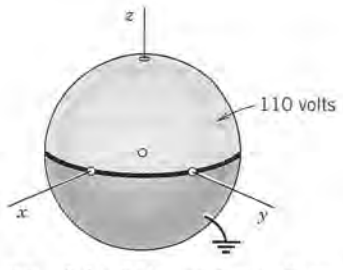

Fig. 310. Spherical capacitor in Example 1

$$(22) \qquad A_n = \frac{55(2n+1)}{2^n} \sum_{m=0}^{M} (-1)^m \frac{(2n-2m)!}{m!(n-m)!(n-2m+1)!}.$$

Taking $n = 0$, we get $A_0 = 55$ (since $0! = 1$). For $n = 1, 2, 3, \cdots$ we get

$$A_1 = \frac{165}{2} \cdot \frac{2!}{0!1!2!} = \frac{165}{2},$$

$$A_2 = \frac{275}{4} \left(\frac{4!}{0!2!3!} - \frac{2!}{1!1!1!} \right) = 0,$$

$$A_3 = \frac{385}{8} \left(\frac{6!}{0!3!4!} - \frac{4!}{1!2!2!} \right) = -\frac{385}{8}, \qquad \text{etc.}$$

Hence the ***potential* (17) *inside the sphere*** is (since $P_0 = 1$)

$$(23) \qquad u(r, \phi) = 55 + \frac{165}{2} r P_1(\cos\phi) - \frac{385}{8} r^3 P_3(\cos\phi) + \cdots \qquad \text{(Fig. 311)}$$

with P_1, P_3, $\cdots$ given by (11′), Sec. 5.3. Since $R = 1$, we see from (19) and (21) in this section that $B_n = A_n$, and (20) thus gives the ***potential outside the sphere***

$$(24) \qquad u(r, \phi) = \frac{55}{r} + \frac{165}{2r^2} P_1(\cos\phi) - \frac{385}{8r^4} P_3(\cos\phi) + \cdots.$$

Partial sums of these series can now be used for computing approximate values of the inner and outer potential. Also, it is interesting to see that far away from the sphere the potential is approximately that of a point charge, namely, $55/r$. (Compare with Theorem 3 in Sec. 9.7.)

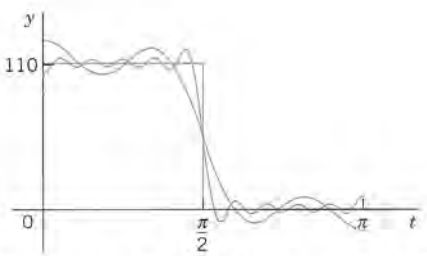

Fig. 311. Partial sums of the first 4, 6, and 11 nonzero terms of (23) for $r = R = 1$

EXAMPLE 2 **Simpler Cases. Help with Problems**

The technicalities occurring in cases like that of Example 1 can often be avoided. For instance, find the potential inside the sphere S: $r = R = 1$ when S is kept at the potential $f(\phi) = \cos 2\phi$. (Can you see the potential on S? What is it at the North Pole? The equator? The South Pole?)

Solution. $w = \cos\phi$, $\cos 2\phi = 2\cos^2\phi - 1 = 2w^2 - 1 = \frac{4}{3}P_2(w) - \frac{1}{3} = \frac{4}{3}(\frac{3}{2}w^2 - \frac{1}{2}) - \frac{1}{3}$. Hence the potential in the interior of the sphere is

$$u = \tfrac{4}{3}r^2P_2(w) - \tfrac{1}{3} = \tfrac{4}{3}r^2P_2(\cos\phi) - \tfrac{1}{3} = \tfrac{2}{3}r^2(3\cos^2\phi - 1) - \tfrac{1}{3}.$$

PROBLEM SET 12.10

1. Derive (7) from $\nabla^2 u$ in Cartesian coordinates. (Show the details.)
2. Find the surfaces on which the functions u_1, u_2, u_3 are zero.
3. Sketch the functions $P_n(\cos\phi)$ for $n = 0, 1, 2$ (see (11′) in Sec. 5.3).
4. Sketch the functions $P_3(\cos\phi)$ and $P_4(\cos\phi)$.
5. Verify that u_n and u_n^* in (16) are solutions of (8).

6–11 POTENTIALS DEPENDING ONLY ON r

6. **(Dimension 3)** Show that the only solution of the Laplace equation depending only on $r = \sqrt{x^2 + y^2 + z^2}$ is $u = c/r + k$ with constant c and k.
7. **(Dimension 3)** Verify that $u = c/r$, $r = \sqrt{x^2 + y^2 + z^2}$, satisfies Laplace's equation in spherical coordinates.
8. **(Dirichlet problem).** Find the electrostatic potential between two concentric spheres of radii $r_1 = 10$ cm and $r_2 = 20$ cm kept at potentials $U_1 = 260$ V and $U_2 = 110$ V, respectively.
9. **(Dimension 2, logarithmic potential)** Show that the only solution of the two-dimensional Laplace equation depending only on $r = \sqrt{x^2 + y^2}$ is $u = c \ln r + k$ with constant c and k.
10. **(Logarithmic potential)** Find the electrostatic potential between two coaxial cylinders of radii $r_1 = 10$ cm and $r_2 = 20$ cm kept at potentials $U_1 = 260$ V and $U_2 = 110$ V, respectively. Compare with Prob. 8. Comment.
11. **(Heat problem)** If the surface of the ball $r^2 = x^2 + y^2 + z^2 \leqq R^2$ is kept at temperature zero and the initial temperature in the ball is $f(r)$, show that the temperature $u(r, t)$ in the ball is a solution of $u_t = c^2(u_{rr} + 2u_r/r)$ satisfying the conditions $u(R, t) = 0$, $u(r, 0) = f(r)$. Show that setting $v = ru$ gives $v_t = c^2 v_{rr}$, $v(R, t) = 0$, $v(r, 0) = rf(r)$. Include the condition $v(0, t) = 0$ (which holds because u must be bounded at $r = 0$), and solve the resulting problem by separating variables.
12. **(Two-dimensional potential problems)** Show that the functions $x^2 - y^2$, xy, $x/(x^2 + y^2)$, $e^x \cos y$, $e^x \sin y$, $\cos x \cosh y$, $\ln(x^2 + y^2)$, and $\arctan(y/x)$ satisfy Laplace's equation $u_{xx} + u_{yy} = 0$. (Two-dimensional potential problems are best solved by ***complex analysis***, as we shall see in Chap. 18.)

13–17 BOUNDARY VALUE PROBLEMS IN SPHERICAL COORDINATES r, θ, ϕ

Find the potential in the interior of the sphere S: $r = R = 1$ if this interior is free of charges and the potential on S is:

13. $f(\phi) = 100$
14. $f(\phi) = \cos\phi$
15. $f(\phi) = \cos 3\phi$
16. $f(\phi) = \sin^2\phi$
17. $f(\phi) = 35\cos 4\phi + 20\cos 2\phi + 9$
18. Show that in Prob. 13 the potential exterior to the sphere is the same as that of a point charge at the origin. Is this physically plausible?
19. Sketch the intersection of the equipotential surfaces in Prob. 14 with the xz-plane.
20. Find the potential exterior to the sphere in Example 2 of the text and in Prob. 15.
21. What is the temperature in a ball of radius 1 and of homogeneous material if its lower boundary hemisphere is kept at 0°C and its upper at 100°C?
22. **(Reflection in a sphere)** Let r, θ, ϕ be spherical coordinates. If $u(r, \theta, \phi)$ satisfies $\nabla^2 u = 0$, show that $v(r, \theta, \phi) = u(1/r, \theta, \phi)/r$ satisfies $\nabla^2 v = 0$. What does this give for (16)?
23. **(Reflection in a circle)** Let r, θ be polar coordinates. If $u(r, \theta)$ satisfies $\nabla^2 u = 0$, show that the function $v(r, \theta) = u(1/r, \theta)$ satisfies $\nabla^2 v = 0$. What are $u = r\cos\theta$ and v in terms of x and y? Answer the same question for $u = r^2 \cos\theta \sin\theta$ and v.
24. **TEAM PROJECT. Transmission Line and Related PDEs.** Consider a long cable or telephone wire (Fig. 312) that is imperfectly insulated, so that leaks occur along the entire length of the cable. The source S of the current $i(x, t)$ in the cable is at $x = 0$, the receiving end T at $x = l$. The current flows from S to T, through the load, and returns to the ground. Let the constants R, L, C, and G denote the resistance, inductance, capacitance to ground, and conductance to ground, respectively, of the cable per unit length.

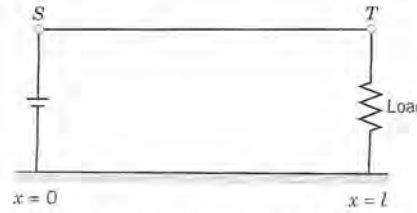

Fig. 312. Transmission line

(a) Show that (**"first transmission line equation"**)

$$-\frac{\partial u}{\partial x} = Ri + L\frac{\partial i}{\partial t}$$

where $u(x, t)$ is the potential in the cable. *Hint:* Apply Kirchhoff's voltage law to a small portion of the cable between x and $x + \Delta x$ (difference of the potentials at x and $x + \Delta x$ = resistive drop + inductive drop).

(b) Show that for the cable in (a) (**"second transmission line equation"**),

$$-\frac{\partial i}{\partial x} = Gu + C\frac{\partial u}{\partial t}$$

Hint: Use Kirchhoff's current law (difference of the currents at x and $x + \Delta x$ = loss due to leakage to ground + capacitive loss).

(c) Second-order PDEs. Show that elimination of i or u from the transmission line equations leads to

$$u_{xx} = LCu_{tt} + (RC + GL)u_t + RGu,$$

$$i_{xx} = LCi_{tt} + (RC + GL)i_t + RGi.$$

(d) Telegraph equations. For a submarine cable, G is negligible and the frequencies are low. Show that this leads to the so-called *submarine cable equations* or **telegraph equations**

$$u_{xx} = RCu_t, \qquad i_{xx} = RCi_t.$$

Find the potential in a submarine cable with ends ($x = 0, x = l$) grounded and initial voltage distribution $U_0 = const.$

(e) High-frequency line equations. Show that in the case of alternating currents of high frequencies the equations in (c) can be approximated by the so-called **high-frequency line equations**

$$u_{xx} = LCu_{tt}, \qquad i_{xx} = LCi_{tt}.$$

Solve the first of them, assuming that the initial potential is

$$U_0 \sin(\pi x/l),$$

and $u_t(x, 0) = 0$ and $u = 0$ at the ends $x = 0$ and $x = l$ for all t.

12.11 Solution of PDEs by Laplace Transforms

Readers familiar with Chap. 6 may wonder whether Laplace transforms can also be used for solving *partial* differential equations. The answer is yes, particularly if one of the independent variables ranges over the positive axis. The steps to obtain a solution are similar to those in Chap. 6. For a PDE in two variables they are as follows.

1. Take the Laplace transform with respect to one of the two variables, usually t. This gives an ***ODE for the transform*** of the unknown function. This is so since the derivatives of this function with respect to the other variable slip into the transformed equation. The latter also incorporates the given boundary and initial conditions.
2. Solving that ODE, obtain the transform of the unknown function.
3. Taking the inverse transform, obtain the solution of the given problem.

If the coefficients of the given equation do not depend on t, the use of Laplace transforms will simplify the problem.

We explain the method in terms of a typical example.

EXAMPLE 1 Semi-Infinite String

Find the displacement $w(x, t)$ of an elastic string subject to the following conditions. (We write w since we need u to denote the unit step function.)

(i) The string is initially at rest on the x-axis from $x = 0$ to ∞ (*"semi-infinite string"*).

(ii) For $t > 0$ the left end of the string ($x = 0$) is moved in a given fashion, namely, according to a single sine wave

$$w(0, t) = f(t) = \begin{cases} \sin t & \text{if } 0 \leqq t \leqq 2\pi \\ 0 & \text{otherwise} \end{cases}$$ (Fig. 313).

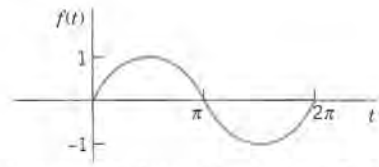

Fig. 313. Motion of the left end of the string in Example 1 as a function of time t

(iii) Furthermore, $\lim_{x\to\infty} w(x, t) = 0$ for $t \geqq 0$.

Of course there is no infinite string, but our model describes a long string or rope (of negligible weight) with its right end fixed far out on the x-axis.

Solution. We have to solve the wave equation (Sec. 12.2)

$$\frac{\partial^2 w}{\partial t^2} = c^2 \frac{\partial^2 w}{\partial x^2}, \qquad c^2 = \frac{T}{\rho} \tag{1}$$

for positive x and t, subject to the "boundary conditions"

$$w(0, t) = f(t), \qquad \lim_{x\to\infty} w(x, t) = 0 \qquad (t \geqq 0) \tag{2}$$

with f as given above, and the initial conditions

$$\text{(a)}\quad w(x, 0) = 0, \qquad \text{(b)}\quad w_t(x, 0) = 0. \tag{3}$$

We take the Laplace transform ***with respect to t.*** By (2) in Sec. 6.2,

$$\mathcal{L}\left\{\frac{\partial^2 w}{\partial t^2}\right\} = s^2\mathcal{L}\{w\} - sw(x, 0) - w_t(x, 0) = c^2\mathcal{L}\left\{\frac{\partial^2 w}{\partial x^2}\right\}.$$

The expression $-sw(x, 0) - w_t(x, 0)$ drops out because of (3). On the right we assume that we may interchange integration and differentiation. Then

$$\mathcal{L}\left\{\frac{\partial^2 w}{\partial x^2}\right\} = \int_0^\infty e^{-st} \frac{\partial^2 w}{\partial x^2}\, dt = \frac{\partial^2}{\partial x^2} \int_0^\infty e^{-st} w(x, t)\, dt = \frac{\partial^2}{\partial x^2}\, \mathcal{L}\{w(x, t)\}.$$

Writing $W(x, s) = \mathcal{L}\{w(x, t)\}$, we thus obtain

$$s^2 W = c^2 \frac{\partial^2 W}{\partial x^2}, \qquad \text{thus} \qquad \frac{\partial^2 W}{\partial x^2} - \frac{s^2}{c^2} W = 0.$$

Since this equation contains only a derivative with respect to x, it may be regarded as an ***ordinary differential equation*** for $W(x, s)$ considered as a function of x. A general solution is

$$W(x, s) = A(s)e^{sx/c} + B(s)e^{-sx/c}. \tag{4}$$

From (2) we obtain, writing $F(s) = \mathcal{L}\{f(t)\}$,

$$W(0, s) = \mathcal{L}\{w(0, t)\} = \mathcal{L}\{f(t)\} = F(s).$$

Assuming that we can interchange integration and taking the limit, we have

$$\lim_{x\to\infty} W(x, s) = \lim_{x\to\infty} \int_0^\infty e^{-st} w(x, t)\, dt = \int_0^\infty e^{-st} \lim_{x\to\infty} w(x, t)\, dt = 0.$$

This implies $A(s) = 0$ in (4) because $c > 0$, so that for every fixed positive s the function $e^{sx/c}$ increases as x increases. Note that we may assume $s > 0$ since a Laplace transform generally exists for *all* s greater than some fixed k (Sec. 6.2). Hence we have

$$W(0, s) = B(s) = F(s),$$

so that (4) becomes

$$W(x, s) = F(s)e^{-sx/c}.$$

From the second shifting theorem (Sec. 6.3) with $a = x/c$ we obtain the inverse transform

$$w(x, t) = f\left(t - \frac{x}{c}\right) u\left(t - \frac{x}{c}\right) \tag{5}$$

(Fig. 314)

that is,

$$w(x, t) = \sin\left(t - \frac{x}{c}\right) \quad \text{if} \quad \frac{x}{c} < t < \frac{x}{c} + 2\pi \quad \text{or} \quad ct > x > (t - 2\pi)c$$

and zero otherwise. This is a single sine wave traveling to the right with speed c. Note that a point x remains at rest until $t = x/c$, the time needed to reach that x if one starts at $t = 0$ (start of the motion of the left end) and travels with speed c. The result agrees with our physical intuition. Since we proceeded formally, we must verify that (5) satisfies the given conditions. We leave this to the student. ■

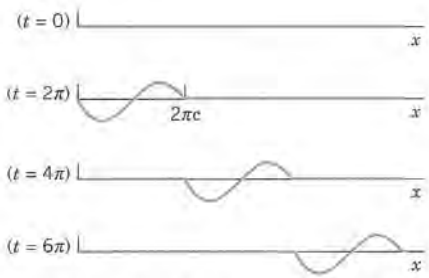

Fig. 314. Traveling wave in Example 1

This is the end of Chap. 12, in which we concentrated on the most important partial differential equations (PDEs) in physics and engineering. This is also the end of Part C on Fourier analysis and PDEs.

We have seen that PDEs have various basic engineering applications, which make them the subject of many ongoing research projects.

Numerics for PDEs follows in Secs. 21.4–21.7, which are independent of the other sections in Part E on numerics.

In the next part, Part D on **complex analysis,** we turn to an area of a different nature that is also highly important to the engineer, as our examples and problems will show. This will include another approach to the (two-dimensional) **Laplace equation** and its applications in Chap. 18.

PROBLEM SET 12.11

1. Sketch a figure similar to Fig. 314 if $c = 1$ and f is "triangular" as in Example 1, Sec. 12.3.
2. How does the speed of the wave in Example 1 depend on the tension and on the mass of the string?
3. Verify the solution in Example 1. What traveling wave do we obtain in Example 1 in the case of a (nonterminating) sinusoidal motion of the left end starting at $t = 0$?

4–6 SOLVE BY LAPLACE TRANSFORMS

4. $\dfrac{\partial w}{\partial x} + x\dfrac{\partial w}{\partial t} = x,\ w(x, 0) = 1,\ w(0, t) = 1$

5. $x\dfrac{\partial w}{\partial x} + \dfrac{\partial w}{\partial t} = xt, \quad w(x, 0) = 0 \text{ if } x \geqq 0,$
$w(0, t) = 0 \text{ if } t \geqq 0$

6. $\dfrac{\partial^2 w}{\partial x^2} = 100\dfrac{\partial^2 w}{\partial t^2} + 100\dfrac{\partial w}{\partial t} + 25w,$
$w(x, 0) = 0 \text{ if } x \geqq 0, \quad w_t(x, 0) = 0 \text{ if } t \geqq 0,$
$w(0, t) = \sin t \text{ if } t \geqq 0$

7. Solve Prob. 5 by another method.

8–10 HEAT PROBLEM

Find the temperature $w(x, t)$ in a semi-infinite laterally insulated bar extending from $x = 0$ along the x-axis to infinity, assuming that the initial temperature is 0, $w(x, t) \to 0$ as $x \to \infty$ for every fixed $t \geqq 0$, and $w(0, t) = f(t)$. Proceed as follows.

8. Set up the model and show that the Laplace transform leads to

$$sW = c^2\frac{\partial^2 W}{\partial x^2} \quad (W = \mathcal{L}\{w\})$$

and

$$W = F(s)e^{-\sqrt{s}x/c} \quad (F = \mathcal{L}\{f\}).$$

Applying the convolution theorem, show that

$$w(x, t) = \frac{x}{2c\sqrt{\pi}}\int_0^t f(t - \tau)\tau^{-3/2}e^{-x^2/(4c^2\tau)}\,d\tau.$$

9. Let $w(0, t) = f(t) = u(t)$ (Sec. 6.3). Denote the corresponding w, W, and F by w_0, W_0, and F_0. Show that then in Prob. 8,

$$w_0(x, t) = \frac{x}{2c\sqrt{\pi}}\int_0^t \tau^{-3/2}e^{-x^2/(4c^2\tau)}\,d\tau$$
$$= 1 - \operatorname{erf}\left(\frac{x}{2c\sqrt{t}}\right)$$

with the error function erf as defined in Problem Set 12.6.

10. (Duhamel's formula[4]) Show that in Prob. 9,

$$W_0(x, s) = \frac{1}{s}e^{-\sqrt{s}x/c}$$

and the convolution theorem gives *Duhamel's formula*

$$w(x, t) = \int_0^t f(t - \tau)\frac{\partial w_0}{\partial \tau}\,d\tau.$$

CHAPTER 12 REVIEW QUESTIONS AND PROBLEMS

1. Write down the three probably most important PDEs from memory and state their main applications.
2. What is the method of separating variables for PDEs? Give an example from memory.
3. What is the superposition principle? Give a typical application.
4. What role did Fourier series play in this chapter? Fourier integrals?
5. What are the eigenfunctions and their frequencies of the vibrating string? Of the heat equation?
6. What additional conditions did we consider for the wave equation? For the heat equation?
7. Name and explain the three kinds of boundary conditions.
8. What do you know about types of PDEs? About transformation to normal forms?
9. What is d'Alembert's method? To what PDE does it apply?
10. When and why did we use polar coordinates? Spherical coordinates?
11. When and why did Legendre's equation occur in this chapter? Bessel's equation?
12. What are the eigenfunctions of the circular membrane? How do their frequencies differ in principle from those of the eigenfunctions of the vibrating string?
13. Explain mathematically (not physically) why we got exponential functions in separating the heat equation, but not for the wave equation.
14. What is the error function? Why did it occur and where?
15. Explain the idea of using Laplace transform methods for PDEs. Give an example from memory.
16. For what k and m are $x^4 + kx^2y^2 + y^4$ and $\sin mx \sinh y$ solutions of Laplace's equation?
17. Verify that $(x^2 - y^2)/(x^2 + y^2)^2$ satisfies Laplace's equation.

18–21 Solve for $u = u(x, y)$:

18. $u_{yy} + 16u = 0$

19. $u_{xx} + u_x - 2u = 0$

20. $u_{xy} + u_y + x + y + 1 = 0$

21. $u_{yy} + u_y = 0, \; u(x, 0) = f(x), \; u_y(x, 0) = g(x)$

22. Find all solution $u(x, y) = F(x)G(y)$ of Laplace's equation in two variables.

[4]JEAN-MARIE CONSTANT DUHAMEL (1797–1872), French mathematician.

23–26 Find and sketch or graph (as in Fig. 285 in Sec. 12.3) the deflection $u(x, t)$ of a vibrating string of length π, extending from $x = 0$ to $x = \pi$, and $c^2 = T/\rho = 1$, starting with velocity 0 and deflection

23. $f(x) = \sin x - \frac{1}{2}\sin 2x$

24. $f(x) = \frac{1}{2}\pi - |x - \frac{1}{2}\pi|$

25. $f(x) = \sin^3 x$

26. $f(x) = x(\pi - x)$

27–30 Find the temperature distribution in a laterally insulated thin copper bar ($c^2 = K/\rho\sigma = 1.158\ \text{cm}^2/\text{sec}$), 50 cm long and of constant cross section with endpoints at $x = 0$ and 50 kept at 0°C and initial temperature

27. $f(x) = \sin(\pi x/50)$

28. $f(x) = x(50 - x)$

29. $f(x) = 25 - |25 - x|$

30. $f(x) = 4\sin^3(\pi x/10)$

31–33 Find the temperature $u(x, t)$ in a laterally insulated bar of length π, extending from $x = 0$ to $x = \pi$, with $c^2 = 1$ for adiabatic boundary condition (see Problem Set 12.5) and initial temperature

31. $100\cos 4x$

32. $3x^2$

33. $\pi - 2|x - \frac{1}{2}\pi|$

34. Using partial sums, graph $u(x, t)$ in Prob. 33 for several constant t on common axes. Do these graphs agree with your physical intuition?

35. Let $f(x, y) = u(x, y, 0)$ be the initial temperature in a thin square plate of side π with edges kept at 0°C and faces perfectly insulated. Separating variables, obtain from $u_t = c^2\nabla^2 u$ the solution

$$u(x, y, t) = \sum_{m=1}^{\infty}\sum_{n=1}^{\infty} B_{mn}\sin mx\sin ny\, e^{-c^2(m^2+n^2)t}$$

where

$$B_{mn} = \frac{4}{\pi^2}\int_0^{\pi}\int_0^{\pi} f(x, y)\sin mx\sin ny\, dx\, dy.$$

36. Find the temperature in Prob. 35 if $f(x, y) = x(\pi - x)y(\pi - y)$.

37–42 Transform to normal form and solve (showing the details!)

37. $u_{xy} = u_{xx}$

38. $u_{xx} + 4u_{xy} + 4u_{yy} = 0$

39. $u_{xx} + 4u_{yy} = 0$

40. $2u_{xx} + 5u_{xy} + 2u_{yy} = 0$

41. $u_{xx} + 2u_{xy} + u_{yy} = 0$

42. $u_{yy} + u_{xy} - 2u_{xx} = 0$

43–47 Show that the following membranes of area 1 with $c^2 = 1$ have the frequencies of the fundamental mode as given (4-decimal values). Compare.

43. Circle: $\alpha_1/(2\sqrt{\pi}) = 0.6784$

44. Square: $1\sqrt{2} = 0.7071$

45. Rectangle (sides 1:2): $\sqrt{5/8} = 0.7906$

46. Semicircle: $3.832/\sqrt{8\pi} = 0.7644$

47. Quadrant of circle: $\alpha_{12}/(4\sqrt{\pi}) = 0.7244$ ($\alpha_{12} = 5.13562$ = first positive zero of J_2)

48–50 Find the electrostatic potential in the following (charge-free) regions:

48. Between two concentric spheres of radii r_0 and r_1 kept at the potentials u_0 and u_1, respectively.

49. Between two coaxial circular cylinders of radii r_0 and r_1 kept at the potential u_0 and u_1, respectively. (Compare with Prob. 48.)

50. In the interior of a sphere of radius 1 kept at the potential $f(\phi) = \cos 3\phi + 3\cos\phi$ (referred to our usual spherical coordinates).

SUMMARY OF CHAPTER 12
Partial Differential Equations (PDEs)

Whereas ODEs (Chaps. 1–6) serve as models of problems involving only *one* independent variable, problems involving *two or more* independent variables (space variables or time t and one or several space variables) lead to PDEs. This accounts for the enormous importance of PDEs to the engineer and physicist. Most important are:

(1) $u_{tt} = c^2 u_{xx}$ One-dimensional wave equation (Secs. 12.2–12.4)

(2) $u_{tt} = c^2(u_{xx} + u_{yy})$ Two-dimensional wave equation (Secs. 12.7–12.9)

(3) $u_t = c^2 u_{xx}$ One-dimensional heat equation (Secs. 12.5, 12.6)

(4) $\nabla^2 u = u_{xx} + u_{yy} = 0$ Two-dimensional Laplace equation (Secs. 12.5, 12.9)

(5) $\nabla^2 u = u_{xx} + u_{yy} + u_{zz} = 0$ Three-dimensional Laplace equation (Sec. 12.10).

Equations (1) and (2) are hyperbolic, (3) is parabolic, (4) and (5) are elliptic.

In practice, one is interested in obtaining the solution of such an equation in a given region satisfying given additional conditions, such as **initial conditions** (conditions at time $t = 0$) or **boundary conditions** (prescribed values of the solution u or some of its derivatives on the boundary surface S, or boundary curve C, of the region) or both. For (1) and (2) one prescribes two initial conditions (initial displacement and initial velocity). For (3) one prescribes the initial temperature distribution. For (4) and (5) one prescribes a boundary condition and calls the resulting problem a (see Sec. 12.5)

Dirichlet problem if u is prescribed on S,
Neumann problem if $u_n = \partial u/\partial n$ is prescribed on S,
Mixed problem if u is prescribed on one part of S and u_n on the other.

A general method for solving such problems is the method of **separating variables** or **product method,** in which one assumes solutions in the form of products of functions each depending on one variable only. Thus equation (1) is solved by setting $u(x, t) = F(x)G(t)$; see Sec. 12.3; similarly for (3) (see Sec. 12.5). Substitution into the given equation yields ***ordinary*** differential equations for F and G, and from these one gets infinitely many solutions $F = F_n$ and $G = G_n$ such that the corresponding functions

$$u_n(x, t) = F_n(x)G_n(t)$$

are solutions of the PDE satisfying the given boundary conditions. These are the **eigenfunctions** of the problem, and the corresponding **eigenvalues** determine the frequency of the vibration (or the rapidity of the decrease of temperature in the case of the heat equation, etc.). To satisfy also the initial condition (or conditions), one must consider infinite series of the u_n, whose coefficients turn out to be the Fourier coefficients of the functions f and g representing the given initial conditions (Secs. 12.3, 12.5). Hence **Fourier series** (and *Fourier integrals*) are of basic importance here (Secs. 12.3, 12.5, 12.6, 12.8).

Steady-state problems are problems in which the solution does not depend on time t. For these, the heat equation $u_t = c^2 \nabla^2 u$ becomes the Laplace equation.

Before solving an initial or boundary value problem, one often transforms the PDE into coordinates in which the boundary of the region considered is given by simple formulas. Thus in polar coordinates given by $x = r \cos \theta$, $y = r \sin \theta$, the **Laplacian** becomes (Sec. 12.9)

$$\nabla^2 u = u_{rr} + \frac{1}{r} u_r + \frac{1}{r^2} u_{\theta\theta}; \tag{6}$$

for spherical coordinates see Sec. 12.10. If one now separates the variables, one gets **Bessel's equation** from (2) and (6) (vibrating circular membrane, Sec. 12.9) and **Legendre's equation** from (5) transformed into spherical coordinates (Sec. 12.10).

Complex Analysis

CHAPTER 13 Complex Numbers and Functions

CHAPTER 14 Complex Integration

CHAPTER 15 Power Series, Taylor Series

CHAPTER 16 Laurent Series. Residue Integration

CHAPTER 17 Conformal Mapping

CHAPTER 18 Complex Analysis and Potential Theory

Many engineering problems can be modeled, investigated, and solved by functions of a complex variable. For simpler problems, some acquaintance with complex numbers will suffice. This is true for simpler electric circuits and mechanical vibrating systems. For more complicated problems in heat conduction, fluid flow, electrostatics, etc., one needs *the theory of complex analytic functions,* briefly called **complex analysis.** The importance of the latter in applied mathematics has three main reasons:

1. Most importantly, the real and imaginary parts of an analytic function satisfy Laplace's equation in two real variables. Hence two-dimensional potential problems can be solved by methods for analytic functions, and this is often simpler than working in real.

2. Many complicated real and complex integrals in applications can be evaluated by the elegant methods of complex integration.

3. Most functions in engineering mathematics are analytic functions, and their study as functions of a complex variable leads to a deeper understanding of their properties and to interrelations in complex that have no analog in real calculus.

CHAPTER 13

Complex Numbers and Functions

Complex numbers and their geometric representation in the **complex plane** are discussed in Secs. 13.1 and 13.2. Complex analysis is concerned with complex **analytic functions** as defined in Sec. 13.3. Checking for analyticity is done by the **Cauchy–Riemann equations** (Sec. 13.4). These equations are of basic importance, also because of their relation to **Laplace's equation**.

The remaining sections of the chapter are devoted to elementary complex functions (exponential, trigonometric, hyperbolic, and logarithmic functions). These generalize the familiar real functions of calculus. Their detailed knowledge is an absolute necessity in practical work, just as that of their real counterparts is in calculus.

Prerequisite: Elementary calculus.
References and Answers to Problems: App. 1 Part D, App. 2.

13.1 Complex Numbers. Complex Plane

Equations without *real* solutions, such as $x^2 = -1$ or $x^2 - 10x + 40 = 0$, were observed early in history and led to the introduction of complex numbers.[1] By definition, a **complex number** z is an ordered pair (x, y) of real numbers x and y, written

$$z = (x, y).$$

x is called the **real part** and y the **imaginary part** of z, written

$$x = \operatorname{Re} z, \qquad y = \operatorname{Im} z.$$

By definition, two complex numbers are **equal** if and only if their real parts are equal and their imaginary parts are equal.

(0, 1) is called the **imaginary unit** and is denoted by i,

(1) $$i = (0, 1).$$

[1]First to use complex numbers for this purpose was the Italian mathematician GIROLAMO CARDANO (1501–1576), who found the formula for solving cubic equations. The term "complex number" was introduced by CARL FRIEDRICH GAUSS (see the footnote in Sec. 5.4), who also paved the way for a general use of complex numbers.

Addition, Multiplication. Notation $z = x + iy$

Addition of two complex numbers $z_1 = (x_1, y_1)$ and $z_2 = (x_2, y_2)$ is defined by

$$z_1 + z_2 = (x_1, y_1) + (x_2, y_2) = (x_1 + x_2, \quad y_1 + y_2). \tag{2}$$

Multiplication is defined by

$$z_1 z_2 = (x_1, y_1)(x_2, y_2) = (x_1 x_2 - y_1 y_2, \quad x_1 y_2 + x_2 y_1). \tag{3}$$

In particular, these two definitions imply that

$$(x_1, 0) + (x_2, 0) = (x_1 + x_2, 0)$$

and

$$(x_1, 0)(x_2, 0) = (x_1 x_2, 0)$$

as for real numbers x_1, x_2. Hence the complex numbers ***"extend"*** the real numbers. We can thus write

$$(x, 0) = x. \qquad \text{Similarly,} \qquad (0, y) = iy$$

because by (1) and the definition of multiplication we have

$$iy = (0, 1)y = (0, 1)(y, 0) = (0 \cdot y - 1 \cdot 0, \quad 0 \cdot 0 + 1 \cdot y) = (0, y).$$

Together we have by addition $(x, y) = (x, 0) + (0, y) = x + iy$:

In practice, complex numbers $z = (x, y)$ are written

$$z = x + iy \tag{4}$$

or $z = x + yi$, e.g., $17 + 4i$ (instead of $i4$).

Electrical engineers often write j instead if i because they need i for the current.

If $x = 0$, then $z = iy$ and is called **pure imaginary.** Also, (1) and (3) give

$$i^2 = -1 \tag{5}$$

because by the definition of multiplication, $i^2 = ii = (0, 1)(0, 1) = (-1, 0) = -1$.

For **addition** the standard notation (4) gives [see (2)]

$$(x_1 + iy_1) + (x_2 + iy_2) = (x_1 + x_2) + i(y_1 + y_2).$$

For **multiplication** the standard notation gives the following very simple recipe. Multiply each term by each other term and use $i^2 = -1$ when it occurs [see (3)]:

$$\begin{aligned}(x_1 + iy_1)(x_2 + iy_2) &= x_1 x_2 + ix_1 y_2 + iy_1 x_2 + i^2 y_1 y_2 \\ &= (x_1 x_2 - y_1 y_2) + i(x_1 y_2 + x_2 y_1).\end{aligned}$$

This agrees with (3). And it shows that $x + iy$ is a more practical notation for complex numbers than (x, y).

If you know vectors, you see that (2) is vector addition, whereas the multiplication (3) has no counterpart in the usual vector algebra.

EXAMPLE 1 **Real Part, Imaginary Part, Sum and Product of Complex Numbers**

Let $z_1 = 8 + 3i$ and $z_2 = 9 - 2i$. Then $\operatorname{Re} z_1 = 8$, $\operatorname{Im} z_1 = 3$, $\operatorname{Re} z_2 = 9$, $\operatorname{Im} z_2 = -2$ and

$$z_1 + z_2 = (8 + 3i) + (9 - 2i) = 17 + i,$$

$$z_1 z_2 = (8 + 3i)(9 - 2i) = 72 + 6 + i(-16 + 27) = 78 + 11i.$$

Subtraction, Division

Subtraction and **division** are defined as the inverse operations of addition and multiplication, respectively. Thus the **difference** $z = z_1 - z_2$ is the complex number z for which $z_1 = z + z_2$. Hence by (2),

(6) $$z_1 - z_2 = (x_1 - x_2) + i(y_1 - y_2).$$

The **quotient** $z = z_1/z_2$ $(z_2 \neq 0)$ is the complex number z for which $z_1 = zz_2$. If we equate the real and the imaginary parts on both sides of this equation, setting $z = x + iy$, we obtain $x_1 = x_2x - y_2y$, $y_1 = y_2x + x_2y$. The solution is

(7*) $$z = \frac{z_1}{z_2} = x + iy, \qquad x = \frac{x_1x_2 + y_1y_2}{x_2^2 + y_2^2}, \qquad y = \frac{x_2y_1 - x_1y_2}{x_2^2 + y_2^2}.$$

The ***practical rule*** used to get this is by multiplying numerator and denominator of z_1/z_2 by $x_2 - iy_2$ and simplifiying:

(7) $$z = \frac{x_1 + iy_1}{x_2 + iy_2} = \frac{(x_1 + iy_1)(x_2 - iy_2)}{(x_2 + iy_2)(x_2 - iy_2)} = \frac{x_1x_2 + y_1y_2}{x_2^2 + y_2^2} + i\,\frac{x_2y_1 - x_1y_2}{x_2^2 + y_2^2}.$$

EXAMPLE 2 **Difference and Quotient of Complex Numbers**

For $z_1 = 8 + 3i$ and $z_2 = 9 - 2i$ we get $z_1 - z_2 = (8 + 3i) - (9 - 2i) = -1 + 5i$ and

$$\frac{z_1}{z_2} = \frac{8 + 3i}{9 - 2i} = \frac{(8 + 3i)(9 + 2i)}{(9 - 2i)(9 + 2i)} = \frac{66 + 43i}{81 + 4} = \frac{66}{85} + \frac{43}{85}\,i.$$

Check the division by multiplication to get $8 + 3i$.

Complex numbers satisfy the same commutative, associative, and distributive laws as real numbers (see the problem set).

Complex Plane

This was algebra. Now comes geometry: the geometrical representation of complex numbers as points in the plane. This is of great practical importance. The idea is quite simple and natural. We choose two perpendicular coordinate axes, the horizontal x-axis, called the **real axis,** and the vertical y-axis, called the **imaginary axis.** On both axes we choose the same unit of length (Fig. 315). This is called a **Cartesian coordinate system.**

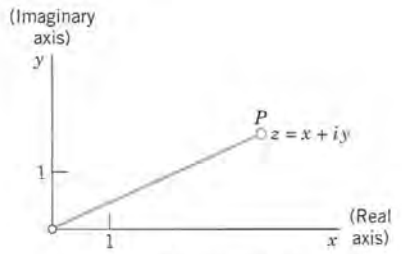

Fig. 315. The complex plane

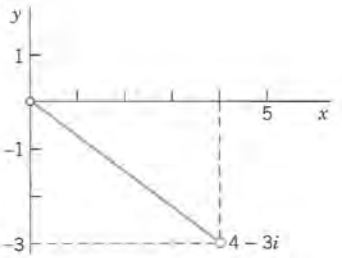

Fig. 316. The number $4 - 3i$ in the complex plane

We now plot a given complex number $z = (x, y) = x + iy$ as the point P with coordinates x, y. The xy-plane in which the complex numbers are represented in this way is called the **complex plane.**[2] Figure 316 shows an example.

Instead of saying "the point represented by z in the complex plane" we say briefly and simply ***"the point z in the complex plane."*** This will cause no misunderstandings.

Addition and subtraction can now be visualized as illustrated in Figs. 317 and 318.

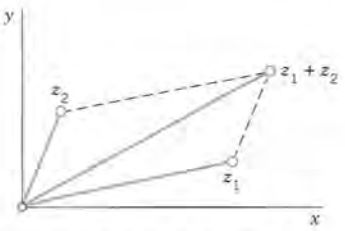

Fig. 317. Addition of complex numbers

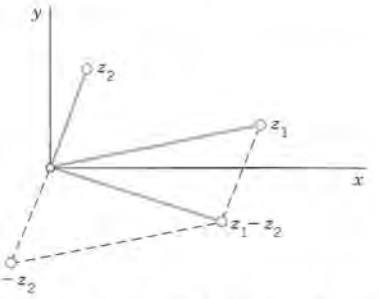

Fig. 318. Subtraction of complex numbers

Complex Conjugate Numbers

The complex conjugate $\bar{z}$ of a complex number $z = x + iy$ is defined by

$$\bar{z} = x - iy.$$

It is obtained geometrically by reflecting the point z in the real axis. Figure 319 shows this for $z = 5 + 2i$ and its conjugate $\bar{z} = 5 - 2i$.

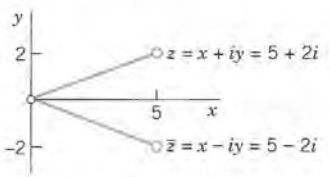

Fig. 319. Complex conjugate numbers

[2]Sometimes called the **Argand diagram,** after the French mathematician JEAN ROBERT ARGAND (1768–1822), born in Geneva and later librarian in Paris. His paper on the complex plane appeared in 1806, nine years after a similar memoir by the Norwegian mathematician CASPAR WESSEL (1745–1818), a surveyor of the Danish Academy of Science.

The complex conjugate is important because it permits us to switch from complex to real. Indeed, by multiplication, $z\bar{z} = x^2 + y^2$ (verify!). By addition and subtraction, $z + \bar{z} = 2x$, $z - \bar{z} = 2iy$. We thus obtain for the real part x and the imaginary part y (not iy!) of $z = x + iy$ the important formulas

$$\textbf{(8)} \qquad \operatorname{Re} z = x = \frac{1}{2}(z + \bar{z}), \qquad \operatorname{Im} z = y = \frac{1}{2i}(z - \bar{z}).$$

If z is real, $z = x$, then $\bar{z} = z$ by the definition of $\bar{z}$, and conversely. Working with conjugates is easy, since we have

$$\textbf{(9)} \qquad \overline{(z_1 + z_2)} = \bar{z}_1 + \bar{z}_2, \qquad \overline{(z_1 - z_2)} = \bar{z}_1 - \bar{z}_2,$$
$$\overline{(z_1 z_2)} = \bar{z}_1 \bar{z}_2, \qquad \overline{\left(\frac{z_1}{z_2}\right)} = \frac{\bar{z}_1}{\bar{z}_2}.$$

EXAMPLE 3 Illustration of (8) and (9)

Let $z_1 = 4 + 3i$ and $z_2 = 2 + 5i$. Then by (8),

$$\operatorname{Im} z_1 = \frac{1}{2i}[(4 + 3i) - (4 - 3i)] = \frac{3i + 3i}{2i} = 3.$$

Also, the multiplication formula in (9) is verified by

$$\overline{(z_1 z_2)} = \overline{(4 + 3i)(2 + 5i)} = \overline{(-7 + 26i)} = -7 - 26i,$$
$$\bar{z}_1 \bar{z}_2 = (4 - 3i)(2 - 5i) = -7 - 26i.$$

PROBLEM SET 13.1

1. **(Powers of i)** Show that $i^2 = -1$, $i^3 = -i$, $i^4 = 1$, $i^5 = i, \cdots$ and $1/i = -i$, $1/i^2 = -1$, $1/i^3 = i, \cdots$.
2. **(Rotation)** Multiplication by i is geometrically a counterclockwise rotation through $\pi/2$ (90°). Verify this by graphing z and iz and the angle of rotation for $z = 2 + 2i$, $z = -1 - 5i$, $z = 4 - 3i$.
3. **(Division)** Verify the calculation in (7).
4. **(Multiplication)** If the product of two complex numbers is zero, show that at least one factor must be zero.
5. Show that $z = x + iy$ is pure imaginary if and only if $\bar{z} = -z$.
6. **(Laws for conjugates)** Verify (9) for $z_1 = 24 + 10i$, $z_2 = 4 + 6i$.

7–15 COMPLEX ARITHMETIC

Let $z_1 = 2 + 3i$ and $z_2 = 4 - 5i$. Showing the details of your work, find (in the form $x + iy$):

7. $(5z_1 + 3z_2)^2$
8. $\bar{z}_1 \bar{z}_2$
9. $\operatorname{Re}(1/z_1^2)$
10. $\operatorname{Re}(z_2^2)$, $(\operatorname{Re} z_2)^2$
11. z_2/z_1
12. $\bar{z}_1/\bar{z}_2$, $\overline{(z_1/z_2)}$
13. $(4z_1 - z_2)^2$
14. $\bar{z}_1/z_1$, $z_1/\bar{z}_1$
15. $(z_1 + z_2)/(z_1 - z_2)$

16–19

Let $z = x + iy$. Find:

16. $\operatorname{Im} z^3$, $(\operatorname{Im} z)^3$
17. $\operatorname{Re}(1/\bar{z})$
18. $\operatorname{Im}[(1 + i)^8 z^2]$
19. $\operatorname{Re}(1/\bar{z}^2)$

20. **(Laws of addition and multiplication)** Derive the following laws for complex numbers from the corresponding laws for real numbers.

$$z_1 + z_2 = z_2 + z_1, \quad z_1 z_2 = z_2 z_1 \quad \textit{(Commutative laws)}$$
$$(z_1 + z_2) + z_3 = z_1 + (z_2 + z_3), \quad \textit{(Associative laws)}$$
$$(z_1 z_2) z_3 = z_1 (z_2 z_3)$$
$$z_1(z_2 + z_3) = z_1 z_2 + z_1 z_3 \quad \textit{(Distributive law)}$$
$$0 + z = z + 0 = z,$$
$$z + (-z) = (-z) + z = 0, \qquad z \cdot 1 = z.$$

13.2 Polar Form of Complex Numbers. Powers and Roots

The complex plane becomes even more useful and gives further insight into the arithmetic operations for complex numbers if besides the xy-coordinates we also employ the usual polar coordinates r, θ defined by

$$x = r\cos\theta, \qquad y = r\sin\theta. \tag{1}$$

We see that then $z = x + iy$ takes the so-called **polar form**

$$z = r(\cos\theta + i\sin\theta). \tag{2}$$

r is called the **absolute value** or **modulus** of z and is denoted by $|z|$. Hence

$$|z| = r = \sqrt{x^2 + y^2} = \sqrt{z\bar{z}}\,. \tag{3}$$

Geometrically, $|z|$ is the distance of the point z from the origin (Fig. 320). Similarly, $|z_1 - z_2|$ is the distance between z_1 and z_2 (Fig. 321).

θ is called the **argument** of z and is denoted by $\arg z$. Thus (Fig. 320)

$$\theta = \arg z = \arctan\frac{y}{x} \qquad (z \neq 0). \tag{4}$$

Geometrically, θ is the directed angle from the positive x-axis to OP in Fig. 320. Here, as in calculus, all ***angles are measured in radians and positive in the counterclockwise sense.***

For $z = 0$ this angle θ is undefined. (Why?) For a given $z \neq 0$ it is determined only up to integer multiples of 2π since cosine and sine are periodic with period 2π. But one often wants to specify a unique value of $\arg z$ of a given $z \neq 0$. For this reason one defines the **principal value** $\operatorname{Arg} z$ (with capital A!) of $\arg z$ by the double inequality

$$-\pi < \operatorname{Arg} z \leqq \pi. \tag{5}$$

Then we have $\operatorname{Arg} z = 0$ for positive real $z = x$, which is practical, and $\operatorname{Arg} z = \pi$ (not $-\pi$!) for negative real z, e.g., for $z = -4$. The principal value (5) will be important in connection with roots, the complex logarithm (Sec. 13.7), and certain integrals. Obviously, for a given $z \neq 0$ the other values of $\arg z$ are $\arg z = \operatorname{Arg} z \pm 2n\pi$ $(n = \pm 1, \pm 2, \cdots)$.

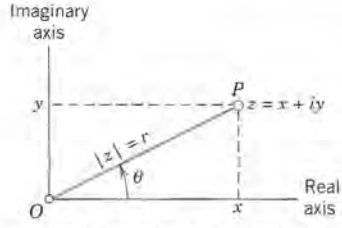

Fig. 320. Complex plane, polar form of a complex number

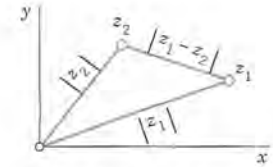

Fig. 321. Distance between two points in the complex plane

EXAMPLE 1 **Polar Form of Complex Numbers. Principal Value Arg z**

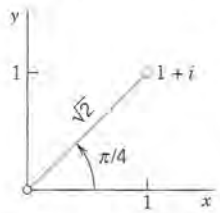

Fig. 322. Example 1

$z = 1 + i$ (Fig. 322) has the polar form $z = \sqrt{2}\,(\cos \frac{1}{4}\pi + i \sin \frac{1}{4}\pi)$. Hence we obtain

$$|z| = \sqrt{2}, \qquad \arg z = \tfrac{1}{4}\pi \pm 2n\pi \ (n = 0, 1, \cdots), \qquad \text{and} \qquad \operatorname{Arg} z = \tfrac{1}{4}\pi \quad \text{(the principal value)}.$$

Similarly, $z = 3 + 3\sqrt{3}i = 6\,(\cos \frac{1}{3}\pi + i \sin \frac{1}{3}\pi)$, $|z| = 6$, and $\operatorname{Arg} z = \frac{1}{3}\pi$. ■

CAUTION! In using (4), we must pay attention to the quadrant in which z lies, since $\tan \theta$ has period π, so that the arguments of z and $-z$ have the same tangent. *Example:* for $\theta_1 = \arg (1 + i)$ and $\theta_2 = \arg (-1 - i)$ we have $\tan \theta_1 = \tan \theta_2 = 1$.

Triangle Inequality

Inequalities such as $x_1 < x_2$ make sense for *real* numbers, but not in complex because *there is no natural way of ordering complex numbers*. However, inequalities between absolute values (which are real!), such as $|z_1| < |z_2|$ (meaning that z_1 is closer to the origin than z_2) are of great importance. The daily bread of the complex analyst is the **triangle inequality**

$$\textbf{(6)} \qquad |z_1 + z_2| \leqq |z_1| + |z_2| \qquad \text{(Fig. 323)}$$

which we shall use quite frequently. This inequality follows by noting that the three points 0, z_1, and $z_1 + z_2$ are the vertices of a triangle (Fig. 323) with sides $|z_1|$, $|z_2|$, and $|z_1 + z_2|$, and one side cannot exceed the sum of the other two sides. A formal proof is left to the reader (Prob. 35). (The triangle degenerates if z_1 and z_2 lie on the same straight line through the origin.)

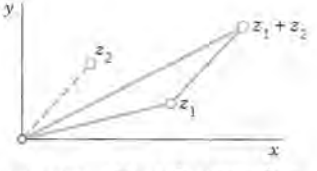

Fig. 323. Triangle inequality

By induction we obtain from (6) the **generalized triangle inequality**

$$\textbf{(6*)} \qquad |z_1 + z_2 + \cdots + z_n| \leqq |z_1| + |z_2| + \cdots + |z_n|;$$

that is, *the absolute value of a sum cannot exceed the sum of the absolute values of the terms.*

EXAMPLE 2 **Triangle Inequality**

If $z_1 = 1 + i$ and $z_2 = -2 + 3i$, then (sketch a figure!)

$$|z_1 + z_2| = |-1 + 4i| = \sqrt{17} = 4.123 < \sqrt{2} + \sqrt{13} = 5.020.$$ ■

Multiplication and Division in Polar Form

This will give us a "geometrical" understanding of multiplication and division. Let

$$z_1 = r_1(\cos \theta_1 + i \sin \theta_1) \qquad \text{and} \qquad z_2 = r_2(\cos \theta_2 + i \sin \theta_2).$$

Multiplication. By (3) in Sec. 13.1 the product is at first

$$z_1 z_2 = r_1 r_2[(\cos\theta_1 \cos\theta_2 - \sin\theta_1 \sin\theta_2) + i(\sin\theta_1 \cos\theta_2 + \cos\theta_1 \sin\theta_2)].$$

The addition rules for the sine and cosine [(6) in App. A3.1] now yield

$$z_1 z_2 = r_1 r_2[\cos(\theta_1 + \theta_2) + i \sin(\theta_1 + \theta_2)]. \tag{7}$$

Taking absolute values on both sides of (7), we see that *the absolute value of a product equals the* ***product*** *of the absolute values of the factors,*

$$|z_1 z_2| = |z_1||z_2|. \tag{8}$$

Taking arguments in (7) shows that *the argument of a product equals the* ***sum*** *of the arguments of the factors,*

$$\arg(z_1 z_2) = \arg z_1 + \arg z_2 \qquad \text{(up to multiples of } 2\pi). \tag{9}$$

Division. We have $z_1 = (z_1/z_2)z_2$. Hence $|z_1| = |(z_1/z_2)z_2| = |z_1/z_2||z_2|$ and by division by $|z_2|$

$$\left|\frac{z_1}{z_2}\right| = \frac{|z_1|}{|z_2|} \qquad (z_2 \neq 0). \tag{10}$$

Similarly, $\arg z_1 = \arg[(z_1/z_2)z_2] = \arg(z_1/z_2) + \arg z_2$ and by subtraction of $\arg z_2$

$$\arg\frac{z_1}{z_2} = \arg z_1 - \arg z_2 \qquad \text{(up to multiples of } 2\pi). \tag{11}$$

Combining (10) and (11) we also have the analog of (7),

$$\frac{z_1}{z_2} = \frac{r_1}{r_2}[\cos(\theta_1 - \theta_2) + i \sin(\theta_1 - \theta_2)]. \tag{12}$$

To comprehend this formula, note that it is the polar form of a complex number of absolute value r_1/r_2 and argument $\theta_1 - \theta_2$. But these are the absolute value and argument of z_1/z_2, as we can see from (10), (11), and the polar forms of z_1 and z_2.

EXAMPLE 3 **Illustration of Formulas (8)–(11)**

Let $z_1 = -2 + 2i$ and $z_2 = 3i$. Then $z_1 z_2 = -6 - 6i$, $z_1/z_2 = 2/3 + (2/3)i$. Hence (make a sketch)

$$|z_1 z_2| = 6\sqrt{2} = 3\sqrt{8} = |z_1||z_2|, \qquad |z_1/z_2| = 2\sqrt{2}/3 = |z_1|/|z_2|,$$

and for the arguments we obtain $\operatorname{Arg} z_1 = 3\pi/4$, $\operatorname{Arg} z_2 = \pi/2$,

$$\operatorname{Arg}(z_1 z_2) = -\frac{3\pi}{4} = \operatorname{Arg} z_1 + \operatorname{Arg} z_2 - 2\pi, \qquad \operatorname{Arg}(z_1/z_2) = \frac{\pi}{4} = \operatorname{Arg} z_1 - \operatorname{Arg} z_2. \quad \blacksquare$$

EXAMPLE 4 **Integer Powers of z. De Moivre's Formula**

From (8) and (9) with $z_1 = z_2 = z$ we obtain by induction for $n = 0, 1, 2, \cdots$

$$z^n = r^n(\cos n\theta + i \sin n\theta). \tag{13}$$

Similarly, (12) with $z_1 = 1$ and $z_2 = z^n$ gives (13) for $n = -1, -2, \cdots$. For $|z| = r = 1$, formula (13) becomes **De Moivre's formula**[3]

$$(\cos \theta + i \sin \theta)^n = \cos n\theta + i \sin n\theta. \tag{13*}$$

We can use this to express $\cos n\theta$ and $\sin n\theta$ in terms of powers of $\cos \theta$ and $\sin \theta$. For instance, for $n = 2$ we have on the left $\cos^2 \theta + 2i \cos \theta \sin \theta - \sin^2 \theta$. Taking the real and imaginary parts on both sides of (13*) with $n = 2$ gives the familiar formulas

$$\cos 2\theta = \cos^2 \theta - \sin^2 \theta, \qquad \sin 2\theta = 2 \cos \theta \sin \theta.$$

This shows that *complex* methods often simplify the derivation of *real* formulas. Try $n = 3$. ■

Roots

If $z = w^n$ $(n = 1, 2, \cdots)$, then to each value of w there corresponds *one* value of z. We shall immediately see that, conversely, to a given $z \neq 0$ there correspond precisely n distinct values of w. Each of these values is called an ***n*th root** of z, and we write

$$w = \sqrt[n]{z}. \tag{14}$$

Hence this symbol is ***multivalued,*** namely, *n-valued.* The n values of $\sqrt[n]{z}$ can be obtained as follows. We write z and w in polar form

$$z = r(\cos \theta + i \sin \theta) \qquad \text{and} \qquad w = R(\cos \phi + i \sin \phi).$$

Then the equation $w^n = z$ becomes, by De Moivre's formula (with ϕ instead of θ)

$$w^n = R^n(\cos n\phi + i \sin n\phi) = z = r(\cos \theta + i \sin \theta).$$

The absolute values on both sides must be equal; thus, $R^n = r$, so that $R = \sqrt[n]{r}$, where $\sqrt[n]{r}$ is positive real (an absolute value must be nonnegative!) and thus uniquely determined. Equating the arguments $n\phi$ and θ and recalling that θ is determined only up to integer multiples of 2π, we obtain

$$n\phi = \theta + 2k\pi, \qquad \text{thus} \qquad \phi = \frac{\theta}{n} + \frac{2k\pi}{n}$$

where k is an integer. For $k = 0, 1, \cdots, n - 1$ we get n *distinct* values of w. Further integers of k would give values already obtained. For instance, $k = n$ gives $2k\pi/n = 2\pi$,

[3]ABRAHAM DE MOIVRE (1667–1754), French mathematician, who pioneered the use of complex numbers in trigonometry and also contributed to probability theory (see Sec. 24.8).

hence the w corresponding to $k = 0$, etc. Consequently, $\sqrt[n]{z}$, for $z \neq 0$, has the n distinct values

$$\textbf{(15)} \qquad \sqrt[n]{z} = \sqrt[n]{r}\left(\cos\frac{\theta + 2k\pi}{n} + i\sin\frac{\theta + 2k\pi}{n}\right)$$

where $k = 0, 1, \cdots, n-1$. These n values lie on a circle of radius $\sqrt[n]{r}$ with center at the origin and constitute the vertices of a regular polygon of n sides. The value of $\sqrt[n]{z}$ obtained by taking the principal value of $\arg z$ and $k = 0$ in (15) is called the **principal value** of $w = \sqrt[n]{z}$.

Taking $z = 1$ in (15), we have $|z| = r = 1$ and $\operatorname{Arg} z = 0$. Then (15) gives

$$\textbf{(16)} \qquad \sqrt[n]{1} = \cos\frac{2k\pi}{n} + i\sin\frac{2k\pi}{n}, \qquad k = 0, 1, \cdots, n-1.$$

These n values are called the ***n*th roots of unity.** They lie on the circle of radius 1 and center 0, briefly called the **unit circle** (and used quite frequently!). Figures 324–326 show $\sqrt[3]{1} = 1, -\frac{1}{2} \pm \frac{1}{2}\sqrt{3}\,i$, $\sqrt[4]{1} = \pm 1, \pm i$, and $\sqrt[5]{1}$.

If ω denotes the value corresponding to $k = 1$ in (16), then the n values of $\sqrt[n]{1}$ can be written as

$$1, \omega, \omega^2, \cdots, \omega^{n-1}.$$

More generally, if w_1 is any nth root of an arbitrary complex number z ($\neq 0$), then the n values of $\sqrt[n]{z}$ in (15) are

$$\text{(17)} \qquad w_1, \qquad w_1\omega, \qquad w_1\omega^2, \qquad \cdots, \qquad w_1\omega^{n-1}$$

because multiplying w_1 by ω^k corresponds to increasing the argument of w_1 by $2k\pi/n$. Formula (17) motivates the introduction of roots of unity and shows their usefulness.

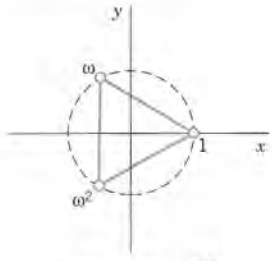

Fig. 324. $\sqrt[3]{1}$

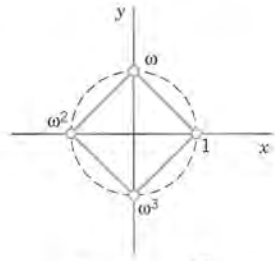

Fig. 325. $\sqrt[4]{1}$

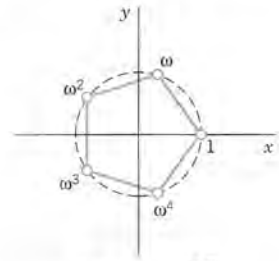

Fig. 326. $\sqrt[5]{1}$

PROBLEM SET 13.2

1–8 POLAR FORM

Do these problems very carefully since polar forms will be needed frequently. Represent in polar form and graph in the complex plane as in Fig. 322 on p. 608. (Show the details of your work.)

1. $3 - 3i$

2. $2i, -2i$

3. -5

4. $\frac{1}{2} + \frac{1}{4}\pi i$

5. $\dfrac{1 + i}{1 - i}$

6. $\dfrac{3\sqrt{2} + 2i}{-\sqrt{2} - (2/3)i}$

7. $\dfrac{-6 + 5i}{3i}$ **8.** $\dfrac{2 + 3i}{5 + 4i}$

9–15 PRINCIPAL ARGUMENT

Determine the principal value of the argument.

9. $-1 - i$
10. $-20 + i, -20 - i$
11. $4 \pm 3i$
12. $-\pi^2$
13. $7 \pm 7i$
14. $(1 + i)^{12}$
15. $(9 + 9i)^3$

16–20 CONVERSION TO $x + iy$

Represent in the form $x + iy$ and graph it in the complex plane.

16. $\cos \frac{1}{2}\pi + i \sin (\pm\frac{1}{2}\pi)$
17. $3(\cos 0.2 + i \sin 0.2)$
18. $4(\cos \frac{1}{3}\pi \pm i \sin \frac{1}{3}\pi)$
19. $\cos(-1) + i \sin(-1)$
20. $12(\cos \frac{3}{2}\pi + i \sin \frac{3}{2}\pi)$

21–25 ROOTS

Find and graph all roots in the complex plane.

21. $\sqrt{-i}$
22. $\sqrt[8]{1}$
23. $\sqrt[4]{-1}$
24. $\sqrt[3]{3 + 4i}$
25. $\sqrt[5]{-1}$

26. TEAM PROJECT. Square Root. (a) Show that $w = \sqrt{z}$ has the values

$$w_1 = \sqrt{r}\left[\cos\frac{\theta}{2} + i\sin\frac{\theta}{2}\right],$$

$$(18)\quad w_2 = \sqrt{r}\left[\cos\left(\frac{\theta}{2} + \pi\right) + i\sin\left(\frac{\theta}{2} + \pi\right)\right] = -w_1.$$

(b) Obtain from (18) the often more practical formula

$$(19)\quad \sqrt{z} = \pm\left[\sqrt{\tfrac{1}{2}(|z| + x)} + (\operatorname{sign} y)\, i\sqrt{\tfrac{1}{2}(|z| + x)}\right]$$

where sign $y = 1$ if $y \geqq 0$, sign $y = -1$ if $y < 0$, and all square roots of positive numbers are taken with positive sign. *Hint:* Use (10) in App. A3.1 with $x = \theta/2$.

(c) Find the square roots of $4i$, $16 - 30i$, and $9 + 8\sqrt{7}i$ by both (18) and (19) and comment on the work involved.

(d) Do some further examples of your own and apply a method of checking your results.

27–30 EQUATIONS

Solve and graph all solutions, showing the details:

27. $z^2 - (8 - 5i)z + 40 - 20i = 0$ (Use (19).)
28. $z^4 + (5 - 14i)z^2 - (24 + 10i) = 0$
29. $8z^2 - (36 - 6i)z + 42 - 11i = 0$
30. $z^4 + 16 = 0$. Then use the solutions to factor $z^4 + 16$ into quadratic factors with *real* coefficients.

31. CAS PROJECT. Roots of Unity and Their Graphs. Write a program for calculating these roots and for graphing them as points on the unit circle. Apply the program to $z^n = 1$ with $n = 2, 3, \cdots, 10$. Then extend the program to one for arbitrary roots, using an idea near the end of the text, and apply the program to examples of your choice.

32–35 INEQUALITIES AND AN EQUATION

Verify or prove as indicated.

32. (Re and Im) Prove $|\operatorname{Re} z| \leqq |z|$, $|\operatorname{Im} z| \leqq |z|$.

33. (Parallelogram equality) Prove

$$|z_1 + z_2|^2 + |z_1 - z_2|^2 = 2(|z_1|^2 + |z_2|^2).$$

Explain the name.

34. (Triangle inequality) Verify (6) for $z_1 = 4 + 7i$, $z_2 = 5 + 2i$.

35. (Triangle inequality) Prove (6).

13.3 Derivative. Analytic Function

Our study of complex functions will involve point sets in the complex plane. Most important will be the following ones.

Circles and Disks. Half-Planes

The **unit circle** $|z| = 1$ (Fig. 327) has already occurred in Sec. 13.2. Figure 328 shows a general circle of radius ρ and center a. Its equation is

$$|z - a| = \rho$$

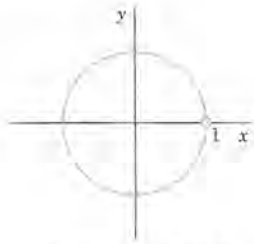

Fig. 327. Unit circle

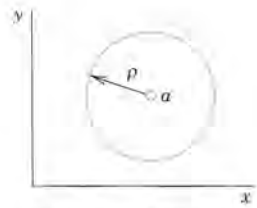

Fig. 328. Circle in the complex plane

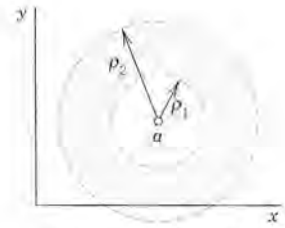

Fig. 329. Annulus in the complex plane

because it is the set of all z whose distance $|z - a|$ from the center a equals ρ. Accordingly, its interior (**"open circular disk"**) is given by $|z - a| < \rho$, its interior plus the circle itself (**"closed circular disk"**) by $|z - a| \leqq \rho$, and its exterior by $|z - a| > \rho$. As an example, sketch this for $a = 1 + i$ and $\rho = 2$, to make sure that you understand these inequalities.

An open circular disk $|z - a| < \rho$ is also called a **neighborhood** of a or, more precisely, a *ρ-neighborhood* of a. And a has infinitely many of them, one for each value of ρ (> 0), and a is a point of each of them, by definition!

In modern literature *any set* containing a ρ-neighborhood of a is also called a *neighborhood* of a.

Figure 329 shows an **open annulus** (circular ring) $\rho_1 < |z - a| < \rho_2$, which we shall need later. This is the set of all z whose distance $|z - a|$ from a is greater than ρ_1 but less than ρ_2. Similarly, the **closed annulus** $\rho_1 \leqq |z - a| \leqq \rho_2$ includes the two circles.

Half-Planes. By the (open) *upper* **half-plane** we mean the set of all points $z = x + iy$ such that $y > 0$. Similarly, the condition $y < 0$ defines the *lower half-plane*, $x > 0$ the *right half-plane*, and $x < 0$ the *left half-plane*.

For Reference: Concepts on Sets in the Complex Plane

To our discussion of special sets let us add some general concepts related to sets that we shall need throughout Chaps. 13–18; keep in mind that you can find them here.

By a **point set** in the complex plane we mean any sort of collection of finitely many or infinitely many points. Examples are the solutions of a quadratic equation, the points of a line, the points in the interior of a circle as well as the sets discussed just before.

A set S is called **open** if every point of S has a neighborhood consisting entirely of points that belong to S. For example, the points in the interior of a circle or a square form an open set, and so do the points of the right half-plane $\operatorname{Re} z = x > 0$.

A set S is called **connected** if any two of its points can be joined by a broken line of finitely many straight-line segments all of whose points belong to S. An open and connected set is called a **domain.** Thus an open disk and an open annulus are domains. An open square with a diagonal removed is not a domain since this set is not connected. (Why?)

The **complement** of a set S in the complex plane is the set of all points of the complex plane that ***do not belong*** to S. A set S is called **closed** if its complement is open. For example, the points on and inside the unit circle form a closed set ("closed unit disk") since its complement $|z| > 1$ is open.

A **boundary point** of a set S is a point every neighborhood of which contains both points that belong to S and points that do not belong to S. For example, the boundary

points of an annulus are the points on the two bounding circles. Clearly, if a set S is open, then no boundary point belongs to S; if S is closed, then every boundary point belongs to S. The set of all boundary points of a set S is called the **boundary** of S.

A **region** is a set consisting of a domain plus, perhaps, some or all of its boundary points. WARNING! "Domain" is the *modern* term for an open connected set. Nevertheless, some authors still call a domain a "region" and others make no distinction between the two terms.

Complex Function

Complex analysis is concerned with complex functions that are differentiable in some domain. Hence we should first say what we mean by a complex function and then define the concepts of limit and derivative in complex. This discussion will be similar to that in calculus. Nevertheless it needs great attention because it will show interesting basic differences between real and complex calculus.

Recall from calculus that a *real* function f defined on a set S of real numbers (usually an interval) is a rule that assigns to every x in S a real number $f(x)$, called the *value* of f at x. Now in complex, S is a set of *complex* numbers. And a **function** f defined on S is a rule that assigns to every z in S a complex number w, called the *value* of f at z. We write

$$w = f(z).$$

Here z varies in S and is called a **complex variable.** The set S is called the *domain of definition* of f or, briefly, the **domain** of f. (In most cases S will be open and connected, thus a domain as defined just before.)

Example: $w = f(z) = z^2 + 3z$ is a complex function defined for all z; that is, its domain S is the whole complex plane.

The set of all values of a function f is called the **range** *of* f.

w is complex, and we write $w = u + iv$, where u and v are the real and imaginary parts, respectively. Now w depends on $z = x + iy$. Hence u becomes a real function of x and y, and so does v. We may thus write

$$w = f(z) = u(x, y) + iv(x, y).$$

This shows that a *complex* function $f(z)$ is equivalent to a *pair* of *real* functions $u(x, y)$ and $v(x, y)$, each depending on the two real variables x and y.

EXAMPLE 1 **Function of a Complex Variable**

Let $w = f(z) = z^2 + 3z$. Find u and v and calculate the value of f at $z = 1 + 3i$.

Solution. $u = \text{Re } f(z) = x^2 - y^2 + 3x$ and $v = 2xy + 3y$. Also,

$$f(1 + 3i) = (1 + 3i)^2 + 3(1 + 3i) = 1 - 9 + 6i + 3 + 9i = -5 + 15i.$$

This shows that $u(1, 3) = -5$ and $v(1, 3) = 15$. Check this by using the expressions for u and v. ■

EXAMPLE 2 **Function of a Complex Variable**

Let $w = f(z) = 2iz + 6\bar{z}$. Find u and v and the value of f at $z = \frac{1}{2} + 4i$.

Solution. $f(z) = 2i(x + iy) + 6(x - iy)$ gives $u(x, y) = 6x - 2y$ and $v(x, y) = 2x - 6y$. Also,

$$f(\tfrac{1}{2} + 4i) = 2i(\tfrac{1}{2} + 4i) + 6(\tfrac{1}{2} - 4i) = i - 8 + 3 - 24i = -5 - 23i.$$

Check this as in Example 1. ■

Remarks on Notation and Terminology

1. Strictly speaking, $f(z)$ denotes the value of f at z, but it is a convenient abuse of language to talk about *the function* $f(z)$ (instead of *the function* f), thereby exhibiting the notation for the independent variable.

2. We assume all functions to be ***single-valued relations,*** as usual: to each z in S there corresponds but *one* value $w = f(z)$ (but, of course, several z may give the same value $w = f(z)$, just as in calculus). Accordingly, we shall *not use* the term "multivalued function" (used in some books on complex analysis) for a multivalued relation, in which to a z there corresponds more than one w.

Limit, Continuity

A function $f(z)$ is said to have the **limit** l as z approaches a point z_0, written

$$\lim_{z \to z_0} f(z) = l, \tag{1}$$

if f is defined in a neighborhood of z_0 (except perhaps at z_0 itself) and if the values of f are "close" to l for all z "close" to z_0; in precise terms, if for every positive real ϵ we can find a positive real δ such that for all $z \neq z_0$ in the disk $|z - z_0| < \delta$ (Fig. 330) we have

$$|f(z) - l| < \epsilon; \tag{2}$$

geometrically, if for every $z \neq z_0$ in that δ-disk the value of f lies in the disk (2).

Formally, this definition is similar to that in calculus, but there is a big difference. Whereas in the real case, x can approach an x_0 only along the real line, here, by definition, z may approach z_0 ***from any direction*** in the complex plane. This will be quite essential in what follows.

If a limit exists, it is unique. (See Team Project 26.)

A function $f(z)$ is said to be **continuous** at $z = z_0$ if $f(z_0)$ is defined and

$$\lim_{z \to z_0} f(z) = f(z_0). \tag{3}$$

Note that by definition of a limit this implies that $f(z)$ is defined in some neighborhood of z_0.

$f(z)$ is said to be *continuous in a domain* if it is continuous at each point of this domain.

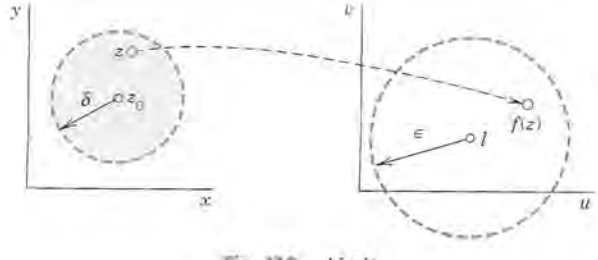

Fig. 330. Limit

Derivative

The **derivative** of a complex function f at a point z_0 is written $f'(z_0)$ and is defined by

$$f'(z_0) = \lim_{\Delta z \to 0} \frac{f(z_0 + \Delta z) - f(z_0)}{\Delta z} \tag{4}$$

provided this limit exists. Then f is said to be **differentiable** at z_0. If we write $\Delta z = z - z_0$, we have $z = z_0 + \Delta z$ and (4) takes the form

$$f'(z_0) = \lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0}. \tag{4'}$$

Now comes an ***important point.*** Remember that, by the definition of limit, $f(z)$ is defined in a neighborhood of z_0 and z in (4′) may approach z_0 from any direction in the complex plane. Hence differentiability at z_0 means that, along whatever path z approaches z_0, the quotient in (4′) always approaches a certain value and all these values are equal. This is important and should be kept in mind.

EXAMPLE 3 **Differentiability. Derivative**

The function $f(z) = z^2$ is differentiable for all z and has the derivative $f'(z) = 2z$ because

$$f'(z) = \lim_{\Delta z \to 0} \frac{(z + \Delta z)^2 - z^2}{\Delta z} = \lim_{\Delta z \to 0} \frac{z^2 + 2z\Delta z + (\Delta z)^2 - z^2}{\Delta z} = \lim_{\Delta z \to 0} (2z + \Delta z) = 2z. \quad \blacksquare$$

*The **differentiation rules** are the same as in real calculus,* since their proofs are literally the same. Thus for any analytic functions f and g and constants c we have

$$(cf)' = cf', \quad (f + g)' = f' + g', \quad (fg)' = f'g + fg', \quad \left(\frac{f}{g}\right)' = \frac{f'g - fg'}{g^2}$$

as well as the chain rule and the power rule $(z^n)' = nz^{n-1}$ (n integer).

Also, if $f(z)$ is differentiable at z_0, it is continuous at z_0. (See Team Project 26.)

EXAMPLE 4 **$\bar{z}$ not Differentiable**

It may come as a surprise that there are many complex functions that do not have a derivative at any point. For instance, $f(z) = \bar{z} = x - iy$ is such a function. To see this, we write $\Delta z = \Delta x + i\Delta y$ and obtain

$$\frac{f(z + \Delta z) - f(z)}{\Delta z} = \frac{\overline{(z + \Delta z)} - \bar{z}}{\Delta z} = \frac{\overline{\Delta z}}{\Delta z} = \frac{\Delta x - i\Delta y}{\Delta x + i\Delta y}. \tag{5}$$

If $\Delta y = 0$, this is $+1$. If $\Delta x = 0$, this is -1. Thus (5) approaches $+1$ along path I in Fig. 331 but -1 along path II. Hence, by definition, the limit of (5) as $\Delta z \to 0$ does not exist at any z. $\blacksquare$

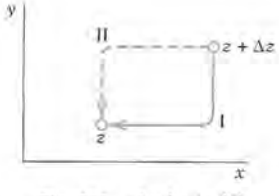

Fig. 331. Paths in (5)

Surprising as Example 4 may be, it merely illustrates that differentiability of a *complex* function is a rather severe requirement.

The idea of proof (approach of z from different directions) is basic and will be used again as the crucial argument in the next section.

Analytic Functions

Complex analysis is concerned with the theory and application of "analytic functions," that is, functions that are differentiable in some domain, so that we can do "calculus in complex." The definition is as follows.

DEFINITION

Analyticity

A function $f(z)$ is said to be *analytic in a domain* D if $f(z)$ is defined and differentiable at all points of D. The function $f(z)$ is said to be *analytic at a point* $z = z_0$ in D if $f(z)$ is analytic in a neighborhood of z_0.

Also, by an **analytic function** we mean a function that is analytic in *some* domain.

Hence analyticity of $f(z)$ at z_0 means that $f(z)$ has a derivative at every point in some neighborhood of z_0 (including z_0 itself since, by definition, z_0 is a point of all its neighborhoods). This concept is *motivated* by the fact that it is of no practical interest if a function is differentiable merely at a single point z_0 but not throughout some neighborhood of z_0. Team Project 26 gives an example.

A more modern term for *analytic in D* is *holomorphic in D.*

EXAMPLE 5 **Polynomials, Rational Functions**

The nonnegative integer powers $1, z, z^2, \cdots$ are analytic in the entire complex plane, and so are **polynomials,** that is, functions of the form

$$f(z) = c_0 + c_1 z + c_2 z^2 + \cdots + c_n z^n$$

where $c_0, \cdots, c_n$ are complex constants.

The quotient of two polynomials $g(z)$ and $h(z)$,

$$f(z) = \frac{g(z)}{h(z)},$$

is called a **rational function.** This f is analytic except at the points where $h(z) = 0$; here we assume that common factors of g and h have been canceled.

Many further analytic functions will be considered in the next sections and chapters. ■

The concepts discussed in this section extend familiar concepts of calculus. Most important is the concept of an analytic function, the exclusive concern of complex analysis. Although many simple functions are not analytic, the large variety of remaining functions will yield a most beautiful branch of mathematics that is very useful in engineering and physics.

PROBLEM SET 13.3

1–10 CURVES AND REGIONS OF PRACTICAL INTEREST

Find and sketch or graph the sets in the complex plane given by

1. $|z - 3 - 2i| = \frac{4}{3}$

2. $1 \leqq |z - 1 + 4i| \leqq 5$

3. $0 < |z - 1| < 1$

4. $-\pi < \operatorname{Re} z < \pi$

5. $\operatorname{Im} z^2 = 2$

6. $\operatorname{Re} z > -1$

7. $|z + 1| = |z - 1|$

8. $|\operatorname{Arg} z| \leqq \frac{1}{4}\pi$

9. $\operatorname{Re} z \leqq \operatorname{Im} z$

10. $\operatorname{Re} (1/z) < 1$

11. WRITING PROJECT. Sets in the Complex Plane. Extend the part of the text on sets in the complex plane by formulating that part in your own words and including examples of your own and comparing with calculus when applicable.

COMPLEX FUNCTIONS AND DERIVATIVES

12–15 Function Values. Find Re f and Im f. Also find their values at the given point z.

12. $f = 3z^2 - 6z + 3i$, $z = 2 + i$

13. $f = z/(z + 1)$, $z = 4 - 5i$

14. $f = 1/(1 - z)$, $z = \frac{1}{2} + \frac{1}{4}i$

15. $f = 1/z^2$, $z = 1 + i$

16–19 Continuity. Find out (and give reason) whether $f(z)$ is continuous at $z = 0$ if $f(0) = 0$ and for $z \neq 0$ the function f is equal to:

16. $[\text{Re}\,(z^2)]/|z|^2$

17. $[\text{Im}\,(z^2)]/|z|$

18. $|z|^2\,\text{Re}\,(1/z)$

19. $(\text{Im}\,z)/(1 - |z|)$

20–24 Derivative. Differentiate

20. $(z^2 - 9)/(z^2 + 1)$

21. $(z^3 + i)^2$

22. $(3z + 4i)/(1.5iz - 2)$

23. $i/(1 - z)^2$

24. $z^2/(z + i)^2$

25. CAS PROJECT. Graphing Functions. Find and graph Re f, Im f, and $|f|$ as surfaces over the z-plane. Also graph the two families of curves Re $f(z) = const$ and Im $f(z) = const$ in the same figure, and the curves $|f(z)| = const$ in another figure, where (a) $f(z) = z^2$, (b) $f(z) = 1/z$, (c) $f(z) = z^4$.

26. TEAM PROJECT. Limit, Continuity, Derivative

(a) Limit. Prove that (1) is equivalent to the pair of relations

$$\lim_{z \to z_0} \text{Re}\, f(z) = \text{Re}\, l, \qquad \lim_{z \to z_0} \text{Im}\, f(z) = \text{Im}\, l.$$

(b) Limit. If $\lim_{z \to z_0} f(z)$ exists, show that this limit is unique.

(c) Continuity. If $z_1, z_2, \cdots$ are complex numbers for which $\lim_{n \to \infty} z_n = a$, and if $f(z)$ is continuous at $z = a$, show that $\lim_{n \to \infty} f(z_n) = f(a)$.

(d) Continuity. If $f(z)$ is differentiable at z_0, show that $f(z)$ is continuous at z_0.

(e) Differentiability. Show that $f(z) = \text{Re}\, z = x$ is not differentiable at any z. Can you find other such functions?

(f) Differentiability. Show that $f(z) = |z|^2$ is differentiable only at $z = 0$; hence it is nowhere analytic.

13.4 Cauchy–Riemann Equations. Laplace's Equation

The Cauchy–Riemann equations are the most important equations in this chapter and one of the pillars on which complex analysis rests. They provide a criterion (a test) for the analyticity of a complex function

$$w = f(z) = u(x, y) + iv(x, y).$$

Roughly, f is analytic in a domain D if and only if the first partial derivatives of u and v satisfy the two **Cauchy–Riemann equations**[4]

(1) $$u_x = v_y, \qquad u_y = -v_x$$

[4]The French mathematician AUGUSTIN-LOUIS CAUCHY (see Sec. 2.5) and the German mathematicians BERNHARD RIEMANN (1826–1866) and KARL WEIERSTRASS (1815–1897; see also Sec. 15.5) are the founders of complex analysis. Riemann received his Ph.D. (in 1851) under Gauss (Sec. 5.4) at Göttingen, where he also taught until he died, when he was only 39 years old. He introduced the concept of the integral as it is used in basic calculus courses, and made important contributions to differential equations, number theory, and mathematical physics. He also developed the so-called Riemannian geometry, which is the mathematical foundation of Einstein's theory of relativity; see Ref. [GR9] in App. 1.

everywhere in D; here $u_x = \partial u/\partial x$ and $u_y = \partial u/\partial y$ (and similarly for v) are the usual notations for partial derivatives. The precise formulation of this statement is given in Theorems 1 and 2.

Example: $f(z) = z^2 = x^2 - y^2 + 2ixy$ is analytic for all z (see Example 3 in Sec. 13.3), and $u = x^2 - y^2$ and $v = 2xy$ satisfy (1), namely, $u_x = 2x = v_y$ as well as $u_y = -2y = -v_x$. More examples will follow.

THEOREM 1

Cauchy–Riemann Equations

Let $f(z) = u(x, y) + iv(x, y)$ be defined and continuous in some neighborhood of a point $z = x + iy$ and differentiable at z itself. Then at that point, the first-order partial derivatives of u and v exist and satisfy the Cauchy–Riemann equations (1).

Hence if $f(z)$ is analytic in a domain D, those partial derivatives exist and satisfy (1) *at all points of D.*

PROOF By assumption, the derivative $f'(z)$ at z exists. It is given by

$$f'(z) = \lim_{\Delta z \to 0} \frac{f(z + \Delta z) - f(z)}{\Delta z}. \tag{2}$$

The idea of the proof is very simple. By the definition of a limit in complex (Sec. 13.3) we can let Δz approach zero along any path in a neighborhood of z. Thus we may choose the two paths I and II in Fig. 332 and equate the results. By comparing the real parts we shall obtain the first Cauchy–Riemann equation and by comparing the imaginary parts the second. The technical details are as follows.

We write $\Delta z = \Delta x + i\Delta y$. Then $z + \Delta z = x + \Delta x + i(y + \Delta y)$, and in terms of u and v the derivative in (2) becomes

$$f'(z) = \lim_{\Delta z \to 0} \frac{[u(x + \Delta x, y + \Delta y) + iv(x + \Delta x, y + \Delta y)] - [u(x, y) + iv(x, y)]}{\Delta x + i\Delta y}. \tag{3}$$

We first choose path I in Fig. 332. Thus we let $\Delta y \to 0$ first and then $\Delta x \to 0$. After Δy is zero, $\Delta z = \Delta x$. Then (3) becomes, if we first write the two u-terms and then the two v-terms,

$$f'(z) = \lim_{\Delta x \to 0} \frac{u(x + \Delta x, y) - u(x, y)}{\Delta x} + i \lim_{\Delta x \to 0} \frac{v(x + \Delta x, y) - v(x, y)}{\Delta x}.$$

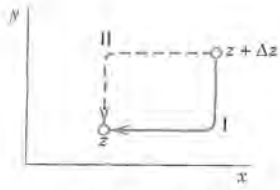

Fig. 332. Paths in (2)

Since $f'(z)$ exists, the two real limits on the right exist. By definition, they are the partial derivatives of u and v with respect to x. Hence the derivative $f'(z)$ of $f(z)$ can be written

$$f'(z) = u_x + iv_x. \tag{4}$$

Similarly, if we choose path II in Fig. 332, we let $\Delta x \to 0$ first and then $\Delta y \to 0$. After Δx is zero, $\Delta z = i\Delta y$, so that from (3) we now obtain

$$f'(z) = \lim_{\Delta y \to 0} \frac{u(x, y + \Delta y) - u(x, y)}{i\,\Delta y} + i \lim_{\Delta y \to 0} \frac{v(x, y + \Delta y) - v(x, y)}{i\,\Delta y}.$$

Since $f'(z)$ exists, the limits on the right exist and give the partial derivatives of u and v with respect to y; noting that $1/i = -i$, we thus obtain

$$f'(z) = -iu_y + v_y. \tag{5}$$

The existence of the derivative $f'(z)$ thus implies the existence of the four partial derivatives in (4) and (5). By equating the real parts u_x and v_y in (4) and (5) we obtain the first Cauchy–Riemann equation (1). Equating the imaginary parts gives the other. This proves the first statement of the theorem and implies the second because of the definition of analyticity. ■

Formulas (4) and (5) are also quite practical for calculating derivatives $f'(z)$, as we shall see.

EXAMPLE 1 **Cauchy–Riemann Equations**

$f(z) = z^2$ is analytic for all z. It follows that the Cauchy–Riemann equations must be satisfied (as we have verified above).

For $f(z) = \bar{z} = x - iy$ we have $u = x$, $v = -y$ and see that the second Cauchy–Riemann equation is satisfied, $u_y = -v_x = 0$, but the first is not: $u_x = 1 \neq v_y = -1$. We conclude that $f(z) = \bar{z}$ is not analytic, confirming Example 4 of Sec. 13.3. Note the savings in calculation! ■

The Cauchy–Riemann equations are fundamental because they are not only necessary but also sufficient for a function to be analytic. More precisely, the following theorem holds.

THEOREM 2

Cauchy–Riemann Equations

If two real-valued continuous functions $u(x, y)$ and $v(x, y)$ of two real variables x and y have ***continuous*** *first partial derivatives that satisfy the Cauchy–Riemann equations in some domain D, then the complex function $f(z) = u(x, y) + iv(x, y)$ is analytic in D.*

The proof is more involved than that of Theorem 1 and we leave it optional (see App. 4).

Theorems 1 and 2 are of great practical importance, since by using the Cauchy–Riemann equations we can now easily find out whether or not a given complex function is analytic.

EXAMPLE 2 Cauchy–Riemann Equations. Exponential Function

Is $f(z) = u(x, y) + iv(x, y) = e^x(\cos y + i \sin y)$ analytic?

Solution. We have $u = e^x \cos y$, $v = e^x \sin y$ and by differentiation

$$u_x = e^x \cos y, \qquad v_y = e^x \cos y$$
$$u_y = -e^x \sin y, \qquad v_x = e^x \sin y.$$

We see that the Cauchy–Riemann equations are satisfied and conclude that $f(z)$ is analytic for all z. ($f(z)$ will be the complex analog of e^x known from calculus.) ■

EXAMPLE 3 An Analytic Function of Constant Absolute Value Is Constant

The Cauchy–Riemann equations also help in deriving general properties of analytic functions.

For instance, show that if $f(z)$ is analytic in a domain D and $|f(z)| = k = const$ in D, then $f(z) = const$ in D. (We shall make crucial use of this in Sec. 18.6 in the proof of Theorem 3.)

Solution. By assumption, $|f|^2 = |u + iv|^2 = u^2 + v^2 = k^2$. By differentiation,

$$uu_x + vv_x = 0,$$
$$uu_y + vv_y = 0.$$

Now use $v_x = -u_y$ in the first equation and $v_y = u_x$ in the second, to get

$$\text{(6)} \qquad \begin{aligned} &\text{(a)} \quad uu_x - vu_y = 0, \\ &\text{(b)} \quad uu_y + vu_x = 0. \end{aligned}$$

To get rid of u_y, multiply (6a) by u and (6b) by v and add. Similarly, to eliminate u_x, multiply (6a) by $-v$ and (6b) by u and add. This yields

$$(u^2 + v^2)u_x = 0,$$
$$(u^2 + v^2)u_y = 0.$$

If $k^2 = u^2 + v^2 = 0$, then $u = v = 0$; hence $f = 0$. If $k^2 = u^2 + v^2 \neq 0$, then $u_x = u_y = 0$. Hence, by the Cauchy–Riemann equations, also $v_x = v_y = 0$. Together this implies $u = const$ and $v = const$; hence $f = const$. ■

We mention that if we use the polar form $z = r(\cos \theta + i \sin \theta)$ and set $f(z) = u(r, \theta) + iv(r, \theta)$, then the **Cauchy–Riemann equations** are (Prob. 11)

$$\text{(7)} \qquad u_r = \frac{1}{r} v_\theta, \qquad v_r = -\frac{1}{r} u_\theta \qquad (r > 0).$$

Laplace's Equation. Harmonic Functions

The great importance of complex analysis in engineering mathematics results mainly from the fact that both the real part and the imaginary part of an analytic function satisfy Laplace's equation, the most important PDE of physics, which occurs in gravitation, electrostatics, fluid flow, heat conduction, and so on (see Chaps. 12 and 18).

THEOREM 3

Laplace's Equation

If $f(z) = u(x, y) + iv(x, y)$ is analytic in a domain D, then both u and v satisfy **Laplace's equation**

(8) $$\nabla^2 u = u_{xx} + u_{yy} = 0$$

(∇^2 read "nabla squared") *and*

(9) $$\nabla^2 v = v_{xx} + v_{yy} = 0,$$

in D and have continuous second partial derivatives in D.

PROOF Differentiating $u_x = v_y$ with respect to x and $u_y = -v_x$ with respect to y, we have

(10) $$u_{xx} = v_{yx}, \qquad u_{yy} = -v_{xy}.$$

Now the derivative of an analytic function is itself analytic, as we shall prove later (in Sec. 14.4). This implies that u and v have continuous partial derivatives of all orders; in particular, the mixed second derivatives are equal: $v_{yx} = v_{xy}$. By adding (10) we thus obtain (8). Similarly, (9) is obtained by differentiating $u_x = v_y$ with respect to y and $u_y = -v_x$ with respect to x and subtracting, using $u_{xy} = u_{yx}$. ∎

Solutions of Laplace's equation having ***continuous*** second-order partial derivatives are called **harmonic functions** and their theory is called **potential theory** (see also Sec. 12.10). Hence the real and imaginary parts of an analytic function are harmonic functions.

If two harmonic functions u and v satisfy the Cauchy–Riemann equations in a domain D, they are the real and imaginary parts of an analytic function f in D. Then v is said to be a **harmonic conjugate function** of u in D. (Of course, this has absolutely nothing to do with the use of "conjugate" for $\bar{z}$.)

EXAMPLE 4 **How to Find a Harmonic Conjugate Function by the Cauchy–Riemann Equations**

Verify that $u = x^2 - y^2 - y$ is harmonic in the whole complex plane and find a harmonic conjugate function v of u.

Solution. $\nabla^2 u = 0$ by direct calculation. Now $u_x = 2x$ and $u_y = -2y - 1$. Hence because of the Cauchy–Riemann equations a conjugate v of u must satisfy

$$v_y = u_x = 2x, \qquad v_x = -u_y = 2y + 1.$$

Integrating the first equation with respect to y and differentiating the result with respect to x, we obtain

$$v = 2xy + h(x), \qquad v_x = 2y + \frac{dh}{dx}.$$

A comparison with the second equation shows that $dh/dx = 1$. This gives $h(x) = x + c$. Hence $v = 2xy + x + c$ (c any real constant) is the most general harmonic conjugate of the given u. The corresponding analytic function is

$$f(z) = u + iv = x^2 - y^2 - y + i(2xy + x + c) = z^2 + iz + ic. \quad ∎$$

Example 4 illustrates that *a conjugate of a given harmonic function is uniquely determined up to an arbitrary real additive constant.*

The Cauchy–Riemann equations are the most important equations in this chapter. Their relation to Laplace's equation opens wide ranges of engineering and physical applications, as we shall show in Chap. 18.

PROBLEM SET 13.4

1–10 CAUCHY–RIEMANN EQUATIONS

Are the following functions analytic? [Use (1) or (7).]

1. $f(z) = z^4$
2. $f(z) = \text{Im}\ (z^2)$
3. $e^{2x}(\cos y + i \sin y)$
4. $f(z) = 1/(1 - z^4)$
5. $e^{-x}(\cos y - i \sin y)$
6. $f(z) = \text{Arg}\ \pi z$
7. $f(z) = \text{Re}\ z + \text{Im}\ z$
8. $f(z) = \ln |z| + i\ \text{Arg}\ z$
9. $f(z) = i/z^8$
10. $f(z) = z^2 + 1/z^2$
11. **(Cauchy–Riemann equations in polar form)** Derive (7) from (1).

12–21 HARMONIC FUNCTIONS

Are the following functions harmonic? If your answer is yes, find a corresponding analytic function $f(z) = u(x, y) + iv(x, y)$.

12. $u = xy$
13. $v = xy$
14. $v = -y/(x^2 + y^2)$
15. $u = \ln |z|$
16. $v = \ln |z|$
17. $u = x^3 - 3xy^2$
18. $u = 1/(x^2 + y^2)$
19. $v = (x^2 - y^2)^2$
20. $u = \cos x \cosh y$
21. $u = e^{-x} \sin 2y$

22–24 Determine a, b, c such that the given functions are harmonic and find a harmonic conjugate.

22. $u = e^{3x} \cos ay$
23. $u = \sin x \cosh cy$
24. $u = ax^3 + by^3$
25. **(Harmonic conjugate)** Show that if u is harmonic and v is a harmonic conjugate of u, then u is a harmonic conjugate of $-v$.
26. **TEAM PROJECT. Conditions for $f(z) = const$.** Let $f(z)$ be analytic. Prove that each of the following conditions is sufficient for $f(z) = const$.
    (a) $\text{Re}\ f(z) = const$
    (b) $\text{Im}\ f(z) = const$
    (c) $f'(z) = 0$
    (d) $|f(z)| = const$ (see Example 3)
27. **(Two further formulas for the derivative).** Formulas (4), (5), and (11) (below) are needed from time to time. Derive

    (11) $\quad f'(z) = u_x - iu_y, \qquad f'(z) = v_y + iv_x.$
28. **CAS PROJECT. Equipotential Lines.** Write a program for graphing equipotential lines $u = const$ of a harmonic function u and of its conjugate v on the same axes. Apply the program to (a) $u = x^2 - y^2$, $v = 2xy$, (b) $u = x^3 - 3xy^2$, $v = 3x^2y - y^3$, (c) $u = e^x \cos y$, $v = e^x \sin y$.

13.5 Exponential Function

In the remaining sections of this chapter we discuss the basic elementary complex functions, the exponential function, trigonometric functions, logarithm, and so on. They will be counterparts to the familiar functions of calculus, to which they reduce when $z = x$ is real. They are indispensable throughout applications, and some of them have interesting properties not shared by their real counterparts.

We begin with one of the most important analytic functions, the complex **exponential function**

$$e^z, \qquad \text{also written} \qquad \exp z.$$

The definition of e^z in terms of the real functions e^x, $\cos y$, and $\sin y$ is

$$\text{(1)} \qquad e^z = e^x(\cos y + i \sin y).$$

This definition is motivated by the fact the e^z ***extends*** the real exponential function e^x of calculus in a natural fashion. Namely:

(A) $e^z = e^x$ for real $z = x$ because $\cos y = 1$ and $\sin y = 0$ when $y = 0$.

(B) e^z is analytic for all z. (Proved in Example 2 of Sec. 13.4.)

(C) The derivative of e^z is e^z, that is,

$$(e^z)' = e^z. \tag{2}$$

This follows from (4) in Sec. 13.4,

$$(e^z)' = (e^x \cos y)_x + i(e^x \sin y)_x = e^x \cos y + ie^x \sin y = e^z.$$

REMARK. This definition provides for a relatively simple discussion. We could define e^z by the familiar series $1 + x + x^2/2! + x^3/3! + \cdots$ with x replaced by z, but we would then have to discuss complex series at this very early stage. (We will show the connection in Sec. 15.4.)

Further Properties. A function $f(z)$ that is analytic for all z is called an **entire function.** Thus, e^z is entire. Just as in calculus the ***functional relation***

$$e^{z_1+z_2} = e^{z_1}e^{z_2} \tag{3}$$

holds for any $z_1 = x_1 + iy_1$ and $z_2 = x_2 + iy_2$. Indeed, by (1),

$$e^{z_1}e^{z_2} = e^{x_1}(\cos y_1 + i \sin y_1)\, e^{x_2}(\cos y_2 + i \sin y_2).$$

Since $e^{x_1}e^{x_2} = e^{x_1+x_2}$ for these *real* functions, by an application of the addition formulas for the cosine and sine functions (similar to that in Sec. 13.2) we see that

$$e^{z_1}e^{z_2} = e^{x_1+x_2}[\cos (y_1 + y_2) + i \sin (y_1 + y_2)] = e^{z_1+z_2}$$

as asserted. An interesting special case of (3) is $z_1 = x$, $z_2 = iy$; then

$$e^z = e^x e^{iy}. \tag{4}$$

Furthermore, for $z = iy$ we have from (1) the so-called **Euler formula**

$$e^{iy} = \cos y + i \sin y. \tag{5}$$

Hence the **polar form** of a complex number, $z = r(\cos \theta + i \sin \theta)$, may now be written

$$z = re^{i\theta}. \tag{6}$$

From (5) we obtain

$$e^{2\pi i} = 1 \tag{7}$$

as well as the important formulas (verify!)

$$e^{\pi i/2} = i, \qquad e^{\pi i} = -1, \qquad e^{-\pi i/2} = -i, \qquad e^{-\pi i} = -1. \tag{8}$$

Another consequence of (5) is

$$|e^{iy}| = |\cos y + i \sin y| = \sqrt{\cos^2 y + \sin^2 y} = 1. \tag{9}$$

That is, for pure imaginary exponents the exponential function has absolute value 1, a result you should remember. From (9) and (1),

$$|e^z| = e^x. \qquad \text{Hence} \qquad \arg e^z = y \pm 2n\pi \ (n = 0, 1, 2, \cdots), \tag{10}$$

since $|e^z| = e^x$ shows that (1) is actually e^z in polar form.

From $|e^z| = e^x \neq 0$ in (10) we see that

$$e^z \neq 0 \qquad \text{for all } z. \tag{11}$$

So here we have an entire function that never vanishes, in contrast to (nonconstant) polynomials, which are also entire (Example 5 in Sec. 13.3) but always have a zero, as is proved in algebra.

Periodicity of e^z with period $2\pi i$,

$$e^{z+2\pi i} = e^z \qquad \text{for all } z \tag{12}$$

is a basic property that follows from (1) and the periodicity of cos y and sin y. Hence all the values that $w = e^z$ can assume are already assumed in the horizontal strip of width 2π

$$-\pi < y \leqq \pi \qquad \text{(Fig. 333).} \tag{13}$$

This infinite strip is called a **fundamental region** of e^z.

EXAMPLE 1 **Function Values. Solution of Equations.**

Computation of values from (1) provides no problem. For instance, verify that

$$e^{1.4-0.6i} = e^{1.4}(\cos 0.6 - i \sin 0.6) = 4.055(0.8253 - 0.5646i) = 3.347 - 2.289i$$

$$|e^{1.4-0.6i}| = e^{1.4} = 4.055, \qquad \operatorname{Arg} e^{1.4-0.6i} = -0.6.$$

To illustrate (3), take the product of

$$e^{2+i} = e^2(\cos 1 + i \sin 1) \qquad \text{and} \qquad e^{4-i} = e^4(\cos 1 - i \sin 1)$$

and verify that it equals $e^2 e^4(\cos^2 1 + \sin^2 1) = e^6 = e^{(2+i)+(4-i)}$.

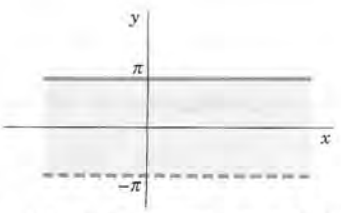

Fig. 333. Fundamental region of the exponential function e^z in the z-plane

To solve the equation $e^z = 3 + 4i$, note first that $|e^z| = e^x = 5$, $x = \ln 5 = 1.609$ is the real part of all solutions. Now, since $e^x = 5$,

$$e^x \cos y = 3, \qquad e^x \sin y = 4, \qquad \cos y = 0.6, \qquad \sin y = 0.8, \qquad y = 0.927.$$

Ans. $z = 1.609 + 0.927i \pm 2n\pi i$ $(n = 0, 1, 2, \cdorn)$. These are infinitely many solutions (due to the periodicity of e^z). They lie on the vertical line $x = 1.609$ at a distance 2π from their neighbors. ■

To summarize: many properties of $e^z = \exp z$ parallel those of e^x; an exception is the periodicity of e^z with $2\pi i$, which suggested the concept of a fundamental region. Keep in mind that e^z is an *entire function.* (Do you still remember what that means?)

PROBLEM SET 13.5

1. Using the Cauchy–Riemann equations, show that e^z is entire.

2–8 **Values of e^z.** Compute e^z in the form $u + iv$ and $|e^z|$, where z equals:

2. $3 + \pi i$
3. $1 + 2i$
4. $\sqrt{2} - \frac{1}{2}\pi i$
5. $7\pi i/2$
6. $(1 + i)\pi$
7. $0.8 - 5i$
8. $9\pi i/2$

9–12 **Real and Imaginary Parts.** Find Re and Im of:

9. e^{-2z}
10. e^{z^3}
11. e^{z^2}
12. $e^{1/z}$

13–17 **Polar Form.** Write in polar form:

13. $\sqrt{i}$
14. $1 + i$
15. $\sqrt[n]{z}$
16. $3 + 4i$
17. -9

18–21 **Equations.** Find all solutions and graph some of them in the complex plane.

18. $e^{3z} = 4$
19. $e^z = -2$
20. $e^z = 0$
21. $e^z = 4 - 3i$

22. TEAM PROJECT. Further Properties of the Exponential Function. (a) Analyticity. Show that e^z is entire. What about $e^{1/z}$? $e^{\bar{z}}$? $e^x(\cos ky + i \sin ky)$? (Use the Cauchy–Riemann equations.)

(b) Special values. Find all z such that (i) e^z is real, (ii) $|e^{-z}| < 1$, (iii) $e^{\bar{z}} = \overline{e^z}$.

(c) Harmonic function. Show that $u = e^{xy} \cos(x^2/2 - y^2/2)$ is harmonic and find a conjugate.

(d) Uniqueness. It is interesting that $f(z) = e^z$ is uniquely determined by the two properties $f(x + i0) = e^x$ and $f'(z) = f(z)$, where f is assumed to be entire. Prove this using the Cauchy–Riemann equations.

13.6 Trigonometric and Hyperbolic Functions

Just as we extended the real e^x to the complex e^z in Sec. 13.5, we now want to extend the familiar *real* trigonometric functions to *complex trigonometric functions.* We can do this by the use of the Euler formulas (Sec. 13.5)

$$e^{ix} = \cos x + i \sin x, \qquad e^{-ix} = \cos x - i \sin x.$$

By addition and subtraction we obtain for the *real* cosine and sine

$$\cos x = \frac{1}{2}(e^{ix} + e^{-ix}), \qquad \sin x = \frac{1}{2i}(e^{ix} - e^{-ix}).$$

This suggests the following definitions for complex values $z = x + iy$:

(1) $$\cos z = \frac{1}{2}\,(e^{iz} + e^{-iz}), \qquad \sin z = \frac{1}{2i}\,(e^{iz} - e^{-iz}).$$

It is quite remarkable that here in complex, functions come together that are unrelated in real. This is not an isolated incident but is typical of the general situation and shows the advantage of working in complex.

Furthermore, as in calculus we define

(2) $$\tan z = \frac{\sin z}{\cos z}, \qquad \cot z = \frac{\cos z}{\sin z}$$

and

(3) $$\sec z = \frac{1}{\cos z}, \qquad \csc z = \frac{1}{\sin z}.$$

Since e^z is entire, $\cos z$ and $\sin z$ are entire functions. $\tan z$ and $\sec z$ are not entire; they are analytic except at the points where $\cos z$ is zero; and $\cot z$ and $\csc z$ are analytic except where $\sin z$ is zero. Formulas for the derivatives follow readily from $(e^z)' = e^z$ and (1)–(3); as in calculus,

(4) $$(\cos z)' = -\sin z, \qquad (\sin z)' = \cos z, \qquad (\tan z)' = \sec^2 z,$$

etc. Equation (1) also shows that **Euler's formula** ***is valid in complex:***

(5) $$e^{iz} = \cos z + i \sin z \qquad \text{for all } z.$$

The real and imaginary parts of $\cos z$ and $\sin z$ are needed in computing values, and they also help in displaying properties of our functions. We illustrate this with a typical example.

EXAMPLE 1 **Real and Imaginary Parts. Absolute Value. Periodicity**

Show that

(6)
(a) $\cos z = \cos x \cosh y - i \sin x \sinh y$
(b) $\sin z = \sin x \cosh y + i \cos x \sinh y$

and

(7)
(a) $|\cos z|^2 = \cos^2 x + \sinh^2 y$
(b) $|\sin z|^2 = \sin^2 x + \sinh^2 y$

and give some applications of these formulas.

Solution. From (1),

$$\begin{aligned}\cos z &= \tfrac{1}{2}(e^{i(x+iy)} + e^{-i(x+iy)}) \\ &= \tfrac{1}{2}e^{-y}(\cos x + i \sin x) + \tfrac{1}{2}e^{y}(\cos x - i \sin x) \\ &= \tfrac{1}{2}(e^{y} + e^{-y}) \cos x - \tfrac{1}{2}i(e^{y} - e^{-y}) \sin x.\end{aligned}$$

This yields (6a) since, as is known form calculus,

(8) $$\cosh y = \tfrac{1}{2}(e^{y} + e^{-y}), \qquad \sinh y = \tfrac{1}{2}(e^{y} - e^{-y});$$

(6b) is obtained similarly. From (6a) and $\cosh^2 y = 1 + \sinh^2 y$ we obtain

$$|\cos z|^2 = (\cos^2 x)\,(1 + \sinh^2 y) + \sin^2 x \sinh^2 y.$$

Since $\sin^2 x + \cos^2 x = 1$, this gives (7a), and (7b) is obtained similarly.

For instance, $\cos(2 + 3i) = \cos 2 \cosh 3 - i \sin 2 \sinh 3 = -4.190 - 9.109i$.

From (6) we see that $\cos z$ and $\sin z$ are ***periodic with period 2π,*** just as in real. Periodicity of $\tan z$ and $\cot z$ with period π now follows.

Formula (7) points to an essential difference between the real and the complex cosine and sine; whereas $|\cos x| \leqq 1$ and $|\sin x| \leqq 1$, the complex cosine and sine functions are ***no longer bounded*** but approach infinity in absolute value as $y \to \infty$, since then $\sinh y \to \infty$ in (7). ■

EXAMPLE 2 **Solutions of Equations. Zeros of cos z and sin z**

Solve (a) $\cos z = 5$ (which has no real solution!), (b) $\cos z = 0$, (c) $\sin z = 0$.

Solution. (a) $e^{2iz} - 10e^{iz} + 1 = 0$ from (1) by multiplication by e^{iz}. This is a quadratic equation in e^{iz}, with solutions (rounded off to 3 decimals)

$$e^{iz} = e^{-y+ix} = 5 \pm \sqrt{25 - 1} = 9.899 \quad \text{and} \quad 0.101.$$

Thus $e^{-y} = 9.899$ or 0.101, $e^{ix} = 1$, $y = \pm 2.292$, $x = 2n\pi$. *Ans.* $z = \pm 2n\pi \pm 2.292i$ $(n = 0, 1, 2, \cdots)$.

Can you obtain this from (6a)?

(b) $\cos x = 0$, $\sinh y = 0$ by (7a), $y = 0$. *Ans.* $z = \pm\frac{1}{2}(2n + 1)\pi$ $(n = 0, 1, 2, \cdots)$.

(c) $\sin x = 0$, $\sinh y = 0$ by (7b). *Ans.* $z = \pm n\pi$ $(n = 0, 1, 2, \cdots)$. Hence the only zeros of $\cos z$ and $\sin z$ are those of the real cosine and sine functions. ■

General formulas *for the real trigonometric functions continue to hold for complex values.* This follows immediately from the definitions. We mention in particular the addition rules

$$\begin{aligned} \cos(z_1 \pm z_2) &= \cos z_1 \cos z_2 \mp \sin z_1 \sin z_2 \\ \sin(z_1 \pm z_2) &= \sin z_1 \cos z_2 \pm \sin z_2 \cos z_1 \end{aligned} \tag{9}$$

and the formula

$$\cos^2 z + \sin^2 z = 1. \tag{10}$$

Some further useful formulas are included in the problem set.

Hyperbolic Functions

The complex **hyperbolic cosine** and **sine** are defined by the formulas

$$\cosh z = \tfrac{1}{2}(e^z + e^{-z}), \qquad \sinh z = \tfrac{1}{2}(e^z - e^{-z}). \tag{11}$$

This is suggested by the familiar definitions for a real variable [see (8)]. These functions are entire, with derivatives

$$(\cosh z)' = \sinh z, \qquad (\sinh z)' = \cosh z, \tag{12}$$

as in calculus. The other hyperbolic functions are defined by

$$\text{(13)} \qquad \tanh z = \frac{\sinh z}{\cosh z}, \qquad \coth z = \frac{\cosh z}{\sinh z},$$
$$\operatorname{sech} z = \frac{1}{\cosh z}, \qquad \operatorname{csch} z = \frac{1}{\sinh z}.$$

Complex Trigonometric and Hyperbolic Functions Are Related. If in (11), we replace z by iz and then use (1), we obtain

$$\textbf{(14)} \qquad \cosh iz = \cos z, \qquad \sinh iz = i \sin z.$$

Similarly, if in (1) we replace z by iz and then use (11), we obtain conversely

$$\textbf{(15)} \qquad \cos iz = \cosh z, \qquad \sin iz = i \sinh z.$$

Here we have another case of *unrelated* real functions that have *related* complex analogs, pointing again to the advantage of working in complex in order to get both a more unified formalism and a deeper understanding of special functions. This is one of the main reasons for the importance of complex analysis to the engineer and physicist.

PROBLEM SET 13.6

1. Prove that $\cos z$, $\sin z$, $\cosh z$, $\sinh z$ are entire functions.

2. Verify by differentiation that Re $\cos z$ and Im $\sin z$ are harmonic.

3–6 FORMULAS FOR HYPERBOLIC FUNCTIONS

Show that

3. $\cosh z = \cosh x \cos y + i \sinh x \sin y$

$\sinh z = \sinh x \cos y + i \cosh x \sin y.$

4. $\cosh (z_1 + z_2) = \cosh z_1 \cosh z_2 + \sinh z_1 \sinh z_2$

$\sinh (z_1 + z_2) = \sinh z_1 \cosh z_2 + \cosh z_1 \sinh z_2.$

5. $\cosh^2 z - \sinh^2 z = 1$

6. $\cosh^2 z + \sinh^2 z = \cosh 2z$

7–15 Function Values. Compute (in the form $u + iv$)

7. $\cos (1 + i)$ **8.** $\sin (1 + i)$

9. $\sin 5i$, $\cos 5i$ **10.** $\cos 3\pi i$

11. $\cosh (-2 + 3i)$, $\cos (-3 - 2i)$

12. $-i \sinh (-\pi + 2i)$, $\sin (2 + \pi i)$

13. $\cosh (2n + 1)\pi i$, $n = 1, 2, \cdots$

14. $\sinh (4 - 3i)$ **15.** $\cosh (4 - 6\pi i)$

16. (Real and imaginary parts) Show that

$$\operatorname{Re} \tan z = \frac{\sin x \cos x}{\cos^2 x + \sinh^2 y},$$

$$\operatorname{Im} \tan z = \frac{\sinh y \cosh y}{\cos^2 x + \sinh^2 y}.$$

17–21 Equations. Find all solutions of the following equations.

17. $\cosh z = 0$ **18.** $\sin z = 100$

19. $\cos z = 2i$ **20.** $\cosh z = -1$

21. $\sinh z = 0$

22. Find all z for which (a) $\cos z$, (b) $\sin z$ has real values.

23–25 Equations and Inequalities. Using the definitions, prove:

23. $\cos z$ is even, $\cos (-z) = \cos z$, and $\sin z$ is odd, $\sin (-z) = -\sin z$.

24. $|\sinh y| \leqq |\cos z| \leqq \cosh y$, $|\sinh y| \leqq |\sin z| \leqq \cosh y$. Conclude that the complex cosine and sine are not bounded in the whole complex plane.

25. $\sin z_1 \cos z_2 = \frac{1}{2}[\sin (z_1 + z_2) + \sin (z_1 - z_2)]$

13.7 Logarithm. General Power

We finally introduce the *complex logarithm,* which is more complicated than the real logarithm (which it includes as a special case) and historically puzzled mathematicians for some time (so if you first get puzzled—which need not happen!—be patient and work through this section with extra care).

The **natural logarithm** of $z = x + iy$ is denoted by $\ln z$ (sometimes also by $\log z$) and is defined as the inverse of the exponential function; that is, $w = \ln z$ is defined for $z \neq 0$ by the relation

$$e^w = z.$$

(Note that $z = 0$ is impossible, since $e^w \neq 0$ for all w; see Sec. 13.5.) If we set $w = u + iv$ and $z = re^{i\theta}$, this becomes

$$e^w = e^{u+iv} = re^{i\theta}.$$

Now from Sec. 13.5 we know that e^{u+iv} has the absolute value e^u and the argument v. These must be equal to the absolute value and argument on the right:

$$e^u = r, \qquad v = \theta.$$

$e^u = r$ gives $u = \ln r$, where $\ln r$ is the familiar *real* natural logarithm of the positive number $r = |z|$. Hence $w = u + iv = \ln z$ is given by

$$\ln z = \ln r + i\theta \qquad (r = |z| > 0, \quad \theta = \arg z). \tag{1}$$

Now comes an important point (without analog in real calculus). Since the argument of z is determined only up to integer multiples of 2π, ***the complex natural logarithm*** $\ln z$ ***($z \neq 0$) is infinitely many-valued.***

The value of $\ln z$ corresponding to the principal value $\operatorname{Arg} z$ (see Sec. 13.2) is denoted by $\operatorname{Ln} z$ (Ln with capital L) and is called the **principal value** of $\ln z$. Thus

$$\operatorname{Ln} z = \ln |z| + i \operatorname{Arg} z \qquad (z \neq 0). \tag{2}$$

The uniqueness of $\operatorname{Arg} z$ for given z ($\neq 0$) implies that $\operatorname{Ln} z$ is single-valued, that is, a function in the usual sense. Since the other values of $\arg z$ differ by integer multiples of 2π, the other values of $\ln z$ are given by

$$\ln z = \operatorname{Ln} z \pm 2n\pi i \qquad (n = 1, 2, \cdots). \tag{3}$$

They all have the same real part, and their imaginary parts differ by integer multiples of 2π.

If z is positive real, then $\operatorname{Arg} z = 0$, and $\operatorname{Ln} z$ becomes identical with the real natural logarithm known from calculus. If z is negative real (so that the natural logarithm of calculus is not defined!), then $\operatorname{Arg} z = \pi$ and

$$\operatorname{Ln} z = \ln |z| + \pi i \qquad (z \text{ negative real}).$$

From (1) and $e^{\ln r} = r$ for positive real r we obtain

$$e^{\ln z} = z \tag{4a}$$

as expected, but since $\arg(e^z) = y \pm 2n\pi$ is multivalued, so is

$$\ln(e^z) = z \pm 2n\pi i, \qquad n = 0, 1, \cdots. \tag{4b}$$

EXAMPLE 1 Natural Logarithm. Principal Value

$$\ln 1 = 0, \pm 2\pi i, \pm 4\pi i, \cdots \qquad \operatorname{Ln} 1 = 0$$

$$\ln 4 = 1.386\,294 \pm 2n\pi i \qquad \operatorname{Ln} 4 = 1.386\,294$$

$$\ln(-1) = \pm\pi i, \pm 3\pi i, \pm 5\pi i, \cdots \qquad \operatorname{Ln}(-1) = \pi i$$

$$\ln(-4) = 1.386\,294 \pm (2n+1)\pi i \qquad \operatorname{Ln}(-4) = 1.386\,294 + \pi i$$

$$\ln i = \pi i/2, -3\pi/2, 5\pi i/2, \cdots \qquad \operatorname{Ln} i = \pi i/2$$

$$\ln 4i = 1.386\,294 + \pi i/2 \pm 2n\pi i \qquad \operatorname{Ln} 4i = 1.386\,294 + \pi i/2$$

$$\ln(-4i) = 1.386\,294 - \pi i/2 \pm 2n\pi i \qquad \operatorname{Ln}(-4i) = 1.386\,294 - \pi i/2$$

$$\ln(3-4i) = \ln 5 + i \arg(3-4i) \qquad \operatorname{Ln}(3-4i) = 1.609\,438 - 0.927\,295i$$

$$= 1.609\,438 - 0.927\,295i \pm 2n\pi i \qquad \text{(Fig. 334)}$$

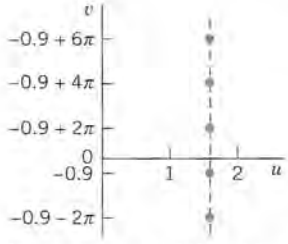

Fig. 334. Some values of $\ln(3-4i)$ in Example 1

The familiar relations for the natural logarithm continue to hold for complex values, that is,

$$\text{(5)} \qquad \text{(a)} \quad \ln(z_1 z_2) = \ln z_1 + \ln z_2, \qquad \text{(b)} \quad \ln(z_1/z_2) = \ln z_1 - \ln z_2$$

but these relations are to be understood in the sense that each value of one side is also contained among the values of the other side; see the next example.

EXAMPLE 2 Illustration of the Functional Relation (5) in Complex

Let

$$z_1 = z_2 = e^{\pi i} = -1.$$

If we take the principal values

$$\operatorname{Ln} z_1 = \operatorname{Ln} z_2 = \pi i,$$

then (5a) holds provided we write $\ln(z_1 z_2) = \ln 1 = 2\pi i$; however, it is not true for the principal value, $\operatorname{Ln}(z_1 z_2) = \operatorname{Ln} 1 = 0$.

THEOREM 1

Analyticity of the Logarithm

For every $n = 0, \pm 1, \pm 2, \cdots$ *formula* (3) *defines a function, which is analytic, except at* 0 *and on the negative real axis, and has the derivative*

(6) $$(\ln z)' = \frac{1}{z} \qquad (z \text{ not } 0 \text{ or negative real}).$$

PROOF We show that the Cauchy–Riemann equations are satisfied. From (1)–(3) we have

$$\ln z = \ln r + i(\theta + c) = \frac{1}{2} \ln (x^2 + y^2) + i\left(\arctan \frac{y}{x} + c\right)$$

where the constant c is a multiple of 2π. By differentiation,

$$u_x = \frac{x}{x^2 + y^2} = v_y = \frac{1}{1 + (y/x)^2} \cdot \frac{1}{x}$$

$$u_y = \frac{y}{x^2 + y^2} = -v_x = -\frac{1}{1 + (y/x)^2} \left(-\frac{y}{x^2}\right).$$

Hence the Cauchy–Riemann equations hold. [Confirm this by using these equations in polar form, which we did not use since we proved them only in the problems (to Sec. 13.4).] Formula (4) in Sec. 13.4 now gives (6),

$$(\ln z)' = u_x + iv_x = \frac{x}{x^2 + y^2} + i\,\frac{1}{1 + (y/x)^2} \left(-\frac{y}{x^2}\right) = \frac{x - iy}{x^2 + y^2} = \frac{1}{z}. \qquad \blacksquare$$

Each of the infinitely many functions in (3) is called a **branch** of the logarithm. The negative real axis is known as a **branch cut** and is usually graphed as shown in Fig. 335. The branch for $n = 0$ is called the **principal branch** of $\ln z$.

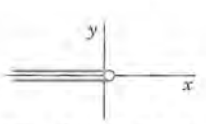

Fig. 335. Branch cut for ln z

General Powers

General powers of a complex number $z = x + iy$ are defined by the formula

(7) $$z^c = e^{c \ln z} \qquad (c \text{ complex}, z \neq 0).$$

Since $\ln z$ is infinitely many-valued, z^c will, in general, be multivalued. The particular value

$$z^c = e^{c \operatorname{Ln} z}$$

is called the **principal value** *of* z^c.

If $c = n = 1, 2, \cdots$, then z^n is single-valued and identical with the usual nth power of z. If $c = -1, -2, \cdots$, the situation is similar.

If $c = 1/n$, where $n = 2, 3, \cdots$, then

$$z^c = \sqrt[n]{z} = e^{(1/n)\ln z} \qquad (z \neq 0),$$

the exponent is determined up to multiples of $2\pi i/n$ and we obtain the n distinct values of the nth root, in agreement with the result in Sec. 13.2. If $c = p/q$, the quotient of two positive integers, the situation is similar, and z^c has only finitely many distinct values. However, if c is real irrational or genuinely complex, then z^c is infinitely many-valued.

EXAMPLE 3 **General Power**

$$i^i = e^{i \ln i} = \exp(i \ln i) = \exp\left[i\left(\frac{\pi}{2} i \pm 2n\pi i\right)\right] = e^{-(\pi/2) \mp 2n\pi}.$$

All these values are real, and the principal value ($n = 0$) is $e^{-\pi/2}$.

Similarly, by direct calculation and multiplying out in the exponent,

$$(1 + i)^{2-i} = \exp[(2 - i) \ln (1 + i)] = \exp\left[(2 - i)\left(\ln \sqrt{2} + \tfrac{1}{4}\pi i \pm 2n\pi i\right)\right]$$
$$= 2e^{\pi/4 \pm 2n\pi}\left[\sin\left(\tfrac{1}{2} \ln 2\right) + i \cos\left(\tfrac{1}{2} \ln 2\right)\right]. \quad \blacksquare$$

It is a ***convention*** that for real positive $z = x$ the expression z^c means $e^{c \ln x}$ where $\ln x$ is the elementary real natural logarithm (that is, the principal value $\operatorname{Ln} z$ ($z = x > 0$) in the sense of our definition). Also, if $z = e$, the base of the natural logarithm, $z^c = e^c$ is *conventionally* regarded as the unique value obtained from (1) in Sec. 13.5.

From (7) we see that for any complex number a,

(8) $$a^z = e^{z \ln a}.$$

We have now introduced the complex functions needed in practical work, some of them (e^z, $\cos z$, $\sin z$, $\cosh z$, $\sinh z$) entire (Sec. 13.5), some of them ($\tan z$, $\cot z$, $\tanh z$, $\coth z$) analytic except at certain points, and one of them ($\ln z$) splitting up into infinitely many functions, each analytic except at 0 and on the negative real axis.

For the **inverse trigonometric** and **hyperbolic functions** see the problem set.

PROBLEM SET 13.7

1–9 **Principal Value Ln z.** Find $\operatorname{Ln} z$ when z equals:

1. -10
2. $2 + 2i$
3. $2 - 2i$
4. $-5 \pm 0.1i$
5. $-3 - 4i$
6. -100
7. $0.6 + 0.8i$
8. $-ei$
9. $1 - i$

10–16 **All Values of ln z.** Find all values and graph some of them in the complex plane.

10. $\ln 1$
11. $\ln (-1)$
12. $\ln e$
13. $\ln (-6)$
14. $\ln (4 + 3i)$
15. $\ln (-e^{-i})$
16. $\ln (e^{3i})$

17. Show that the set of values of $\ln (i^2)$ differs from the set of values of $2 \ln i$.

18–21 **Equations.** Solve for z:

18. $\ln z = (2 - \frac{1}{2}i)\pi$
19. $\ln z = 0.3 + 0.7i$
20. $\ln z = e - \pi i$
21. $\ln z = 2 + \frac{1}{4}\pi i$

22–28 **General Powers.** Showing the details of your work, find the principal value of:

22. i^{2i}, $(2i)^i$
23. 4^{3+i}
24. $(1 - i)^{1+i}$
25. $(1 + i)^{1-i}$
26. $(-1)^{1-2i}$
27. $i^{1/2}$
28. $(3 - 4i)^{1/3}$

29. How can you find the answer to Prob. 24 from the answer to Prob. 25?

30. TEAM PROJECT. Inverse Trigonometric and Hyperbolic Functions. By definition, the **inverse sine** $w = \arcsin z$ is the relation such that $\sin w = z$. The **inverse cosine** $w = \arccos z$ is the relation such that $\cos w = z$. The **inverse tangent, inverse cotangent, inverse hyperbolic sine,** etc., are defined and denoted in a similar fashion. (Note that all these relations are ***multivalued.***) Using $\sin w = (e^{iw} - e^{-iw})/(2i)$ and similar representations of $\cos w$, etc., show that

(a) $\arccos z = -i \ln (z + \sqrt{z^2 - 1})$

(b) $\arcsin z = -i \ln (iz + \sqrt{1 - z^2})$

(c) $\operatorname{arccosh} z = \ln (z + \sqrt{z^2 - 1})$

(d) $\operatorname{arcsinh} z = \ln (z + \sqrt{z^2 + 1})$

(e) $\arctan z = \dfrac{i}{2} \ln \dfrac{i + z}{i - z}$

(f) $\operatorname{arctanh} z = \dfrac{1}{2} \ln \dfrac{1 + z}{1 - z}$

(g) Show that $w = \arcsin z$ is infinitely many-valued, and if w_1 is one of these values, the others are of the form $w_1 \pm 2n\pi$ and $\pi - w_1 \pm 2n\pi$, $n = 0, 1, \cdots$. (The *principal value of* $w = u + iv = \arcsin z$ is defined to be the value for which $-\pi/2 \leqq u \leqq \pi/2$ if $v \geqq 0$ and $-\pi/2 < u < \pi/2$ if $v < 0$.)

CHAPTER 13 REVIEW QUESTIONS AND PROBLEMS

1. Add, subtract, multiply, and divide $26 - 7i$ and $3 + 4i$ as well as their complex conjugates.

2. Write the two given numbers in Prob. 1 in polar form. Find the principal value of their arguments.

3. What is the triangle inequality? Its geometric meaning? Its significance?

4. If you know the values of $\sqrt[6]{1}$, how do you get from them the values of $\sqrt[6]{z}$ for any z?

5. State the definition of the derivative from memory. It looks similar to that in calculus. But what is the big difference?

6. What is an analytic function? How would you test for analyticity?

7. Can a function be differentiable at a point without being analytic there? If yes, give an example.

8. Are $|z|$, $\bar{z}$, $\operatorname{Re} z$, $\operatorname{Im} z$ analytic? Give reason.

9. State the definitions of e^z, $\cos z$, $\sin z$, $\cosh z$, $\sinh z$ and the relations between these functions. Do these relations have analogs in real?

10. What properties of e^z are similar to those of e^x? Which one is different?

11. What is the fundamental region of e^z? Its significance?

12. What is an entire function? Give examples.

13. Why is $\ln z$ much more complicated than $\ln x$? Explain from memory.

14. What is the principal value of $\ln z$?

15. How is the general power z^c defined? Give examples.

16–21 **Complex Numbers.** Find, in the form $x + iy$, showing the details:

16. $(1 + i)^{12}$
17. $(-2 + 6i)^2$
18. $1/(3 - 7i)$
19. $(1 - i)/(1 + i)^2$
20. $\sqrt{-5 - 12i}$
21. $(43 - 19i)/(8 + i)$

22–26 **Polar Form.** Represent in polar form, with the principal argument:

22. $1 - 3i$
23. $-6 + 6i$
24. $\sqrt{20}/(4 + 2i)$
25. $-12i$
26. $2 + 2i$

27–30 **Roots.** Find and graph all values of

27. $\sqrt{8i}$
28. $\sqrt[4]{256}$
29. $\sqrt[4]{-1}$
30. $\sqrt{32 - 24i}$

31–35 **Analytic Functions.** Find $f(z) = u(x, y) + iv(x, y)$ with u or v as given. Check for analyticity.

31. $u = x/(x^2 + y^2)$
32. $v = e^{-3x} \sin 3y$
33. $u = x^2 - 2xy - y^2$
34. $u = \cos 2x \cosh 2y$
35. $v = e^{x^2 - y^2} \sin 2xy$

36–39 **Harmonic Functions.** Are the following functions harmonic? If so, find a harmonic conjugate.

36. x^2y^2
37. xy
38. $e^{-x/2} \cos \frac{1}{2}y$
39. $x^2 + y^2$

40–45 **Special Function Values.** Find the values of

40. $\sin (3 + 4\pi i)$
41. $\sinh 4\pi i$
42. $\cos (5\pi + 2i)$
43. $\operatorname{Ln} (0.8 + 0.6i)$
44. $\tan (1 + i)$
45. $\cosh (1 + \pi i)$

SUMMARY OF CHAPTER 13
Complex Numbers and Functions

For arithmetic operations with **complex numbers**

(1) $$z = x + iy = re^{i\theta} = r(\cos\theta + i\sin\theta),$$

$r = |z| = \sqrt{x^2 + y^2}$, $\theta = \arctan(y/x)$, and for their representation in the complex plane, see Secs. 13.1 and 13.2.

A complex function $f(z) = u(x, y) + iv(x, y)$ is **analytic** in a domain D if it has a **derivative** (Sec. 13.3)

(2) $$f'(z) = \lim_{\Delta z \to 0} \frac{f(z + \Delta z) - f(z)}{\Delta z}$$

everywhere in D. Also, $f(z)$ is *analytic at a point* $z = z_0$ if it has a derivative in a neighborhood of z_0 (not merely at z_0 itself).

If $f(z)$ is analytic in D, then $u(x, y)$ and $v(x, y)$ satisfy the (very important!) **Cauchy–Riemann equations** (Sec. 13.4)

(3) $$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}, \qquad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

everywhere in D. Then u and v also satisfy **Laplace's equation**

(4) $$u_{xx} + u_{yy} = 0, \qquad v_{xx} + v_{yy} = 0$$

everywhere in D. If $u(x, y)$ and $v(x, y)$ are continuous and have *continuous* partial derivatives in D that satisfy (3) in D, then $f(z) = u(x, y) + iv(x, y)$ is analytic in D. See Sec. 13.4. (More on Laplace's equation and complex analysis follows in Chap. 18.)

The complex **exponential function** (Sec. 13.5)

(5) $$e^z = \exp z = e^x(\cos y + i\sin y)$$

reduces to e^x if $z = x$ ($y = 0$). It is periodic with $2\pi i$ and has the derivative e^z.

The **trigonometric functions** are (Sec. 13.6)

(6)
$$\cos z = \frac{1}{2}(e^{iz} + e^{-iz}) = \cos x \cosh y - i \sin x \sinh y$$
$$\sin z = \frac{1}{2i}(e^{iz} - e^{-iz}) = \sin x \cosh y + i \cos x \sinh y$$

and, furthermore,

$$\tan z = (\sin z)/\cos z, \qquad \cot z = 1/\tan z, \quad \text{etc.}$$

The **hyperbolic functions** are (Sec. 13.6)

(7) $\cosh z = \frac{1}{2}(e^z + e^{-z}) = \cos iz, \qquad \sinh z = \frac{1}{2}(e^z - e^{-z}) = -i \sin iz$

etc. The functions (5)–(7) are **entire,** that is, analytic everywhere in the complex plane.

The **natural logarithm** is (Sec. 13.7)

(8) $$\ln z = \ln |z| + i \arg z = \ln |z| + i \operatorname{Arg} z \pm 2n\pi i$$

where $z \neq 0$ and $n = 0, 1, \cdots$. $\operatorname{Arg} z$ is the **principal value** of $\arg z$, that is, $-\pi < \operatorname{Arg} z \leqq \pi$. We see that $\ln z$ is infinitely many-valued. Taking $n = 0$ gives the **principal value** $\operatorname{Ln} z$ of $\ln z$; thus $\operatorname{Ln} z = \ln |z| + i \operatorname{Arg} z$.

General powers are defined by (Sec. 13.7)

(9) $$z^c = e^{c \ln z} \qquad (c \text{ complex}, z \neq 0).$$

CHAPTER 14

Complex Integration

Two main reasons account for the importance of integration in the complex plane. The practical reason is that complex integration can evaluate certain real integrals appearing in applications that are not accessible by real integral calculus. The theoretical reason is that some basic properties of analytic functions are difficult to prove by other methods. A striking property of this type is the existence of higher derivatives of an analytic function.

Complex integration also plays a role in connection with special functions, such as the gamma function (see [GR1], p. 255), the error function, various polynomials (see [GR10]) and others, and the application of these functions in physics.

In this chapter we define and explain complex integrals. The most important result in the chapter is **Cauchy's integral theorem** or the *Cauchy–Goursat theorem,* as it is also called (Sec. 14.2). It implies **Cauchy's integral formula** (Sec. 14.3), which in turn implies the existence of all higher derivatives of an analytic function. Hence in this respect, complex analytic functions behave much more simply than real-valued functions of real variables, which may have derivatives only up to a certain order.

A further method of complex integration, known as integration by residues, and its application to real integrals will need complex series and follows in Chap. 16.

Prerequisite: Chap. 13
References and Answers to Problems: App. 1 Part D, App. 2.

14.1 Line Integral in the Complex Plane

As in calculus we distinguish between definite integrals and indefinite integrals or antiderivatives. An **indefinite integral** is a function whose derivative equals a given analytic function in a region. By inverting known differentiation formulas we may find many types of indefinite integrals.

Complex definite integrals are called (complex) **line integrals.** They are written

$$\int_C f(z)\,dz.$$

Here the **integrand** $f(z)$ is integrated over a given curve C or a portion of it (an *arc,* but we shall say ***"curve"*** in either case, for simplicity). This curve C in the complex plane is called the **path of integration.** We may represent C by a parametric representation

$$\textbf{(1)} \qquad z(t) = x(t) + iy(t) \qquad (a \leqq t \leqq b).$$

The sense of increasing t is called the **positive sense** on C, and we say that C is **oriented** by (1).

For instance, $z(t) = t + 3it$ $(0 \leqq t \leqq 2)$ gives a portion (a segment) of the line $y = 3x$. The function $z(t) = 4\cos t + 4i \sin t$ $(-\pi \leqq t \leqq \pi)$ represents the circle $|z| = 4$, and so on. More examples follow below.

We assume C to be a **smooth curve,** that is, C has a continuous and nonzero derivative

$$\dot{z}(t) = \frac{dz}{dt} = \dot{x}(t) + i\dot{y}(t)$$

at each point. Geometrically this means that C has everywhere a continuously turning tangent, as follows directly from the definition

$$\dot{z}(t) = \lim_{\Delta t \to 0} \frac{z(t + \Delta t) - z(t)}{\Delta t} \qquad \text{(Fig. 336).}$$

Here we use a dot since a prime $'$ denotes the derivative with respect to z.

Definition of the Complex Line Integral

This is similar to the method in calculus. Let C be a smooth curve in the complex plane given by (1), and let $f(z)$ be a continuous function given (at least) at each point of C. We now subdivide (we ***"partition"***) the interval $a \leqq t \leqq b$ in (1) by points

$$t_0 (= a), \quad t_1, \quad \cdots, \quad t_{n-1}, \quad t_n (= b)$$

where $t_0 < t_1 < \cdots < t_n$. To this subdivision there corresponds a subdivision of C by points

$$z_0, \quad z_1, \quad \cdots, \quad z_{n-1}, \quad z_n (= Z) \qquad \text{(Fig. 337),}$$

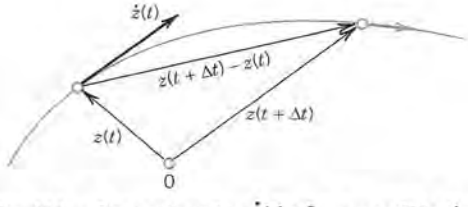

Fig. 336. Tangent vector $\dot{z}(t)$ of a curve C in the complex plane given by $z(t)$. The arrowhead on the curve indicates the *positive sense* (sense of increasing t).

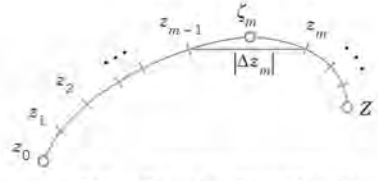

Fig. 337. Complex line integral

where $z_j = z(t_j)$. On each portion of subdivision of C we choose an arbitrary point, say, a point ζ_1 between z_0 and z_1 (that is, $\zeta_1 = z(t)$ where t satisfies $t_0 \leqq t \leqq t_1$), a point ζ_2 between z_1 and z_2, etc. Then we form the sum

$$(2) \qquad S_n = \sum_{m=1}^{n} f(\zeta_m)\, \Delta z_m \qquad \text{where} \qquad \Delta z_m = z_m - z_{m-1}.$$

We do this for each $n = 2, 3, \cdots$ in a completely independent manner, but so that the greatest $|\Delta t_m| = |t_m - t_{m-1}|$ approaches zero as $n \to \infty$. This implies that the greatest

$|\Delta z_m|$ also approaches zero. Indeed, it cannot exceed the length of the arc of C from z_{m-1} to z_m and the latter goes to zero since the arc length of the smooth curve C is a continuous function of t. The limit of the sequence of complex numbers $S_2, S_3, \cdots$ thus obtained is called the **line integral** (or simply the *integral*) of $f(z)$ over the path of integration C with the orientation given by (1). This line integral is denoted by

$$\text{(3)} \qquad \int_C f(z)\,dz, \qquad \text{or by} \qquad \oint_C f(z)\,dz$$

if C is a **closed path** (one whose terminal point Z coincides with its initial point z_0, as for a circle or for a curve shaped like an 8).

General Assumption. *All paths of integration for complex line integrals are assumed to be* **piecewise smooth,** *that is, they consist of finitely many smooth curves joined end to end.*

Basic Properties Directly Implied by the Definition

1. **Linearity.** Integration is a **linear operation,** that is, we can integrate sums term by term and can take out constant factors from under the integral sign. This means that if the integrals of f_1 and f_2 over a path C exist, so does the integral of $k_1f_1 + k_2f_2$ over the same path and

$$\text{(4)} \qquad \int_C [k_1f_1(z) + k_2f_2(z)]\,dz = k_1\int_C f_1(z)\,dz + k_2\int_C f_2(z)\,dz.$$

2. **Sense reversal** in integrating over the ***same*** path, from z_0 to Z (left) and from Z to z_0 (right), introduces a minus sign as shown,

$$\text{(5)} \qquad \int_{z_0}^{Z} f(z)\,dz = -\int_{Z}^{z_0} f(z)\,dz.$$

3. **Partitioning of path** (see Fig. 338)

$$\text{(6)} \qquad \int_C f(z)\,dz = \int_{C_1} f(z)\,dz + \int_{C_2} f(z)\,dz.$$

Fig. 338. Partitioning of path [formula (6)]

Existence of the Complex Line Integral

Our assumptions that $f(z)$ is continuous and C is piecewise smooth imply the existence of the line integral (3). This can be seen as follows.

As in the preceding chapter let us write $f(z) = u(x, y) + iv(x, y)$. We also set

$$\zeta_m = \xi_m + i\eta_m \qquad \text{and} \qquad \Delta z_m = \Delta x_m + i\Delta y_m.$$

Then (2) may be written

$$S_n = \sum (u + iv)(\Delta x_m + i\Delta y_m) \tag{7}$$

where $u = u(\zeta_m, \eta_m)$, $v = v(\zeta_m, \eta_m)$ and we sum over m from 1 to n. Performing the multiplication, we may now split up S_n into four sums:

$$S_n = \sum u\,\Delta x_m - \sum v\,\Delta y_m + i\left[\sum u\,\Delta y_m + \sum v\,\Delta x_m\right].$$

These sums are real. Since f is continuous, u and v are continuous. Hence, if we let n approach infinity in the aforementioned way, then the greatest Δx_m and Δy_m will approach zero and each sum on the right becomes a real line integral:

$$\lim_{n\to\infty} S_n = \int_C f(z)\,dz = \int_C u\,dx - \int_C v\,dy + i\left[\int_C u\,dy + \int_C v\,dx\right]. \tag{8}$$

This shows that under our assumptions on f and C the line integral (3) exists and its value is independent of the choice of subdivisions and intermediate points ζ_m. ■

First Evaluation Method: Indefinite Integration and Substitution of Limits

This method is the analog of the evaluation of definite integrals in calculus by the well-known formula

$$\int_a^b f(x)\,dx = F(b) - F(a) \qquad [F'(x) = f(x)].$$

It is simpler than the next method, but it is suitable for analytic functions only. To formulate it, we need the following concept of general interest.

A domain D is called **simply connected** if every **simple closed curve** (closed curve without self-intersections) encloses only points of D.

For instance, a circular disk is simply connected, whereas an annulus (Sec. 13.3) is not simply connected. (Explain!)

THEOREM 1

Indefinite Integration of Analytic Functions

Let $f(z)$ be analytic in a simply connected domain D. Then there exists an indefinite integral of $f(z)$ in the domain D, that is, an analytic function $F(z)$ such that $F'(z) = f(z)$ in D, and for all paths in D joining two points z_0 and z_1 in D we have

$$\int_{z_0}^{z_1} f(z)\,dz = F(z_1) - F(z_0) \qquad [F'(z) = f(z)]. \tag{9}$$

(Note that we can write z_0 and z_1 instead of C, since we get the same value for all those C from z_0 to z_1.)

This theorem will be proved in the next section.

Simple connectedness is quite essential in Theorem 1, as we shall see in Example 5.

Since analytic functions are our main concern, and since differentiation formulas will often help in finding $F(z)$ for a given $f(z) = F'(z)$, the present method is of great practical interest.

If $f(z)$ is entire (Sec. 13.5), we can take for D the complex plane (which is certainly simply connected).

EXAMPLE 1 $$\int_0^{1+i} z^2\,dz = \frac{1}{3}\,z^3\Big|_0^{1+i} = \frac{1}{3}\,(1+i)^3 = -\frac{2}{3} + \frac{2}{3}\,i$$ ■

EXAMPLE 2 $$\int_{-\pi i}^{\pi i} \cos z\,dz = \sin z\Big|_{-\pi i}^{\pi i} = 2\sin \pi i = 2i \sinh \pi = 23.097i$$ ■

EXAMPLE 3 $$\int_{8+\pi i}^{8-3\pi i} e^{z/2}\,dz = 2e^{z/2}\Big|_{8+\pi i}^{8-3\pi i} = 2(e^{4-3\pi i/2} - e^{4+\pi i/2}) = 0$$

since e^z is periodic with period $2\pi i$. ■

EXAMPLE 4 $\displaystyle\int_{-i}^{i} \frac{dz}{z} = \operatorname{Ln} i - \operatorname{Ln}(-i) = \frac{i\pi}{2} - \left(-\frac{i\pi}{2}\right) = i\pi$. Here D is the complex plane without 0 and the negative real axis (where $\operatorname{Ln} z$ is not analytic). Obviously, D is a simply connected domain. ■

Second Evaluation Method: Use of a Representation of a Path

This method is not restricted to analytic functions but applies to any continuous complex function.

THEOREM 2

Integration by the Use of the Path

Let C be a piecewise smooth path, represented by $z = z(t)$, where $a \leqq t \leqq b$. Let $f(z)$ be a continuous function on C. Then

(10) $$\int_C f(z)\,dz = \int_a^b f[z(t)]\dot{z}(t)\,dt \qquad \left(\dot{z} = \frac{dz}{dt}\right).$$

PROOF The left side of (10) is given by (8) in terms of real line integrals, and we show that the right side of (10) also equals (8). We have $z = x + iy$, hence $\dot{z} = \dot{x} + i\dot{y}$. We simply write u for $u[x(t), y(t)]$ and v for $v[x(t), y(t)]$. We also have $dx = \dot{x}\,dt$ *and* $dy = \dot{y}\,dt$. Consequently, in (10)

$$\begin{aligned}\int_a^b f[z(t)]\dot{z}(t)\,dt &= \int_a^b (u + iv)(\dot{x} + i\dot{y})\,dt \\ &= \int_C [u\,dx - v\,dy + i(u\,dy + v\,dx)] \\ &= \int_C (u\,dx - v\,dy) + i\int_C (u\,dy + v\,dx).\end{aligned}$$ ■

COMMENT. In (7) and (8) of the existence proof of the complex line integral we referred to real line integrals. If one wants to avoid this, one can take (10) as a *definition* of the complex line integral.

Steps in Applying Theorem 2

(A) Represent the path C in the form $z(t)$ $(a \leqq t \leqq b)$.

(B) Calculate the derivative $\dot{z}(t) = dz/dt$.

(C) Substitute $z(t)$ for every z in $f(z)$ (hence $x(t)$ for x and $y(t)$ for y).

(D) Integrate $f[z(t)]\dot{z}(t)$ over t from a to b.

EXAMPLE 5 **A Basic Result: Integral of $1/z$ Around the Unit Circle**

We show that by integrating $1/z$ counterclockwise around the unit circle (the circle of radius 1 and center 0; see Sec. 13.3) we obtain

$$\textbf{(11)} \qquad \oint_C \frac{dz}{z} = 2\pi i \qquad (C \text{ the unit circle, counterclockwise}).$$

This is a very important result that we shall need quite often.

Solution. **(A)** We may represent the unit circle C in Fig. 327 of Sec. 13.3 by

$$z(t) = \cos t + i \sin t = e^{it} \qquad (0 \leqq t \leqq 2\pi),$$

so that counterclockwise integration corresponds to an increase of t from 0 to 2π.

(B) Differentiation gives $\dot{z}(t) = ie^{it}$ (chain rule!).

(C) By substitution, $f(z(t)) = 1/z(t) = e^{-it}$.

(D) From (10) we thus obtain the result

$$\oint_C \frac{dz}{z} = \int_0^{2\pi} e^{-it} i e^{it}\, dt = i \int_0^{2\pi} dt = 2\pi i.$$

Check this result by using $z(t) = \cos t + i \sin t$.

Simple connectedness is essential in Theorem 1. Equation (9) in Theorem 1 gives 0 for any closed path because then $z_1 = z_0$, so that $F(z_1) - F(z_0) = 0$. Now $1/z$ is not analytic at $z = 0$. But any *simply connected* domain containing the unit circle must contain $z = 0$, so that Theorem 1 does not apply—it is not enough that $1/z$ is analytic in an annulus, say, $\frac{1}{2} < |z| < \frac{3}{2}$, because an annulus is not simply connected! ■

EXAMPLE 6 **Integral of $1/z^m$ with Integer Power m**

Let $f(z) = (z - z_0)^m$ where m is the integer and z_0 a constant. Integrate counterclockwise around the circle C of radius ρ with center at z_0 (Fig. 339).

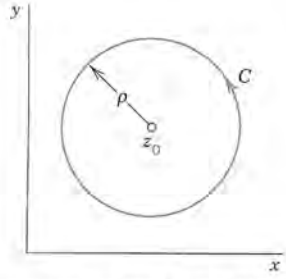

Fig. 339. Path in Example 6

Solution. We may represent C in the form

$$z(t) = z_0 + \rho(\cos t + i \sin t) = z_0 + \rho e^{it} \qquad (0 \leqq t \leqq 2\pi).$$

Then we have

$$(z - z_0)^m = \rho^m e^{imt}, \qquad dz = i\rho e^{it}\, dt$$

and obtain

$$\oint_C (z - z_0)^m\, dz = \int_0^{2\pi} \rho^m e^{imt}\, i\rho e^{it}\, dt = i\rho^{m+1} \int_0^{2\pi} e^{i(m+1)t}\, dt.$$

By the Euler formula (5) in Sec. 13.6 the right side equals

$$i\rho^{m+1} \left[\int_0^{2\pi} \cos(m + 1)t\, dt + i \int_0^{2\pi} \sin(m + 1)t\, dt \right].$$

If $m = -1$, we have $\rho^{m+1} = 1$, $\cos 0 = 1$, $\sin 0 = 0$. We thus obtain $2\pi i$. For integer $m \neq 1$ each of the two integrals is zero because we integrate over an interval of length 2π, equal to a period of sine and cosine. Hence the result is

(12)
$$\oint_C (z - z_0)^m\, dz = \begin{cases} 2\pi i & (m = -1), \\ 0 & (m \neq -1 \text{ and integer}). \end{cases}$$

■

Dependence on path. Now comes a very important fact. If we integrate a given function $f(z)$ from a point z_0 to a point z_1 along different paths, the integrals will in general have different values. In other words, ***a complex line integral depends not only on the endpoints of the path but in general also on the path itself.*** The next example gives a first impression of this, and a systematic discussion follows in the next section.

EXAMPLE 7 **Integral of a Nonanalytic Function. Dependence on Path**

Integrate $f(z) = \operatorname{Re} z = x$ from 0 to $1 + 2i$ (a) along C^* in Fig. 340, (b) along C consisting of C_1 and C_2.

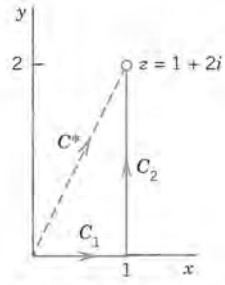

Fig. 340. Paths in Example 7

Solution. **(a)** C^* can be represented by $z(t) = t + 2it$ $(0 \leqq t \leqq 1)$. Hence $\dot{z}(t) = 1 + 2i$ and $f[z(t)] = x(t) = t$ on C^*. We now calculate

$$\int_{C^*} \operatorname{Re} z\, dz = \int_0^1 t(1 + 2i)\, dt = \tfrac{1}{2}(1 + 2i) = \tfrac{1}{2} + i.$$

(b) We now have

$$C_1\text{: } z(t) = t, \qquad \dot{z}(t) = 1, \qquad f(z(t)) = x(t) = t \qquad (0 \leqq t \leqq 1)$$

$$C_2\text{: } z(t) = 1 + it, \qquad \dot{z}(t) = i, \qquad f(z(t)) = x(t) = 1 \qquad (0 \leqq t \leqq 2).$$

Using (6) we calculate

$$\int_C \operatorname{Re} z\,dz = \int_{C_1} \operatorname{Re} z\,dz + \int_{C_2} \operatorname{Re} z\,dz = \int_0^1 r\,dt + \int_0^2 1 \cdot i\,dt = \tfrac{1}{2} + 2i.$$

Note that this result differs from the result in (a). ■

Bounds for Integrals. *ML*-Inequality

There will be a frequent need for estimating the absolute value of complex line integrals. The basic formula is

(13) $$\left|\int_C f(z)\,dz\right| \leqq ML \qquad \textbf{(}\boldsymbol{ML}\textbf{-inequality);}$$

L is the length of C and M a constant such that $|f(z)| \leqq M$ everywhere on C.

PROOF Taking the absolute value in (2) and applying the generalized inequality (6*) in Sec. 13.2, we obtain

$$|S_n| = \left|\sum_{m=1}^{n} f(\zeta_m)\,\Delta z_m\right| \leqq \sum_{m=1}^{n} |f(\zeta_m)|\,|\Delta z_m| \leqq M \sum_{m=1}^{n} |\Delta z_m|.$$

Now $|\Delta z_m|$ is the length of the chord whose endpoints are z_{m-1} and z_m (see Fig. 337 on p. 638). Hence the sum on the right represents the length L^* of the broken line of chords whose endpoints are $z_0, z_1, \cdots, z_n\ (= Z)$. If n approaches infinity in such a way that the greatest $|\Delta t_m|$ and thus $|\Delta z_m|$ approach zero, then L^* approaches the length L of the curve C, by the definition of the length of a curve. From this the inequality (13) follows. ■

We cannot see from (13) how close to the bound ML the actual absolute value of the integral is, but this will be no handicap in applying (13). For the time being we explain the practical use of (13) by a simple example.

EXAMPLE 8 **Estimation of an Integral**

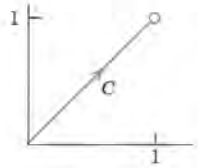

Fig. 341. Path in Example 8

Find an upper bound for the absolute value of the integral

$$\int_C z^2\,dz, \qquad C \text{ the straight-line segment from 0 to } 1 + i, \text{ Fig. 341.}$$

Solution. $L = \sqrt{2}$ and $|f(z)| = |z^2| \leqq 2$ on C gives by (13)

$$\left|\int_C z^2\,dz\right| \leqq 2\sqrt{2} = 2.8284.$$

The absolute value of the integral is $\left|-\frac{2}{3} + \frac{2}{3}\,i\right| = \frac{2}{3}\sqrt{2} = 0.9428$ (see Example 1). ■

Summary on Integration. Line integrals of $f(z)$ can always be evaluated by (10), using a representation (1) of the path of integration. If $f(z)$ is analytic, indefinite integration by (9) as in calculus will be simpler.

PROBLEM SET 14.1

1–9 PARAMETRIC REPRESENTATIONS

Find and sketch the path and its orientation given by:

1. $z(t) = (1 + 3i)t$ $(1 \leqq t \leqq 4)$
2. $z(t) = 5 - 2it$ $(-3 \leqq t \leqq 3)$
3. $z(t) = 4 + i + 3e^{it}$ $(0 \leqq t \leqq 2\pi)$
4. $z(t) = 1 + i + e^{-\pi it}$ $(0 \leqq t \leqq 2)$
5. $z(t) = e^{it}$ $(0 \leqq t \leqq \pi)$
6. $z(t) = 3 + 4i + 5e^{it}$ $(\pi \leqq t \leqq 2\pi)$
7. $z(t) = 6\cos 2t + 5i \sin 2t$ $(0 \leqq t \leqq \pi)$
8. $z(t) = 1 + 2t + 8it^2$ $(-1 \leqq t \leqq 1)$
9. $z(t) = t + \frac{1}{2}it^3$ $(-1 \leqq t \leqq 2)$

10–18 PARAMETRIC REPRESENTATIONS

Sketch and represent parametrically:

10. Segment from $1 + i$ to $4 - 2i$
11. Unit circle (clockwise)
12. Segment from $a + ib$ to $c + id$
13. Hyperbola $xy = 1$ from $1 + i$ to $4 + \frac{1}{4}i$
14. Semi-ellipse $x^2/a^2 + y^2/b^2 = 1$, $y \geqq 0$
15. Parabola $y = 4 - 4x^2$ $(-1 \leqq x \leqq 1)$
16. $|z - 2 + 3i| = 4$ (counterclockwise)
17. $|z + a + ib| = r$ (clockwise)
18. Ellipse $4(x - 1)^2 + 9(y + 2)^2 = 36$

19–29 INTEGRATION

Integrate by the first method or state why it does not apply and then use the second method. (Show the details of your work.)

19. $\int_C \operatorname{Re} z\, dz$, C the shortest path from 0 to $1 + i$
20. $\int_C \operatorname{Re} z\, dz$, C the parabola $y = x^2$ from 0 to $1 + i$
21. $\int_C e^{2z}\, dz$, C the shortest path from πi to $2\pi i$
22. $\int_C \sin z\, dz$, C any path from 0 to $2i$
23. $\int_C \cos^2 z\, dz$ from $-\pi i$ along $|z| = \pi$ to πi in the right half-plane
24. $\int_C (z + z^{-1})\, dz$, C the unit circle (counterclockwise)
25. $\int_C \cosh 4z\, dz$, C any path from $-\pi i/8$ to $\pi i/8$
26. $\int_C \bar{z}\, dz$, C from $-1 + i$ along the parabola $y = x^2$ to $1 + i$
27. $\int_C \sec^2 z\, dz$, C any path from $\pi/4$ to $\pi i/4$
28. $\int_C \operatorname{Im} z^2\, dz$ counterclockwise around the triangle with vertices $z = 0, 1, i$
29. $\int_C ze^{z^2/2}\, dz$, C from i along the axes to 1
30. **(Sense reversal)** Verify (5) for $f(z) = z^2$, where C is the segment from $-1 - i$ to $1 + i$.
31. **(Path partitioning)** Verify (6) for $f(z) = 1/z$ and C_1 and C_2 the upper and lower halfs of the unit circle
32. **(*ML*-inequality)** Find an upper bound of the absolute value of the integral in Prob. 19.
33. **(Linearity)** Illustrate (4) with an example of your own. Prove (4).
34. **TEAM PROJECT. Integration. (a) Comparison.** Write a short report comparing the essential points of the two integration methods.

    (b) Comparison. Evaluate $\int_C f(z)\, dz$ by Theorem 1 and check the result by Theorem 2, where:

    (i) $f(z) = z^4$ and C is the semicircle $|z| = 2$ from $-2i$ to $2i$ in the right half-plane,

    (ii) $f(z) = e^{2z}$ and C is the shortest path from 0 to $1 + 2i$.

    (c) Continuous deformation of path. Experiment with a family of paths with common endpoints, say, $z(t) = t + ia \sin t$, $0 \leqq t \leqq \pi$, with real parameter a. Integrate nonanalytic functions ($\operatorname{Re} z$, $\operatorname{Re}(z^2)$, etc.) and explore how the result depends on a. Then take analytic functions of your choice. (Show the details of your work.) Compare and comment.

    (d) Continuous deformation of path. Choose another family, for example, semi-ellipses $z(t) = a\cos t + i \sin t$, $-\pi/2 \leqq t \leqq \pi/2$, and experiment as in (c).
35. **CAS PROJECT. Integration.** Write programs for the two integration methods. Apply them to problems of your choice. Could you make them into a joint program that also decides which of the two methods to use in a given case?

14.2 Cauchy's Integral Theorem

We have just seen in Sec. 14.1 that a line integral of a function $f(z)$ generally depends not merely on the endpoints of the path, but also on the choice of the path itself. This dependence often complicates situations. Hence conditions under which this does ***not*** occur are of considerable importance. Namely, if $f(z)$ is analytic in a domain D and D is simply connected (see Sec. 14.1 and also below), then the integral will not depend on the choice of a path between given points. This result (Theorem 2) follows from Cauchy's integral theorem, along with other basic consequences that make ***Cauchy's integral theorem the most important theorem in this chapter*** and fundamental throughout complex analysis.

Let us begin by repeating and illustrating the definition of simple connectedness (Sec. 14.1) and adding some more details.

1. A **simple closed path** is a closed path (Sec. 14.1) that does not intersect or touch itself (Fig. 342). For example, a circle is simple, but a curve shaped like an 8 is not simple.

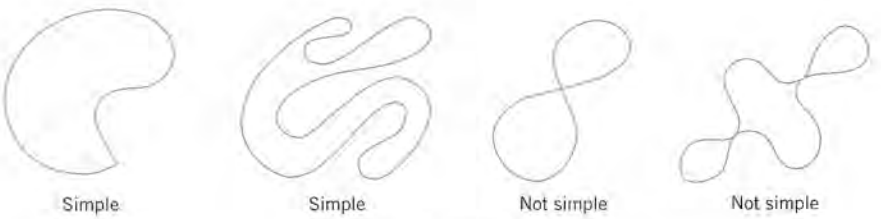

Fig. 342. Closed paths

2. A **simply connected domain** D in the complex plane is a domain (Sec. 13.3) such that every simple closed path in D encloses only points of D. *Examples:* The interior of a circle ("open disk"), ellipse, or any simple closed curve. A domain that is not simply connected is called **multiply connected.** *Examples:* An annulus (Sec. 13.3), a disk without the center, for example, $0 < |z| < 1$. See also Fig. 343.

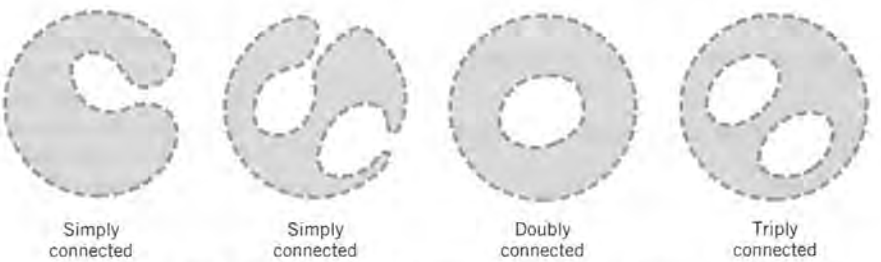

Fig. 343. Simply and multiply connected domains

More precisely, a **bounded domain** D (that is, a domain that lies entirely in some circle about the origin) is called ***p*-fold connected** if its boundary consists of p closed connected sets without common points. These sets can be curves, segments, or single points (such as $z = 0$ for $0 < |z| < 1$, for which $p = 2$). Thus, D has $p - 1$ **"holes",** where "hole" may also mean a segment or even a single point. Hence an annulus is doubly connected ($p = 2$).

THEOREM 1

Cauchy's Integral Theorem

If $f(z)$ is analytic in a simply connected domain D, then for every simple closed path C in D,

$$\oint_C f(z)\,dz = 0. \tag{1}$$

See Fig. 344.

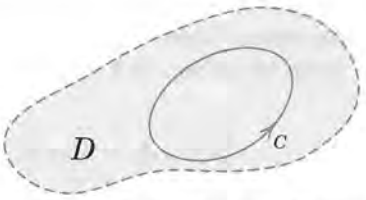

Fig. 344. Cauchy's integral theorem

Before we prove the theorem, let us consider some examples in order to really understand what is going on. A simple closed path is sometimes called a *contour* and an integral over such a path a **contour integral.** Thus, (1) and our examples involve contour integrals.

EXAMPLE 1 **No Singularities (Entire Functions)**

$$\oint_C e^z\,dz = 0, \qquad \oint_C \cos z\,dz = 0, \qquad \oint_C z^n\,dz = 0 \qquad (n = 0, 1, \cdorn)$$

for any closed path, since these functions are entire (analytic for all z). ■

EXAMPLE 2 **Singularities Outside the Contour**

$$\oint_C \sec z\,dz = 0, \qquad \oint_C \frac{dz}{z^2 + 4} = 0$$

where C is the unit circle, $\sec z = 1/\cos z$ is not analytic at $z = \pm\pi/2, \pm 3\pi/2, \cdots$, but all these points lie outside C; none lies on C or inside C. Similarly for the second integral, whose integrand is not analytic at $z = \pm 2i$ outside C. ■

EXAMPLE 3 **Nonanalytic Function**

$$\oint_C \bar{z}\,dz = \int_0^{2\pi} e^{-it} ie^{it}\,dt = 2\pi i$$

where C: $z(t) = e^{it}$ is the unit circle. This does not contradict Cauchy's theorem because $f(z) = \bar{z}$ is not analytic. ■

EXAMPLE 4 **Analyticity Sufficient, Not Necessary**

$$\oint_C \frac{dz}{z^2} = 0$$

where C is the unit circle. This result does *not* follow from Cauchy's theorem, because $f(z) = 1/z^2$ is not analytic at $z = 0$. Hence *the condition that f be analytic in D is sufficient rather than necessary for* (1) *to be true.* ■

EXAMPLE 5 **Simple Connectedness Essential**

$$\oint_C \frac{dz}{z} = 2\pi i$$

for counterclockwise integration around the unit circle (see Sec. 14.1). C lies in the annulus $\frac{1}{2} < |z| < \frac{3}{2}$ where $1/z$ is analytic, but this domain is not simply connected, so that Cauchy's theorem cannot be applied. Hence ***the condition that the domain D be simply connected is essential.***

In other words, by Cauchy's theorem, if $f(z)$ is analytic on a simple closed path C and everywhere inside C, with no exception, not even a single point, then (1) holds. The point that causes trouble here is $z = 0$ where $1/z$ is not analytic. ■

PROOF Cauchy proved his integral theorem under the additional assumption that the derivative $f'(z)$ is continuous (which is true, but would need an extra proof). His proof proceeds as follows. From (8) in Sec. 14.1 we have

$$\oint_C f(z)\,dz = \oint_C (u\,dx - v\,dy) + i \oint_C (u\,dy + v\,dx).$$

Since $f(z)$ is analytic in D, its derivative $f'(z)$ exists in D. Since $f'(z)$ is assumed to be continuous, (4) and (5) in Sec. 13.4 imply that u and v have *continuous* partial derivatives in D. Hence Green's theorem (Sec. 10.4) (with u and $-v$ instead of F_1 and F_2) is applicable and gives

$$\oint_C (u\,dx - v\,dy) = \iint_R \left(-\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) dx\,dy$$

where R is the region bounded by C. The second Cauchy–Riemann equation (Sec. 13.4) shows that the integrand on the right is identically zero. Hence the integral on the left is zero. In the same fashion it follows by the use of the first Cauchy–Riemann equation that the last integral in the above formula is zero. This completes Cauchy's proof. ■

Goursat's proof *without the condition that $f'(z)$ is continuous*[1] is much more complicated. We leave it optional and include it in App. 4.

Independence of Path

We know from the preceding section that the value of a line integral of a given function $f(z)$ from a point z_1 to a point z_2 will in general depend on the path C over which we integrate, not merely on z_1 and z_2. It is important to characterize situations in which this difficulty of path dependence does not occur. This task suggests the following concept. We call an integral of $f(z)$ **independent of path in a domain D** if for every z_1, z_2 in D its value depends (besides on $f(z)$, of course) only on the initial point z_1 and the terminal point z_2, but not on the choice of the path C in D [so that every path in D from z_1 to z_2 gives the same value of the integral of $f(z)$].

[1] ÉDOUARD GOURSAT (1858–1936), French mathematician. Cauchy published the theorem in 1825. The removal of that condition by Goursat (see *Transactions Amer. Math. Soc.*, vol. 1, 1900) is quite important, for instance, in connection with the fact that derivatives of analytic functions are also analytic, as we shall prove soon. Goursat also made important contributions to PDEs.

THEOREM 2

Independence of Path

If $f(z)$ is analytic in a simply connected domain D, then the integral of $f(z)$ is independent of path in D.

PROOF Let z_1 and z_2 be any points in D. Consider two paths C_1 and C_2 in D from z_1 to z_2 without further common points, as in Fig. 345. Denote by C_2^* the path C_2 with the orientation reserved (Fig. 346). Integrate from z_1 over C_1 to z_2 and over C_2^* back to z_1. This is a simple closed path, and Cauchy's theorem applies under our assumptions of the present theorem and gives zero:

$$(2') \qquad \int_{C_1} f\,dz + \int_{C_2^*} f\,dz = 0, \qquad \text{thus} \qquad \int_{C_1} f\,dz = -\int_{C_2^*} f\,dz.$$

But the minus sign on the right disappears if we integrate in the reverse direction, from z_1 to z_2, which shows that the integrals of $f(z)$ over C_1 and C_2 are equal,

$$(2) \qquad \int_{C_1} f(z)\,dz = \int_{C_2} f(z)\,dz \qquad \text{(Fig. 345).}$$

This proves the theorem for paths that have only the endpoints in common. For paths that have finitely many further common points, apply the present argument to each "loop" (portions of C_1 and C_2 between consecutive common points; four loops in Fig. 347). For paths with infinitely many common points we would need additional argumentation not to be presented here. ■

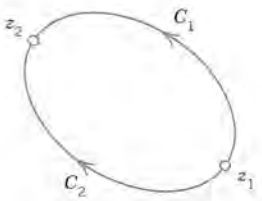

Fig. 345. Formula (2)

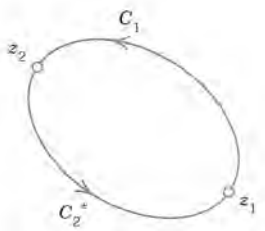

Fig. 346. Formula (2′)

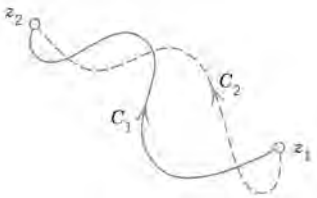

Fig. 347. Paths with more common points

Principle of Deformation of Path

This idea is related to path independence. We may imagine that the path C_2 in (2) was obtained from C_1 by continuously moving C_1 (with ends fixed!) until it coincides with C_2. Figure 348 shows two of the infinitely many intermediate paths for which the integral always retains its value (because of Theorem 2). Hence we may impose a continuous deformation of the path of an integral, keeping the ends fixed. As long as our deforming path always contains only points at which $f(z)$ is analytic, the integral retains the same value. This is called the **principle of deformation of path.**

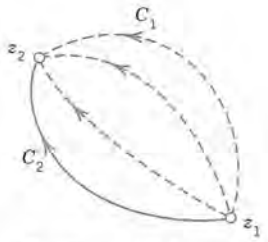

Fig. 348. Continuous deformation of path

EXAMPLE 6 A Basic Result: Integral of Integer Powers

From Example 6 in Sec. 14.1 and the principle of deformation of path it follows that

$$\oint (z - z_0)^m \, dz = \begin{cases} 2\pi i & (m = -1) \\ 0 & (m \neq -1 \text{ and integer}) \end{cases} \tag{3}$$

for counterclockwise integration around ***any simple closed path containing z_0 in its interior.***

Indeed, the circle $|z - z_0| = \rho$ in Example 6 of Sec. 14.1 can be continuously deformed in two steps into a path as just indicated, namely, by first deforming, say, one semicircle and then the other one. (Make a sketch). ■

Existence of Indefinite Integral

We shall now justify our indefinite integration method in the preceding section [formula (9) in Sec. 14.1]. The proof will need Cauchy's integral theorem.

THEOREM 3

Existence of Indefinite Integral

If $f(z)$ is analytic in a simply connected domain D, then there exists an indefinite integral $F(z)$ of $f(z)$ in D—thus, $F'(z) = f(z)$—which is analytic in D, and for all paths in D joining any two points z_0 and z_1 in D, the integral of $f(z)$ from z_0 to z_1 can be evaluated by formula (9) *in* Sec. 14.1.

PROOF The conditions of Cauchy's integral theorem are satisfied. Hence the line integral of $f(z)$ from any z_0 in D to any z in D is independent of path in D. We keep z_0 fixed. Then this integral becomes a function of z, call if $F(z)$,

$$F(z) = \int_{z_0}^{z} f(z^*) \, dz^* \tag{4}$$

which is uniquely determined. We show that this $F(z)$ is analytic in D and $F'(z) = f(z)$. The idea of doing this is as follows. Using (4) we form the difference quotient

$$\frac{F(z + \Delta z) - F(z)}{\Delta z} = \frac{1}{\Delta z} \left[\int_{z_0}^{z+\Delta z} f(z^*) \, dz^* - \int_{z_0}^{z} f(z^*) \, dz^* \right] = \frac{1}{\Delta z} \int_{z}^{z+\Delta z} f(z^*) \, dz^*. \tag{5}$$

We now subtract $f(z)$ from (5) and show that the resulting expression approaches zero as $\Delta z \to 0$. The details are as follows.

We keep z fixed. Then we choose $z + \Delta z$ in D so that the whole segment with endpoints z and $z + \Delta z$ is in D (Fig. 349). This can be done because D is a domain, hence it contains a neighborhood of z. We use this segment as the path of integration in (5). Now we subtract $f(z)$. This is a constant because z is kept fixed. Hence we can write

$$\int_z^{z+\Delta z} f(z)\, dz^* = f(z) \int_z^{z+\Delta z} dz^* = f(z)\, \Delta z. \qquad \text{Thus} \qquad f(z) = \frac{1}{\Delta z} \int_z^{z+\Delta z} f(z)\, dz^*.$$

By this trick and from (5) we get a single integral:

$$\frac{F(z + \Delta z) - F(z)}{\Delta z} - f(z) = \frac{1}{\Delta z} \int_z^{z+\Delta z} [f(z^*) - f(z)]\, dz^*.$$

Since $f(z)$ is analytic, it is continuous. An $\epsilon > 0$ being given, we can thus find a $\delta > 0$ such that $|f(z^*) - f(z)| < \epsilon$ when $|z^* - z| < \delta$. Hence, letting $|\Delta z| < \delta$, we see that the *ML*-inequality (Sec. 14.1) yields

$$\left| \frac{F(z + \Delta z) - F(z)}{\Delta z} - f(z) \right| = \frac{1}{|\Delta z|} \left| \int_z^{z+\Delta z} [f(z^*) - f(z)]\, dz^* \right| \leqq \frac{1}{|\Delta z|}\, \epsilon |\Delta z| = \epsilon.$$

By the definition of limit and derivative, this proves that

$$F'(z) = \lim_{\Delta z \to 0} \frac{F(z + \Delta z) - F(z)}{\Delta z} = f(z).$$

Since z is any point in D, this implies that $F(z)$ is analytic in D and is an indefinite integral or antiderivative of $f(z)$ in D, written

$$F(z) = \int f(z)\, dz.$$

Also, if $G'(z) = f(z)$, then $F'(z) - G'(z) \equiv 0$ in D; hence $F(z) - G(z)$ is constant in D (see Team Project 26 in Problem Set 13.4). That is, two indefinite integrals of $f(z)$ can differ only by a constant. The latter drops out in (9) of Sec. 14.1, so that we can use any indefinite integral of $f(z)$. This proves Theorem 3. ■

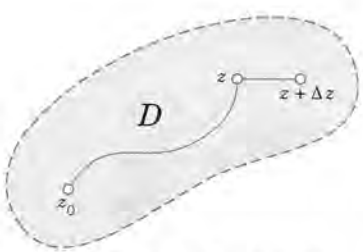

Fig. 349. Path of integration

Cauchy's Integral Theorem for Multiply Connected Domains

Cauchy's theorem applies to multiply connected domains. We first explain this for a **doubly connected domain** D with outer boundary curve C_1 and inner C_2 (Fig. 350). If a function $f(z)$ is analytic in any domain D^* that contains D and its boundary curves, we claim that

(6)
$$\oint_{C_1} f(z)\,dz = \oint_{C_2} f(z)\,dz \qquad \text{(Fig. 350)}$$

both integrals being taken counterclockwise (or both clockwise, and regardless of whether or not the full interior of C_2 belongs to D^*).

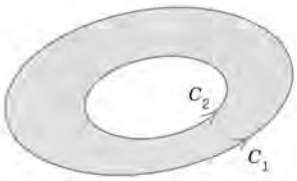

Fig. 350. Paths in (5)

PROOF By two cuts $\tilde{C}_1$ and $\tilde{C}_2$ (Fig. 351) we cut D into two simply connected domains D_1 and D_2 in which and on whose boundaries $f(z)$ is analytic. By Cauchy's integral theorem the integral over the entire boundary of D_1 (taken in the sense of the arrows in Fig. 351) is zero, and so is the integral over the boundary of D_2, and thus their sum. In this sum the integrals over the cuts $\tilde{C}_1$ and $\tilde{C}_2$ cancel because we integrate over them in both directions—this is the key—and we are left with the integrals over C_1 (counterclockwise) and C_2 (clockwise; see Fig. 351); hence by reversing the integration over C_2 (to counterclockwise) we have

$$\oint_{C_1} f\,dz - \oint_{C_2} f\,dz = 0$$

and (6) follows. ■

For domains of higher connectivity the idea remains the same. Thus, for a **triply connected domain** we use three cuts $\tilde{C}_1, \tilde{C}_2, \tilde{C}_3$ (Fig. 352). Adding integrals as before, the integrals over the cuts cancel and the sum of the integrals over C_1 (counterclockwise) and C_2, C_3 (clockwise) is zero. Hence the integral over C_1 equals the sum of the integrals over C_2 and C_3, all three now taken counterclockwise. Similarly for quadruply connected domains, and so on.

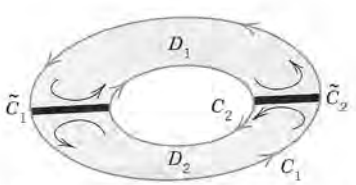

Fig. 351. Doubly connected domain

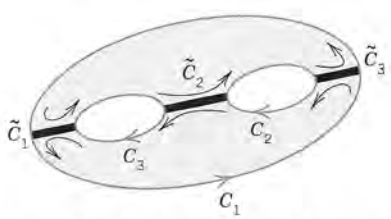

Fig. 352. Triply connected domain

PROBLEM SET 14.2

1–11 CAUCHY'S INTEGRAL THEOREM APPLICABLE?

Integrate $f(z)$ counterclockwise around the unit circle, indicating whether Cauchy's integral theorem applies. (Show the details of your work.)

1. $f(z) = \operatorname{Re} z$
2. $f(z) = 1/(3z - \pi i)$
3. $f(z) = e^{z^2/2}$
4. $f(z) = 1/\bar{z}$
5. $f(z) = \tan z^2$
6. $f(z) = \sec(z/2)$
7. $f(z) = 1/(z^8 - 1.2)$
8. $f(z) = 1/(4z - 3)$
9. $f(z) = 1/(2|z|^3)$
10. $f(z) = \bar{z}^2$
11. $f(z) = z^2 \cot z$

12–17 COMMENTS ON TEXT AND EXAMPLES

12. **(Singularities)** Can we conclude in Example 2 that the integral of $1/(z^2 + 4)$ taken over (a) $|z - 2| = 2$, (b) $|z - 2| = 3$ is zero? Give reasons.

13. **(Cauchy's integral theorem)** Verify Theorem 1 for the integral of z^2 over the boundary of the square with vertices $1 + i$, $-1 + i$, $-1 - i$, and $1 - i$ (counterclockwise).

14. **(Cauchy's integral theorem)** For what contours C will it follow from Theorem 1 that

$$\text{(a)} \oint_C \frac{dz}{z} = 0, \qquad \text{(b)} \oint_C \frac{\cos z}{z^6 - z^2}\, dz = 0,$$

$$\text{(c)} \oint_C \frac{e^{1/z}}{z^2 + 9}\, dz = 0?$$

15. **(Deformation principle)** Can we conclude from Example 4 that the integral is also zero over the contour in Problem 13?

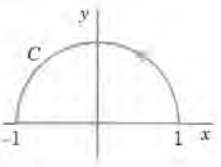
16. **(Deformation principle)** If the integral of a function $f(z)$ over the unit circle equals 3 and over the circle $|z| = 2$ equals 5, can we conclude that $f(z)$ is analytic everywhere in the annulus $1 < |z| < 2$?

17. **(Path independence)** Verify Theorem 2 for the integral of $\cos z$ from 0 to $(1 + i)\pi$ (a) over the shortest path, (b) over the x-axis to π and then straight up to $(1 + i)\pi$.

18. **TEAM PROJECT. Cauchy's Integral Theorem.**
(a) Main Aspects. Each of the problems in Examples 1–5 explains a basic fact in connection with Cauchy's theorem. Find five examples of your own, more complicated ones if possible, each illustrating one of those facts.
(b) Partial fractions. Write $f(z)$ in terms of partial fractions and integrate it counterclockwise over the unit circle, where

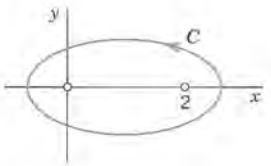
$$\text{(i)}\ f(z) = \frac{2z + 3i}{z^2 + \frac{1}{4}} \qquad \text{(ii)}\ f(z) = \frac{z + 1}{z^2 + 2z}.$$

(c) Deformation of path. Review (c) and (d) of Team Project 34, Sec. 14.1, in the light of the principle of deformation of path. Then consider another family of paths with common endpoints, say, $z(t) = t + ia(t - t^2)$, $0 \leqq t \leqq 1$, and experiment with the integration of analytic and nonanalytic functions of your choice over these paths (e.g., z, $\operatorname{Im} z$, z^2, $\operatorname{Re} z^2$, $\operatorname{Im} z^2$, etc).



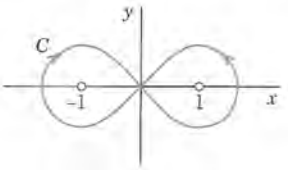
19–30 FURTHER CONTOUR INTEGRALS

Evaluate (showing the details and using partial fractions if necessary)



19. $\oint_C \dfrac{dz}{2z - i}$, C the circle $|z| = 3$ (counterclockwise)

20. $\oint_C \tanh z\, dz$, C the circle $|z - \frac{1}{4}\pi i| = \frac{1}{2}$ (clockwise)



21. $\oint_C \operatorname{Re} 2z\, dz$, C as shown

22. $\oint_C \dfrac{7z - 6}{z^2 - 2z}\, dz$, C as shown

23. $\oint_C \dfrac{dz}{z^2 - 1}$, C as shown

24. $\oint_C \dfrac{e^{2z}}{4z}\, dz$, C consists of $|z| = 2$ (clockwise) and $|z| = \frac{1}{2}$ (counterclockwise)

25. $\oint_C \frac{\cos z}{z}\,dz$, C consists of $|z| = 1$ (counterclockwise) and $|z| = 3$ (clockwise)

26. $\oint_C \operatorname{Ln}(2 + z)\,dz$, C the boundary of the square with vertices $\pm 1, \pm i$

27. $\oint_C \frac{dz}{z^2 + 1}$, C: (a) $|z| = \frac{1}{2}$, (b) $|z - i| = \frac{3}{2}$ (counterclockwise)

28. $\oint_C \frac{dz}{z^2 + 1}$, C: (a) $|z + i| = 1$, (b) $|z - i| = 1$ (counterclockwise)

29. $\oint_C \frac{\sin z}{z + 2i}\,dz$, C: $|z - 4 - 2i| = 5.5$ (clockwise)

30. $\oint_C \frac{\tan(z/2)}{z^4 - 16}\,dz$, C the boundary of the square with vertices $\pm 1, \pm i$ (clockwise)

14.3 Cauchy's Integral Formula

The most important consequence of Cauchy's integral theorem is Cauchy's integral formula. This formula is useful for evaluating integrals, as we show below. Even more important is its key role in proving the surprising fact that analytic functions have derivatives of all orders (Sec. 14.4), in establishing Taylor series representations (Sec. 15.4), and so on. Cauchy's integral formula and its conditions of validity may be stated as follows.

THEOREM 1

Cauchy's Integral Formula

Let $f(z)$ be analytic in a simply connected domain D. Then for any point z_0 in D and any simple closed path C in D that encloses z_0 (Fig. 353),

(1) $$\oint_C \frac{f(z)}{z - z_0}\,dz = 2\pi i f(z_0)$$ **(Cauchy's integral formula)**

the integration being taken counterclockwise. Alternatively (for representing $f(z_0)$ by a contour integral, divide (1) by $2\pi i$),

(1*) $$f(z_0) = \frac{1}{2\pi i}\oint_C \frac{f(z)}{z - z_0}\,dz$$ **(Cauchy's integral formula).**

PROOF By addition and subtraction, $f(z) = f(z_0) + [f(z) - f(z_0)]$. Inserting this into (1) on the left and taking the constant factor $f(z_0)$ out from under the integral sign, we have

(2) $$\oint_C \frac{f(z)}{z - z_0}\,dz = f(z_0)\oint_C \frac{dz}{z - z_0} + \oint_C \frac{f(z) - f(z_0)}{z - z_0}\,dz.$$

The first term on the right equals $f(z_0) \cdot 2\pi i$ (see Example 6 in Sec. 14.2 with $m = -1$). This proves the theorem, provided the second integral on the right is zero. This is what we are now going to show. Its integrand is analytic, except at z_0. Hence by (6) in Sec. 14.2 we can replace C by a small circle K of radius ρ and center z_0 (Fig. 354), without

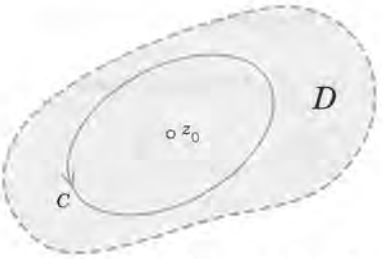


Fig. 353. Cauchy's integral formula

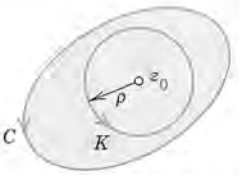

Fig. 354. Proof of Cauchy's integral formula

altering the value of the integral. Since $f(z)$ is analytic, it is continuous (Team Project 26, Sec. 13.3). Hence an $\epsilon > 0$ being given, we can find a $\delta > 0$ such that $|f(z) - f(z_0)| < \epsilon$ for all z in the disk $|z - z_0| < \delta$. Choosing the radius ρ of K smaller than δ, we thus have the inequality

$$\left| \frac{f(z) - f(z_0)}{z - z_0} \right| < \frac{\epsilon}{\rho}$$

at each point of K. The length of K is $2\pi\rho$. Hence, by the *ML*-inequality in Sec. 14.1,

$$\left| \oint_K \frac{f(z) - f(z_0)}{z - z_0} \, dz \right| < \frac{\epsilon}{\rho} \, 2\pi\rho = 2\pi\epsilon.$$

Since ϵ (> 0) can be chosen arbitrarily small, it follows that the last integral in (2) must have the value zero, and the theorem is proved. ■

EXAMPLE 1 **Cauchy's Integral Formula**

$$\oint_C \frac{e^z}{z - 2} \, dz = 2\pi i e^z \Big|_{z=2} = 2\pi i e^2 = 46.4268i$$

for any contour enclosing $z_0 = 2$ (since e^z is entire), and zero for any contour for which $z_0 = 2$ lies outside (by Cauchy's integral theorem). ■

EXAMPLE 2 **Cauchy's Integral Formula**

$$\begin{aligned} \oint_C \frac{z^3 - 6}{2z - i} \, dz &= \oint_C \frac{\frac{1}{2}z^3 - 3}{z - \frac{1}{2}i} \, dz \\ &= 2\pi i \left[\tfrac{1}{2}z^3 - 3\right]\Big|_{z=i/2} \\ &= \frac{\pi}{8} - 6\pi i \qquad (z_0 = \tfrac{1}{2}i \text{ inside } C). \end{aligned}$$

■

EXAMPLE 3 **Integration Around Different Contours**

Integrate

$$g(z) = \frac{z^2 + 1}{z^2 - 1} = \frac{z^2 + 1}{(z + 1)(z - 1)}$$

counterclockwise around each of the four circles in Fig. 355.

Solution. $g(z)$ is not analytic at -1 and 1. These are the points we have to watch for. We consider each circle separately.

(a) The circle $|z - 1| = 1$ encloses the point $z_0 = 1$ where $g(z)$ is not analytic. Hence in (1) we have to write

$$g(z) = \frac{z^2 + 1}{z^2 - 1} = \frac{z^2 + 1}{z + 1} \frac{1}{z - 1};$$

thus

$$f(z) = \frac{z^2 + 1}{z + 1}$$

and (1) gives

$$\oint_C \frac{z^2 + 1}{z^2 - 1}\, dz = 2\pi i f(1) = 2\pi i \left[\frac{z^2 + 1}{z + 1} \right]_{z=1} = 2\pi i.$$

(b) gives the same as (a) by the principle of deformation of path.

(c) The function $g(z)$ is as before, but $f(z)$ changes because we must take $z_0 = -1$ (instead of 1). This gives a factor $z - z_0 = z + 1$ in (1). Hence we must write

$$g(z) = \frac{z^2 + 1}{z - 1} \frac{1}{z + 1};$$

thus

$$f(z) = \frac{z^2 + 1}{z - 1}.$$

Compare this for a minute with the previous expression and then go on:

$$\oint_C \frac{z^2 + 1}{z^2 - 1}\, dz = 2\pi i f(-1) = 2\pi i \left[\frac{z^2 + 1}{z - 1} \right]_{z=-1} = -2\pi i.$$

(d) gives 0. Why? ■

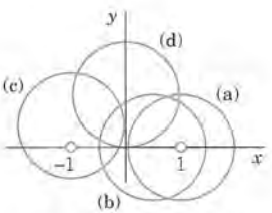

Fig. 355. Example 3

Multiply connected domains may be handled as in Sec. 14.2. For instance, if $f(z)$ is analytic on C_1 and C_2 and in the ring-shaped domain bounded by C_1 and C_2 (Fig. 356) and z_0 is any point in that domain, then

(3)
$$f(z_0) = \frac{1}{2\pi i} \oint_{C_1} \frac{f(z)}{z - z_0}\, dz + \frac{1}{2\pi i} \oint_{C_2} \frac{f(z)}{z - z_0}\, dz,$$

where the outer integral (over C_1) is taken counterclockwise and the inner clockwise, as indicated in Fig. 356.

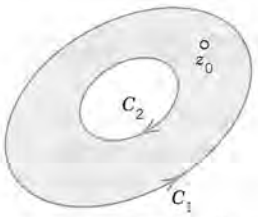

Fig. 356. Formula (3)

Our discussion in this section has illustrated the use of Cauchy's integral formula in integration. In the next section we show that the formula plays the key role in proving the surprising fact that an analytic function has derivatives of all orders, which are thus analytic functions themselves.

PROBLEM SET 14.3

1–4 CONTOUR INTEGRATION

Integrate $(z^2 - 4)/(z^2 + 4)$ counterclockwise around the circle:

1. $|z - i| = 2$
2. $|z - 1| = 2$
3. $|z + 3i| = 2$
4. $|z| = \pi/2$

5–17 CONTOUR INTEGRATION

Using Cauchy's integral formula (and showing the details), integrate counterclockwise (or as indicated)

5. $\oint_C \dfrac{z + 2}{z - 2}\, dz$, C: $|z - 1| = 2$
6. $\oint_C \dfrac{e^{3z}}{3z - i}\, dz$, C: $|z| = 1$
7. $\oint_C \dfrac{\sinh \pi z}{z^2 - 3z}\, dz$, C: $|z| = 1$
8. $\oint_C \dfrac{dz}{z^2 - 1}$, C: $|z - 1| = \pi/2$
9. $\oint_C \dfrac{dz}{z^2 - 1}$, C: $|z + 1| = 1$
10. $\oint_C \dfrac{e^z}{z - 2i}\, dz$, C: $|z - 2i| = 4$
11. $\oint_C \dfrac{\cos z}{2z}\, dz$, C: $|z| = \frac{1}{2}$
12. $\oint_C \dfrac{\tan z}{z - i}\, dz$, C the boundary of the triangle with vertices 0 and $\pm 1 + 2i$
13. $\oint_C \dfrac{e^{-3\pi z}}{2z + i}\, dz$, C the boundary of the square with vertices ± 1, $\pm i$
14. $\oint_C \dfrac{\operatorname{Ln}(z + 1)}{z^2 + 1}\, dz$, C consists of $|z - 2i| = 2$ (counterclockwise) and $|z - 2i| = \frac{1}{2}$ (clockwise)
15. $\oint_C \dfrac{\operatorname{Ln}(z - 1)}{z - 5}\, dz$, C: $|z - 4| = 2$
16. $\oint_C \dfrac{\sin z}{z^2 - 2iz}\, dz$, C consists of $|z| = 3$ (counterclockwise) and $|z| = 1$ (clockwise)
17. $\oint_C \dfrac{\cosh^2 z}{(z - 1 - i)z^2}\, dz$, C as in Prob. 16
18. Show that $\oint_C (z - z_1)^{-1}(z - z_2)^{-1}\, dz = 0$ for a simple closed path C enclosing z_1 and z_2, which are arbitrary.
19. **CAS PROJECT. Contour Integration.** Experiment to find out to what extent your CAS can do contour integration (a) by using the second method in Sec. 14.1, (b) by Cauchy's integral formula.
20. **TEAM PROJECT. Cauchy's Integral Theorem.** Gain additional insight into the proof of Cauchy's integral theorem by producing (2) with a contour enclosing z_0 (as in Fig. 353) and taking the limit as in the text. Choose

    (a) $\oint_C \dfrac{z^3 - 6}{z - \frac{1}{2}i}\, dz$, (b) $\oint_C \dfrac{\sin z}{z - \frac{1}{2}\pi}\, dz$,

    and (c) two other examples of your choice.

14.4 Derivatives of Analytic Functions

In this section we use Cauchy's integral formula to show the basic fact that ***complex analytic functions have derivatives of all orders.*** This is very surprising because it differs strikingly from the situation in real calculus. Indeed, if a *real* function is once differentiable, nothing follows about the existence of second or higher derivatives. Thus, in this respect, complex analytic functions behave much more simply than real functions that are once differentiable.

The existence of those derivatives will result from a general integral formula, as follows.

THEOREM 1

Derivatives of an Analytic Function

If $f(z)$ is analytic in a domain D, then it has derivatives of all orders in D, which are then also analytic functions in D. The values of these derivatives at a point z_0 in D are given by the formulas

$$(1') \qquad f'(z_0) = \frac{1}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^2}\, dz$$

$$(1'') \qquad f''(z_0) = \frac{2!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^3}\, dz$$

and in general

$$\textbf{(1)} \qquad f^{(n)}(z_0) = \frac{n!}{2\pi i} \oint_C \frac{f(z)}{(z - z_0)^{n+1}}\, dz \qquad (n = 1, 2, \cdots);$$

here C is any simple closed path in D that encloses z_0 and whose full interior belongs to D; and we integrate counterclockwise around C (Fig. 357).

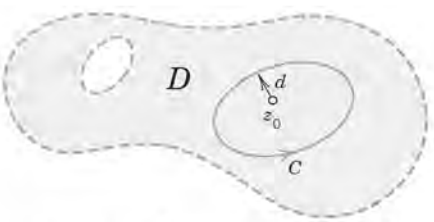

Fig. 357. Theorem 1 and its proof

COMMENT. For memorizing (1), it is useful to observe that these formulas are obtained formally by differentiating the Cauchy formula (1*), Sec. 14.3, under the integral sign *with respect to* z_0.

PROOF We prove (1′), starting from the definition of the derivative

$$f'(z_0) = \lim_{\Delta z \to 0} \frac{f(z_0 + \Delta z) - f(z_0)}{\Delta z}.$$

On the right we represent $f(z_0 + \Delta z)$ and $f(z_0)$ by Cauchy's integral formula:

$$\frac{f(z_0 + \Delta z) - f(z_0)}{\Delta z} = \frac{1}{2\pi i \Delta z}\left[\oint_C \frac{f(z)}{z - (z_0 + \Delta z)}\,dz - \oint_C \frac{f(z)}{z - z_0}\,dz\right].$$

We now write the two integrals as a single integral. Taking the common denominator gives the numerator $f(z)\{z - z_0 - [z - (z_0 + \Delta z)]\} = f(z)\,\Delta z$, so that a factor Δz drops out and we get

$$\frac{f(z_0 + \Delta z) - f(z_0)}{\Delta z} = \frac{1}{2\pi i}\oint_C \frac{f(z)}{(z - z_0 - \Delta z)(z - z_0)}\,dz.$$

Clearly, we can now establish (1′) by showing that, as $\Delta z \to 0$, the integral on the right approaches the integral in (1′). To do this, we consider the difference between these two integrals. We can write this difference as a single integral by taking the common denominator and simplifying the numerator (as just before). This gives

$$\oint_C \frac{f(z)}{(z - z_0 - \Delta z)(z - z_0)}\,dz - \oint_C \frac{f(z)}{(z - z_0)^2}\,dz = \oint_C \frac{f(z)\Delta z}{(z - z_0 - \Delta z)(z - z_0)^2}\,dz.$$

We show by the *ML*-inequality (Sec. 14.1) that the integral on the right approaches zero as $\Delta z \to 0$.

Being analytic, the function $f(z)$ is continuous on C, hence bounded in absolute value, say, $|f(z)| \leqq K$. Let d be the smallest distance from z_0 to the points of C (see Fig. 357). Then for all z on C,

$$|z - z_0|^2 \geqq d^2, \qquad \text{hence} \qquad \frac{1}{|z - z_0|^2} \leqq \frac{1}{d^2}.$$

Furthermore, by the triangle inequality for all z on C we then also have

$$d \leqq |z - z_0| = |z - z_0 - \Delta z + \Delta z| \leqq |z - z_0 - \Delta z| + |\Delta z|.$$

We now subtract $|\Delta z|$ on both sides and let $|\Delta z| \leqq d/2$, so that $-|\Delta z| \geqq -d/2$. Then

$$\tfrac{1}{2}d \leqq d - |\Delta z| \leqq |z - z_0 - \Delta z|. \qquad \text{Hence} \qquad \frac{1}{|z - z_0 - \Delta z|} \leqq \frac{2}{d}.$$

Let L be the length of C. If $|\Delta z| \leqq d/2$, then by the *ML*-inequality

$$\left|\oint_C \frac{f(z)\Delta z}{(z - z_0 - \Delta z)(z - z_0)^2}\,dz\right| \leqq KL\,|\Delta z|\,\frac{2}{d}\cdot\frac{1}{d^2}.$$

This approaches zero as $\Delta z \to 0$. Formula (1′) is proved.

Note that we used Cauchy's integral formula (1*), Sec. 14.3, but if all we had known about $f(z_0)$ is the fact that it can be represented by (1*), Sec. 14.3, our argument would have established the existence of the derivative $f'(z_0)$ of $f(z)$. This is essential to the continuation and completion of this proof, because it implies that (1″) can be proved by a similar argument, with f replaced by f', and that the general formula (1) follows by induction. ■

EXAMPLE 1 **Evaluation of Line Integrals**

From (1′), for any contour enclosing the point πi (counterclockwise)

$$\oint_C \frac{\cos z}{(z - \pi i)^2}\, dz = 2\pi i(\cos z)'\Big|_{z=\pi i} = -2\pi i \sin \pi i = 2\pi \sinh \pi.$$ ■

EXAMPLE 2 From (1″), for any contour enclosing the point $-i$ we obtain by counterclockwise integration

$$\oint_C \frac{z^4 - 3z^2 + 6}{(z + i)^3}\, dz = \pi i(z^4 - 3z^2 + 6)''\Big|_{z=-i} = \pi i\left[12z^2 - 6\right]_{z=-i} = -18\pi i.$$ ■

EXAMPLE 3 By (1′), for any contour for which 1 lies inside and $\pm 2i$ lie outside (counterclockwise),

$$\oint_C \frac{e^z}{(z - 1)^2(z^2 + 4)}\, dz = 2\pi i\left(\frac{e^z}{z^2 + 4}\right)'\Big|_{z=1}$$

$$= 2\pi i \frac{e^z(z^2 + 4) - e^z 2z}{(z^2 + 4)^2}\Big|_{z=1} = \frac{6e\pi}{25}\, i \approx 2.050i.$$ ■

Cauchy's Inequality. Liouville's and Morera's Theorems

As a new aspect, let us now show that Cauchy's integral theorem is also fundamental in deriving general results on analytic functions.

Cauchy's Inequality. Theorem 1 yields a basic inequality that has many applications. To get it, all we have to do is to choose for C in (1) a circle of radius r and center z_0 and apply the ML-inequality (Sec. 14.1); with $|f(z)| \leqq M$ on C we obtain from (1)

$$|f^{(n)}(z_0)| = \frac{n!}{2\pi}\left|\oint_C \frac{f(z)}{(z - z_0)^{n+1}}\, dz\right| \leqq \frac{n!}{2\pi}\, M\, \frac{1}{r^{n+1}}\, 2\pi r.$$

This gives **Cauchy's inequality**

$$|f^{(n)}(z_0)| \leqq \frac{n!M}{r^n}. \tag{2}$$

To gain a first impression of the importance of this inequality, let us prove a famous theorem on entire functions (definition in Sec. 13.5). (For Liouville, see Sec. 5.7.)

THEOREM 2

Liouville's Theorem

If an entire function is bounded in absolute value in the whole complex plane, then this function must be a constant.

PROOF By assumption, $|f(z)|$ is bounded, say, $|f(z)| < K$ for all z. Using (2), we see that $|f'(z_0)| < K/r$. Since $f(z)$ is entire, this holds for every r, so that we can take r as large as we please and conclude that $f'(z_0) = 0$. Since z_0 is arbitrary, $f'(z) = u_x + iv_x = 0$ for all z (see (4) in Sec. 13.4), hence $u_x = v_x = 0$, and $u_y = v_y = 0$ by the Cauchy–Riemann equations. Thus $u = const$, $v = const$, and $f = u + iv = const$ for all z. This completes the proof. ■

Another very interesting consequence of Theorem 1 is

THEOREM 3

Morera's[2] Theorem (Converse of Cauchy's Integral Theorem)

If $f(z)$ is continuous in a simply connected domain D and if

(3) $$\oint_C f(z)\,dz = 0$$

for every closed path in D, then $f(z)$ is analytic in D.

PROOF In Sec. 14.2 we showed that if $f(z)$ is analytic in a simply connected domain D, then

$$F(z) = \int_{z_0}^{z} f(z^*)\,dz^*$$

is analytic in D and $F'(z) = f(z)$. In the proof we used only the continuity of $f(z)$ and the property that its integral around every closed path in D is zero; from these assumptions we concluded that $F(z)$ is analytic. By Theorem 1, the derivative of $F(z)$ is analytic, that is, $f(z)$ is analytic in D, and Morera's theorem is proved. ■

PROBLEM SET 14.4

1–8 CONTOUR INTEGRATION

Integrate counterclockwise around the circle $|z| = 2$. (n is a positive integer, a is arbitrary.) Show the details of your work.

1. $\dfrac{\cosh 3z}{z^5}$

2. $\dfrac{\sin z}{(z - \pi i/2)^4}$

3. $\dfrac{e^z \cos z}{(z - \pi/2)^2}$

4. $\dfrac{\cos z}{z^{2n+1}}$

5. $\dfrac{\sinh az}{z^4}$

6. $\dfrac{\operatorname{Ln}(z + 3) + \cos z}{(z + 1)^2}$

7. $\dfrac{z^n}{(z - a)^{n+1}}$

8. $\dfrac{e^z}{(z - a)^n}$

[2]GIACINTO MORERA (1856–1909), Italian mathematician who worked in Genoa and Turin.

9–13 INTEGRATION AROUND DIFFERENT CONTOURS

Integrate around C. Show the details.

9. $\dfrac{(1 + 2z)\cos z}{(2z - 1)^2}$, C the unit circle, counterclockwise

10. $\dfrac{\sin 4z}{(z - 4)^3}$, C consists of $|z| = 5$ (counterclockwise) and $|z - 3| = \frac{3}{2}$ (clockwise)

11. $\dfrac{\tan \pi z}{z^2}$, C the ellipse $16x^2 + y^2 = 1$, counterclockwise

12. $\dfrac{e^{2z}}{z(z - 2i)^2}$, C consists of $|z - i| = 3$ (counterclockwise) and $|z| = 1$ (clockwise)

13. $\dfrac{e^{z/2}}{(z - a)^4}$, C the circle $|z - 2 - i| = 3$, counterclockwise

14. **TEAM PROJECT. Theory on Growth**

(a) Growth of entire functions. If $f(z)$ is not a constant and is analytic for all (finite) z, and R and M are any positive real numbers (no matter how large), show that there exist values of z for which $|z| > R$ and $|f(z)| > M$.

(b) Growth of polynomials. If $f(z)$ is a polynomial of degree $n > 0$ and M is an arbitrary positive real number (no matter how large), show that there exists a positive real number R such that $|f(z)| > M$ for all $|z| > R$.

(c) Exponential function. Show that $f(z) = e^z$ has the property characterized in (a) but does not have that characterized in (b).

(d) Fundamental theorem of algebra. *If $f(z)$ is a polynomial in z, not a constant, then $f(z) = 0$ for at least one value of z.* Prove this, using (a).

15. **(Proof of Theorem 1)** Complete the proof of Theorem 1 by performing the induction mentioned at the end.

CHAPTER 14 REVIEW QUESTIONS AND PROBLEMS

1. What is a path of integration? What did we assume about paths?
2. State the definition of a complex line integral from memory.
3. What do we mean by saying that complex integration is a linear operation?
4. Make a list of integration methods discussed. Illustrate each with a simple example.
5. Which integration methods apply to analytic functions only?
6. What value do you get if you integrate $1/z$ counterclockwise around the unit circle? (You should memorize this basic result.) If you integrate $1/z^2$, $1/z^3$, $\cdots$?
7. Which theorem in this chapter do you regard as most important? State it from memory.
8. What is independence of path? What is the principle of deformation of path? Why is this important?
9. Do not confuse Cauchy's integral theorem and Cauchy's integral formula. State both. How are they related?
10. How can you extend Cauchy's integral theorem to doubly and triply connected domains?
11. If integrating $f(z)$ over the boundary circles of an annulus D gives different values, can $f(z)$ be analytic in D? (Give reason.)
12. Is $\left|\int_C f(z)\,dz\right| = \int_C |f(z)|\,dz$? How would you find a bound for the integral on the left?
13. Is $\text{Re} \int_C f(z)\,dz = \int_C \text{Re}\, f(z)\,dz$? Give examples.
14. How did we use integral formulas for derivatives in integration?
15. What is Liouville's theorem? Give examples. State consequences.

16–30 INTEGRATION

Integrate by a suitable method:

16. $4z^3 + 2z$ from $-i$ to $2 + i$ along any path
17. $5z - 3/z$ counterclockwise around the unit circle
18. $z + 1/z$ counterclockwise around $|z + 3i| = 2$
19. e^{2z} from $-2 + 3\pi i$ along the straight segment to $-2 + 5\pi i$
20. $e^{z^2}/(z - 1)^2$ counterclockwise around $|z| = 2$
21. $z/(z^2 + 1)$ clockwise around $|z + i| = 1$
22. Re z from 0 to 4 and then vertically up to $4 + 3i$
23. $\cosh 4z$ from 0 to $2i$ along the imaginary axis
24. e^z/z over C consisting of $|z| = 1$ (counterclockwise) and $|z| = \frac{1}{2}$ (clockwise)
25. $(\sin z)/z$ clockwise around a circle containing $z = 0$ in its interior
26. Im z counterclockwise around $|z| = r$
27. $(\text{Ln}\, z)/(z - 2i)^2$ counterclockwise around $|z - 2i| = 1$
28. $(\tan \pi z)/(z - 1)^2$ counterclockwise around $|z - 1| = 0.2$
29. $|z| + z$ clockwise around the unit circle
30. $(z - i)^{-3}(z^3 + \sin z)$ counterclockwise around any circle with center i

SUMMARY OF CHAPTER 14
Complex Integration

The **complex line integral** of a function $f(z)$ taken over a path C is denoted by

(1) $$\int_C f(z)\,dz \qquad \text{or, if } C \text{ is closed, also by} \qquad \oint_C f(z) \qquad \text{(Sec. 14.1).}$$

If $f(z)$ is analytic in a simply connected domain D, then we can evaluate (1) as in calculus by indefinite integration and substitution of limits, that is,

(2) $$\int_C f(z)\,dz = F(z_1) - F(z_0) \qquad [F'(z) = f(z)]$$

for every path C in D from a point z_0 to a point z_1 (see Sec. 14.1). These assumptions imply **independence of path,** that is, (2) depends only on z_0 and z_1 (and on $f(z)$, of course) but not on the choice of C (Sec. 14.2). The existence of an $F(z)$ such that $F'(z) = f(z)$ is proved in Sec. 14.2 by Cauchy's integral theorem (see below).

A general method of integration, not restricted to analytic functions, uses the equation $z = z(t)$ of C, where $a \leqq t \leqq b$,

(3) $$\int_C f(z)\,dz = \int_a^b f(z(t))\dot{z}(t)\,dt \qquad \left(\dot{z} = \frac{dz}{dt}\right).$$

Cauchy's integral theorem is the most important theorem in this chapter. It states that if $f(z)$ is analytic in a simply connected domain D, then for every closed path C in D (Sec. 14.2),

(4) $$\oint_C f(z)\,dz = 0.$$

Under the same assumptions and for any z_0 in D and closed path C in D containing z_0 in its interior we also have **Cauchy's integral formula**

(5) $$f(z_0) = \frac{1}{2\pi i}\oint_C \frac{f(z)}{z - z_0}\,dz.$$

Furthermore, under these assumptions $f(z)$ has derivatives of all orders in D that are themselves analytic functions in D and (Sec. 14.4)

(6) $$f^{(n)}(z_0) = \frac{n!}{2\pi i}\oint_C \frac{f(z)}{(z - z_0)^{n+1}}\,dz \qquad (n = 1, 2, \cdots).$$

This implies *Morera's theorem* (the converse of Cauchy's integral theorem) and *Cauchy's inequality* (Sec. 14.4), which in turn implies *Liouville's theorem* that an entire function that is bounded in the whole complex plane must be constant.

CHAPTER 15

Power Series, Taylor Series

Complex power series, in particular, Taylor series, are analogs of real power and Taylor series in calculus. However, they are much more fundamental in complex analysis than their real counterparts in calculus. The reason is that power series represent analytic functions (Sec. 15.3) and, conversely, every analytic function can be represented by power series, called Taylor series (Sec. 15.4).

Use Sec. 15.1 for reference if you are familiar with convergence tests for *real* series—in complex this is quite similar. The last section (15.5) on uniform convergence is *optional.*

Prerequisite: Chaps. 13, 14.
Sections that may be omitted in a shorter course: 14.1, 14.5.
References and Answers to Problems: App. 1 Part D, App. 2.

15.1 Sequences, Series, Convergence Tests

In this section we define the basic concepts for ***complex*** sequences and series and discuss tests for convergence and divergence. This is very similar to *real* sequences and series in calculus. ***If you feel at home with the latter and want to take for granted that the ratio test also holds in complex, skip this section and go to Sec.*** **15.2.**

Sequences

The basic definitions are as in calculus. An *infinite sequence* or, briefly, a **sequence,** is obtained by assigning to each positive integer n a number z_n, called a **term** of the sequence, and is written

$$z_1, z_2, \cdots \qquad \text{or} \qquad \{z_1, z_2, \cdots\} \qquad \text{or briefly} \qquad \{z_n\}.$$

We may also write $z_0, z_1, \cdots$ or $z_2, z_3, \cdots$ or start with some other integer if convenient.

A **real sequence** is one whose terms are real.

Convergence. A **convergent sequence** $z_1, z_2, \cdots$ is one that has a limit c, written

$$\lim_{n\to\infty} z_n = c \qquad \text{or simply} \qquad z_n \to c.$$

By definition of **limit** this means that for every $\epsilon > 0$ we can find an N such that

$$|z_n - c| < \epsilon \qquad \text{for all } n > N; \tag{1}$$

geometrically, all terms z_n with $n > N$ lie in the open disk of radius ϵ and center c (Fig. 358) and only finitely many terms do not lie in that disk. [For a *real* sequence, (1) gives an open interval of length 2ϵ and real midpoint c on the real line; see Fig. 359.]

A **divergent sequence** is one that does not converge.

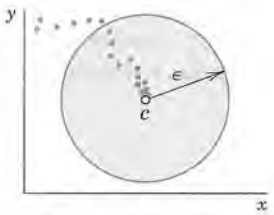

Fig. 358. Convergent complex sequence

Fig. 359. Convergent real sequence

EXAMPLE 1 **Convergent and Divergent Sequences**

The sequence $\{i^n/n\} = \{i, -1/2, -i/3, 1/4, \cdots\}$ is convergent with limit 0.

The sequence $\{i^n\} = \{i, -1, -i, 1, \cdots\}$ is divergent, and so is $\{z_n\}$ with $z_n = (1 + i)^n$. ■

EXAMPLE 2 **Sequences of the Real and the Imaginary Parts**

The sequence $\{z_n\}$ with $z_n = x_n + iy_n = 1 - 1/n^2 + i(2 + 4/n)$ is $6i, 3/4 + 4i, 8/9 + 10i/3, 15/16 + 3i, \cdots$. (Sketch it.) It converges with the limit $c = 1 + 2i$. Observe that $\{x_n\}$ has the limit $1 = \text{Re } c$ and $\{y_n\}$ has the limit $2 = \text{Im } c$. This is typical. It illustrates the following theorem by which the convergence of a *complex* sequence can be referred back to that of the two *real* sequences of the real parts and the imaginary parts. ■

THEOREM 1

Sequences of the Real and the Imaginary Parts

A sequence $z_1, z_2, \cdots, z_n, \cdots$ of complex numbers $z_n = x_n + iy_n$ (where $n = 1, 2, \cdots$) converges to $c = a + ib$ if and only if the sequence of the real parts $x_1, x_2, \cdots$ converges to a and the sequence of the imaginary parts $y_1, y_2, \cdots$ converges to b.

PROOF Convergence $z_n \to c = a + ib$ implies convergence $x_n \to a$ and $y_n \to b$ because if $|z_n - c| < \epsilon$, then z_n lies within the circle of radius ϵ about $c = a + ib$, so that (Fig. 360a)

$$|x_n - a| < \epsilon, \qquad |y_n - b| < \epsilon.$$

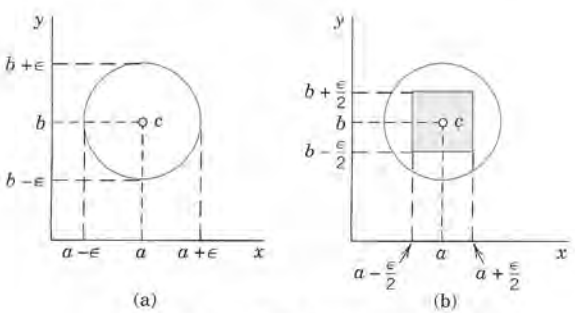

Fig. 360. Proof of Theorem 1

Conversely, if $x_n \to a$ and $y_n \to b$ as $n \to \infty$, then for a given $\epsilon > 0$ we can choose N so large that, for every $n > N$,

$$|x_n - a| < \frac{\epsilon}{2}, \qquad |y_n - b| < \frac{\epsilon}{2}.$$

These two inequalities imply that $z_n = x_n + iy_n$ lies in a square with center c and side ϵ. Hence, z_n must lie within a circle of radius ϵ with center c (Fig. 360b). ■

Series

Given a sequence $z_1, z_2, \cdots, z_m, \cdots$, we may form the sequence of the sums

$$s_1 = z_1, \qquad s_2 = z_1 + z_2, \qquad s_3 = z_1 + z_2 + z_3, \quad \cdots$$

and in general

$$s_n = z_1 + z_2 + \cdots + z_n \qquad (n = 1, 2, \cdots). \tag{2}$$

s_n is called the ***n*th partial sum** of the *infinite series* or **series**

$$\sum_{m=1}^{\infty} z_m = z_1 + z_2 + \cdots. \tag{3}$$

The $z_1, z_2, \cdots$ are called the **terms** of the series. (Our usual ***summation letter*** is n, unless we need n for another purpose, as here, and we then use m as the summation letter.)

A **convergent series** is one whose sequence of partial sums converges, say,

$$\lim_{n\to\infty} s_n = s. \qquad \text{Then we write} \qquad s = \sum_{m=1}^{\infty} z_m = z_1 + z_2 + \cdots$$

and call s the **sum** or *value* of the series. A series that is not convergent is called a **divergent series.**

If we omit the terms of s_n from (3), there remains

$$R_n = z_{n+1} + z_{n+2} + z_{n+3} + \cdots. \tag{4}$$

This is called the **remainder** *of the series* (3) *after the term* z_n. Clearly, if (3) converges and has the sum s, then

$$s = s_n + R_n, \qquad \text{thus} \qquad R_n = s - s_n.$$

Now $s_n \to s$ by the definition of convergence; hence $R_n \to 0$. In applications, when s is unknown and we compute an approximation s_n of s, then $|R_n|$ is the error, and $R_n \to 0$ means that we can make $|R_n|$ as small as we please, by choosing n large enough.

An application of Theorem 1 to the partial sums immediately relates the convergence of a complex series to that of the two series of its real parts and of its imaginary parts:

THEOREM 2

Real and Imaginary Parts

A series (3) *with* $z_m = x_m + iy_m$ *converges and has the sum* $s = u + iv$ *if and only if* $x_1 + x_2 + \cdots$ *converges and has the sum* u *and* $y_1 + y_2 + \cdots$ *converges and has the sum* v.

Tests for Convergence and Divergence of Series

Convergence tests in complex are practically the same as in calculus. We apply them before we use a series, to make sure that the series converges.

Divergence can often be shown very simply as follows.

THEOREM 3

Divergence

If a series $z_1 + z_2 + \cdots$ *converges, then* $\lim_{m\to\infty} z_m = 0$. *Hence if this does not hold, the series diverges.*

PROOF If $z_1 + z_2 + \cdots$ converges, with the sum s, then, since $z_m = s_m - s_{m-1}$,

$$\lim_{m\to\infty} z_m = \lim_{m\to\infty} (s_m - s_{m-1}) = \lim_{m\to\infty} s_m - \lim_{m\to\infty} s_{m-1} = s - s = 0. \qquad \blacksquare$$

CAUTION! $z_m \to 0$ is *necessary* for convergence but *not sufficient,* as we see from the harmonic series $1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots$, which satisfies this condition but diverges, as is shown in calculus (see, for example, Ref. [GR11] in App. 1).

The practical difficulty in proving convergence is that in most cases the sum of a series is unknown. Cauchy overcame this by showing that a series converges if and only if its partial sums eventually get close to each other:

THEOREM 4

Cauchy's Convergence Principle for Series

A series $z_1 + z_2 + \cdots$ *is convergent if and only if for every given* $\epsilon > 0$ *(no matter how small) we can find an* N *(which depends on* ϵ*, in general) such that*

(5) $\quad |z_{n+1} + z_{n+2} + \cdots + z_{n+p}| < \epsilon \qquad$ for every $n > N$ *and* $p = 1, 2, \cdots$

The somewhat involved proof is left optional (see App. 4).

Absolute Convergence. A series $z_1 + z_2 + \cdots$ is called **absolutely convergent** if the series of the absolute values of the terms

$$\sum_{m=1}^{\infty} |z_m| = |z_1| + |z_2| + \cdots$$

is convergent.

If $z_1 + z_2 + \cdots$ converges but $|z_1| + |z_2| + \cdots$ diverges, then the series $z_1 + z_2 + \cdots$ is called, more precisely, **conditionally convergent.**

EXAMPLE 3 **A Conditionally Convergent Series**

The series $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + - \cdots$ converges, but only conditionally since the harmonic series diverges, as mentioned above (after Theorem 3). ■

If a series is absolutely convergent, it is convergent.

This follows readily from Cauchy's principle (see Team Project 30). This principle also yields the following general convergence test.

THEOREM 5 **Comparison Test**

If a series $z_1 + z_2 + \cdots$ is given and we can find a convergent series $b_1 + b_2 + \cdots$ with nonnegative real terms such that $|z_1| \leqq b_1$, $|z_2| \leqq b_2$, $\cdots$, then the given series converges, even absolutely.

PROOF By Cauchy's principle, since $b_1 + b_2 + \cdots$ converges, for any given $\epsilon > 0$ we can find an N such that

$$b_{n+1} + \cdots + b_{n+p} < \epsilon \qquad \text{for every } n > N \text{ and } p = 1, 2, \cdots.$$

From this and $|z_1| \leqq b_1$, $|z_2| \leqq b_2$, $\cdots$ we conclude that for those n and p,

$$|z_{n+1}| + \cdots + |z_{n+p}| \leqq b_{n+1} + \cdots + b_{n+p} < \epsilon.$$

Hence, again by Cauchy's principle, $|z_1| + |z_2| + \cdots$ converges, so that $z_1 + z_2 + \cdots$ is absolutely convergent. ■

A good comparison series is the geometric series, which behaves as follows.

THEOREM 6 **Geometric Series**

The ***geometric series***

(6*)
$$\sum_{m=0}^{\infty} q^m = 1 + q + q^2 + \cdots$$

converges with the sum $1/(1 - q)$ if $|q| < 1$ and diverges if $|q| \geqq 1$.

PROOF If $|q| \geqq 1$, then $|q^m| \geqq 1$ and Theorem 3 implies divergence.

Now let $|q| < 1$. The nth partial sum is

$$s_n = 1 + q + \cdots + q^n.$$

From this,

$$qs_n = \qquad q + \cdots + q^n + q^{n+1}.$$

On subtraction, most terms on the right cancel in pairs, and we are left with

$$s_n - qs_n = (1 - q)s_n = 1 - q^{n+1}.$$

Now $1 - q \neq 0$ since $q \neq 1$, and we may solve for s_n, finding

$$(6) \qquad s_n = \frac{1 - q^{n+1}}{1 - q} = \frac{1}{1 - q} - \frac{q^{n+1}}{1 - q}.$$

Since $|q| < 1$, the last term approaches zero as $n \to \infty$. Hence if $|q| < 1$, the series is convergent and has the sum $1/(1 - q)$. This completes the proof. ■

Ratio Test

This is the most important test in our further work. We get it by taking the geometric series as comparison series $b_1 + b_2 + \cdots$ in Theorem 5:

THEOREM 7

Ratio Test

If a series $z_1 + z_2 + \cdots$ with $z_n \neq 0$ $(n = 1, 2, \cdots)$ has the property that for every n greater than some N,

$$(7) \qquad \left| \frac{z_{n+1}}{z_n} \right| \leqq q < 1 \qquad (n > N)$$

(where $q < 1$ is fixed), this series converges absolutely. If for every $n > N$,

$$(8) \qquad \left| \frac{z_{n+1}}{z_n} \right| \geqq 1 \qquad (n > N),$$

the series diverges.

PROOF If (8) holds, then $|z_{n+1}| \geqq |z_n|$ for $n > N$, so that divergence of the series follows from Theorem 3.

If (7) holds, then $|z_{n+1}| \leqq |z_n|\, q$ for $n > N$, in particular,

$$|z_{N+2}| \leqq |z_{N+1}|q, \qquad |z_{N+3}| \leqq |z_{N+2}|q \leqq |z_{N+1}|q^2, \qquad \text{etc.},$$

and in general, $|z_{N+p}| \leqq |z_{N+1}|q^{p-1}$. Since $q < 1$, we obtain from this and Theorem 6

$$|z_{N+1}| + |z_{N+2}| + |z_{N+3}| + \cdots \leqq |z_{N+1}|\,(1 + q + q^2 + \cdots) \leqq |z_{N+1}|\,\frac{1}{1 - q}.$$

Absolute convergence of $z_1 + z_2 + \cdots$ now follows from Theorem 5. ■

CAUTION! The inequality (7) implies $|z_{n+1}/z_n| < 1$, but this does ***not*** imply convergence, as we see from the harmonic series, which satisfies $z_{n+1}/z_n = n/(n + 1) < 1$ for all n but diverges.

If the sequence of the ratios in (7) and (8) converges, we get the more convenient

THEOREM 8

Ratio Test

If a series $z_1 + z_2 + \cdots$ *with* $z_n \neq 0$ $(n = 1, 2, \cdots)$ *is such that* $\lim_{n\to\infty} \left|\frac{z_{n+1}}{z_n}\right| = L$, *then:*

(a) *If* $L < 1$, *the series converges absolutely.*

(b) *If* $L > 1$, *the series diverges.*

(c) *If* $L = 1$, *the series may converge or diverge, so that the test fails and permits no conclusion.*

PROOF **(a)** We write $k_n = |z_{n+1}/z_n|$ and let $L = 1 - b < 1$. Then by the definition of limit, the k_n must eventually get close to $1 - b$, say, $k_n \leqq q = 1 - \frac{1}{2}b < 1$ for all n greater than some N. Convergence of $z_1 + z_2 + \cdots$ now follows from Theorem 7.

(b) Similarly, for $L = 1 + c > 1$ we have $k_n \geqq 1 + \frac{1}{2}c > 1$ for all $n > N^*$ (sufficiently large), which implies divergence of $z_1 + z_2 + \cdots$ by Theorem 7.

(c) The harmonic series $1 + \frac{1}{2} + \frac{1}{3} + \cdots$ has $z_{n+1}/z_n = n/(n + 1)$, hence $L = 1$, and diverges. The series

$$1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \frac{1}{25} + \cdots \qquad \text{has} \qquad \frac{z_{n+1}}{z_n} = \frac{n^2}{(n+1)^2},$$

hence also $L = 1$, but it converges. Convergence follows from (Fig. 361)

$$s_n = 1 + \frac{1}{4} + \cdots + \frac{1}{n^2} \leqq 1 + \int_1^n \frac{dx}{x^2} = 2 - \frac{1}{n},$$

so that $s_1, s_2, \cdots$ is a bounded sequence and is monotone increasing (since the terms of the series are all positive); both properties together are sufficient for the convergence of the real sequence $s_1, s_2, \cdots$. (In calculus this is proved by the so-called *integral test*, whose idea we have used.) ■

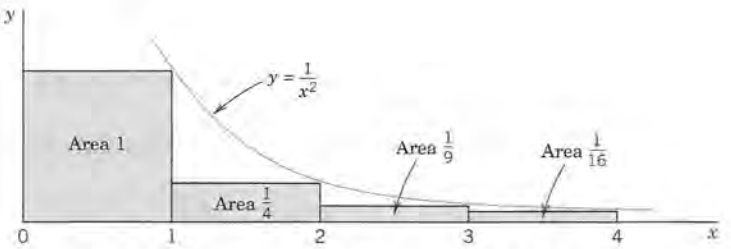

Fig. 361. Convergence of the series $1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \cdots$

EXAMPLE 4 **Ratio Test**

Is the following series convergent or divergent? (First guess, then calculate.)

$$\sum_{n=0}^{\infty} \frac{(100 + 75i)^n}{n!} = 1 + (100 + 75i) + \frac{1}{2!}(100 + 75i)^2 + \cdots$$

Solution. By Theorem 8, the series is convergent, since

$$\left|\frac{z_{n+1}}{z_n}\right| = \frac{|100 + 75i|^{n+1}/(n+1)!}{|100 + 75i|^n/n!} = \frac{|100 + 75i|}{n+1} = \frac{125}{n+1} \quad \to \quad L = 0. \qquad \blacksquare$$

EXAMPLE 5 **Theorem 7 More General than Theorem 8**

Let $a_n = i/2^{3n}$ and $b_n = 1/2^{3n+1}$. Is the following series convergent or divergent?

$$a_0 + b_0 + a_1 + b_1 + \cdots = i + \frac{1}{2} + \frac{i}{8} + \frac{1}{16} + \frac{i}{64} + \frac{1}{128} + \cdots$$

Solution. The ratios of the absolute values of successive terms are $\frac{1}{2}, \frac{1}{4}, \frac{1}{2}, \frac{1}{4}, \cdots$. Hence convergence follows from Theorem 7. Since the sequence of these ratios has no limit, Theorem 8 is not applicable. $\blacksquare$

Root Test

The ratio test and the root test are the two practically most important tests. The ratio test is usually simpler, but the root test is somewhat more general.

THEOREM 9 **Root Test**

If a series $z_1 + z_2 + \cdots$ is such that for every n greater than some N,

$$\sqrt[n]{|z_n|} \leqq q < 1 \qquad (n > N) \tag{9}$$

(where $q < 1$ is fixed), this series converges absolutely. If for infinitely many n,

$$\sqrt[n]{|z_n|} \geqq 1, \tag{10}$$

the series diverges.

PROOF If (9) holds, then $|z_n| \leqq q^n < 1$ for all $n > N$. Hence the series $|z_1| + |z_2| + \cdots$ converges by comparison with the geometric series, so that the series $z_1 + z_2 + \cdots$ converges absolutely. If (10) holds, then $|z_n| \geqq 1$ for infinitely many n. Divergence of $z_1 + z_2 + \cdots$ now follows from Theorem 3. $\blacksquare$

CAUTION! Equation (9) implies $\sqrt[n]{|z_n|} < 1$, but this does not imply convergence, as we see from the harmonic series, which satisfies $\sqrt[n]{1/n} < 1$ (for $n > 1$) but diverges.

If the sequence of the roots in (9) and (10) converges, we more conveniently have

THEOREM 10 **Root Test**

If a series $z_1 + z_2 + \cdots$ is such that $\lim_{n\to\infty} \sqrt[n]{|z_n|} = L$, then:

(a) *The series converges absolutely if $L < 1$.*

(b) *The series diverges if $L > 1$.*

(c) *If $L = 1$, the test fails; that is, no conclusion is possible.*

PROOF The proof parallels that of Theorem 8.

(a) Let $L = 1 - a^* < 1$. Then by the definition of a limit we have $\sqrt[n]{|z_n|} < q = 1 - \frac{1}{2}a^* < 1$ for all n greater than some (sufficiently large) N^*. Hence $|z_n| < q^n < 1$ for all $n > N^*$. Absolute convergence of the series $z_1 + z_2 + \cdots$ now follows by the comparison with the geometric series.

(b) If $L > 1$, then we also have $\sqrt[n]{|z_n|} > 1$ for all sufficiently large n. Hence $|z_n| > 1$ for those n. Theorem 3 now implies that $z_1 + z_2 + \cdots$ diverges.

(c) Both the *divergent* harmonic series and the *convergent* series $1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \frac{1}{25} + \cdots$ give $L = 1$. This can be seen from $(\ln n)/n \to 0$ and

$$\sqrt[n]{\frac{1}{n}} = \frac{1}{n^{1/n}} = \frac{1}{e^{(1/n)\ln n}} \to \frac{1}{e^0}, \qquad \sqrt[n]{\frac{1}{n^2}} = \frac{1}{n^{2/n}} = \frac{1}{e^{(2/n)\ln n}} \to \frac{1}{e^0}. \quad \blacksquare$$

PROBLEM SET 15.1

1–10 SEQUENCES

Are the following sequences $z_1, z_2, \cdots, z_n, \cdots$ bounded? Convergent? Find their limit points. (Show the details of your work.)

1. $z_n = (-1)^n + i/2^n$
2. $z_n = e^{-n\pi i/4}$
3. $z_n = (-1)^n/(n + i)$
4. $z_n = (1 + i)^n$
5. $z_n = \operatorname{Ln}((2 + i)^n)$
6. $z_n = (3 + 4i)^n/n!$
7. $z_n = \sin(n\pi/4) + i^n$
8. $z_n = \left[(1 + 3i)/\sqrt{10}\right]^n$
9. $z_n = (0.9 + 0.1i)^{2n}$
10. $z_n = (5 + 5i)^{-n}$

11. Illustrate Theorem 1 by an example of your own.
12. **(Uniqueness of limit)** Show that if a sequence converges, its limit is unique.
13. **(Addition)** If $z_1, z_2, \cdots$ converges with the limit l and $z_1^*, z_2^*, \cdots$ converges with the limit l^*, show that $z_1 + z_1^*, z_2 + z_2^*, \cdots$ converges with the limit $l + l^*$.
14. **(Multiplication)** Show that under the assumptions of Prob. 13 the sequence $z_1 z_1^*, z_2 z_2^*, \cdots$ converges with the limit ll^*.
15. **(Boundedness)** Show that a complex sequence is bounded if and only if the two corresponding sequences of the real parts and of the imaginary parts are bounded.

16–24 SERIES

Are the following series convergent or divergent? (Give a reason.)

16. $\sum_{n=0}^{\infty} \frac{(10 - 15i)^n}{n!}$
17. $\sum_{n=0}^{\infty} \frac{(-1)^n(1 + 2i)^{2n+1}}{(2n + 1)!}$
18. $\sum_{n=0}^{\infty} \frac{i^n}{n^2 - 2i}$
19. $\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$
20. $\sum_{n=2}^{\infty} \frac{1}{\ln n}$
21. $\sum_{n=1}^{\infty} \frac{i^n}{n}$
22. $\sum_{n=0}^{\infty} \frac{(n!)^3}{(3n)!}(1 + i)^n$
23. $\sum_{n=0}^{\infty} \frac{n - i}{3n + 2i}$
24. $\sum_{n=1}^{\infty} n^2\left(\frac{i}{3}\right)^n$

25. What is the difference between (7) and just stating $|z_{n+1}/z_n| < 1$?
26. Illustrate Theorem 2 by an example of your choice.
27. For what n do we obtain the term of greatest absolute value of the series in Example 4? About how big is it? First guess, then calculate it by the Stirling formula in Sec. 24.4.
28. Give another example showing that Theorem 7 is more general than Theorem 8.
29. **CAS PROJECT. Sequences and Series. (a)** Write a program for graphing complex **sequences.** Apply it to sequences of your choice that have interesting "geometrical" properties (e.g., lying on an ellipse, spiraling toward its limit, etc.).

    (b) Write a program for computing and graphing numeric values of the first n partial sums of a **series** of complex numbers. Use the program to experiment with the rapidity of convergence of series of your choice.
30. **TEAM PROJECT. Series. (a) Absolute convergence.** Show that if a series converges absolutely, it is convergent.

    (b) Write a short report on the basic concepts and properties of series of numbers, explaining in each case whether or not they carry over from real series (discussed in calculus) to complex series, with reasons given.

(c) Estimate of the remainder. Let $|z_{n+1}/z_n| \leqq q < 1$, so that the series $z_1 + z_2 + \cdots$ converges by the ratio test. Show that the remainder $R_n = z_{n+1} + z_{n+2} + \cdots$ satisfies the inequality $|R_n| \leqq |z_{n+1}|/(1 - q)$.

(d) Using (c), find how many terms suffice for computing the sum s of the series

$$\sum_{n=1}^{\infty} \frac{n + i}{2^n n}$$

with an error not exceeding 0.05 and compute s to this accuracy.

(e) Find other applications of the estimate in (c).

15.2 Power Series

Power series are the most important series in complex analysis because we shall see that their sums are analytic functions, and every analytic function can be represented by power series (Theorem 5 in Sec. 15.3 and Theorem 1 in Sec. 15.4).

A **power series** *in powers of* $z - z_0$ is a series of the form

$$\textbf{(1)} \qquad \sum_{n=0}^{\infty} a_n(z - z_0)^n = a_0 + a_1(z - z_0) + a_2(z - z_0)^2 + \cdots$$

where z is a complex variable, a_0, a_1, $\cdots$ are complex (or real) constants, called the **coefficients** of the series, and z_0 is a complex (or real) constant, called the **center** of the series. This generalizes real power series of calculus.

If $z_0 = 0$, we obtain as a particular case a *power series in powers of* z*:*

$$\textbf{(2)} \qquad \sum_{n=0}^{\infty} a_n z^n = a_0 + a_1 z + a_2 z^2 + \cdots.$$

Convergence Behavior of Power Series

Power series have variable terms (functions of z), but ***if we fix z, then all the concepts for series with constant terms in the last section apply.*** Usually a series with variable terms will converge for some z and diverge for others. For a power series the situation is simple. The series (1) may converge in a disk with center z_0 or in the whole z-plane or only at z_0. We illustrate this with typical examples and then prove it.

EXAMPLE 1 Convergence in a Disk. Geometric Series

The *geometric series*

$$\sum_{n=0}^{\infty} z^n = 1 + z + z^2 + \cdots$$

converges absolutely if $|z| < 1$ and diverges if $|z| \geqq 1$ (see Theorem 6 in Sec. 15.1). ■

EXAMPLE 2 Convergence for Every z

The power series (which will be the Maclaurin series of e^z in Sec. 15.4)

$$\sum_{n=0}^{\infty} \frac{z^n}{n!} = 1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \cdots$$

is absolutely convergent for every z, In fact, by the ratio test, for any fixed z,

$$\left| \frac{z^{n+1}/(n+1)!}{z^n/n!} \right| = \frac{|z|}{n+1} \to 0 \quad \text{as} \quad n \to \infty.$$

■

EXAMPLE 3 **Convergence Only at the Center. (Useless Series)**

The following power series converges only at $z = 0$, but diverges for every $z \neq 0$, as we shall show.

$$\sum_{n=0}^{\infty} n! z^n = 1 + z + 2z^2 + 6z^3 + \cdots$$

In fact, from the ratio test we have

$$\left| \frac{(n+1)! z^{n+1}}{n! z^n} \right| = (n+1)\,|z| \to \infty \quad \text{as} \quad n \to \infty \quad (z \text{ fixed and} \neq 0).$$

■

THEOREM 1

Convergence of a Power Series

(a) *Every power series* (1) *converges at the center* z_0.

(b) *If* (1) *converges at a point* $z = z_1 \neq z_0$, *it converges absolutely for every* z *closer to* z_0 *than* z_1, *that is,* $|z - z_0| < |z_1 - z_0|$. See Fig. 362.

(c) *If* (1) *diverges at a* $z = z_2$, *it diverges for every* z *farther away from* z_0 *than* z_2. See Fig. 362.

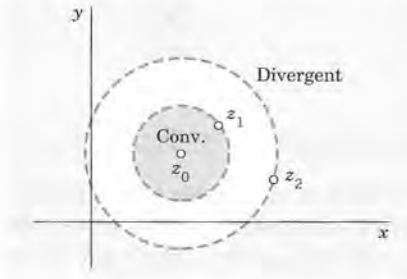

Fig. 362. Theroem 1

PROOF **(a)** For $z = z_0$ the series reduces to the single term a_0.

(b) Convergence at $z = z_1$ gives by Theorem 3 in Sec. 15.1 $a_n(z_1 - z_0)^n \to 0$ as $n \to \infty$. This implies boundedness in absolute value,

$$|a_n(z_1 - z_0)^n| < M \qquad \text{for every } n = 0, 1, \cdots.$$

Multiplying and dividing $a_n(z - z_0)^n$ by $(z_1 - z_0)^n$ we obtain from this

$$|a_n(z - z_0)^n| = \left| a_n(z_1 - z_0)^n \left(\frac{z - z_0}{z_1 - z_0} \right)^n \right| \leqq M \left| \frac{z - z_0}{z_1 - z_0} \right|^n.$$

Summation over n gives

$$\sum_{n=1}^{\infty} |a_n(z - z_0)^n| \leqq M \sum_{n=1}^{\infty} \left| \frac{z - z_0}{z_1 - z_0} \right|^n. \tag{3}$$

Now our assumption $|z - z_0| < |z_1 - z_0|$ implies that $|(z - z_0)/(z_1 - z_0)| < 1$. Hence the series on the right side of (3) is a converging geometric series (see Theorem 6 in Sec. 15.1). Absolute convergence of (1) as stated in (b) now follows by the comparison test in Sec. 15.1.

(c) If this were false, we would have convergence at a z_3 farther away from z_0 than z_2. This would imply convergence at z_2, by (b), a contradiction to our assumption of divergence at z_2. ■

Radius of Convergence of a Power Series

Convergence for every z (the nicest case, Example 2) or for no $z \neq z_0$ (the useless case, Example 3) needs no further discussion, and we put these cases aside for a moment. We consider the ***smallest*** circle with center z_0 that includes all the points at which a given power series (1) converges. Let R denote its radius. The circle

$$|z - z_0| = R \qquad \text{(Fig. 363)}$$

is called the **circle of convergence** and its radius R the **radius of convergence** of (1). Theorem 1 then implies convergence everywhere within that circle, that is, for all z for which

$$|z - z_0| < R \tag{4}$$

(the open disk with center z_0 and radius R). Also, since R is as *small* as possible, the series (1) diverges for all z for which

$$|z - z_0| > R. \tag{5}$$

No general statements can be made about the convergence of a power series (1) ***on the circle of convergence*** itself. The series (1) may converge at some or all or none of these points. Details will not be essential to us. Hence a simple example may just give us the idea.

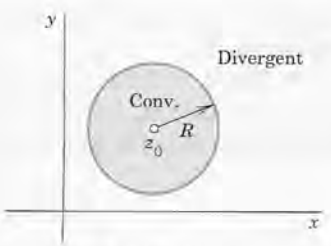

Fig. 363. Circle of convergence

EXAMPLE 4 **Behavior on the Circle of Convergence**

On the circle of convergence (radius $R = 1$ in all three series),

$\sum z^n/n^2$ converges everywhere since $\sum 1/n^2$ converges,

$\sum z^n/n$ converges at -1 (by Leibniz's test) but diverges at 1,

$\sum z^n$ diverges everywhere. ■

Notations $R = \infty$ and $R = 0$. To incorporate these two excluded cases in the present notation, we write

$R = \infty$ if the series (1) converges for all z (as in Example 2),

$R = 0$ if (1) converges only at the center $z = z_0$ (as in Example 3).

These are convenient notations, but nothing else.

Real Power Series. In this case in which powers, coefficients, and center are real, formula (4) gives the **convergence interval** $|x - x_0| < R$ of length $2R$ on the real line.

Determination of the Radius of Convergence from the Coefficients. For this important practical task we can use

THEOREM 2 **Radius of Convergence R**

Suppose that the sequence $|a_{n+1}/a_n|$, $n = 1, 2, \cdots$, converges with limit L^*. If $L^* = 0$, then $R = \infty$; that is, the power series (1) converges for all z. If $L^* \neq 0$ (hence $L^* > 0$), then

$$R = \frac{1}{L^*} = \lim_{n\to\infty} \left| \frac{a_n}{a_{n+1}} \right| \qquad \textbf{(Cauchy–Hadamard formula[1]).} \tag{6}$$

If $|a_{n+1}/a_n| \to \infty$, then $R = 0$ (convergence only at the center z_0).

PROOF For (1) the ratio of the terms in the ratio test (Sec. 15.1) is

$$\left| \frac{a_{n+1}(z - z_0)^{n+1}}{a_n(z - z_0)^n} \right| = \left| \frac{a_{n+1}}{a_n} \right| |z - z_0|. \qquad \text{The limit is} \qquad L = L^*|z - z_0|.$$

Let $L^* \neq 0$, thus $L^* > 0$. We have convergence if $L = L^*|z - z_0| < 1$, thus $|z - z_0| < 1/L^*$, and divergence if $|z - z_0| > 1/L^*$. By (4) and (5) this shows that $1/L^*$ is the convergence radius and proves (6).

If $L^* = 0$, then $L = 0$ for every z, which gives convergence for all z by the ratio test. If $|a_{n+1}/a_n| \to \infty$, then $|a_{n+1}/a_n||z - z_0| > 1$ for any $z \neq z_0$ and all sufficiently large n. This implies divergence for all $z \neq z_0$ by the ratio test (Theorem 7, Sec. 15.1). ■

[1]Named after the French mathematicians A. L. CAUCHY (see Sec. 2.5) and JACQUES HADAMARD (1865–1963). Hadamard made basic contributions to the theory of power series and devoted his lifework to partial differential equations.

Formula (6) will not help if L^* does not exist, but extensions of Theorem 2 are still possible, as we discuss in Example 6 below.

EXAMPLE 5 Radius of Convergence

By (6) the radius of convergence of the power series $\sum_{n=0}^{\infty} \frac{(2n)!}{(n!)^2}(z-3i)^n$ is

$$R = \lim_{n\to\infty}\left[\frac{(2n)!}{(n!)^2}\Big/\frac{(2n+2)!}{((n+1)!)^2}\right] = \lim_{n\to\infty}\left[\frac{(2n)!}{(2n+2)!}\cdot\frac{((n+1)!)^2}{(n!)^2}\right] = \lim_{n\to\infty}\frac{(n+1)^2}{(2n+2)(2n+1)} = \frac{1}{4}.$$

The series converges in the open disk $|z-3i| < \frac{1}{4}$ of radius $\frac{1}{4}$ and center $3i$. ■

EXAMPLE 6 Extension of Theorem 2

Find the radius of convergence R of the power series

$$\sum_{n=0}^{\infty}\left[1+(-1)^n+\frac{1}{2^n}\right]z^n = 3+\frac{1}{2}z+\left(2+\frac{1}{4}\right)z^2+\frac{1}{8}z^3+\left(2+\frac{1}{16}\right)z^4+\cdots.$$

Solution. The sequence of the ratios $1/6, 2(2+\frac{1}{4}), 1/(8(2+\frac{1}{4})), \cdots$ does not converge, so that Theorem 2 is of no help. It can be shown that

$$(6^*) \qquad R = 1/\tilde{L}, \qquad \tilde{L} = \lim_{n\to\infty}\sqrt[n]{|a_n|}.$$

This still does not help here, since $\{\sqrt[n]{|a_n|}\}$ does not converge because $\sqrt[n]{|a_n|} = \sqrt[n]{1/2^n} = 1/2$ for odd n, whereas for even n we have

$$\sqrt[n]{|a_n|} = \sqrt[n]{2+1/2^n} \to 1 \qquad \text{as} \qquad n\to\infty,$$

so that $\sqrt[n]{|a_n|}$ has the two limit points $1/2$ and 1. It can further be shown that

$$(6^{**}) \qquad R = 1/\tilde{l}, \qquad \tilde{l} \text{ the greatest limit point of the sequence } \left\{\sqrt[n]{|a_n|}\right\}.$$

Here $\tilde{l} = 1$, so that $R = 1$. *Answer.* The series converges for $|z| < 1$. ■

Summary. Power series converge in an open circular disk or some even for every z (or some only at the center, but they are useless); for the radius of convergence, see (6) or Example 6.

Except for the useless ones, power series have sums that are analytic functions (as we show in the next section); this accounts for their importance in complex analysis.

PROBLEM SET 15.2

1. **(Powers missing)** Show that if $\Sigma a_n z^n$ has radius of convergence R (assumed finite), then $\Sigma a_n z^{2n}$ has radius of convergence $\sqrt{R}$. Give examples.
2. **(Convergence behavior)** Illustrate the facts shown by Examples 1–3 by further examples of your own.

3–18 RADIUS OF CONVERGENCE

Find the center and the radius of convergence of the following power series. (Show the details.)

3. $\sum_{n=1}^{\infty}\frac{(z+i)^n}{n^2}$
4. $\sum_{n=0}^{\infty}\frac{n^n}{n!}(z+2i)^n$
5. $\sum_{n=0}^{\infty}\frac{n!}{n^n}(z+1)^n$
6. $\sum_{n=0}^{\infty}\frac{2^{100n}}{n!}z^n$
7. $\sum_{n=0}^{\infty}\left(\frac{a}{b}\right)^n z^n$
8. $\sum_{n=0}^{\infty}\frac{(-1)^n}{2^{2n}(n!)^2}z^{2n}$
9. $\sum_{n=0}^{\infty}(n-i)^n z^n$
10. $\sum_{n=0}^{\infty}\frac{(2z)^{2n}}{(2n)!}$
11. $\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}z^n$
12. $\sum_{n=0}^{\infty}\frac{4^n}{(1+i)^n}(z-5)^n$

13. $\sum_{n=2}^{\infty} n(n-1)(z-3+2i)^n$

14. $\sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} z^{2n}$

15. $\sum_{n=0}^{\infty} 2^n(z-i)^{4n}$

16. $\sum_{n=0}^{\infty} \left(\frac{2+3i}{5-i}\right)^n (z-\pi)^n$

17. $\sum_{n=0}^{\infty} \frac{n^4}{2^n} z^{2n}$

18. $\sum_{n=0}^{\infty} \frac{(4n)!}{2^n(n!)^4} (z+\pi i)^n$

19. CAS PROJECT. Radius of Convergence. Write a program for computing R from (6), (6*), or (6**), in this order, depending on the existence of the limits needed. Test the program on series of your choice and such that all three formulas (6), (6*), and (6**) will come up.

20. TEAM PROJECT. Radius of Convergence. (a) Formula (6) for R contains $|a_n/a_{n+1}|$, not $|a_{n+1}/a_n|$. How could you memorize this by using a qualitative argument?

(b) Change of coefficients. What happens to R $(0 < R < \infty)$ if you (i) multiply all a_n by $k \neq 0$, (ii) multiply a_n by $k^n \neq 0$, (iii) replace a_n by $1/a_n$?

(c) Example 6 extends Theorem 2 to nonconvergent cases of a_n/a_{n+1}. Do you understand the principle of "mixing" by which Example 6 was obtained? Use this principle for making up further examples.

(d) Does there exist a power series in powers of z that converges at $z = 30 + 10i$ and diverges at $z = 31 - 6i$? (Give reason.)

15.3 Functions Given by Power Series

The main goal of this section is to show that power series represent analytic functions (Theorem 5). Along our way we shall see that power series behave nicely under addition, multiplication, differentiation, and integration, which makes these series very useful in complex analysis.

To simplify the formulas in this section, we take $z_0 = 0$ and write

$$\textbf{(1)} \qquad \sum_{n=0}^{\infty} a_n z^n.$$

This is no restriction because a series in powers of $\hat{z} - z_0$ with any z_0 can always be reduced to the form (1) if we set $\hat{z} - z_0 = z$.

Terminology and Notation. If any given power series (1) has a nonzero radius of convergence R (thus $R > 0$), its sum is a function of z, say $f(z)$. Then we write

$$(2) \qquad f(z) = \sum_{n=0}^{\infty} a_n z^n = a_0 + a_1 z + a_2 z^2 + \cdots \qquad (|z| < R).$$

We say that $f(z)$ *is* **represented** *by the power series* or that *it is* **developed** *in the power series*. For instance, the geometric series *represents* the function $f(z) = 1/(1-z)$ in the interior of the unit circle $|z| = 1$. (See Theorem 6 in Sec. 15.1.)

Uniqueness of a Power Series Representation. This is our next goal. It means that *a function $f(z)$ cannot be represented by two different power series with the same center.* We claim that if $f(z)$ can at all be developed in a power series with center z_0, the development is unique. This important fact is frequently used in complex analysis (as well as in calculus). We shall prove it in Theorem 2. The proof will follow from

THEOREM 1

Continuity of the Sum of a Power Series

If a function $f(z)$ can be represented by a power series (2) *with radius of convergence $R > 0$, then $f(z)$ is continuous at $z = 0$.*

PROOF From (2) with $z = 0$ we have $f(0) = a_0$. Hence by the definition of continuity we must show that $\lim_{z \to 0} f(z) = f(0) = a_0$. That is, we must show that for a given $\epsilon > 0$ there is a $\delta > 0$ such that $|z| < \delta$ implies $|f(z) - a_0| < \epsilon$. Now (2) converges absolutely for $|z| \leqq r$ with any r such that $0 < r < R$, by Theorem 1 in Sec. 15.2. Hence the series

$$\sum_{n=1}^{\infty} |a_n| r^{n-1} = \frac{1}{r} \sum_{n=1}^{\infty} |a_n| r^n$$

converges. Let $S \neq 0$ be its sum. ($S = 0$ is trivial.) Then for $0 < |z| \leqq r$,

$$|f(z) - a_0| = \left| \sum_{n=1}^{\infty} a_n z^n \right| \leqq |z| \sum_{n=1}^{\infty} |a_n| \, |z|^{n-1} \leqq |z| \sum_{n=1}^{\infty} |a_n| r^{n-1} = |z| S$$

and $|z|S < \epsilon$ when $|z| < \delta$, where $\delta > 0$ is less than r and less than ϵ/S. Hence $|z|S < \delta S < (\epsilon/S)S = \epsilon$. This proves the theorem. ∎

From this theorem we can now readily obtain the desired uniqueness theorem (again assuming $z_0 = 0$ without loss of generality):

THEOREM 2

Identity Theorem for Power Series. Uniqueness

Let the power series $a_0 + a_1 z + a_2 z^2 + \cdots$ and $b_0 + b_1 z + b_2 z^2 + \cdots$ both be convergent for $|z| < R$, where R is positive, and let them both have the same sum for all these z. Then the series are identical, that is, $a_0 = b_0$, $a_1 = b_1$, $a_2 = b_2$, $\cdots$.

Hence if a function $f(z)$ can be represented by a power series with any center z_0, this representation is ***unique.***

PROOF We proceed by induction. By assumption,

$$a_0 + a_1 z + a_2 z^2 + \cdots = b_0 + b_1 z + b_2 z^2 + \cdots \qquad (|z| < R).$$

The sums of these two power series are continuous at $z = 0$, by Theorem 1. Hence if we consider $|z| > 0$ and let $z \to 0$ on both sides, we see that $a_0 = b_0$: the assertion is true for $n = 0$. Now assume that $a_n = b_n$ for $n = 0, 1, \cdots, m$. Then on both sides we may omit the terms that are equal and divide the result by z^{m+1} ($\neq 0$); this gives

$$a_{m+1} + a_{m+2} z + a_{m+3} z^2 + \cdots = b_{m+1} + b_{m+2} z + b_{m+3} z^2 + \cdots.$$

Similarly as before by letting $z \to 0$ we conclude from this that $a_{m+1} = b_{m+1}$. This completes the proof. ∎

Operations on Power Series

Interesting in itself, this discussion will serve as a preparation for our main goal, namely, to show that functions represented by power series are analytic.

Termwise addition or subtraction of two power series with radii of convergence R_1 and R_2 yields a power series with radius of convergence at least equal to the smaller of R_1 and R_2. *Proof.* Add (or subtract) the partial sums s_n and s_n^* term by term and use $\lim (s_n \pm s_n^*) = \lim s_n \pm \lim s_n^*$.

Termwise multiplication of two power series

$$f(z) = \sum_{k=0}^{\infty} a_k z^k = a_0 + a_1 z + \cdots$$

and

$$g(z) = \sum_{m=0}^{\infty} b_m z^m = b_0 + b_1 z + \cdots$$

means the multiplication of each term of the first series by each term of the second series and the collection of like powers of z. This gives a power series, which is called the **Cauchy product** of the two series and is given by

$$a_0 b_0 + (a_0 b_1 + a_1 b_0) z + (a_0 b_2 + a_1 b_1 + a_2 b_0) z^2 + \cdots = \sum_{n=0}^{\infty} (a_0 b_n + a_1 b_{n-1} + \cdots + a_n b_0) z^n.$$

We mention without proof that this power series converges absolutely for each z within the circle of convergence of each of the two given series and has the sum $s(z) = f(z)g(z)$. For a proof, see [D5] listed in App. 1.

Termwise differentiation and integration of power series is permissible, as we show next. We call **derived series** *of the power series* (1) the power series obtained from (1) by termwise differentiation, that is,

$$\textbf{(3)} \qquad \sum_{n=1}^{\infty} n a_n z^{n-1} = a_1 + 2a_2 z + 3a_3 z^2 + \cdots.$$

THEOREM 3

Termwise Differentiation of a Power Series

The derived series of a power series has the same radius of convergence as the original series.

PROOF This follows from (6) in Sec. 15.2 because

$$\lim_{n\to\infty} \frac{n|a_n|}{(n+1)\,|a_{n+1}|} = \lim_{n\to\infty} \frac{n}{n+1} \lim_{n\to\infty} \left|\frac{a_n}{a_{n+1}}\right| = \lim_{n\to\infty} \left|\frac{a_n}{a_{n+1}}\right|$$

or, if the limit does not exist, from (6**) in Sec. 15.2 by noting that $\sqrt[n]{n} \to 1$ as $n \to \infty$. ■

EXAMPLE 1 Application of Theorem 3

Find the radius of convergence R of the following series by applying Theorem 3.

$$\sum_{n=2}^{\infty} \binom{n}{2} z^n = z^2 + 3z^3 + 6z^4 + 10z^5 + \cdots.$$

Solution. Differentiate the geometric series twice term by term and multiply the result by $z^2/2$. This yields the given series. Hence $R = 1$ by Theorem 3. ∎

THEOREM 4

Termwise Integration of Power Series

The power series

$$\sum_{n=0}^{\infty} \frac{a_n}{n+1} z^{n+1} = a_0 z + \frac{a_1}{2} z^2 + \frac{a_2}{3} z^3 + \cdots$$

obtained by integrating the series $a_0 + a_1 z + a_2 z^2 + \cdots$ term by term has the same radius of convergence as the original series.

The proof is similar to that of Theorem 3.

With Theorem 3 as a tool, we are now ready to establish our main result in this section.

Power Series Represent Analytic Functions

THEOREM 5

Analytic Functions. Their Derivatives

A power series with a nonzero radius of convergence R represents an analytic function at every point interior to its circle of convergence. The derivatives of this function are obtained by differentiating the original series term by term. All the series thus obtained have the same radius of convergence as the original series. Hence, by the first statement, each of them represents an analytic function.

PROOF **(a)** We consider any power series (1) with positive radius of convergence R. Let $f(z)$ be its sum and $f_1(z)$ the sum of its derived series; thus

$$(4) \qquad f(z) = \sum_{n=0}^{\infty} a_n z^n \qquad \text{and} \qquad f_1(z) = \sum_{n=1}^{\infty} n a_n z^{n-1}.$$

We show that $f(z)$ is analytic and has the derivative $f_1(z)$ in the interior of the circle of convergence. We do this by proving that for any fixed z with $|z| < R$ and $\Delta z \to 0$ the difference quotient $[f(z + \Delta z) - f(z)]/\Delta z$ approaches $f_1(z)$. By termwise addition we first have from (4)

$$(5) \qquad \frac{f(z+\Delta z) - f(z)}{\Delta z} - f_1(z) = \sum_{n=2}^{\infty} a_n \left[\frac{(z+\Delta z)^n - z^n}{\Delta z} - n z^{n-1} \right].$$

Note that the summation starts with 2, since the constant term drops out in taking the difference $f(z + \Delta z) - f(z)$, and so does the linear term when we subtract $f_1(z)$ from the difference quotient.

(b) We claim that the series in (5) can be written

$$(6) \qquad \sum_{n=2}^{\infty} a_n \Delta z[(z+\Delta z)^{n-2} + 2z(z+\Delta z)^{n-3} + \cdots + (n-2)z^{n-3}(z+\Delta z) + (n-1)z^{n-2}].$$

The somewhat technical proof of this is given in App. 4.

(c) We consider (6). The brackets contain $n-1$ terms, and the largest coefficient is $n-1$. Since $(n-1)^2 \leqq n(n-1)$, we see that for $|z| \leqq R_0$ and $|z+\Delta z| \leqq R_0$, $R_0 < R$, the absolute value of this series (6) cannot exceed

$$(7) \qquad |\Delta z| \sum_{n=2}^{\infty} |a_n| n(n-1) R_0^{n-2}.$$

This series with a_n instead of $|a_n|$ is the second derived series of (2) at $z = R_0$ and converges absolutely by Theorem 3 of this section and Theorem 1 of Sec. 15.2. Hence our present series (7) converges. Let the sum of (7) (without the factor $|\Delta z|$) be $K(R_0)$. Since (6) is the right side of (5), our present result is

$$\left| \frac{f(z+\Delta z) - f(z)}{\Delta z} - f_1(z) \right| \leqq |\Delta z| \, K(R_0).$$

Letting $\Delta z \to 0$ and noting that R_0 $(< R)$ is arbitrary, we conclude that $f(z)$ is analytic at any point interior to the circle of convergence and its derivative is represented by the derived series. From this the statements about the higher derivatives follow by induction. ■

Summary. The results in this section show that power series are about as nice as we could hope for: we can differentiate and integrate them term by term (Theorems 3 and 4). Theorem 5 accounts for the great importance of power series in complex analysis: the sum of such a series (with a positive radius of convergence) is an analytic function and has derivatives of all orders, which thus in turn are analytic functions. But this is only part of the story. In the next section we show that, conversely, *every* given analytic function $f(z)$ can be represented by power series, called **Taylor series** and being the complex analog of the real Taylor series of calculus.

PROBLEM SET 15.3

1–10 RADIUS OF CONVERGENCE BY DIFFERENTIATION OR INTEGRATION

Find the radius of convergence in two ways: (a) directly by the Cauchy–Hadamard formula in Sec. 15.2, (b) from a series of simpler terms by using Theorem 3 or Theorem 4.

1. $\displaystyle\sum_{n=2}^{\infty} \frac{n(n-1)}{3^n} (z-2i)^n$

2. $\displaystyle\sum_{n=1}^{\infty} \frac{4^n}{n(n+1)} z^n$

3. $\displaystyle\sum_{n=1}^{\infty} \frac{n}{2^n} (z+i)^{2n}$

4. $\displaystyle\sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} \left(\frac{z}{\pi}\right)^{2n+1}$

5. $\displaystyle\sum_{n=1}^{\infty} \frac{3^n n(n+1)}{5^n} (z-1)^{2n}$

6. $\displaystyle\sum_{n=k}^{\infty} \binom{n}{k} \left(\frac{z}{4}\right)^n$

7. $\displaystyle\sum_{n=1}^{\infty} \frac{(-7)^n}{n(n+1)(n+2)} z^{2n}$

8. $\displaystyle\sum_{n=1}^{\infty} \frac{2n(2n-1)}{n^n} z^{2n-2}$

9. $\sum_{n=0}^{\infty} \left[\binom{n+k}{k}\right]^{-1} z^{n+k}$

10. $\sum_{n=0}^{\infty} \binom{n+m}{m} z^n$

11. (Addition and subtraction) Write out the details of the proof on termwise addition and subtraction of power series.

12. (Cauchy product) Show that $(1-z)^{-2} = \Sigma_{n=0}^{\infty}(n+1)z^n$ (a) by using the Cauchy product, (b) by differentiating a suitable series.

13. (Cauchy product) Show that the Cauchy product of $\Sigma_{n=0}^{\infty} z^n/n!$ multiplied by itself gives $\Sigma_{n=0}^{\infty}(2z)^n/n!$.

14. (On Theorem 3) Prove that $\sqrt[n]{n} \to 1$ as $n \to \infty$ (as claimed in the proof of Theorem 3).

15. (On Theorems 3 and 4) Find further examples of your own.

16–20 APPLICATIONS OF THE IDENTITY THEOREM

State clearly and explicitly where and how you are using Theorem 2.

16. (Binomial coefficients) Using $(1+z)^p(1+z)^q = (1+z)^{p+q}$, obtain the basic relation

$$\sum_{n=0}^{r} \binom{p}{n}\binom{q}{r-n} = \binom{p+q}{r}.$$

17. (Odd function) If $f(z)$ in (1) is *odd* (i.e., $f(-z) = -f(z)$), show that $a_n = 0$ for even n. Give examples.

18. (Even functions) If $f(z)$ in (1) is *even* (i.e., $f(-z) = f(z)$), show that $a_n = 0$ for odd n. Give examples.

19. Find applications of Theorem 2 in differential equations and elsewhere

20. TEAM PROJECT. Fibonacci numbers.[2] **(a)** The Fibonacci numbers are recursively defined by $a_0 = a_1 = 1$, $a_{n+1} = a_n + a_{n-1}$ if $n = 1, 2, \cdots$. Find the limit of the sequence (a_{n+1}/a_n).

(b) Fibonacci's rabbit problem. Compute a list of $a_1, \cdots, a_{12}$. Show that $a_{12} = 233$ is the number of pairs of rabbits after 12 months if initially there is 1 pair and each pair generates 1 pair per month, beginning in the second month of existence (no deaths occurring).

(c) Generating function. Show that the *generating function* of the **Fibonacci numbers** is $f(z) = 1/(1 - z - z^2)$; that is, if a power series (1) represents this $f(z)$, its coefficients must be the Fibonacci numbers and conversely. *Hint.* Start from $f(z)(1 - z - z^2) = 1$ and use Theorem 2.

15.4 Taylor and Maclaurin Series

The **Taylor series**[3] of a function $f(z)$, the complex analog of the real Taylor series is

$$\textbf{(1)} \qquad f(z) = \sum_{n=1}^{\infty} a_n(z - z_0)^n \qquad \text{where} \qquad a_n = \frac{1}{n!} f^{(n)}(z_0)$$

or, by (1), Sec. 14.4,

$$\textbf{(2)} \qquad a_n = \frac{1}{2\pi i} \oint_C \frac{f(z^*)}{(z^* - z_0)^{n+1}}\, dz^*.$$

In (2) we integrate counterclockwise around a simple closed path C that contains z_0 in its interior and is such that $f(z)$ is analytic in a domain containing C and every point inside C.

A **Maclaurin series**[3] is a Taylor series with center $z_0 = 0$.

---

[2]LEONARDO OF PISA, called FIBONACCI (= son of Bonaccio), about 1180–1250, Italian mathematician, credited with the first renaissance of mathematics on Christian soil.

[3]BROOK TAYLOR (1685–1731), English mathematician who introduced real Taylor series. COLIN MACLAURIN (1698–1746), Scots mathematician, professor at Edinburgh.

The **remainder** of the Taylor series (1) after the term $a_n(z - z_0)^n$ is

$$R_n(z) = \frac{(z - z_0)^{n+1}}{2\pi i} \oint_C \frac{f(z^*)}{(z^* - z_0)^{n+1}(z^* - z)}\, dz^* \tag{3}$$

(proof below). Writing out the corresponding partial sum of (1), we thus have

$$\begin{aligned} f(z) = f(z_0) + \frac{z - z_0}{1!} f'(z_0) + \frac{(z - z_0)^2}{2!} f''(z_0) + \cdots \\ + \frac{(z - z_0)^n}{n!} f^{(n)}(z_0) + R_n(z). \end{aligned} \tag{4}$$

This is called **Taylor's formula** *with remainder.*

We see that ***Taylor series are power series.*** From the last section we know that power series represent analytic functions. And we now show that *every* analytic function can be represented by power series, namely, by Taylor series (with various centers). This makes Taylor series very important in complex analysis. Indeed, they are more fundamental in complex analysis than their real counterparts are in calculus.

THEOREM 1

Taylor's Theorem

Let $f(z)$ be analytic in a domain D, and let $z = z_0$ be any point in D. Then there exists precisely one Taylor series (1) with center z_0 that represents $f(z)$. This representation is valid in the largest open disk with center z_0 in which $f(z)$ is analytic. The remainders $R_n(z)$ of (1) can be represented in the form (3). The coefficients satisfy the inequality

$$|a_n| \leqq \frac{M}{r^n} \tag{5}$$

where M is the maximum of $|f(z)|$ on a circle $|z - z_0| = r$ in D whose interior is also in D.

PROOF The key tool is Cauchy's integral formula in Sec. 14.3; writing z and z^* instead of z_0 and z (so that z^* is the variable of integration), we have

$$f(z) = \frac{1}{2\pi i} \oint_C \frac{f(z^*)}{z^* - z}\, dz^*. \tag{6}$$

z lies inside C, for which we take a circle of radius r with center z_0 and interior in D (Fig. 364). We develop $1/(z^* - z)$ in (6) in powers of $z - z_0$. By a ***standard algebraic manipulation*** (worth remembering!) we first have

$$\frac{1}{z^* - z} = \frac{1}{z^* - z_0 - (z - z_0)} = \frac{1}{(z^* - z_0)\left(1 - \dfrac{z - z_0}{z^* - z_0}\right)}. \tag{7}$$

For later use we note that since z^* is on C while z is inside C, we have

$$(7^*) \qquad \left| \frac{z - z_0}{z^* - z_0} \right| < 1 \qquad \text{(Fig. 364).}$$

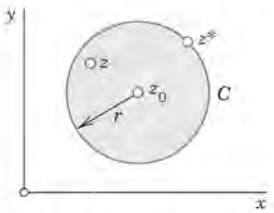

Fig. 364. Cauchy formula (6)

To (7) we now apply the sum formula for a finite geometric sum

$$(8^*) \qquad 1 + q + \cdots + q^n = \frac{1 - q^{n+1}}{1 - q} = \frac{1}{1 - q} - \frac{q^{n+1}}{1 - q} \qquad (q \neq 1),$$

which we use in the form (take the last term to the other side and interchange sides)

$$(8) \qquad \frac{1}{1 - q} = 1 + q + \cdots + q^n + \frac{q^{n+1}}{1 - q}.$$

Applying this with $q = (z - z_0)/(z^* - z_0)$ to the right side of (7), we get

$$\frac{1}{z^* - z} = \frac{1}{z^* - z_0} \left[1 + \frac{z - z_0}{z^* - z_0} + \left(\frac{z - z_0}{z^* - z_0} \right)^2 + \cdots + \left(\frac{z - z_0}{z^* - z_0} \right)^n \right] + \frac{1}{z^* - z} \left(\frac{z - z_0}{z^* - z_0} \right)^{n+1}$$

We insert this into (6). Powers of $z - z_0$ do not depend on the variable of integration z^*, so that we may take them out from under the integral sign. This yields

$$f(z) = \frac{1}{2\pi i} \oint_C \frac{f(z^*)}{z^* - z_0} \, dz^* + \frac{z - z_0}{2\pi i} \oint_C \frac{f(z^*)}{(z^* - z_0)^2} \, dz^* + \cdots + \frac{(z - z_0)^n}{2\pi i} \oint_C \frac{f(z^*)}{(z^* - z_0)^{n+1}} \, dz^* + R_n(z)$$

with $R_n(z)$ given by (3). The integrals are those in (2) related to the derivatives, so that we have proved the Taylor formula (4).

Since analytic functions have derivatives of all orders, we can take n in (4) as large as we please. If we let n approach infinity, we obtain (1). Clearly, (1) will converge and represent $f(z)$ if and only if

$$(9) \qquad \lim_{n \to \infty} R_n(z) = 0.$$

We prove (9) as follows. Since z^* lies on C, whereas z lies inside C (Fig. 364), we have $|z^* - z| > 0$. Since $f(z)$ is analytic inside and on C, it is bounded, and so is the function $f(z^*)/(z^* - z)$, say,

$$\left| \frac{f(z^*)}{z^* - z} \right| \leqq \widetilde{M}$$

for all z^* on C. Also, C has the radius $r = |z^* - z_0|$ and the length $2\pi r$. Hence by the *ML*-inequality (Sec. 14.1) we obtain from (3)

$$(10) \qquad \begin{aligned} |R_n| &= \frac{|z - z_0|^{n+1}}{2\pi} \left| \oint_C \frac{f(z^*)}{(z^* - z_0)^{n+1}(z^* - z)} \, dz^* \right| \\ &\leqq \frac{|z - z_0|^{n+1}}{2\pi} \widetilde{M} \frac{1}{r^{n+1}} 2\pi r = \widetilde{M} \left| \frac{z - z_0}{r} \right|^{n+1}. \end{aligned}$$

Now $|z - z_0| < r$ because z lies *inside* C. Thus $|z - z_0|/r < 1$, so that the right side approaches 0 as $n \to \infty$. This proves the convergence of the Taylor series. Uniqueness follows from Theorem 2 in the last section. Finally, (5) follows from (1) and the Cauchy inequality in Sec. 14.4. This proves Taylor's theorem. ■

Accuracy of Approximation. We can achieve any preassinged accuracy in approximating $f(z)$ by a partial sum of (1) by choosing n large enough. This is the practical aspect of formula (9).

Singularity, Radius of Convergence. On the circle of convergence of (1) there is at least one **singular point** of $f(z)$, that is, a point $z = c$ at which $f(z)$ is not analytic (but such that every disk with center c contains points at which $f(z)$ *is* analytic). We also say that $f(z)$ **is singular** at c or **has a singularity** at c. Hence the radius of convergence R of (1) is usually equal to the distance from z_0 to the nearest singular point of $f(z)$.

(Sometimes R can be greater than that distance: $\operatorname{Ln} z$ is singular on the negative real axis, whose distance from $z_0 = -1 + i$ is 1, but the Taylor series of $\operatorname{Ln} z$ with center $z_0 = -1 + i$ has radius of convergence $\sqrt{2}$.)

Power Series as Taylor Series

Taylor series are power series—of course! Conversely, we have

THEOREM 2

Relation to the Last Section

A power series with a nonzero radius of convergence is the Taylor series of its sum.

PROOF Given the power series

$$f(z) = a_0 + a_1(z - z_0) + a_2(z - z_0)^2 + a_3(z - z_0)^3 + \cdots.$$

Then $f(z_0) = a_0$. By Theorem 5 in Sec. 15.3 we obtain

$$f'(z) = a_1 + 2a_2(z - z_0) + 3a_3(z - z_0)^2 + \cdots, \qquad \text{thus} \qquad f'(z_0) = a_1$$

$$f''(z) = 2a_2 + 3 \cdot 2(z - z_0) + \cdots, \qquad \text{thus} \qquad f''(z_0) = 2!a_2$$

and in general $f^{(n)}(z_0) = n!a_n$. With these coefficients the given series becomes the Taylor series of $f(z)$ with center z_0.

Comparison with Real Functions. One surprising property of complex analytic functions is that they have derivatives of all orders, and now we have discovered the other surprising property that they can always be represented by power series of the form (1). This is not true in general for ***real functions;*** there are real functions that have derivatives of all orders but cannot be represented by a power series. (Example: $f(x) = \exp(-1/x^2)$ if $x \neq 0$ and $f(0) = 0$; this function cannot be represented by a Maclaurin series in an open disk with center 0 because all its derivatives at 0 are zero.)

Important Special Taylor Series

These are as in calculus, with x replaced by complex z. Can you see why? (*Answer.* The coefficient formulas are the same.)

EXAMPLE 1 **Geometric Series**

Let $f(z) = 1/(1 - z)$. Then we have $f^{(n)}(z) = n!/(1 - z)^{n+1}$, $f^{(n)}(0) = n!$. Hence the Maclaurin expansion of $1/(1 - z)$ is the geometric series

$$\frac{1}{1-z} = \sum_{n=0}^{\infty} z^n = 1 + z + z^2 + \cdots \qquad (|z| < 1). \tag{11}$$

$f(z)$ is singular at $z = 1$; this point lies on the circle of convergence.

EXAMPLE 2 **Exponential Function**

We know that the exponential function e^z (Sec. 13.5) is analytic for all z, and $(e^z)' = e^z$. Hence from (1) with $z_0 = 0$ we obtain the Maclaurin series

$$e^z = \sum_{n=0}^{\infty} \frac{z^n}{n!} = 1 + z + \frac{z^2}{2!} + \cdots. \tag{12}$$

This series is also obtained if we replace x in the familiar Maclaurin series of e^x by z.

Furthermore, by setting $z = iy$ in (12) and separating the series into the real and imaginary parts (see Theorem 2, Sec. 15.1) we obtain

$$e^{iy} = \sum_{n=0}^{\infty} \frac{(iy)^n}{n!} = \sum_{k=0}^{\infty} (-1)^k \frac{y^{2k}}{(2k)!} + i \sum_{k=0}^{\infty} (-1)^k \frac{y^{2k+1}}{(2k+1)!}.$$

Since the series on the right are the familiar Maclaurin series of the real functions $\cos y$ and $\sin y$, this shows that we have rediscovered the **Euler formula**

$$e^{iy} = \cos y + i \sin y. \tag{13}$$

Indeed, one may use (12) for ***defining*** e^z and derive from (12) the basic properties of e^z. For instance, the differentiation formula $(e^z)' = e^z$ follows readily from (12) by termwise differentiation.

EXAMPLE 3 **Trigonometric and Hyperbolic Functions**

By substituting (12) into (1) of Sec. 13.6 we obtain

$$\cos z = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n}}{(2n)!} = 1 - \frac{z^2}{2!} + \frac{z^4}{4!} - + \cdots$$

(14)

$$\sin z = \sum_{n=0}^{\infty} (-1)^n \frac{z^{2n+1}}{(2n+1)!} = z - \frac{z^3}{3!} + \frac{z^5}{5!} - + \cdots.$$

When $z = x$ these are the familiar Maclaurin series of the real functions $\cos x$ and $\sin x$. Similarly, by substituting (12) into (11), Sec. 13.6, we obtain

$$\cosh z = \sum_{n=0}^{\infty} \frac{z^{2n}}{(2n)!} = 1 + \frac{z^2}{2!} + \frac{z^4}{4!} + \cdots$$

(15)

$$\sinh z = \sum_{n=0}^{\infty} \frac{z^{2n+1}}{(2n+1)!} = z + \frac{z^3}{3!} + \frac{z^5}{5!} \cdots. \qquad \blacksquare$$

EXAMPLE 4 **Logarithm**

From (1) it follows that

$$\textbf{(16)} \qquad \operatorname{Ln}(1+z) = z - \frac{z^2}{2} + \frac{z^3}{3} - + \cdots \qquad (|z| < 1).$$

Replacing z by $-z$ and multiplying both sides by -1, we get

$$(17) \qquad -\operatorname{Ln}(1-z) = \operatorname{Ln}\frac{1}{1-z} = z + \frac{z^2}{2} + \frac{z^3}{3} + \cdots \qquad (|z| < 1).$$

By adding both series we obtain

$$(18) \qquad \operatorname{Ln}\frac{1+z}{1-z} = 2\left(z + \frac{z^3}{3} + \frac{z^5}{5} + \cdots\right) \qquad (|z| < 1). \qquad \blacksquare$$

Practical Methods

The following examples show ways of obtaining Taylor series more quickly than by the use of the coefficient formulas. Regardless of the method used, the result will be the same. This follows from the uniqueness (see Theorem 1).

EXAMPLE 5 **Substitution**

Find the Maclaurin series of $f(z) = 1/(1+z^2)$.

Solution. By substituting $-z^2$ for z in (11) we obtain

$$(19) \qquad \frac{1}{1+z^2} = \frac{1}{1-(-z^2)} = \sum_{n=0}^{\infty} (-z^2)^n = \sum_{n=0}^{\infty} (-1)^n z^{2n} = 1 - z^2 + z^4 - z^6 + \cdots \quad (|z| < 1). \qquad \blacksquare$$

EXAMPLE 6 Integration

Find the Maclaurin series of $f(z) = \arctan z$.

Solution. We have $f'(z) = 1/(1 + z^2)$. Integrating (19) term by term and using $f(0) = 0$ we get

$$\arctan z = \sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} z^{2n+1} = z - \frac{z^3}{3} + \frac{z^5}{5} - + \cdots \qquad (|z| < 1);$$

this series represents the principal value of $w = u + iv = \arctan z$ defined as that value for which $|u| < \pi/2$. ■

EXAMPLE 7 Development by Using the Geometric Series

Develop $1/(c - z)$ in powers of $z - z_0$, where $c - z_0 \neq 0$.

Solution. This was done in the proof of Theorem 1, where $c = z^*$. The beginning was simple algebra and then the use of (11) with z replaced by $(z - z_0)/(c - z_0)$:

$$\frac{1}{c-z} = \frac{1}{c - z_0 - (z - z_0)} = \frac{1}{(c - z_0)\left(1 - \dfrac{z - z_0}{c - z_0}\right)} = \frac{1}{c - z_0} \sum_{n=0}^{\infty} \left(\frac{z - z_0}{c - z_0}\right)^n$$

$$= \frac{1}{c - z_0}\left(1 + \frac{z - z_0}{c - z_0} + \left(\frac{z - z_0}{c - z_0}\right)^2 + \cdots\right).$$

This series converges for

$$\left|\frac{z - z_0}{c - z_0}\right| < 1, \qquad \text{that is,} \qquad |z - z_0| < |c - z_0|.$$ ■

EXAMPLE 8 Binomial Series, Reduction by Partial Fractions

Find the Taylor series of the following function with center $z_0 = 1$.

$$f(z) = \frac{2z^2 + 9z + 5}{z^3 + z^2 - 8z - 12}$$

Solution. We develop $f(z)$ in partial fractions and the first fraction in a **binomial series**

(20)

$$\frac{1}{(1+z)^m} = (1+z)^{-m} = \sum_{n=0}^{\infty} \binom{-m}{n} z^n$$

$$= 1 - mz + \frac{m(m+1)}{2!} z^2 - \frac{m(m+1)(m+2)}{3!} z^3 + \cdots$$

with $m = 2$ and the second fraction in a geometric series, and then add the two series term by term. This gives

$$f(z) = \frac{1}{(z+2)^2} + \frac{2}{z-3} = \frac{1}{[3 + (z-1)]^2} - \frac{2}{2 - (z-1)} = \frac{1}{9}\left(\frac{1}{\left[1 + \frac{1}{3}(z-1)\right]^2}\right) - \frac{1}{1 - \frac{1}{2}(z-1)}$$

$$= \frac{1}{9}\sum_{n=0}^{\infty} \binom{-2}{n} \left(\frac{z-1}{3}\right)^n - \sum_{n=0}^{\infty} \left(\frac{z-1}{2}\right)^n = \sum_{n=0}^{\infty} \left[\frac{(-1)^n(n+1)}{3^{n+2}} - \frac{1}{2^n}\right](z-1)^n$$

$$= -\frac{8}{9} - \frac{31}{54}(z-1) - \frac{23}{108}(z-1)^2 - \frac{275}{1944}(z-1)^3 - \cdots.$$

We see that the first series converges for $|z - 1| < 3$ and the second for $|z - 1| < 2$. This had to be expected because $1/(z + 2)^2$ is singular at -2 and $2/(z - 3)$ at 3, and these points have distance 3 and 2, respectively, from the center $z_0 = 1$. Hence the whole series converges for $|z - 1| < 2$. ■

PROBLEM SET 15.4

1–12 TAYLOR AND MACLAURIN SERIES

Find the Taylor or Maclaurin series of the given function with the given point as center and determine the radius of convergence.

1. e^{-2z}, 0

2. $1/(1 - z^3)$, 0

3. e^z, $-2i$

4. $\cos^2 z$, 0

5. $\sin z$, $\pi/2$

6. $1/z$, 1

7. $1/(1 - z)$, i

8. $\operatorname{Ln}(1 - z)$, i

9. $e^{-z^2/2}$, 0

10. $e^{z^2}\displaystyle\int_0^z e^{-t^2}\,dt$, 0

11. $z^6 - z^4 + z^2 - 1$, 1

12. $\sinh(z - 2i)$, $2i$

13–16 HIGHER TRANSCENDENTAL FUNCTIONS

Find the Maclaurin series by termwise integrating the integrand. (The integrals cannot be evaluated by the usual methods of calculus. They define the **error function** erf z, **sine integral** Si(z), and **Fresnel integrals**[4] S(z) and C(z), which occur in statistics, heat conduction, optics, and other applications. These are special so-called higher transcendental functions.)

13. $\operatorname{erf} z = \dfrac{2}{\sqrt{\pi}}\displaystyle\int_0^z e^{-t^2}\,dt$

14. $\operatorname{Si}(z) = \displaystyle\int_0^z \frac{\sin t}{t}\,dt$

15. $\operatorname{S}(z) = \displaystyle\int_0^z \sin t^2\,dt$

16. $\operatorname{C}(z) = \displaystyle\int_0^z \cos t^2\,dt$

17. CAS PROJECT. sec, tan, arcsin. (a) Euler numbers. The Maclaurin series

$$\sec z = E_0 - \frac{E_2}{2!}z^2 + \frac{E_4}{4!}z^4 - + \cdots \tag{21}$$

defines the *Euler numbers* E_{2n}. Show that $E_0 = 1$, $E_2 = -1$, $E_4 = 5$, $E_6 = -61$. Write a program that computes the E_{2n} from the coefficient formula in (1) or extracts them as a list from the series. (For tables see Ref. [GR1], p. 810, listed in App. 1.)

(b) Bernoulli numbers. The Maclaurin series

$$\frac{z}{e^z - 1} = 1 + B_1 z + \frac{B_2}{2!}z^2 + \frac{B_3}{3!}z^3 + \cdots \tag{22}$$

defines the *Bernoulli numbers* B_n. Using undetermined coefficients, show that

$$B_1 = -\frac{1}{2}, \quad B_2 = \frac{1}{6}, \quad B_3 = 0, \tag{23}$$
$$B_4 = -\frac{1}{30}, \quad B_5 = 0, \quad B_6 = \frac{1}{42}, \cdots.$$

Write a program for computing B_n.

(c) Tangent. Using (1), (2), Sec. 13.6, and (22), show that $\tan z$ has the following Maclaurin series and calculate from it a table of $B_0, \cdots, B_{20}$:

$$\tan z = \frac{2i}{e^{2iz} - 1} - \frac{4i}{e^{4iz} - 1} - i \tag{24}$$
$$= \sum_{n=1}^{\infty} (-1)^{n-1}\frac{2^{2n}(2^{2n} - 1)}{(2n)!}B_{2n}z^{2n-1}.$$

18. (Inverse sine) Developing $1/\sqrt{1 - z^2}$ and integrating, show that

$$\arcsin z = z + \left(\frac{1}{2}\right)\frac{z^3}{3} + \left(\frac{1\cdot 3}{2\cdot 4}\right)\frac{z^5}{5} + \left(\frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\right)\frac{z^7}{7} + \cdots \quad (|z| < 1).$$

Show that this series represents the principal value of $\arcsin z$ (defined in Team Project 30, Sec. 13.7).

19. (Undetermined coefficients) Using the relation $\sin z = \tan z \cos z$ and the Maclaurin series of $\sin z$ and $\cos z$, find the first four nonzero terms of the Maclaurin series of $\tan z$. (Show the details.)

20. TEAM PROJECT. Properties from Maclaurin Series. Clearly, from series we can compute function values. In this project we show that properties of functions can often be discovered from their Taylor or Maclaurin series. Using suitable series, prove the following.

(a) The formulas for the derivatives of e^z, $\cos z$, $\sin z$, $\cosh z$, $\sinh z$, and $\operatorname{Ln}(1 + z)$

(b) $\frac{1}{2}(e^{iz} + e^{-iz}) = \cos z$

(c) $\sin z \neq 0$ for all pure imaginary $z = iy \neq 0$

[4] AUGUSTIN FRESNEL (1788–1827), French physicist and engineer, known for his work in optics.

15.5 Uniform Convergence. Optional

We know that power series are *absolutely convergent* (Sec. 15.2, Theorem 1) and, as another basic property, we now show that they are *uniformly convergent.* Since uniform convergence is of general importance, for instance, in connection with termwise integration of series, we shall discuss it quite thoroughly.

To define uniform convergence, we consider a series whose terms are any complex functions $f_0(z)$, $f_1(z)$, $\cdots$:

$$\sum_{m=0}^{\infty} f_m(z) = f_0(z) + f_1(z) + f_2(z) + \cdots. \tag{1}$$

(This includes power series as a special case in which $f_m(z) = a_m (z - z_0)^m$.) We assume that the series (1) converges for all z in some region G. We call its sum $s(z)$ and its nth partial sum $s_n(z)$; thus

$$s_n(z) = f_0(z) + f_1(z) + \cdots + f_n(z).$$

Convergence in G means the following. If we pick a $z = z_1$ in G, then, by the definition of convergence at z_1, for given $\epsilon > 0$ we can find an $N_1(\epsilon)$ such that

$$|s(z_1) - s_n(z_1)| < \epsilon \qquad \text{for all } n > N_1(\epsilon).$$

If we pick a z_2 in G, keeping ϵ as before, we can find an $N_2(\epsilon)$ such that

$$|s(z_2) - s_n(z_2)| < \epsilon \qquad \text{for all } n > N_2(\epsilon),$$

and so on. Hence, given an $\epsilon > 0$, to each z in G there corresponds a number $N_z(\epsilon)$. This number tells us how many terms we need (what s_n we need) at a z to make $|s(z) - s_n(z)|$ smaller than ϵ. Thus this number $N_z(\epsilon)$ measures the speed of convergence.

Small $N_z(\epsilon)$ means rapid convergence, large $N_z(\epsilon)$ means slow convergence at the point z considered. Now, if we can find an $N(\epsilon)$ larger than all these $N_z(\epsilon)$ for all z in G, we say that the convergence of the series (1) in G is *uniform.* Hence this basic concept is defined as follows.

DEFINITION

Uniform Convergence

A series (1) with sum $s(z)$ is called **uniformly convergent** in a region G if for every $\epsilon > 0$ we can find an $N = N(\epsilon)$, ***not depending on z,*** such that

$$|s(z) - s_n(z)| < \epsilon \qquad \text{for all } n > N(\epsilon) \textbf{ and all } z \textbf{ in } G.$$

Uniformity of convergence is thus a property that always refers to an *infinite set* in the z-plane, that is, a set consisting of infinitely many points.

EXAMPLE 1 **Geometric Series**

Show that the geometric series $1 + z + z^2 + \cdots$ is (a) uniformly convergent in any closed disk $|z| \leqq r < 1$, (b) not uniformly convergent in its whole disk of convergence $|z| < 1$.

Solution. **(a)** For z in that closed disk we have $|1 - z| \geqq 1 - r$ (sketch it). This implies that $1/|1 - z| \leqq 1/(1 - r)$. Hence (remember (8) in Sec. 15.4 with $q = z$)

$$|s(z) - s_n(z)| = \left| \sum_{m=n+1}^{\infty} z^m \right| = \left| \frac{z^{n+1}}{1 - z} \right| \leqq \frac{r^{n+1}}{1 - r}.$$

Since $r < 1$, we can make the right side as small as we want by choosing n large enough, and since the right side does not depend on z (in the closed disk considered), this means that the convergence is uniform.

(b) For given real K (no matter how large) and n we can always find a z in the disk $|z| < 1$ such that

$$\left| \frac{z^{n+1}}{1 - z} \right| = \frac{|z|^{n+1}}{|1 - z|} > K,$$

simply by taking z close enough to 1. Hence no single $N(\epsilon)$ will suffice to make $|s(z) - s_n(z)|$ smaller than a given $\epsilon > 0$ *throughout the whole disk.* By definition, this shows that the convergence of the geometric series in $|z| < 1$ is not uniform. ∎

This example suggests that *for a power series, the uniformity of convergence may at most be disturbed near the circle of convergence.* This is true:

THEOREM 1 **Uniform Convergence of Power Series**

A power series

$$\sum_{m=0}^{\infty} a_m(z - z_0)^m \tag{2}$$

with a nonzero radius of convergence R is uniformly convergent in every circular disk $|z - z_0| \leqq r$ of radius $r < R$.

PROOF For $|z - z_0| \leqq r$ and any positive integers n and p we have

$$|a_{n+1}(z - z_0)^{n+1} + \cdots + a_{n+p}(z - z_0)^{n+p}| \leqq |a_{n+1}|r^{n+1} + \cdots + |a_{n+p}|r^{n+p}. \tag{3}$$

Now (2) converges absolutely if $|z - z_0| = r < R$ (by Theorem 1 in Sec. 15.2). Hence it follows from the Cauchy convergence principle (Sec. 15.1) that, an $\epsilon > 0$ being given, we can find an $N(\epsilon)$ such that

$$|a_{n+1}|r^{n+1} + \cdots + |a_{n+p}|r^{n+p} < \epsilon \qquad \text{for } n > N(\epsilon) \quad \text{and} \quad p = 1, 2, \cdots.$$

From this and (3) we obtain

$$|a_{n+1}(z - z_0)^{n+1} + \cdots + a_{n+p}(z - z_0)^{n+p}| < \epsilon$$

for all z in the disk $|z - z_0| \leqq r$, every $n > N(\epsilon)$, and every $p = 1, 2, \cdots$. Since $N(\epsilon)$ is independent of z, this shows uniform convergence, and the theorem is proved. ∎

Theorem 1 meets with our immediate need and concern, which is power series. The remainder of this section should provide a deeper understanding of the concept of uniform convergence in connection with arbitrary series of variable terms.

Properties of Uniformly Convergent Series

Uniform convergence derives its main importance from two facts:

1. If a series of *continuous* terms is uniformly convergent, its sum is also continuous (Theorem 2, below).

2. Under the same assumptions, termwise integration is permissible (Theorem 3).

This raises two questions:

1. How can a converging series of continuous terms manage to have a discontinuous sum? (Example 2)

2. How can something go wrong in termwise integration? (Example 3)

Another natural question is:

3. What is the relation between absolute convergence and uniform convergence? The surprising answer: none. (Example 5)

These are the ideas we shall discuss.

If we add *finitely many* continuous functions, we get a continuous function as their sum. Example 2 will show that this is no longer true for an infinite series, even if it converges absolutely. However, if it converges *uniformly*, this cannot happen, as follows.

THEOREM 2

Continuity of the Sum

Let the series

$$\sum_{m=0}^{\infty} f_m(z) = f_0(z) + f_1(z) + \cdots$$

be uniformly convergent in a region G. Let $F(z)$ be its sum. Then if each term $f_m(z)$ is continuous at a point z_1 in G, the function $F(z)$ is continuous at z_1.

PROOF Let $s_n(z)$ be the nth partial sum of the series and $R_n(z)$ the corresponding remainder:

$$s_n = f_0 + f_1 + \cdots + f_n, \qquad R_n = f_{n+1} + f_{n+2} + \cdots.$$

Since the series converges uniformly, for a given $\epsilon > 0$ we can find an $N = N(\epsilon)$ such that

$$|R_N(z)| < \frac{\epsilon}{3} \qquad \text{for all } z \text{ in } G.$$

Since $s_N(z)$ is a sum of finitely many functions that are continuous at z_1, this sum is continuous at z_1. Therefore, we can find a $\delta > 0$ such that

$$|s_N(z) - s_N(z_1)| < \frac{\epsilon}{3} \quad \text{for all } z \text{ in } G \text{ for which } |z - z_1| < \delta.$$

Using $F = s_N + R_N$ and the triangle inequality (Sec. 13.2), for these z we thus obtain

$$\begin{aligned} |F(z) - F(z_1)| &= |s_N(z) + R_N(z) - [s_N(z_1) + R_N(z_1)]| \\ &\leqq |s_N(z) - s_N(z_1)| + |R_N(z)| + |R_N(z_1)| < \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3} = \epsilon. \end{aligned}$$

This implies that $F(z)$ is continuous at z_1, and the theorem is proved. ∎

EXAMPLE 2 Series of Continuous Terms with a Discontinuous Sum

Consider the series

$$x^2 + \frac{x^2}{1+x^2} + \frac{x^2}{(1+x^2)^2} + \frac{x^2}{(1+x^2)^3} + \cdots \qquad (x \text{ real}).$$

This is a geometric series with $q = 1/(1+x^2)$ times a factor x^2. Its nth partial sum is

$$s_n(x) = x^2\left[1 + \frac{1}{1+x^2} + \frac{1}{(1+x^2)^2} + \cdots + \frac{1}{(1+x^2)^n}\right].$$

We now use the trick by which one finds the sum of a geometric series, namely, we multiply $s_n(x)$ by $-q = -1/(1+x^2)$,

$$-\frac{1}{1+x^2}\,s_n(x) = -x^2\left[\frac{1}{1+x^2} + \cdots + \frac{1}{(1+x^2)^n} + \frac{1}{(1+x^2)^{n+1}}\right].$$

Adding this to the previous formula, simplifying on the left, and canceling most terms on the right, we obtain

$$\frac{x^2}{1+x^2}\,s_n(x) = x^2\left[1 - \frac{1}{(1+x^2)^{n+1}}\right],$$

thus

$$s_n(x) = 1 + x^2 - \frac{1}{(1+x^2)^n}.$$

The exciting Fig. 365 "explains" what is going on. We see that if $x \neq 0$, the sum is

$$s(x) = \lim_{n\to\infty} s_n(x) = 1 + x^2,$$

but for $x = 0$ we have $s_n(0) = 1 - 1 = 0$ for all n, hence $s(0) = 0$. So we have the surprising fact that the sum is discontinuous (at $x = 0$), although all the terms are continuous and the series converges even absolutely (its terms are nonnegative, thus equal to their absolute value!).

Theorem 2 now tells us that the convergence cannot be uniform in an interval containing $x = 0$. We can also verify this directly. Indeed, for $x \neq 0$ the remainder has the absolute value

$$|R_n(x)| = |s(x) - s_n(x)| = \frac{1}{(1+x^2)^n}$$

and we see that for a given ϵ (< 1) we cannot find an N depending only on ϵ such that $|R_n| < \epsilon$ for all $n > N(\epsilon)$ and all x, say, in the interval $0 \leqq x \leqq 1$. ■

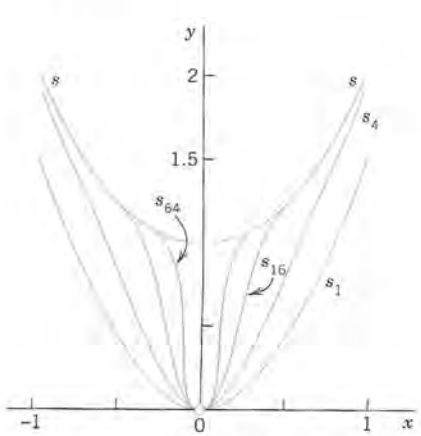

Fig. 365. Partial sums in Example 2

Termwise Integration

This is our second topic in connection with uniform convergence, and we begin with an example to become aware of the danger of just blindly integrating term-by-term.

EXAMPLE 3 **Series for which Termwise Integration is Not Permissible**

Let $u_m(x) = mxe^{-mx^2}$ and consider the series

$$\sum_{m=0}^{\infty} f_m(x) \qquad \text{where} \qquad f_m(x) = u_m(x) - u_{m-1}(x)$$

in the interval $0 \leqq x \leqq 1$. The nth partial sum is

$$s_n = u_1 - u_0 + u_2 - u_1 + \cdots + u_n - u_{n-1} = u_n - u_0 = u_n.$$

Hence the series has the sum $F(x) = \lim_{n\to\infty} s_n(x) = \lim_{n\to\infty} u_n(x) = 0 \quad (0 \leqq x \leqq 1)$. From this we obtain

$$\int_0^1 F(x)\,dx = 0.$$

On the other hand, by integrating term by term and using $f_1 + f_2 + \cdots + f_n = s_n$, we have

$$\sum_{m=1}^{\infty} \int_0^1 f_m(x)\,dx = \lim_{n\to\infty} \sum_{m=1}^{n} \int_0^1 f_m(x)\,dx = \lim_{n\to\infty} \int_0^1 s_n(x)\,dx.$$

Now $s_n = u_n$ and the expression on the right becomes

$$\lim_{n\to\infty} \int_0^1 u_n(x)\,dx = \lim_{n\to\infty} \int_0^1 nxe^{-nx^2}\,dx = \lim_{n\to\infty} \frac{1}{2}\,(1 - e^{-n}) = \frac{1}{2},$$

but not 0. This shows that the series under consideration cannot be integrated term by term from $x = 0$ to $x = 1$. ∎

The series in Example 3 is not uniformly convergent in the interval of integration, and we shall now prove that in the case of a uniformly convergent series of continuous functions we may integrate term by term.

THEOREM 3 **Termwise Integration**

Let

$$F(z) = \sum_{m=0}^{\infty} f_m(z) = f_0(z) + f_1(z) + \cdots$$

be a uniformly convergent series of continuous functions in a region G. Let C be any path in G. Then the series

$$\sum_{m=0}^{\infty} \int_C f_m(z)\,dz = \int_C f_0(z)\,dz + \int_C f_1(z)\,dz + \cdots \tag{4}$$

is convergent and has the sum $\int_C F(z)\,dz$.

PROOF From Theorem 2 it follows that $F(z)$ is continuous. Let $s_n(z)$ be the nth partial sum of the given series and $R_n(z)$ the corresponding remainder. Then $F = s_n + R_n$ and by integration,

$$\int_C F(z)\,dz = \int_C s_n(z)\,dz + \int_C R_n(z)\,dz.$$

Let L be the length of C. Since the given series converges uniformly, for every given $\epsilon > 0$ we can find a number N such that $|R_n(z)| < \epsilon/L$ for all $n > N$ and all z in G. By applying the ML-inequality (Sec. 14.1) we thus obtain

$$\left|\int_C R_n(z)\,dz\right| < \frac{\epsilon}{L}\,L = \epsilon \qquad \text{for all } n > N.$$

Since $R_n = F - s_n$, this means that

$$\left|\int_C F(z)\,dz - \int_C s_n(z)\,dz\right| < \epsilon \qquad \text{for all } n > N.$$

Hence, the series (4) converges and has the sum indicated in the theorem. ∎

Theorems 2 and 3 characterize the two most important properties of uniformly convergent series. Also, since differentiation and integration are inverse processes, Theorem 3 implies

THEOREM 4

Termwise Differentiation

Let the series $f_0(z) + f_1(z) + f_2(z) + \cdots$ be convergent in a region G and let $F(z)$ be its sum. Suppose that the series $f_0'(z) + f_1'(z) + f_2'(z) + \cdots$ converges uniformly in G and its terms are continuous in G. Then

$$F'(z) = f_0'(z) + f_1'(z) + f_2'(z) + \cdots \qquad \textit{for all } z \textit{ in } G.$$

Test for Uniform Convergence

Uniform convergence is usually proved by the following comparison test.

THEOREM 5

Weierstrass[5] *M*-Test for Uniform Convergence

Consider a series of the form (1) *in a region G of the z-plane. Suppose that one can find a convergent series of constant terms,*

$$M_0 + M_1 + M_2 + \cdots, \tag{5}$$

such that $|f_m(z)| \leqq M_m$ for all z in G and every $m = 0, 1, \cdots$. Then (1) *is uniformly convergent in G.*

[5]KARL WEIERSTRASS (1815–1897), great German mathematician, whose lifework was the development of complex analysis based on the concept of power series (see the footnote in Sec. 13.4). He also made basic contributions to the calculus, the calculus of variations, approximation theory, and differential geometry. He obtained the concept of uniform convergence in 1841 (published 1894, *sic!*); the first publication on the concept was by G. G. STOKES (see Sec 10.9) in 1847.

The simple proof is left to the student (Team Project 18).

EXAMPLE 4 **Weierstrass *M*-Test**

Does the following series converge uniformly in the disk $|z| \leqq 1$?

$$\sum_{m=1}^{\infty} \frac{z^m + 1}{m^2 + \cosh m|z|}$$

Solution. Uniform convergence follows by the Weierstrass M-test and the convergence of $\Sigma 1/m^2$ (see Sec. 15.1, in the proof of Theorem 8) because

$$\left| \frac{z^m + 1}{m^2 + \cosh m|z|} \right| \leqq \frac{|z|^m + 1}{m^2} \leqq \frac{2}{m^2}.$$

■

No Relation Between Absolute and Uniform Convergence

We finally show the surprising fact that there are series that converge absolutely but not uniformly, and others that converge uniformly but not absolutely, so that there is no relation between the two concepts.

EXAMPLE 5 **No Relation Between Absolute and Uniform Convergence**

The series in Example 2 converges absolutely but not uniformly, as we have shown. On the other hand, the series

$$\sum_{m=1}^{\infty} \frac{(-1)^{m-1}}{x^2 + m} = \frac{1}{x^2 + 1} - \frac{1}{x^2 + 2} + \frac{1}{x^2 + 3} - + \cdots \qquad (x \text{ real})$$

converges uniformly on the whole real line but not absolutely.

Proof. By the familiar Leibniz test of calculus (see App. A3.3) the remainder R_n does not exceed its first term in absolute value, since we have a series of alternating terms whose absolute values form a monotone decreasing sequence with limit zero. Hence given $\epsilon > 0$, for all x we have

$$|R_n(x)| \leqq \frac{1}{x^2 + n + 1} < \frac{1}{n} < \epsilon \qquad \text{if } n > N(\epsilon) \geqq \frac{1}{\epsilon}.$$

This proves uniform convergence, since $N(\epsilon)$ does not depend on x.

The convergence is not absolute because for any *fixed* x we have

$$\left| \frac{(-1)^{m-1}}{x^2 + m} \right| = \frac{1}{x^2 + m} > \frac{k}{m}$$

where k is a suitable constant, and $k\Sigma 1/m$ diverges. ■

PROBLEM SET 15.5

1–8 UNIFORM CONVERGENCE

Prove that the given series converges uniformly in the indicated region.

1. $\displaystyle\sum_{n=0}^{\infty} (z - 2i)^{2n}, \quad |z - 2i| \leqq 0.999$

2. $\displaystyle\sum_{n=0}^{\infty} \frac{z^{2n+1}}{(2n+1)!}, \quad |z| \leqq 10^{10}$

3. $\displaystyle\sum_{n=0}^{\infty} \frac{\pi^n}{n^4} z^{2n}, \quad |z| \leqq 0.56$

4. $\sum_{n=1}^{\infty} \frac{\sin^n |\pi z|}{n(n+1)}, \quad |z| \leqq 10^5$

5. $\sum_{n=1}^{\infty} \frac{z^n}{n^2}, \quad |z| \leqq 1$

6. $\sum_{n=1}^{\infty} \frac{z^n}{n^2 \cosh n|z|}, \quad |z| \leqq 1$

7. $\sum_{n=0}^{\infty} \frac{\tanh^n |z|}{n^2+1} \quad |z| \leqq 10^{10}$

8. $\sum_{n=1}^{\infty} \frac{\cos n|z|}{n^2}, \quad |z| \leqq 10^{20}$

9–16 POWER SERIES

Find the region of uniform convergence. (Give reason.)

9. $\sum_{n=0}^{\infty} \frac{(z+1-2i)^n}{4^n}$

10. $\sum_{n=0}^{\infty} \frac{(z-i)^{2n}}{(2n)!}$

11. $\sum_{n=1}^{\infty} \frac{(-1)^n}{2^n n} z^n$

12. $\sum_{n=2}^{\infty} \binom{n}{2} (2z-i)^n$

13. $\sum_{n=1}^{\infty} \frac{n!}{n^2} z^n$

14. $\sum_{n=1}^{\infty} (3^n \tanh n) z^{2n}$

15. $\sum_{n=1}^{\infty} \frac{z^{2n}}{5^n n^2}$

16. $\sum_{n=0}^{\infty} \frac{(-1)^n z^{2n}}{(2n)!}$

17. CAS PROJECT. Graphs of Partial Sums. (a) Figure 365. Produce this exciting figure using your software and adding further curves, say, those of s_{256}, s_{1024}, etc.

(b) Power series. Study the nonuniformity of convergence experimentally by plotting partial sums near the endpoints of the convergence interval for real $z = x$.

18. TEAM PROJECT. Uniform Convergence.

(a) Weierstrass *M*-test. Give a proof.

(b) Termwise differentiation. Derive Theorem 4 from Theorem 3.

(c) Subregions. Prove that uniform convergence of a series in a region G implies uniform convergence in any portion of G. Is the converse true?

(d) Example 2. Find the precise region of convergence of the series in Example 2 with x replaced by a complex variable z.

(e) Figure 366. Show that $x^2 \sum_{m=1}^{\infty} (1+x^2)^{-m} = 1$ if $x \neq 0$ and 0 if $x = 0$. Verify by computation that the partial sums s_1, s_2, s_3, look as shown in Fig. 366.

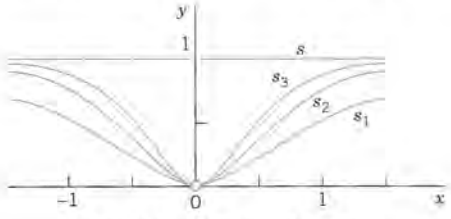

Fig. 366. Sum s and partial sums in Team Project 18(e)

19–20 HEAT EQUATION

Show that (9) in Sec. 12.5 with coefficients (10) is a solution of the heat equation for $t > 0$, assuming that $f(x)$ is continuous on the interval $0 \leqq x \leqq L$ and has one-sided derivatives at all interior points of that interval. Proceed as follows.

19. Show that $|B_n|$ is bounded, say $|B_n| < K$ for all n. Conclude that

$$|u_n| < Ke^{-\lambda_n^2 t_0} \qquad \text{if} \qquad t \geqq t_0 > 0$$

and, by the Weierstrass test, the series (9) converges uniformly with respect to x and t for $t \geqq t_0$, $0 \leqq x \leqq L$. Using Theorem 2, show that $u(x, t)$ is continuous for $t \geqq t_0$ and thus satisfies the boundary conditions (2) for $t \geqq t_0$.

20. Show that $|\partial u_n/\partial t| < \lambda_n^2 Ke^{-\lambda_n^2 t_0}$ if $t \geqq t_0$ and the series of the expressions on the right converges, by the ratio test. Conclude from this, the Weierstrass test, and Theorem 4 that the series (9) can be differentiated term by term with respect to t and the resulting series has the sum $\partial u/\partial t$. Show that (9) can be differentiated twice with respect to x and the resulting series has the sum $\partial^2 u/\partial x^2$. Conclude from this and the result to Prob. 19 that (9) is a solution of the heat equation for all $t \geqq t_0$. (The proof that (9) satisfies the given initial condition can be found in Ref. [C10] listed in App. 1.)

CHAPTER 15 REVIEW QUESTIONS AND PROBLEMS

1. What are power series? Why are these series very important in complex analysis?
2. State from memory the ratio test, the root test, and the Cauchy–Hadamard formula for the radius of convergence.
3. What is absolute convergence? Conditional convergence? Uniform convergence?
4. What do you know about the convergence of power series?
5. What is a Taylor series? What was the idea of obtaining it from Cauchy's integral formula?
6. Give examples of practical methods for obtaining Taylor series.
7. What have power series to do with analytic functions?

8. Can properties of functions be discovered from their Maclaurin series? If so, give examples.

9. Make a list of Maclaurin series of e^z, $\cos z$, $\sin z$, $\cosh z$, $\sinh z$, $\operatorname{Ln}(1 - z)$ from memory.

10. What do you know about adding and multiplying power series?

11–20 RADIUS OF CONVERGENCE

Find the radius of convergence. Can you identify the sum as a familiar function in some of the problems? (Show the details of your work.)

11. $\sum_{n=0}^{\infty} \frac{(3z)^n}{n!}$

12. $\sum_{n=1}^{\infty} \frac{(-2)^{n+1}}{2n} z^n$

13. $\sum_{n=0}^{\infty} \frac{z^{2n+1}}{2n+1}$

14. $\sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} z^n$

15. $\sum_{n=1}^{\infty} \frac{n^5}{n!} (z - 3i)^{2n}$

16. $\sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} (z - 2)^{2n+1}$

17. $\sum_{n=0}^{\infty} \pi^n (z - 2i)^{2n}$

18. $\sum_{n=0}^{\infty} \frac{(2z)^{2n}}{(2n)!}$

19. $\sum_{n=1}^{\infty} \frac{3^n}{n^{10}} z^n$

20. $\sum_{n=0}^{\infty} \frac{(z - i)^n}{(3 + 4i)^n}$

21–30 TAYLOR AND MACLAURIN SERIES

Find the Taylor or Maclaurin series with the given point as center and determine the radius of convergence. (Show details.)

21. e^z, πi

22. $\operatorname{Ln} z$, 2

23. $1/(1 - z)$, -1

24. $1/(4 - 3z)$, $1 + i$

25. $1/(1 - z)^3$, 0

26. $1/z^2$, i

27. $1/z$, $-i$

28. $\int_0^z t^{-1}(e^t - 1)\, dt$, 0

29. $\cos z$, $\frac{1}{2}\pi$

30. $\sin^2 z$, 0

31. Does every function $f(z)$ have a Taylor series?

32. Does there exist a Taylor series in powers of $z - 1 - i$ that diverges at $5 + 5i$ but converges at $4 + 6i$?

33. Do we obtain an analytic function if we replace x by z in the Maclaurin series of a real function $f(x)$?

34. Using Maclaurin series, show that if $f(z)$ is even, its integral (with a suitable constant of integration) is odd.

35. Obtain the first few terms of the Maclaurin series of $\tan z$ by using the Cauchy product and

$$\sin z = \cos z \tan z.$$

SUMMARY OF CHAPTER 15
Power Series, Taylor Series

Sequences, series, and convergence tests are discussed in Sec. 15.1. A **power series** is of the form (Sec. 15.2)

$$(1) \qquad \sum_{n=0}^{\infty} a_n(z - z_0)^n = a_0 + a_1(z - z_0) + a_2(z - z_0)^2 + \cdots;$$

z_0 is its *center*. The series (1) converges for $|z - z_0| < R$ and diverges for $|z - z_0| > R$, where R is the **radius of convergence.** Some power series converge for all z (then we write $R = \infty$). In exceptional cases a power series may converge only at the center; such a series is practically useless. Also, $R = \lim |a_n/a_{n+1}|$ if this limit exists. The series (1) converges absolutely (Sec. 15.2) and **uniformly** (Sec. 15.5) in every closed disk $|z - z_0| \leqq r < R$ $(R > 0)$. It represents an analytic function $f(z)$ for $|z - z_0| < R$. The derivatives $f'(z)$, $f''(z)$, $\cdots$ are obtained by termwise differentiation of (1), and these series have the same radius of convergence R as (1). See Sec. 15.3.

Conversely, *every* analytic function $f(z)$ can be represented by power series. These **Taylor series** of $f(z)$ are of the form (Sec. 15.4)

$$f(z) = \sum_{n=0}^{\infty} \frac{1}{n!} f^{(n)}(z_0)(z - z_0)^n \qquad (|z - z_0| < R), \tag{2}$$

as in calculus. They converge for all z in the open disk with center z_0 and radius generally equal to the distance from z_0 to the nearest **singularity** of $f(z)$ (point at which $f(z)$ ceases to be analytic as defined in Sec. 15.4). If $f(z)$ is **entire** (analytic for all z; see Sec. 13.5), then (2) converges for all z. The functions e^z, $\cos z$, $\sin z$, etc. have Maclaurin series, that is, Taylor series with center 0, similar to those in calculus (Sec. 15.4).

CHAPTER 16

Laurent Series. Residue Integration

Laurent series generalize Taylor series. Indeed, whereas a Taylor series has positive integer powers (and a constant term) and converges in a disk, a **Laurent series** (Sec. 16.1) is a series of positive ***and negative*** integer powers of $z - z_0$ and converges in an annulus (a circular ring) with center z_0. Hence by a Laurent series we can represent a given function $f(z)$ that is analytic in an annulus and may have singularities outside the ring as well as in the "hole" of the annulus.

We know that for a given function the Taylor series with a given center z_0 is unique. We shall see that, in contrast, a function $f(z)$ can have several Laurent series with the same center z_0 and valid in several concentric annuli. The most important of these series is that which converges for $0 < |z - z_0| < R$, that is, everywhere near the center z_0 except at z_0 itself, where z_0 is a singular point of $f(z)$. The series (or finite sum) of the negative powers of *this* Laurent series is called the **principal part** of the singularity of $f(z)$ at z_0, and is used to classify this singularity (Sec. 16.2). The coefficient of the power $1/(z - z_0)$ of *this* series is called the **residue** of $f(z)$ at z_0. Residues are used in an elegant and powerful integration method, called **residue integration,** for complex contour integrals (Sec. 16.3) as well as for certain complicated real integrals (Sec. 16.4).

Prerequisite: Chaps. 13, 14, Sec. 15.2.
Sections that may be omitted in a shorter course: 16.2, 16.4.
References and Answers to Problems: App. 1. Part D, App. 2.

16.1 Laurent Series

Laurent series generalize Taylor series. If in an application we want to develop a function $f(z)$ in powers of $z - z_0$ when $f(z)$ is singular at z_0 (as defined in Sec. 15.4), we cannot use a Taylor series. Instead we may use a new kind of series, called **Laurent series,**[1] consisting of positive integer powers of $z - z_0$ (and a constant) as well as ***negative integer powers*** of $z - z_0$; this is the new feature.

Laurent series are also used for classifying singularities (Sec. 16.2) and in a powerful integration method ("residue integration", Sec. 16.3).

A Laurent series of $f(z)$ converges in an annulus (in the "hole" of which $f(z)$ may have singularities), as follows.

[1]PIERRE ALPHONSE LAURENT (1813–1854), French military engineer and mathematician, published the theorem in 1843.

THEOREM 1

Laurent's Theorem

Let $f(z)$ be analytic in a domain containing two concentric circles C_1 and C_2 with center z_0 and the annulus between them (blue in Fig. 367). *Then $f(z)$ can be represented by the Laurent series*

$$f(z) = \sum_{n=0}^{\infty} a_n(z - z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z - z_0)^n}$$

$$= a_0 + a_1(z - z_0) + a_2(z - z_0)^2 + \cdots \tag{1}$$

$$\cdots + \frac{b_1}{z - z_0} + \frac{b_2}{(z - z_0)^2} + \cdots$$

consisting of nonnegative and negative powers. The coefficients of this Laurent series are given by the integrals

$$a_n = \frac{1}{2\pi i} \oint_C \frac{f(z^*)}{(z^* - z_0)^{n+1}}\, dz^*, \quad b_n = \frac{1}{2\pi i} \oint_C (z^* - z_0)^{n-1} f(z^*)\, dz^*, \tag{2}$$

taken counterclockwise around any simple closed path C that lies in the annulus and encircles the inner circle, as in Fig. 367. [The variable of integration is denoted by z^* since z is used in (1).]

This series converges and represents $f(z)$ in the enlarged open annulus obtained from the given annulus by continuously increasing the outer circle C_1 and decreasing C_2 until each of the two circles reaches a point where $f(z)$ is singular.

In the important special case that z_0 is the only singular point of $f(z)$ inside C_2, this circle can be shrunk to the point z_0, giving convergence in a disk except at the center. In this case the series (or finite sum) of the negative powers of (1) *is called the* **principal part** *of the singularity of $f(z)$ at z_0.*

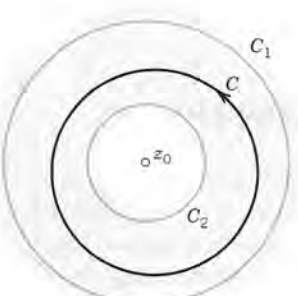

Fig. 367. Laurent's theorem

COMMENT. Obviously, instead of (1), (2) we may write (denoting b_n by a_{-n})

$$f(z) = \sum_{n=-\infty}^{\infty} a_n(z - z_0)^n \tag{1'}$$

where all the coefficients are now given by a single integral formula, namely,

$$(2') \qquad a_n = \frac{1}{2\pi i} \oint_C \frac{f(z^*)}{(z^* - z_0)^{n+1}}\, dz^* \qquad (n = 0, \pm 1, \pm 2, \cdots).$$

PROOF We prove Laurent's theorem. **(a)** ***The nonnegative powers*** are those of a Taylor series. To see this, we use Cauchy's integral formula (3) in Sec. 14.3 with z^* (instead of z) as the variable of integration and z instead of z_0. Let $g(z)$ and $h(z)$ denote the functions represented by the two terms in (3), Sec. 14.3. Then

$$(3) \qquad f(z) = g(z) + h(z) = \frac{1}{2\pi i} \oint_{C_1} \frac{f(z^*)}{z^* - z}\, dz^* - \frac{1}{2\pi i} \oint_{C_2} \frac{f(z^*)}{z^* - z}\, dz^*.$$

Here z is any point in the given annulus and we integrate counterclockwise over both C_1 and C_2, so that the minus sign appears since in (3) of Sec. 14.3 the integration over C_2 is taken clockwise. We transform each of these two integrals as in Sec. 15.4. The first integral is precisely as in Sec. 15.4. Hence we get precisely the same result, namely, the Taylor series of $g(z)$,

$$(4) \qquad g(z) = \frac{1}{2\pi i} \oint_{C_1} \frac{f(z^*)}{z^* - z}\, dz^* = \sum_{n=0}^{\infty} a_n (z - z_0)^n$$

with coefficients [see (2), Sec. 15.4, counterclockwise integration]

$$(5) \qquad a_n = \frac{1}{2\pi i} \oint_{C_1} \frac{f(z^*)}{(z^* - z_0)^{n+1}}\, dz^*.$$

Here we can replace C_1 by C (see Fig. 367), by the principle of deformation of path, since z_0, the point where the integrand in (5) is not analytic, is not a point of the annulus. This proves the formula for the a_n in (2).

(b) ***The negative powers*** in (1) and the formula for b_n in (2) are obtained if we consider $h(z)$ (the second integral times $-1/(2\pi i)$ in (3). Since z lies in the annulus, it lies in the exterior of the path C_2. Hence the situation differs from that for the first integral. The essential point is that instead of [see (7*) in Sec. 15.4]

$$(6) \quad \text{(a)} \quad \left| \frac{z - z_0}{z^* - z_0} \right| < 1 \qquad \text{we now have} \qquad \text{(b)} \quad \left| \frac{z^* - z_0}{z - z_0} \right| < 1.$$

Consequently, we must develop the expression $1/(z^* - z)$ in the integrand of the second integral in (3) in powers of $(z^* - z_0)/(z - z_0)$ (instead of the reciprocal of this) to get a *convergent* series. We find

$$\frac{1}{z^* - z} = \frac{1}{z^* - z_0 - (z - z_0)} = \frac{-1}{(z - z_0)\left(1 - \dfrac{z^* - z_0}{z - z_0}\right)}.$$

Compare this for a moment with (7) in Sec. 15.4, to really understand the difference. Then go on and apply formula (8), Sec. 15.4, for a finite geometric sum, obtaining

$$\frac{1}{z^* - z} = -\frac{1}{z - z_0}\left\{1 + \frac{z^* - z_0}{z - z_0} + \left(\frac{z^* - z_0}{z - z_0}\right)^2 + \cdots + \left(\frac{z^* - z_0}{z - z_0}\right)^n\right\} - \frac{1}{z - z^*}\left(\frac{z^* - z_0}{z - z_0}\right)^{n+1}.$$

Multiplication by $-f(z^*)/2\pi i$ and integration over C_2 on both sides now yield

$$\begin{aligned} h(z) &= -\frac{1}{2\pi i}\oint_{C_2}\frac{f(z^*)}{z^* - z}\,dz^* \\ &= \frac{1}{2\pi i}\left\{\frac{1}{z - z_0}\oint_{C_2} f(z^*)\,dz^* + \frac{1}{(z - z_0)^2}\oint_{C_2}(z^* - z_0)f(z^*)\,dz^* + \cdots \right. \\ &\qquad + \frac{1}{(z - z_0)^n}\oint_{C_2}(z^* - z_0)^{n-1}f(z^*)\,dz^* \\ &\qquad \left. + \frac{1}{(z - z_0)^{n+1}}\oint_{C_2}(z^* - z_0)^n f(z^*)\,dz^*\right\} + R_n^*(z) \end{aligned}$$

with the last term on the right given by

$$R_n^*(z) = \frac{1}{2\pi i(z - z_0)^{n+1}}\oint_{C_2}\frac{(z^* - z_0)^{n+1}}{z - z^*}f(z^*)\,dz^*. \tag{7}$$

As before, we can integrate over C instead of C_2 in the integrals on the right. We see that on the right, the power $1/(z - z_0)^n$ is multiplied by b_n as given in (2). This establishes Laurent's theorem, provided

$$\lim_{n\to\infty} R_n^*(z) = 0. \tag{8}$$

(c) ***Convergence proof of*** **(8).** Very often (1) will have only finitely many negative powers. Then there is nothing to be proved. Otherwise, we begin by noting that $f(z^*)/(z - z^*)$ in (7) is bounded in absolute value, say,

$$\left|\frac{f(z^*)}{z - z^*}\right| < \widetilde{M} \qquad \text{for all } z^* \text{ on } C_2$$

because $f(z^*)$ is analytic in the annulus and on C_2, and z^* lies on C_2 and z outside, so that $z - z^* \neq 0$. From this and the *ML*-inequality (Sec. 14.1) applied to (7) we get the inequality (L = length of C_2, $|z^* - z_0|$ = radius of C_2 = *const*)

$$|R_n^*(z)| \leqq \frac{1}{2\pi|z - z_0|^{n+1}}\,|z^* - z_0|^{n+1}\,\widetilde{M}L = \frac{\widetilde{M}L}{2\pi}\left|\frac{z^* - z_0}{z - z_0}\right|^{n+1}.$$

From (6b) we see that the expression on the right approaches zero as n approaches infinity. This proves (8). The representation (1) with coefficients (2) is now established in the given annulus.

(d) ***Convergence of* (1) *in the enlarged annulus.*** The first series in (1) is a Taylor series [representing $g(z)$]; hence it converges in the disk D with center z_0 whose radius equals the distance of the singularity (or singularities) closest to z_0. Also, $g(z)$ must be singular at all points outside C_1 where $f(z)$ is singular.

The second series in (1), representing $h(z)$, is a power series in $Z = 1/(z - z_0)$. Let the given annulus be $r_2 < |z - z_0| < r_1$, where r_1 and r_2 are the radii of C_1 and C_2, respectively (Fig. 367). This corresponds to $1/r_2 > |Z| > 1/r_1$. Hence this power series in Z must converge at least in the disk $|Z| < 1/r_2$. This corresponds to the exterior $|z - z_0| > r_2$ of C_2, so that $h(z)$ is analytic for all z outside C_2. Also, $h(z)$ must be singular inside C_2 where $f(z)$ is singular, and the series of the negative powers of (1) converges for all z in the exterior E of the circle with center z_0 and radius equal to the maximum distance from z_0 to the singularities of $f(z)$ inside C_2. The domain common to D and E is the enlarged open annulus characterized near the end of Laurent's theorem, whose proof is now complete. ■

Uniqueness. *The Laurent series of a given analytic function $f(z)$ in its annulus of convergence is unique* (see Team Project 24). *However, $f(z)$ may have different Laurent series in two annuli with the same center;* see the examples below. The uniqueness is essential. As for a Taylor series, to obtain the coefficients of Laurent series, we do not generally use the integral formulas (2); instead, we use various other methods, some of which we shall illustrate in our examples. If a Laurent series has been found by any such process, the uniqueness guarantees that it must be ***the*** Laurent series of the given function in the given annulus.

EXAMPLE 1 Use of Maclaurin Series

Find the Laurent series of $z^{-5} \sin z$ with center 0.

Solution. By (14), Sec. 15.4, we obtain

$$z^{-5} \sin z = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} z^{2n-4} = \frac{1}{z^4} - \frac{1}{6z^2} + \frac{1}{120} - \frac{1}{5040} z^2 + - \cdots \qquad (|z| > 0).$$

Here the "annulus" of convergence is the whole complex plane without the origin and the principal part of the series at 0 is $z^{-4} - \frac{1}{6} z^{-2}$. ■

EXAMPLE 2 Substitution

Find the Laurent series of $z^2 e^{1/z}$ with center 0.

Solution. From (12) in Sec. 15.4 with z replaced by $1/z$ we obtain a Laurent series whose principal part is an infinite series,

$$z^2 e^{1/z} = z^2 \left(1 + \frac{1}{1!z} + \frac{1}{2!z^2} + \cdots\right) = z^2 + z + \frac{1}{2} + \frac{1}{3!z} + \frac{1}{4!z^2} + \cdots \qquad (|z| > 0). \blacksquare$$

EXAMPLE 3 Development of $1/(1 - z)$

Develop $1/(1 - z)$ (a) in nonnegative powers of z, (b) in negative powers of z.

Solution.

(a) $$\frac{1}{1 - z} = \sum_{n=0}^{\infty} z^n \qquad \text{(valid if } |z| < 1).$$

(b) $$\frac{1}{1 - z} = \frac{-1}{z(1 - z^{-1})} = -\sum_{n=0}^{\infty} \frac{1}{z^{n+1}} = -\frac{1}{z} - \frac{1}{z^2} - \cdots \qquad \text{(valid if } |z| > 1). \blacksquare$$

EXAMPLE 4 Laurent Expansions in Different Concentric Annuli

Find all Laurent series of $1/(z^3 - z^4)$ with center 0.

Solution. Multiplying by $1/z^3$, we get from Example 3

(I) $$\frac{1}{z^3 - z^4} = \sum_{n=0}^{\infty} z^{n-3} = \frac{1}{z^3} + \frac{1}{z^2} + \frac{1}{z} + 1 + z + \cdots \qquad (0 < |z| < 1),$$

(II) $$\frac{1}{z^3 - z^4} = -\sum_{n=0}^{\infty} \frac{1}{z^{n+4}} = -\frac{1}{z^4} - \frac{1}{z^5} - \cdots \qquad (|z| > 1).$$ ■

EXAMPLE 5 Use of Partial Fractions

Find all Taylor and Laurent series of $f(z) = \dfrac{-2z + 3}{z^2 - 3z + 2}$ with center 0.

Solution. In terms of partial fractions,

$$f(z) = -\frac{1}{z - 1} - \frac{1}{z - 2}.$$

(a) and (b) in Example 3 take care of the first fraction. For the second fraction,

(c) $$-\frac{1}{z - 2} = \frac{1}{2\left(1 - \frac{1}{2}z\right)} = \sum_{n=0}^{\infty} \frac{1}{2^{n+1}} z^n \qquad (|z| < 2),$$

(d) $$-\frac{1}{z - 2} = -\frac{1}{z\left(1 - \frac{2}{z}\right)} = -\sum_{n=0}^{\infty} \frac{2^n}{z^{n+1}} \qquad (|z| > 2).$$

(I) From (a) and (c), valid for $|z| < 1$ (see Fig. 368),

$$f(z) = \sum_{n=0}^{\infty} \left(1 + \frac{1}{2^{n+1}}\right) z^n = \frac{3}{2} + \frac{5}{4} z + \frac{9}{8} z^2 + \cdots.$$

(II) From (c) and (b), valid for $1 < |z| < 2$,

$$f(z) = \sum_{n=0}^{\infty} \frac{1}{2^{n+1}} z^n - \sum_{n=0}^{\infty} \frac{1}{z^{n+1}} = \frac{1}{2} + \frac{1}{4} z + \frac{1}{8} z^2 + \cdots - \frac{1}{z} - \frac{1}{z^2} - \cdots.$$

(III) From (d) and (b), valid for $|z| > 2$,

$$f(z) = -\sum_{n=0}^{\infty} (2^n + 1) \frac{1}{z^{n+1}} = -\frac{2}{z} - \frac{3}{z^2} - \frac{5}{z^3} - \frac{9}{z^4} - \cdots.$$ ■

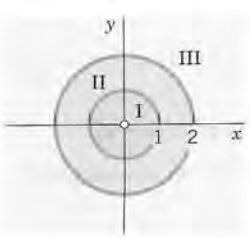

Fig. 368. Regions of convergence in Example 5

If $f(z)$ in Laurent's theorem is analytic inside C_2, the coefficients b_n in (2) are zero by Cauchy's integral theorem, so that the Laurent series reduces to a Taylor series. Examples 3(a) and 5(I) illustrate this.

PROBLEM SET 16.1

1–6 LAURENT SERIES NEAR A SINGULARITY AT 0

Expand the given function in a Laurent series that converges for $0 < |z| < R$ and determine the precise region of convergence. (Show the details of your work.)

1. $\dfrac{1}{z^4 - z^5}$
2. $z \cos \dfrac{1}{z}$
3. $\dfrac{e^{-z}}{z^3}$
4. $\dfrac{\cosh 2z}{z^2}$
5. $z^{-3}e^{1/z^2}$
6. $\dfrac{e^z}{z^2 - z^3}$

7–14 LAURENT SERIES NEAR A SINGULARITY AT z_0

Expand the given function in a Laurent series that converges for $0 < |z - z_0| < R$ and determine the precise region of convergence. (Show details.)

7. $\dfrac{e^z}{z - 1}$, $z_0 = 1$
8. $\dfrac{\sin z}{(z - \frac{1}{4}\pi)^3}$, $z_0 = \frac{1}{4}\pi$
9. $\dfrac{1}{z^2 + 1}$, $z_0 = i$
10. $\dfrac{\cos z}{(z - \pi)^4}$, $z_0 = \pi$
11. $\dfrac{1}{(z + i)^2 - (z + i)}$, $z_0 = -i$
12. $\dfrac{z^3}{(z + i)^2}$, $z_0 = -i$
13. $\dfrac{z^2 - 4}{z - 1}$, $z_0 = 1$
14. $z^2 \sinh \dfrac{1}{z}$, $z_0 = 0$

15–23 TAYLOR AND LAURENT SERIES

Find all Taylor and Laurent series with center $z = z_0$ and determine the precise regions of convergence.

15. $\dfrac{1}{1 - z^3}$, $z_0 = 0$
16. $\dfrac{1}{1 - z^2}$, $z_0 = 1$
17. $\dfrac{z^2}{1 - z^4}$, $z_0 = 0$
18. $\dfrac{1}{z}$, $z_0 = 1$
19. $\dfrac{z^3 - 2iz^2}{(z - i)^2}$, $z_0 = i$
20. $\dfrac{\sinh z}{(z - 1)^4}$, $z_0 = 1$
21. $\dfrac{4z - 1}{z^4 - 1}$, $z_0 = 0$
22. $\dfrac{1}{z^2}$, $z_0 = i$
23. $\dfrac{\sin z}{z + \frac{1}{2}\pi}$, $z_0 = -\frac{1}{2}\pi$

24. **TEAM PROJECT. Laurent Series. (a) Uniqueness.** Prove that the Laurent expansion of a given analytic function in a given annulus is unique.

    (b) Accumulation of singularities. Does $\tan(1/z)$ have a Laurent series that converges in a region $0 < |z| < R$? (Give a reason.)

    (c) Integrals. Expand the following functions in a Laurent series that converges for $|z| > 0$:

$$\frac{1}{z^2}\int_0^z \frac{e^t - 1}{t}\,dt, \qquad \frac{1}{z^3}\int_0^z \frac{\sin t}{t}\,dt.$$

25. **CAS PROJECT. Partial Fractions.** Write a program for obtaining Laurent series by the use of partial fractions. Using the program, verify the calculations in Example 5 of the text. Apply the program to two other functions of your choice.

16.2 Singularities and Zeros. Infinity

Roughly, a *singular point* of an analytic function $f(z)$ is a z_0 at which $f(z)$ ceases to be analytic, and a *zero* is a z at which $f(z) = 0$. Precise definitions follow below. In this section we show that Laurent series can be used for classifying singularities and Taylor series for discussing zeros.

Singularities were defined in Sec. 15.4, as we shall now recall and extend. We also remember that, by definition, a function is a ***single-valued*** relation, as was emphasized in Sec. 13.3.

We say that a function $f(z)$ **is singular** or **has a singularity** at a point $z = z_0$ if $f(z)$ is not analytic (perhaps not even defined) at $z = z_0$, but every neighborhood of $z = z_0$ contains points at which $f(z)$ is analytic. We also say that $z = z_0$ is a **singular point** of $f(z)$.

We call $z = z_0$ an **isolated singularity** of $f(z)$ if $z = z_0$ has a neighborhood without further singularities of $f(z)$. *Example:* $\tan z$ has isolated singularities at $\pm\pi/2, \pm 3\pi/2$, etc.; $\tan(1/z)$ has a nonisolated singularity at 0. (Explain!)

Isolated singularities of $f(z)$ at $z = z_0$ can be classified by the Laurent series

$$(1) \qquad f(z) = \sum_{n=0}^{\infty} a_n(z - z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z - z_0)^n} \qquad \text{(Sec. 16.1)}$$

valid ***in the immediate neighborhood*** of the singular point $z = z_0$, except at z_0 itself, that is, in a region of the form

$$0 < |z - z_0| < R.$$

The sum of the first series is analytic at $z = z_0$, as we know from the last section. The second series, containing the negative powers, is called the **principal part** of (1), as we remember from the last section. If it has only finitely many terms, it is of the form

$$(2) \qquad \frac{b_1}{z - z_0} + \cdots + \frac{b_m}{(z - z_0)^m} \qquad (b_m \neq 0).$$

Then the singularity of $f(z)$ at $z = z_0$ is called a **pole,** and m is called its **order.** Poles of the first order are also known as **simple poles.**

If the principal part of (1) has infinitely many terms, we say that $f(z)$ has at $z = z_0$ an **isolated essential singularity.**

We leave aside nonisolated singularities.

EXAMPLE 1 **Poles. Essential Singularities**

The function

$$f(z) = \frac{1}{z(z - 2)^5} + \frac{3}{(z - 2)^2}$$

has a simple pole at $z = 0$ and a pole of fifth order at $z = 2$. Examples of functions having an isolated essential singularity at $z = 0$ are

$$e^{1/z} = \sum_{n=0}^{\infty} \frac{1}{n!z^n} = 1 + \frac{1}{z} + \frac{1}{2!z^2} + \cdots$$

and

$$\sin \frac{1}{z} = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n + 1)!z^{2n+1}} = \frac{1}{z} - \frac{1}{3!z^3} + \frac{1}{5!z^5} - + \cdots.$$

Section 16.1 provides further examples. For instance, Example 1 shows that $z^{-5} \sin z$ has a fourth-order pole at 0. Example 4 shows that $1/(z^3 - z^4)$ has a third-order pole at 0 and a Laurent series with infinitely many negative powers. This is no contradiction, since this series is valid for $|z| > 1$; it merely tells us that in classifying singularities it is quite important to consider the Laurent series valid ***in the immediate neighborhood*** of a singular point. In Example 4 this is the series (1), which has three negative powers. ■

The classification of singularities into poles and essential singularities is not merely a formal matter, because the behavior of an analytic function in a neighborhood of an essential singularity is entirely different from that in the neighborhood of a pole.

EXAMPLE 2 **Behavior Near a Pole**

$f(z) = 1/z^2$ has a pole at $z = 0$, and $|f(z)| \to \infty$ as $z \to 0$ in any manner. This illustrates the following theorem. ■

THEOREM 1

Poles

If $f(z)$ is analytic and has a pole at $z = z_0$, then $|f(z)| \to \infty$ as $z \to z_0$ in any manner.

The proof is left to the student (see Prob. 12).

EXAMPLE 3 **Behavior Near an Essential Singularity**

The function $f(z) = e^{1/z}$ has an essential singularity at $z = 0$. It has no limit for approach along the imaginary axis; it becomes infinite if $z \to 0$ through positive real values, but it approaches zero if $z \to 0$ through negative real values. It takes on any given value $c = c_0 e^{i\alpha} \neq 0$ in an arbitrarily small ϵ-neighborhood of $z = 0$. To see the letter, we set $z = re^{i\theta}$, and then obtain the following complex equation for r and θ, which we must solve:

$$e^{1/z} = e^{(\cos\theta - i\sin\theta)/r} = c_0 e^{i\alpha}.$$

Equating the absolute values and the arguments, we have $e^{(\cos\theta)/r} = c_0$, that is

$$\cos\theta = r\ln c_0, \qquad \text{and} \qquad -\sin\theta = \alpha r$$

respectively. From these two equations and $\cos^2\theta + \sin^2\theta = r^2(\ln c_0)^2 + \alpha^2 r^2 = 1$ we obtain the formulas

$$r^2 = \frac{1}{(\ln c_0)^2 + \alpha^2} \qquad \text{and} \qquad \tan\theta = -\frac{\alpha}{\ln c_0}.$$

Hence r can be made arbitrarily small by adding multiples of 2π to α, leaving c unaltered. This illustrates the very famous *Picard's theorem* (with $z = 0$ as the exceptional value). For the rather complicated proof, see Ref. [D4], vol. 2, p. 258. For Picard, see Sec. 1.7. ■

THEOREM 2

Picard's Theorem

If $f(z)$ is analytic and has an isolated essential singularity at a point z_0, it takes on every value, with at most one exceptional value, in an arbitrarily small ϵ-neighborhood of z_0.

Removable Singularities. We say that a function $f(z)$ has a *removable singularity* at $z = z_0$ if $f(z)$ is not analytic at $z = z_0$, but can be made analytic there by assigning a suitable value $f(z_0)$. Such singularities are of no interest since they can be removed as just indicated. *Example:* $f(z) = (\sin z)/z$ becomes analytic at $z = 0$ if we define $f(0) = 1$.

Zeros of Analytic Functions

A **zero** of an analytic function $f(z)$ in a domain D is a $z = z_0$ in D such that $f(z_0) = 0$. A zero has **order** n if not only f but also the derivatives $f', f'', \cdots, f^{(n-1)}$ are all 0 at $z = z_0$ but $f^{(n)}(z_0) \neq 0$. A first-order zero is also called a **simple zero.** For a second-order zero, $f(z_0) = f'(z_0) = 0$ but $f''(z_0) \neq 0$. And so on.

EXAMPLE 4 **Zeros**

The function $1 + z^2$ has simple zeros at $\pm i$. The function $(1 - z^4)^2$ has second-order zeros at ± 1 and $\pm i$. The function $(z - a)^3$ has a third-order zero at $z = a$. The function e^z has no zeros (see Sec. 13.5). The function $\sin z$ has simple zeros at $0, \pm\pi, \pm 2\pi, \cdots$, and $\sin^2 z$ has second-order zeros at these points. The function $1 - \cos z$ has second-order zeros at $0, \pm 2\pi, \pm 4\pi, \cdots$, and the function $(1 - \cos z)^2$ has fourth-order zeros at these points. ■

Taylor Series at a Zero. At an nth-order zero $z = z_0$ of $f(z)$, the derivatives $f'(z_0), \cdots, f^{(n-1)}(z_0)$ are zero, by definition. Hence the first few coefficients $a_0, \cdots, a_{n-1}$ of the Taylor series (1), Sec. 15.4, are zero, too, whereas $a_n \neq 0$, so that this series takes the form

$$\begin{aligned} f(z) &= a_n(z - z_0)^n + a_{n+1}(z - z_0)^{n+1} + \cdots \\ &= (z - z_0)^n [a_n + a_{n+1}(z - z_0) + a_{n+2}(z - z_0)^2 + \cdots] \qquad (a_n \neq 0). \end{aligned} \tag{3}$$

This is characteristic of such a zero, because if $f(z)$ has such a Taylor series, it has an nth-order zero at $z = z_0$, as follows by differentiation.

Whereas nonisolated singularities may occur, for zeros we have

THEOREM 3

Zeros

The zeros of an analytic function $f(z)$ ($\not\equiv 0$) are isolated; that is, each of them has a neighborhood that contains no further zeros of $f(z)$.

PROOF The factor $(z - z_0)^n$ in (3) is zero only at $z = z_0$. The power series in the brackets $[\cdots]$ represents an analytic function (by Theorem 5 in Sec. 15.3), call it $g(z)$. Now $g(z_0) = a_n \neq 0$, since an analytic function is continuous, and because of this continuity, also $g(z) \neq 0$ in some neighborhood of $z = z_0$. Hence the same holds of $f(z)$. ∎

This theorem is illustrated by the functions in Example 4.

Poles are often caused by zeros in the denominator. (*Example:* $\tan z$ has poles where $\cos z$ is zero.) This is a major reason for the importance of zeros. The key to the connection is the following theorem, whose proof follows from (3) (see Team Project 24).

THEOREM 4

Poles and Zeros

Let $f(z)$ be analytic at $z = z_0$ and have a zero of nth order at $z = z_0$. Then $1/f(z)$ has a pole of nth order at $z = z_0$; and so does $h(z)/f(z)$, provided $h(z)$ is analytic at $z = z_0$ and $h(z_0) \neq 0$.

Riemann Sphere. Point at Infinity

When we want to study complex functions for large $|z|$, the complex plane will generally become rather inconvenient. Then it may be better to use a representation of complex numbers on the so-called **Riemann sphere.** This is a sphere S of diameter 1 touching the complex z-plane at $z = 0$ (Fig. 369), and we let the image of a point P (a number z in the plane) be the intersection P^* of the segment PN with S, where N is the "North Pole" diametrically opposite to the origin in the plane. Then to each z there corresponds a point on S.

Conversely, each point on S represents a complex number z, except for N, which does not correspond to any point in the complex plane. This suggests that we introduce an additional point, called the **point at infinity** and denoted ∞ ("infinity") and let its image be N. The complex plane together with ∞ is called the **extended complex plane.** The complex plane is often called the *finite complex plane*, for distinction, or simply the

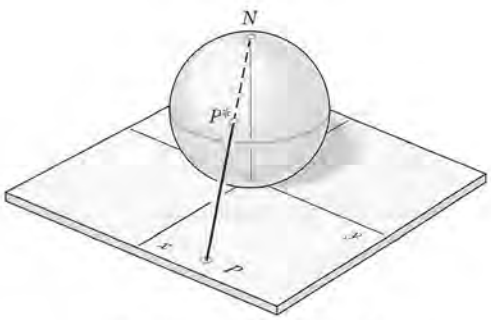

Fig. 369. Riemann sphere

complex plane as before. The sphere S is called the **Riemann sphere.** The mapping of the extended complex plane onto the sphere is known as a **stereographic projection.** (What is the image of the Northern Hemisphere? Of the Western Hemisphere? Of a straight line through the origin?)

Analytic or Singular at Infinity

If we want to investigate a function $f(z)$ for large $|z|$, we may now set $z = 1/w$ and investigate $f(z) = f(1/w) \equiv g(w)$ in a neighborhood of $w = 0$. We define $f(z)$ to be **analytic** or **singular at infinity** if $g(w)$ is analytic or singular, respectively, at $w = 0$. We also define

$$g(0) = \lim_{w \to 0} g(w) \tag{4}$$

if this limit exists.

Furthermore, we say that $f(z)$ has an *nth-order zero at infinity* if $f(1/w)$ has such a zero at $w = 0$. Similarly for poles and essential singularities.

EXAMPLE 5 **Functions Analytic or Singular at Infinity. Entire and Meromorphic Functions**

The function $f(z) = 1/z^2$ is analytic at ∞ since $g(w) = f(1/w) = w^2$ is analytic at $w = 0$, and $f(z)$ has a second-order zero at ∞. The function $f(z) = z^3$ is singular at ∞ and has a third-order pole there since the function $g(w) = f(1/w) = 1/w^3$ has such a pole at $w = 0$. The function e^z has an essential singularity at ∞ since $e^{1/w}$ has such a singularity at $w = 0$. Similarly, $\cos z$ and $\sin z$ have an essential singularity at ∞.

Recall that an **entire function** is one that is analytic everywhere in the (finite) complex plane. Liouville's theorem (Sec. 14.4) tells us that the only *bounded* entire functions are the constants, hence any nonconstant entire function must be unbounded. Hence it has a singularity at ∞, a pole if it is a polynomial or an essential singularity if it is not. The functions just considered are typical in this respect.

An analytic function whose only singularities in the finite plane are poles is called a **meromorphic function.** Examples are rational functions with nonconstant denominator, $\tan z$, $\cot z$, $\sec z$, and $\csc z$. ■

In this section we used Laurent series for investigating singularities. In the next section we shall use these series for an elegant integration method.

PROBLEM SET 16.2

1–10 SINGULARITIES

Determine the location and kind of the singularities of the following functions in the finite plane and at infinity. In the case of poles also state the order.

1. $\tan^2 \pi z$
2. $z + \dfrac{2}{z} - \dfrac{3}{z^2}$
3. $\cot z^2$
4. $z^3 e^{1/(z-1)}$
5. $\cos z - \sin z$
6. $1/(\cos z - \sin z)$

7. $\dfrac{\sin 3z}{(z^4 - 1)^4}$

8. $\dfrac{4}{z - 1} + \dfrac{2}{(z - 1)^2} - \dfrac{8}{(z - 1)^3}$

9. $\cosh\left[1/(z^2 + 1)\right]$

10. $e^{1/(z-1)}/(e^z - 1)$

11. **(Essential singularity)** Discuss e^{1/z^2} in a similar way as $e^{1/z}$ is discussed in Example 3.

12. **(Poles)** Verify Theorem 1 for $f(z) = z^{-3} - z^{-1}$. Prove Theorem 1.

13–22 ZEROS

Determine the location and order of the zeros.

13. $(z + 16i)^4$

14. $(z^4 - 16)^4$

15. $z^{-3} \sin^3 \pi z$

16. $\cosh^2 z$

17. $(3z^2 + 1)e^{-z}$

18. $(z^2 - 1)^2(e^{z^2} - 1)$

19. $(z^2 + 4)(e^z - 1)^2$

20. $(\sin z - 1)^3$

21. $(1 - \cos z)^2$

22. $e^z - e^{2z}$

23. **(Zeros)** If $f(z)$ is analytic and has a zero of order n at $z = z_0$, show that $f^2(z)$ has a zero of order $2n$.

24. **TEAM PROJECT. Zeros. (a) Derivative.** Show that if $f(z)$ has a zero of order $n > 1$ at $z = z_0$, then $f'(z)$ has a zero of order $n - 1$ at z_0.

(b) Poles and zeros. Prove Theorem 4.

(c) Isolated k-points. Show that the points at which a nonconstant analytic function $f(z)$ has a given value k are isolated.

(d) Identical functions. If $f_1(z)$ are analytic in a domain D and equal at a sequence of points z_n in D that converges in D, show that $f_1(z) \equiv f_2(z)$ in D.

25. **(Riemann sphere)** Assuming that we let the image of the x-axis be meridians 0° and 180°, describe and sketch (or graph) the images of the following regions on the Riemann sphere: (a) $|z| > 100$, (b) the lower half-plane, (c) $\frac{1}{2} \leqq |z| \leqq 2$.

16.3 Residue Integration Method

The purpose of Cauchy's residue integration method is the evaluation of integrals

$$\oint_C f(z)\, dz$$

taken around a simple close path C. The idea is as follows.

If $f(z)$ is analytic everywhere on C and inside C, such an integral is zero by Cauchy's integral theorem (Sec. 14.2), and we are done.

If $f(z)$ has a singularity at a point $z = z_0$ inside C, but is otherwise analytic on C and inside C, then $f(z)$ has a Laurent series

$$f(z) = \sum_{n=0}^{\infty} a_n(z - z_0)^n + \frac{b_1}{z - z_0} + \frac{b_2}{(z - z_0)^2} + \cdots$$

that converges for all points near $z = z_0$ (except at $z = z_0$ itself), in some domain of the form $0 < |z - z_0| < R$ (sometimes called a **deleted neighborhood,** an old-fashioned term that we shall not use). Now comes the key idea. The coefficient b_1 of the first negative power $1/(z - z_0)$ of this Laurent series is given by the integral formula (2) in Sec. 16.1 with $n = 1$, namely,

$$b_1 = \frac{1}{2\pi i} \oint_C f(z)\, dz.$$

Now, since we can obtain Laurent series by various methods, without using the integral formulas for the coefficients (see the examples in Sec. 16.1), we can find b_1 by one of those methods and then use the formula for b_1 for evaluating the integral, that is,

(1)
$$\oint_C f(z)\, dz = 2\pi i b_1.$$

Here we integrate counterclockwise around a simple closed path C that contains $z = z_0$ in its interior (but no other singular points of $f(z)$ on or inside C!).

The coefficient b_1 is called the **residue** of $f(z)$ at $z = z_0$ and we denote it by

$$\text{(2)} \qquad b_1 = \operatorname*{Res}_{z=z_0} f(z).$$

EXAMPLE 1 Evaluation of an Integral by Means of a Residue

Integrate the function $f(z) = z^{-4} \sin z$ counterclockwise around the unit circle C.

Solution. From (14) in Sec. 15.4 we obtain the Laurent series

$$f(z) = \frac{\sin z}{z^4} = \frac{1}{z^3} - \frac{1}{3!z} + \frac{z}{5!} - \frac{z^3}{7!} + - \cdots$$

which converges for $|z| > 0$ (that is, for all $z \neq 0$). This series shows that $f(z)$ has a pole of third order at $z = 0$ and the residue $b_1 = -1/3!$. From (1) we thus obtain the answer

$$\oint_C \frac{\sin z}{z^4}\, dz = 2\pi i b_1 = -\frac{\pi i}{3}.$$

EXAMPLE 2 CAUTION! Use the Right Laurent Series!

Integrate $f(z) = 1/(z^3 - z^4)$ clockwise around the circle C: $|z| = 1/2$.

Solution. $z^3 - z^4 = z^3(1 - z)$ shows that $f(z)$ is singular at $z = 0$ and $z = 1$. Now $z = 1$ lies outside C. Hence it is of no interest here. So we need the residue of $f(z)$ at 0. We find it from the Laurent series that converges for $0 < |z| < 1$. This is series (I) in Example 4, Sec. 16.1,

$$\frac{1}{z^3 - z^4} = \frac{1}{z^3} + \frac{1}{z^2} + \frac{1}{z} + 1 + z + \cdots \qquad (0 < |z| < 1).$$

We see from it that this residue is 1. Clockwise integration thus yields

$$\oint_C \frac{dz}{z^3 - z^4} = -2\pi i \operatorname*{Res}_{z=0} f(z) = -2\pi i.$$

CAUTION! Had we used the wrong series (II) in Example 4, Sec. 16.1,

$$\frac{1}{z^3 - z^4} = -\frac{1}{z^4} - \frac{1}{z^5} - \frac{1}{z^6} - \cdots \qquad (|z| > 1),$$

we would have obtained the wrong answer, 0, because this series has no power $1/z$.

Formulas for Residues

To calculate a residue at a pole, we need not produce a whole Laurent series, but, more economically, we can derive formulas for residues once and for all.

Simple Poles. Two formulas for the residue of $f(z)$ at a simple pole at z_0 are

$$\text{(3)} \qquad \operatorname*{Res}_{z=z_0} f(z) = b_1 = \lim_{z \to z_0} (z - z_0) f(z)$$

and, assuming that $f(z) = p(z)/q(z)$, $p(z_0) \neq 0$, and $q(z)$ has a simple zero at z_0 (so that $f(z)$ has at z_0 a simple pole, by Theorem 4 in Sec. 16.2),

$$\text{(4)} \qquad \operatorname*{Res}_{z=z_0} f(z) = \operatorname*{Res}_{z=z_0} \frac{p(z)}{q(z)} = \frac{p(z_0)}{q'(z_0)}.$$

PROOF For a simple pole at $z = z_0$ the Laurent series (1), Sec. 16.1, is

$$f(z) = \frac{b_1}{z - z_0} + a_0 + a_1(z - z_0) + a_2(z - z_0)^2 + \cdots \qquad (0 < |z - z_0| < R).$$

Here $b_1 \neq 0$. (Why?) Multiplying both sides by $z - z_0$ and then letting $z \to z_0$, we obtain the formula (3):

$$\lim_{z \to z_0} (z - z_0) f(z) = b_1 + \lim_{z \to z_0} (z - z_0)[a_0 + a_1(z - z_0) + \cdots] = b_1$$

where the last equality follows from continuity (Theorem 1, Sec. 15.3).

We prove (4). The Taylor series of $q(z)$ at a simple zero z_0 is

$$q(z) = (z - z_0)q'(z_0) + \frac{(z - z_0)^2}{2!} q''(z_0) + \cdots.$$

Substituting this into $f = p/q$ and then f into (3) gives

$$\operatorname*{Res}_{z=z_0} f(z) = \lim_{z \to z_0} (z - z_0) \frac{p(z)}{q(z)} = \lim_{z \to z_0} \frac{(z - z_0)p(z)}{(z - z_0)[q'(z_0) + (z - z_0)q''(z_0)/2 + \cdots]}.$$

$z - z_0$ cancels. By continuity, the limit of the denominator is $q'(z_0)$ and (4) follows. ∎

EXAMPLE 3 Residue at a Simple Pole

$f(z) = (9z + i)/(z^3 + z)$ has a simple pole at i because $z^2 + 1 = (z + i)(z - i)$, and (3) gives the residue

$$\operatorname*{Res}_{z=i} \frac{9z + i}{z(z^2 + 1)} = \lim_{z \to i} (z - i) \frac{9z + i}{z(z + i)(z - i)} = \left[\frac{9z + i}{z(z + i)} \right]_{z=i} = \frac{10i}{-2} = -5i.$$

By (4) with $p(i) = 9i + i$ and $q'(z) = 3z^2 + 1$ we confirm the result,

$$\operatorname*{Res}_{z=i} \frac{9z + i}{z(z^2 + 1)} = \left[\frac{9z + i}{3z^2 + 1} \right]_{z=i} = \frac{10i}{-2} = -5i. \quad ∎$$

Poles of Any Order. The residue of $f(z)$ at an mth-order pole at z_0 is

$$\textbf{(5)} \qquad \operatorname*{Res}_{z=z_0} f(z) = \frac{1}{(m - 1)!} \lim_{z \to z_0} \left\{ \frac{d^{m-1}}{dz^{m-1}} \left[(z - z_0)^m f(z) \right] \right\}.$$

In particular, for a second-order pole ($m = 2$),

$$\textbf{(5*)} \qquad \operatorname*{Res}_{z=z_0} f(z) = \lim_{z \to z_0} \left\{ \left[(z - z_0)^2 f(z) \right]' \right\}.$$

PROOF The Laurent series of $f(z)$ converging near z_0 (except at z_0 itself) is (Sec. 16.2)

$$f(z) = \frac{b_m}{(z - z_0)^m} + \frac{b_{m-1}}{(z - z_0)^{m-1}} + \cdots + \frac{b_1}{z - z_0} + a_0 + a_1(z - z_0) + \cdots$$

where $b_m \neq 0$. The residue wanted is b_1. Multiplying both sides by $(z - z_0)^m$ gives

$$(z - z_0)^m f(z) = b_m + b_{m-1}(z - z_0) + \cdots + b_1(z - z_0)^{m-1} + a_0(z - z_0)^m + \cdots.$$

We see that b_1 is now the coefficient of the power $(z - z_0)^{m-1}$ of the power series of $g(z) = (z - z_0)^m f(z)$. Hence Taylor's theorem (Sec. 15.4) gives (5):

$$b_1 = \frac{1}{(m-1)!} g^{(m-1)}(z_0)$$

$$= \frac{1}{(m-1)!} \frac{d^{m-1}}{dz^{m-1}} [(z - z_0)^m f(z)]. \quad \blacksquare$$

EXAMPLE 4 **Residue at a Pole of Higher Order**

$f(z) = 50z/(z^3 + 2z^2 - 7z + 4)$ has a pole of second order at $z = 1$ because the denominator equals $(z + 4)(z - 1)^2$ (verify!). From (5*) we obtain the residue

$$\operatorname*{Res}_{z=1} f(z) = \lim_{z \to 1} \frac{d}{dz} [(z-1)^2 f(z)]$$

$$= \lim_{z \to 1} \frac{d}{dz} \left(\frac{50z}{z+4} \right)$$

$$= \frac{200}{5^2} = 8. \quad \blacksquare$$

Several Singularities Inside the Contour. Residue Theorem

Residue integration can be extended from the case of a single singularity to the case of several singularities within the contour C. This is the purpose of the residue theorem. The extension is surprisingly simple.

THEOREM 1

Residue Theorem

Let $f(z)$ be analytic inside a simple closed path C and on C, except for finitely many singular points $z_1, z_2, \cdots, z_k$ inside C. Then the integral of $f(z)$ taken counterclockwise around C equals $2\pi i$ times the sum of the residues of $f(z)$ at $z_1, \cdots, z_k$:

(6)
$$\oint_C f(z)\, dz = 2\pi i \sum_{j=1}^{k} \operatorname*{Res}_{z=z_j} f(z).$$

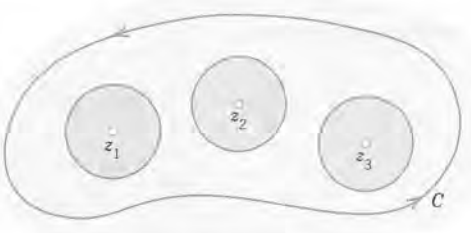

Fig. 370. Residue theorem

PROOF We enclose each of the singular points z_j in a circle C_j with radius small enough that those k circles and C are all separated (Fig. 370). Then $f(z)$ is analytic in the multiply connected domain D bounded by C and $C_1, \cdots, C_k$ and on the entire boundary of D. From Cauchy's integral theorem we thus have

$$\oint_C f(z)\,dz + \oint_{C_1} f(z)\,dz + \oint_{C_2} f(z)\,dz + \cdots + \oint_{C_k} f(z)\,dz = 0, \tag{7}$$

the integral along C being taken *counterclockwise* and the other integrals *clockwise* (as in Figs. 351 and 352, Sec. 14.2). We take the integrals over $C_1, \cdots, C_k$ to the right and compensate the resulting minus sign by reversing the sense of integration. Thus,

$$\oint_C f(z)\,dz = \oint_{C_1} f(z)\,dz + \oint_{C_2} f(z)\,dz + \cdots + \oint_{C_k} f(z)\,dz \tag{8}$$

where all the integrals are now taken counterclockwise. By (1) and (2),

$$\oint_{C_j} f(z)\,dz = 2\pi i \operatorname*{Res}_{z=z_j} f(z), \qquad j = 1, \cdots, k,$$

so that (8) gives (6) and the residue theorem is proved. ■

This important theorem has various applications in connection with complex and real integrals. Let us first consider some complex integrals. (Real integrals follow in the next section.)

EXAMPLE 5 **Integration by the Residue Theorem. Several Contours**

Evaluate the following integral counterclockwise around any simple closed path such that (a) 0 and 1 are inside C, (b) 0 is inside, 1 outside, (c) 1 is inside, 0 outside, (d) 0 and 1 are outside.

$$\oint_C \frac{4 - 3z}{z^2 - z}\,dz$$

Solution. The integrand has simple poles at 0 and 1, with residues [by (3)]

$$\operatorname*{Res}_{z=0} \frac{4 - 3z}{z(z - 1)} = \left[\frac{4 - 3z}{z - 1}\right]_{z=0} = -4, \qquad \operatorname*{Res}_{z=1} \frac{4 - 3z}{z(z - 1)} = \left[\frac{4 - 3z}{z}\right]_{z=1} = 1.$$

[Confirm this by (4).] *Ans.* (a) $2\pi i(-4 + 1) = -6\pi i$, (b) $-8\pi i$, (c) $2\pi i$, (d) 0. ■

EXAMPLE 6 **Another Application of the Residue Theorem**

Integrate $(\tan z)/(z^2 - 1)$ counterclockwise around the circle C: $|z| = 3/2$.

Solution. $\tan z$ is not analytic at $\pm\pi/2, \pm 3\pi/2, \cdots$, but all these points lie outside the contour C. Because of the denominator $z^2 - 1 = (z - 1)(z + 1)$ the given function has simple poles at ± 1. We thus obtain from (4) and the residue theorem

$$\begin{aligned}\oint_C \frac{\tan z}{z^2 - 1}\,dz &= 2\pi i\left(\operatorname*{Res}_{z=1} \frac{\tan z}{z^2 - 1} + \operatorname*{Res}_{z=-1} \frac{\tan z}{z^2 - 1}\right) \\ &= 2\pi i\left(\left.\frac{\tan z}{2z}\right|_{z=1} + \left.\frac{\tan z}{2z}\right|_{z=-1}\right) \\ &= 2\pi i \tan 1 = 9.7855i.\end{aligned}$$

■

EXAMPLE 7 Poles and Essential Singularities

Evaluate the following integral, where C is the ellipse $9x^2 + y^2 = 9$ (counterclockwise, sketch it).

$$\oint_C \left(\frac{ze^{\pi z}}{z^4 - 16} + ze^{\pi/z} \right) dz$$

Solution. Since $z^4 - 16 = 0$ at $\pm 2i$ and ± 2, the first term of the integrand has simple poles at $\pm 2i$ inside C, with residues [by (4); note that $e^{2\pi i} = 1$]

$$\operatorname*{Res}_{z=2i} \frac{ze^{\pi z}}{z^4 - 16} = \left[\frac{ze^{\pi z}}{4z^3} \right]_{z=2i} = -\frac{1}{16},$$

$$\operatorname*{Res}_{z=-2i} \frac{ze^{\pi z}}{z^4 - 16} = \left[\frac{ze^{\pi z}}{4z^3} \right]_{z=-2i} = -\frac{1}{16}$$

and simple poles at ± 2, which lie outside C, so that they are of no interest here. The second term of the integrand has an essential singularity at 0, with residue $\pi^2/2$ as obtained from

$$ze^{\pi/z} = z\left(1 + \frac{\pi}{z} + \frac{\pi^2}{2!z^2} + \frac{\pi^3}{3!z^3} + \cdots\right) = z + \pi + \frac{\pi^2}{2} \cdot \frac{1}{z} + \cdots \qquad (|z| > 0).$$

Ans. $2\pi i(-\frac{1}{16} - \frac{1}{16} + \frac{1}{2}\pi^2) = \pi(\pi^2 - \frac{1}{4})i = 30.221i$ by the residue theorem. ■

PROBLEM SET 16.3

1. Verify the calculations in Example 3 and find the other residues.
2. Verify the calculations in Example 4 and find the other residue.

3–12 RESIDUES

Find all the singular points and the corresponding residues. (Show the details of your work.)

3. $\dfrac{1}{4 + z^2}$
4. $\dfrac{\cos z}{z^6}$
5. $\dfrac{\sin z}{z^6}$
6. $\dfrac{z^2 + 1}{z^2 - z}$
7. $\cot z$
8. $\sec z$
9. $\dfrac{1}{(z^2 - 1)^2}$
10. $\dfrac{1/3}{z^4 - 1}$
11. $\tan z$
12. $\dfrac{z^2}{z^4 - 1}$
13. **CAS PROJECT. Residue at a Pole.** Write a program for calculating the residue at a pole of any order. Use it for solving Probs. 3–8.

14–25 RESIDUE INTEGRATION

Evaluate (counterclockwise). (Show the details.)

14. $\displaystyle\oint_C \frac{\sin \pi z}{z^4}\, dz, \quad C: |z - i| = 2$
15. $\displaystyle\oint_C e^{1/z}\, dz, \quad C: |z| = 1$
16. $\displaystyle\oint_C \frac{dz}{\sinh \frac{1}{2}\pi z}, \quad C: |z - 1| = 1.4$
17. $\displaystyle\oint_C \tan \pi z\, dz, \quad C: |z| = 1$
18. $\displaystyle\oint_C \tan \pi z\, dz, \quad C: |z| = 2$
19. $\displaystyle\oint_C \frac{e^z}{\cos z}\, dz, \quad C: |z| = 4.5$
20. $\displaystyle\oint_C \coth z\, dz, \quad C: |z| = 1$
21. $\displaystyle\oint_C \frac{e^z}{\cos \pi z}\, dz, \quad C: |z - i| = 1.5$
22. $\displaystyle\oint_C \frac{\cosh z}{z^2 - 3iz}\, dz, \quad C: |z| = 1$
23. $\displaystyle\oint_C \frac{\tan \pi z}{z^3}\, dz, \quad C: |z + \frac{1}{2}i| = 1$
24. $\displaystyle\oint_C \frac{1 - 4z + 6z^2}{(z^2 + \frac{1}{4})(2 - z)}\, dz, \quad C: |z| = 1$
25. $\displaystyle\oint_C \frac{30z^2 - 23z + 5}{(2z - 1)^2(3z - 1)}\, dz, \quad C: |z| = 1$

16.4 Residue Integration of Real Integrals

It is quite surprising that certain classes of complicated ***real*** integrals can be integrated by the residue theorem, as we shall see.

Integrals of Rational Functions of cos θ and sin θ

We first consider integrals of the type

$$J = \int_0^{2\pi} F(\cos\theta, \sin\theta)\, d\theta \tag{1}$$

where $F(\cos\theta, \sin\theta)$ is a real rational function of $\cos\theta$ and $\sin\theta$ [for example, $(\sin^2\theta)/(5 - 4\cos\theta)$] and is finite (does not become infinite) on the interval of integration. Setting $e^{i\theta} = z$, we obtain

$$\cos\theta = \frac{1}{2}(e^{i\theta} + e^{-i\theta}) = \frac{1}{2}\left(z + \frac{1}{z}\right)$$
$$\sin\theta = \frac{1}{2i}(e^{i\theta} - e^{-i\theta}) = \frac{1}{2i}\left(z - \frac{1}{z}\right). \tag{2}$$

Since F is rational in $\cos\theta$ and $\sin\theta$, Eq. (2) shows that F is now a rational function of z, say, $f(z)$. Since $dz/d\theta = ie^{i\theta}$, we have $d\theta = dz/iz$ and the given integral takes the form

$$J = \oint_C f(z)\,\frac{dz}{iz} \tag{3}$$

and, as θ ranges from 0 to 2π in (1), the variable $z = e^{i\theta}$ ranges counterclockwise once around the unit circle $|z| = 1$. (Review Sec. 13.5 if necessary.)

EXAMPLE 1 **An Integral of the Type (1)**

Show by the present method that $\displaystyle\int_0^{2\pi} \frac{d\theta}{\sqrt{2} - \cos\theta} = 2\pi$.

Solution. We use $\cos\theta = \frac{1}{2}(z + 1/z)$ and $d\theta = dz/iz$. Then the integral becomes

$$\oint_C \frac{dz/iz}{\sqrt{2} - \frac{1}{2}\left(z + \frac{1}{z}\right)} = \oint_C \frac{dz}{-\frac{i}{2}(z^2 - 2\sqrt{2}z + 1)}$$
$$= -\frac{2}{i}\oint_C \frac{dz}{(z - \sqrt{2} - 1)(z - \sqrt{2} + 1)}.$$

We see that the integrand has a simple pole at $z_1 = \sqrt{2} + 1$ outside the unit circle C, so that it is of no interest here, and another simple pole at $z_2 = \sqrt{2} - 1$ (where $z - \sqrt{2} + 1 = 0$) inside C with residue [by (3), Sec. 16.3]

$$\operatorname*{Res}_{z=z_2} \frac{1}{(z - \sqrt{2} - 1)(z - \sqrt{2} + 1)} = \left[\frac{1}{z - \sqrt{2} - 1}\right]_{z=\sqrt{2}-1}$$
$$= -\frac{1}{2}.$$

Answer: $2\pi i(-2/i)(-1/2) = 2\pi$. (Here $-2/i$ is the factor in front of the last integral.) ■

As another large class, let us consider real integrals of the form

$$\int_{-\infty}^{\infty} f(x)\,dx. \tag{4}$$

Such an integral, whose interval of integration is not finite is called an **improper integral,** and it has the meaning

$$\int_{-\infty}^{\infty} f(x)\,dx = \lim_{a\to-\infty}\int_{a}^{0} f(x)\,dx + \lim_{b\to\infty}\int_{0}^{b} f(x)\,dx. \tag{5'}$$

If both limits exist, we may couple the two independent passages to $-\infty$ and ∞, and write

$$\int_{-\infty}^{\infty} f(x)\,dx = \lim_{R\to\infty}\int_{-R}^{R} f(x)\,dx. \tag{5}$$

The limit in (5) is called the **Cauchy principal value** of the integral. It is written

$$\text{pr. v.}\int_{-\infty}^{\infty} f(x)\,dx.$$

It may exist even if the limits in (5′) do not. *Example:*

$$\lim_{R\to\infty}\int_{-R}^{R} x\,dx = \lim_{R\to\infty}\left(\frac{R^2}{2} - \frac{R^2}{2}\right) = 0, \qquad \text{but} \qquad \lim_{b\to\infty}\int_{0}^{b} x\,dx = \infty.$$

We assume that the function $f(x)$ in (4) is a real rational function whose denominator is different from zero for all real x and is of degree at least two units higher than the degree of the numerator. Then the limits in (5′) exist, and we may start from (5). We consider the corresponding contour integral

$$\oint_{C} f(z)\,dz \tag{5*}$$

around a path C in Fig. 371. Since $f(x)$ is rational, $f(z)$ has finitely many poles in the upper half-plane, and if we choose R large enough, then C encloses all these poles. By the residue theorem we then obtain

$$\oint_{C} f(z)\,dz = \int_{S} f(z)\,dz + \int_{-R}^{R} f(x)\,dx = 2\pi i \sum \text{Res}\, f(z)$$

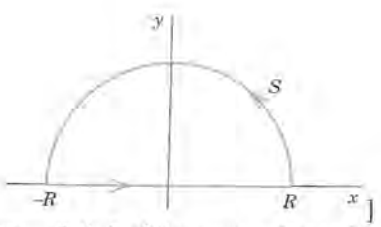

Fig. 371. Path C of the contour integral in (5*)

where the sum consists of all the residues of $f(z)$ at the points in the upper half-plane at which $f(z)$ has a pole. From this we have

$$\int_{-R}^{R} f(x)\,dx = 2\pi i \sum \text{Res } f(z) - \int_S f(z)\,dz. \tag{6}$$

We prove that, if $R \to \infty$, the value of the integral over the semicircle S approaches zero. If we set $z = Re^{i\theta}$, then S is represented by $R = const$, and as z ranges along S, the variable θ ranges from 0 to π. Since, by assumption, the degree of the denominator of $f(z)$ is at least two units higher than the degree of the numerator, we have

$$|f(z)| < \frac{k}{|z|^2} \qquad (|z| = R > R_0)$$

for sufficiently large constants k and R_0. By the *ML*-inequality in Sec. 14.1,

$$\left|\int_S f(z)\,dz\right| < \frac{k}{R^2}\,\pi R = \frac{k\pi}{R} \qquad (R > R_0).$$

Hence, as R approaches infinity, the value of the integral over S approaches zero, and (5) and (6) yield the result

$$\int_{-\infty}^{\infty} f(x)\,dx = 2\pi i \sum \text{Res } f(z) \tag{7}$$

where we sum over all the residues of $f(z)$ at the poles of $f(z)$ in the upper half-plane.

EXAMPLE 2 **An Improper Integral from 0 to ∞**

Using (7), show that

$$\int_0^{\infty} \frac{dx}{1 + x^4} = \frac{\pi}{2\sqrt{2}}.$$

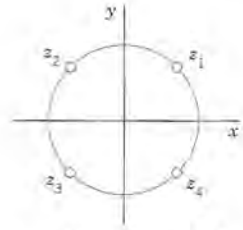

Fig. 372. Example 2

Solution. Indeed, $f(z) = 1/(1 + z^4)$ has four simple poles at the points (make a sketch)

$$z_1 = e^{\pi i/4}, \qquad z_2 = e^{3\pi i/4}, \qquad z_3 = e^{-3\pi i/4}, \qquad z_4 = e^{-\pi i/4}.$$

The first two of these poles lie in the upper half-plane (Fig. 372). From (4) in the last section we find the residues

$$\operatorname*{Res}_{z=z_1} f(z) = \left[\frac{1}{(1+z^4)'}\right]_{z=z_1} = \left[\frac{1}{4z^3}\right]_{z=z_1} = \frac{1}{4}\,e^{-3\pi i/4} = -\frac{1}{4}\,e^{\pi i/4}.$$

$$\operatorname*{Res}_{z=z_2} f(z) = \left[\frac{1}{(1+z^4)'}\right]_{z=z_2} = \left[\frac{1}{4z^3}\right]_{z=z_2} = \frac{1}{4}\,e^{-9\pi i/4} = \frac{1}{4}\,e^{-\pi i/4}.$$

(Here we used $e^{\pi i} = -1$ and $e^{-2\pi i} = 1$.) By (1) in Sec. 13.6 and (7) in this section,

$$\int_{-\infty}^{\infty} \frac{dx}{1+x^4} = -\frac{2\pi i}{4}\,(e^{\pi i/4} - e^{-\pi i/4}) = -\frac{2\pi i}{4}\cdot 2i\cdot \sin\frac{\pi}{4} = \pi \sin\frac{\pi}{4} = \frac{\pi}{\sqrt{2}}.$$

Since $1/(1+x^4)$ is an even function, we thus obtain, as asserted,

$$\int_0^{\infty} \frac{dx}{1+x^4} = \frac{1}{2}\int_{-\infty}^{\infty} \frac{dx}{1+x^4} = \frac{\pi}{2\sqrt{2}}.$$

Fourier Integrals

The method of evaluating (4) by creating a closed contour (Fig. 371) and "blowing it up" extends to integrals

$$\text{(8)}\qquad \int_{-\infty}^{\infty} f(x)\cos sx\,dx \qquad \text{and} \qquad \int_{-\infty}^{\infty} f(x)\sin sx\,dx \qquad (s \text{ real})$$

as they occur in connection with the Fourier integral (Sec. 11.7).

If $f(x)$ is a rational function satisfying the assumption on the degree as for (4), we may consider the corresponding integral

$$\oint_C f(z)e^{isz}\,dz \qquad (s \text{ real and positive})$$

over the contour C in Fig. 371 on p. 719. Instead of (7) we now get

$$\text{(9)}\qquad \int_{-\infty}^{\infty} f(x)e^{isx}\,dx = 2\pi i \sum \operatorname{Res}\left[f(z)e^{isz}\right] \qquad (s > 0)$$

where we sum the residues of $f(z)e^{isz}$ at its poles in the upper half-plane. Equating the real and the imaginary parts on both sides of (9), we have

$$\textbf{(10)}\qquad \begin{aligned} \int_{-\infty}^{\infty} f(x)\cos sx\,dx &= -2\pi \sum \operatorname{Im}\operatorname{Res}\left[f(z)e^{isz}\right], \\ \int_{-\infty}^{\infty} f(x)\sin sx\,dx &= 2\pi \sum \operatorname{Re}\operatorname{Res}\left[f(z)e^{isz}\right]. \end{aligned} \qquad (s > 0)$$

To establish (9), we must show [as for (4)] that the value of the integral over the semicircle S in Fig. 371 approaches 0 as $R \to \infty$. Now $s > 0$ and S lies in the upper half-plane $y \geqq 0$. Hence

$$|e^{isz}| = |e^{is(x+iy)}| = |e^{isx}|\,|e^{-sy}| = 1\cdot e^{-sy} \leqq 1 \qquad (s > 0,\quad y \geqq 0).$$

From this we obtain the inequality $|f(z)e^{isz}| = |f(z)|\,|e^{isz}| \leqq |f(z)|$ $(s > 0,\quad y \geqq 0)$. This reduces our present problem to that for (4). Continuing as before gives (9) and (10).

EXAMPLE 3 **An Application of (10)**

Show that $$\int_{-\infty}^{\infty} \frac{\cos sx}{k^2 + x^2}\, dx = \frac{\pi}{k}\, e^{-ks}, \qquad \int_{-\infty}^{\infty} \frac{\sin sx}{k^2 + x^2}\, dx = 0 \qquad (s > 0,\ k > 0).$$

Solution. In fact, $e^{isz}/(k^2 + z^2)$ has only one pole in the upper half-plane, namely, a simple pole at $z = ik$, and from (4) in Sec. 16.3 we obtain

$$\operatorname*{Res}_{z=ik} \frac{e^{isz}}{k^2 + z^2} = \left[\frac{e^{isz}}{2z}\right]_{z=ik} = \frac{e^{-ks}}{2ik}.$$

Thus

$$\int_{-\infty}^{\infty} \frac{e^{isx}}{k^2 + x^2}\, dx = 2\pi i\, \frac{e^{-ks}}{2ik} = \frac{\pi}{k}\, e^{-ks}.$$

Since $e^{isx} = \cos sx + i \sin sx$, this yields the above results [see also (15) in Sec. 11.7.] ■

Another Kind of Improper Integral

We consider an improper integral

$$\int_A^B f(x)\, dx \tag{11}$$

whose integrand becomes infinite at a point a in the interval of integration,

$$\lim_{x \to a} |f(x)| = \infty.$$

By definition, this integral (11) means

$$\int_A^B f(x)\, dx = \lim_{\epsilon \to 0} \int_A^{a-\epsilon} f(x)\, dx + \lim_{\eta \to 0} \int_{a+\eta}^B f(x)\, dx \tag{12}$$

where both ϵ and η approach zero independently and through positive values. It may happen that neither of these two limits exists if ϵ and η go to 0 independently, but the limit

$$\lim_{\epsilon \to 0} \left[\int_A^{a-\epsilon} f(x)\, dx + \int_{a+\epsilon}^B f(x)\, dx\right] \tag{13}$$

exists. This is called the **Cauchy principal value** of the integral. It is written

$$\text{pr. v.} \int_A^B f(x)\, dx.$$

For example,

$$\text{pr. v.} \int_{-1}^{1} \frac{dx}{x^3} = \lim_{\epsilon \to 0} \left[\int_{-1}^{-\epsilon} \frac{dx}{x^3} + \int_{\epsilon}^{1} \frac{dx}{x^3}\right] = 0;$$

the principal value exists, although the integral itself has no meaning.

In the case of simple poles on the real axis we shall obtain a formula for the principal value of an integral from $-\infty$ to ∞. This formula will result from the following theorem.

THEOREM 1

Simple Poles on the Real Axis

If $f(z)$ has a simple pole at $z = a$ on the real axis, then (Fig. 373)

$$\lim_{r\to 0} \int_{C_2} f(z)\,dz = \pi i \operatorname*{Res}_{z=a} f(z).$$

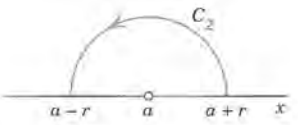

Fig. 373. Theorem 1

PROOF By the definition of a simple pole (Sec. 16.2) the integrand $f(z)$ has for $0 < |z - a| < R$ the Laurent series

$$f(z) = \frac{b_1}{z-a} + g(z), \qquad b_1 = \operatorname*{Res}_{z=a} f(z).$$

Here $g(z)$ is analytic on the semicircle of integration (Fig. 373)

$$C_2\colon \quad z = a + re^{i\theta}, \qquad 0 \leqq \theta \leqq \pi$$

and for all z between C_2 and the x-axis, and thus bounded on C_2, say, $|g(z)| \leqq M$. By integration,

$$\int_{C_2} f(z)\,dz = \int_0^{\pi} \frac{b_1}{re^{i\theta}}\, ire^{i\theta}\,d\theta + \int_{C_2} g(z)\,dz = b_1\pi i + \int_{C_2} g(z)\,dz.$$

The second integral on the right cannot exceed $M\pi r$ in absolute value, by the ML-inequality (Sec. 14.1), and $ML = M\pi r \to 0$ as $r \to 0$. ∎

Figure 374 shows the idea of applying Theorem 1 to obtain the principal value of the integral of a rational function $f(x)$ from $-\infty$ to ∞. For sufficiently large R the integral over the entire contour in Fig. 374 has the value J given by $2\pi i$ times the sum of the residues of $f(z)$ at the singularities in the upper half-plane. We assume that $f(x)$ satisfies the degree

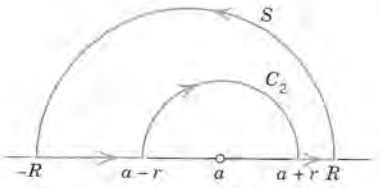

Fig. 374. Application of Theorem 1

condition imposed in connection with (4). Then the value of the integral over the large semicircle S approaches 0 as $R \to \infty$. For $r \to 0$ the integral over C_2 (clockwise!) approaches the value

$$K = -\pi i \operatorname*{Res}_{z=a} f(z)$$

by Theorem 1. Together this shows that the principal value P of the integral from $-\infty$ to ∞ plus K equals J; hence $P = J - K = J + \pi i \operatorname{Res}_{z=a} f(z)$. If $f(z)$ has several simple poles on the real axis, then K will be $-\pi i$ times the sum of the corresponding residues. Hence the desired formula is

(14)
$$\text{pr. v.} \int_{-\infty}^{\infty} f(x)\,dx = 2\pi i \sum \operatorname{Res} f(z) + \pi i \sum \operatorname{Res} f(z)$$

where the first sum extends over all poles in the upper half-plane and the second over all poles on the real axis, the latter being simple by assumption.

EXAMPLE 4 **Poles on the Real Axis**

Find the principal value

$$\text{pr. v.} \int_{-\infty}^{\infty} \frac{dx}{(x^2 - 3x + 2)(x^2 + 1)}.$$

Solution. Since

$$x^2 - 3x + 2 = (x - 1)(x - 2),$$

the integrand $f(x)$, considered for complex z, has simple poles at

$$z = 1, \qquad \operatorname*{Res}_{z=1} f(z) = \left[\frac{1}{(z - 2)(z^2 + 1)}\right]_{z=1} = -\frac{1}{2},$$

$$z = 2, \qquad \operatorname*{Res}_{z=2} f(z) = \left[\frac{1}{(z - 1)(z^2 + 1)}\right]_{z=2} = \frac{1}{5},$$

$$z = i, \qquad \operatorname*{Res}_{z=i} f(z) = \left[\frac{1}{(z^2 - 3z + 2)(z + i)}\right]_{z=i} = \frac{1}{6 + 2i} = \frac{3 - i}{20},$$

and at $z = -i$ in the lower half-plane, which is of no interest here. From (14) we get the answer

$$\text{pr. v.} \int_{-\infty}^{\infty} \frac{dx}{(x^2 - 3x + 2)(x^2 + 1)} = 2\pi i \left(\frac{3 - i}{20}\right) + \pi i \left(-\frac{1}{2} + \frac{1}{5}\right) = \frac{\pi}{10}.$$

More integrals of the kind considered in this section are included in the problem set. Try also your CAS, which may sometimes give you false results on complex integrals.

PROBLEM SET 16.4

1–8 INTEGRALS INVOLVING COSINE AND SINE

Evaluate the following integrals. (Show the details of your work.)

1. $\displaystyle\int_0^{2\pi} \frac{d\theta}{7 + 6\cos\theta}$

2. $\displaystyle\int_0^{\pi} \frac{d\theta}{2 + \cos\theta}$

3. $\displaystyle\int_0^{2\pi} \frac{d\theta}{37 - 12\cos\theta}$

4. $\displaystyle\int_0^{2\pi} \frac{d\theta}{8 - 2\sin\theta}$

5. $\displaystyle\int_0^{2\pi} \frac{d\theta}{5 - 4\sin\theta}$

6. $\displaystyle\int_0^{2\pi} \frac{\sin^2\theta}{5 - 4\cos\theta}\, d\theta$

7. $\displaystyle\int_0^{2\pi} \frac{\cos\theta}{13 - 12\cos 2\theta}\, d\theta.$

   Hint. $\cos 2\theta = \frac{1}{2}\left(z^2 + \frac{1}{z^2}\right)$

8. $\displaystyle\int_0^{2\pi} \frac{1 + 4\cos\theta}{17 - 8\cos\theta}\, d\theta$

9–22 IMPROPER INTEGRALS: INFINITE INTERVAL OF INTEGRATION

Evaluate (showing the details):

9. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{x^2 + 1}$

10. $\displaystyle\int_{-\infty}^{\infty} \frac{x}{x^4 + 1}\, dx$

11. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{x^6 + 1}$

12. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{(x^2 - 2x + 5)^2}$

13. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{(x^2 + 4)^2}$

14. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{x^4 + 16}$

15. $\displaystyle\int_{-\infty}^{\infty} \frac{x^3}{1 + x^8}\, dx$

16. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{(x^2 + 1)(x^2 + 9)}$

17. $\displaystyle\int_{-\infty}^{\infty} \frac{x}{(x^2 - 2x + 2)^2}\, dx$

18. $\displaystyle\int_{-\infty}^{\infty} \frac{x^2 + 1}{x^4 + 1}\, dx$

19. $\displaystyle\int_{-\infty}^{\infty} \frac{\sin x}{x^4 + 1}\, dx$

20. $\displaystyle\int_{-\infty}^{\infty} \frac{\cos x}{x^4 + 1}\, dx$

21. $\displaystyle\int_{-\infty}^{\infty} \frac{\sin 3x}{x^4 + 1}\, dx$

22. $\displaystyle\int_{-\infty}^{\infty} \frac{\cos 4x}{x^4 + 5x^2 + 4}\, dx$

23–27 IMPROPER INTEGRALS: POLES ON THE REAL AXIS

Find the Cauchy principal value (showing details):

23. $\displaystyle\int_{-\infty}^{\infty} \frac{x + 2}{x^3 + x}\, dx$

24. $\displaystyle\int_{-\infty}^{\infty} \frac{x^2}{x^4 - 1}\, dx$

25. $\displaystyle\int_{-\infty}^{\infty} \frac{x + 5}{x^3 - x}\, dx$

26. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{x^4 + 3x^2 - 4}$

27. $\displaystyle\int_{-\infty}^{\infty} \frac{dx}{x^4 - 1}$

28. **TEAM PROJECT. Comments on Real Integrals.**
(a) Formula (10) follows from (9). Give the details.

(b) Use of auxiliary results. Integrating e^{-z^2} around the boundary C of the rectangle with vertices $-a$, a, $a + ib$, $-a + ib$, letting $a \to \infty$, and using

$$\int_0^{\infty} e^{-x^2}\, dx = \frac{\sqrt{\pi}}{2},$$

show that

$$\int_0^{\infty} e^{-x^2} \cos 2bx\, dx = \frac{\sqrt{\pi}}{2}\, e^{-b^2}.$$

(This integral is needed in heat conduction in Sec. 12.6.)

(c) Inspection. Solve Probs. 15 and 21 without calculation.

29. **CAS EXPERIMENT. Check your CAS.** Find out to what extent your CAS can evaluate integrals of the form (1), (4), and (8) correctly. Do this by comparing the results of direct integration (which may come out false) with those of using residues.

30. **CAS EXPERIMENT. Simple Poles on the Real Axis.** Experiment with integrals $\int_{-\infty}^{\infty} f(x)\, dx$, $f(x) = [(x - a_1)(x - a_2) \cdots (x - a_k)]^{-1}$, a_j real and all different, $k > 1$. Conjecture that the principal value of these integrals is 0. Try to prove this for a special k, say, $k = 3$. For general k.

CHAPTER 16 REVIEW QUESTIONS AND PROBLEMS

1. Laurent series generalize Taylor series. Explain the details.
2. Can a function have several Laurent series with the same center? Explain. If your answer is yes, give examples.
3. What is the principal part of a Laurent series? Its significance?
4. What is a pole? An essential singularity? Give examples.
5. What is Picard's theorem? Why did it occur in this chapter?
6. What is the Riemann sphere? The extended complex plane? Its significance?
7. Is e^{1/z^2} analytic or singular at infinity? $\cosh z$? $(z-4)^3$? Explain.
8. What is the residue? Why is it important?
9. State formulas for residues from memory.
10. State some further methods for calculating residues.
11. What is residue integration? To what kind of complex integrals does it apply?
12. By what idea can we apply residue integration to real integrals from $-\infty$ to ∞? Give simple examples.
13. What is a zero of an analytic function? How are zeros classified?
14. What are improper integrals? Cauchy principal values? Give examples.
15. Can the residue at a singular point be 0? At a simple pole?
16. What is a meromorphic function? An entire function? Give examples.

17–28 COMPLEX INTEGRALS

Integrate counterclockwise around C. (Show the details.)

17. $\dfrac{\tan z}{z^4}$, C: $|z| = 1$
18. $\dfrac{\sin 2z}{z^4}$, C: $|z| = 1$
19. $\dfrac{10z}{2z + i}$, C: $|z - 2i| = 3$
20. $\dfrac{iz + 1}{z^2 - iz + 2}$, C: $|z - 1| = 3$
21. $\dfrac{\cosh 5z}{z^2 + 4}$, C: $|z - i| = 2$
22. $\dfrac{4z^3 + 7z}{\cos z}$, C: $|z + 1| = 1$
23. $\cot 8z$, C: $|z| = 0.2$
24. $\dfrac{z^2 \sin z}{4z^2 - 1}$, C: $|z - 1| = 2$
25. $\dfrac{\cos z}{z^n}$, $n = 1, 2, \cdots$, C: $|z| = 1$
26. $\dfrac{z^2 + 1}{z^2 - 2z}$, C: $\dfrac{1}{2}x^2 + y^2 = 1$
27. $\dfrac{15z + 9}{z^3 - 9z}$, C: $|z - 3| = 2$
28. $\dfrac{15z + 9}{z^3 - 9z}$, C: $|z| = 4$

29–35 REAL INTEGRALS

Evaluate by the methods of this chapter (showing the details):

29. $\displaystyle\int_0^{2\pi} \frac{d\theta}{25 - 24\cos\theta}$
30. $\displaystyle\int_0^{\pi} \frac{d\theta}{k + \cos\theta}$, $k > 1$
31. $\displaystyle\int_0^{2\pi} \frac{d\theta}{1 - \frac{1}{2}\sin\theta}$
32. $\displaystyle\int_0^{2\pi} \frac{\sin\theta}{3 + \cos\theta}\, d\theta$
33. $\displaystyle\int_{-\infty}^{\infty} \frac{x}{(1 + x^2)^2}\, dx$
34. $\displaystyle\int_0^{\infty} \frac{dx}{(1 + x^2)^2}$
35. $\displaystyle\int_0^{\infty} \frac{1 + 2x^2}{1 + 4x^4}\, dx$
36. Obtain the answer to Prob. 18 in Sec. 16.4 from the present Prob. 35.

SUMMARY OF CHAPTER 16
Laurent Series. Residue Integration

A **Laurent series** is a series of the form

$$(1) \qquad f(z) = \sum_{n=0}^{\infty} a_n(z - z_0)^n + \sum_{n=1}^{\infty} \frac{b_n}{(z - z_0)^n} \qquad \text{(Sec. 16.1)}$$

or, more briefly written [but this means the same as (1)!]

$$(1^*) \qquad f(z) = \sum_{n=-\infty}^{\infty} a_n(z - z_0)^n, \qquad a_n = \frac{1}{2\pi i} \oint_C \frac{f(z^*)}{(z^* - z_0)^{n+1}}\, dz^*$$

where $n = 0, \pm 1, \pm 2, \cdots$. This series converges in an open annulus (ring) A with center z_0. In A the function $f(z)$ is analytic. At points not in A it may have singularities. The first series in (1) is a power series. In a given annulus, a Laurent series of $f(z)$ is unique, but $f(z)$ may have different Laurent series in different annuli with the same center.

Of particular importance is the Laurent series (1) that converges in a neighborhood of z_0 except at z_0 itself, say, for $0 < |z - z_0| < R$ ($R > 0$, suitable). The series (or finite sum) of the negative powers in this Laurent series is called the **principal part** of $f(z)$ at z_0. The coefficient b_1 of $1/(z - z_0)$ in this series is called the **residue** of $f(z)$ at z_0 and is given by [see (1) and (1*)]

$$(2) \quad b_1 = \operatorname*{Res}_{z=z_0} f(z) = \frac{1}{2\pi i} \oint_C f(z^*)\, dz^*. \qquad \text{Thus} \qquad \oint_C f(z^*)\, dz^* = 2\pi i \operatorname*{Res}_{z=z_0} f(z).$$

b_1 can be used for **integration** as shown in (2) because it can be found from

$$(3) \qquad \operatorname*{Res}_{z=z_0} f(z) = \frac{1}{(m-1)!} \lim_{z \to z_0} \left(\frac{d^{m-1}}{dz^{m-1}} \left[(z - z_0)^m f(z) \right] \right), \qquad \text{(Sec. 16.3),}$$

provided $f(z)$ has at z_0 a **pole of order *m*;** by definition this means that that principal part has $1/(z - z_0)^m$ as its highest negative power. Thus for a simple pole ($m = 1$),

$$\operatorname*{Res}_{z=z_0} f(z) = \lim_{z \to z_0} (z - z_0) f(z); \qquad \text{also,} \qquad \operatorname*{Res}_{z=z_0} \frac{p(z)}{q(z)} = \frac{p(z_0)}{q'(z_0)}.$$

If the principal part is an infinite series, the singularity of $f(z)$ at z_0 is called an **essential singularity** (Sec. 16.2).

Section 16.2 also discusses the *extended complex plane,* that is, the complex plane with an improper point ∞ ("infinity") attached.

Residue integration may also be used to evaluate certain classes of complicated real integrals (Sec. 16.4).

CHAPTER 17

Conformal Mapping

If a complex function $w = f(z)$ is defined in a domain D of the z-plane, then to each point in D there corresponds a point in the w-plane. In this way we obtain a **mapping** of D onto the range of values of $f(z)$ in the w-plane. We shall see that if $f(z)$ is an *analytic* function, then the mapping given by $w = f(z)$ is **conformal** (angle-preserving), except at points where the derivative $f'(z)$ is zero.

Conformality appeared early in history in connection with constructing maps of the globe, which can be conformal (can give directions correctly) or "equiareal" (give areas correctly, except for a scale factor), but cannot have both properties, as can be proved (see [GR8] in App. 1).

Conformality is the most important geometric property of analytic functions and gives the possibility of a geometric approach to complex analysis. Indeed, just as in calculus we use curves of real functions $y = f(x)$ for studying "geometric" properties of functions, in complex analysis we can use conformal mappings for obtaining a deeper understanding of properties of functions, notably of those discussed in Chap. 13.

Indeed, we shall first define the concepts of conformal mapping and then consider mappings by those elementary analytic functions in Chap. 13.

This is one purpose of this chapter. A second purpose, more important to the engineer and physicist, is the use of conformal mapping in connection with potential problems. In fact, in this chapter and in the next one we shall see that conformal mapping yields a standard method for solving **boundary value problems** in (two-dimensional) potential theory by transforming a complicated region into a simpler one. Corresponding applications will concern problems from electrostatics, heat flow, and fluid flow.

In the last section (17.5) we explain the concept of a **Riemann surface,** which fits well into the present discussion of "geometric" ideas.

Prerequisite: Chap. 13.
Sections that may be omitted in a shorter course: 17.3 and 17.5
References and Answers to Problems: App. 1 Part D, App. 2.

17.1 Geometry of Analytic Functions: Conformal Mapping

A complex function

$$w = f(z) = u(x, y) + iv(x, y) \qquad (z = x + iy) \tag{1}$$

of a complex variable z gives a **mapping** of its domain of definition D in the complex z-plane ***into*** the complex w-plane or ***onto*** its range of values in that plane.[1] For any point z_0 in D the point $w_0 = f(z_0)$ is called the **image** of z_0 with respect to f. More generally, for the points of a curve C in D the image points form the **image** of C; similarly for other point sets in D. Also, instead of *the mapping by a function* $w = f(z)$ we shall say more briefly ***the mapping*** $w = f(z)$.

EXAMPLE 1 **Mapping $w = f(z) = z^2$**

Using polar forms $z = re^{i\theta}$ and $w = Re^{i\phi}$, we have $w = z^2 = r^2e^{2i\theta}$. Comparing moduli and arguments gives $R = r^2$ and $\phi = 2\theta$. Hence circles $r = r_0$ are mapped onto circles $R = {r_0}^2$ and rays $\theta = \theta_0$ onto rays $\phi = 2\theta_0$. Figure 375 shows this for the region $1 \leqq |z| \leqq 3/2$, $\pi/6 \leqq \theta \leqq \pi/3$, which is mapped onto the region $1 \leqq |w| \leqq 9/4$, $\pi/3 \leqq \theta \leqq 2\pi/3$.

In Cartesian coordinates we have $z = x + iy$ and

$$u = \text{Re}\,(z^2) = x^2 - y^2, \qquad v = \text{Im}\,(z^2) = 2xy.$$

Hence vertical lines $x = c = const$ are mapped onto $u = c^2 - y^2$, $v = 2cy$. From this we can eliminate y. We obtain $y^2 = c^2 - u$ and $v^2 = 4c^2y^2$. Together,

$$v^2 = 4c^2(c^2 - u) \qquad \text{(Fig. 376).}$$

These parabolas open to the left. Similarly, horizontal lines $y = k = const$ are mapped onto parabolas opening to the right,

$$v^2 = 4k^2(k^2 + u) \qquad \text{(Fig. 376).}$$ ■

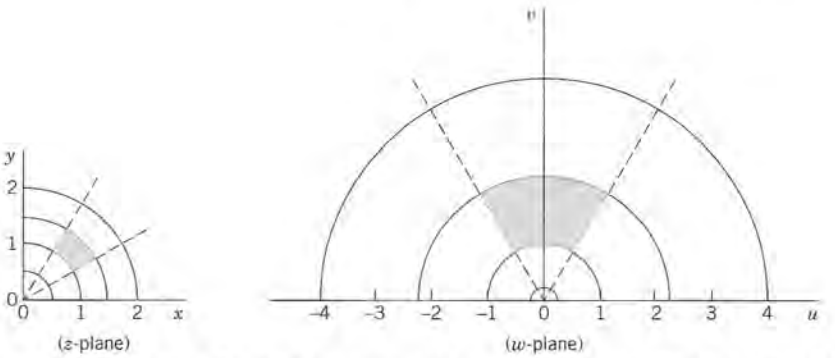

Fig. 375. Mapping $w = z^2$. Lines $|z| = const$, $\arg z = const$ and their images in the w-plane

[1]The general terminology is as follows. A mapping of a set A into a set B is called **surjective** or a mapping of A **onto** B if every element of B is the image of at least one element of A. It is called **injective** or **one-to-one** if different elements of A have different images in B. Finally, it is called **bijective** if it is both surjective and injective.

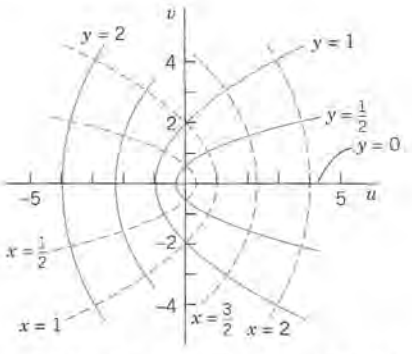

Fig. 376. Images of $x = const$, $y = const$ under $w = z^2$

Conformal Mapping

A mapping $w = f(z)$ is called **conformal** if it preserves angles between oriented curves in magnitude as well as in sense. Figure 377 shows what this means. The **angle** α $(0 \leqq \alpha \leqq \pi)$ between two intersecting curves C_1 and C_2 is defined to be the angle between their oriented tangents at the intersection point z_0. And *conformality* means that the images C_1^* and C_2^* of C_1 and C_2 make the same angle as the curves themselves in both magnitude and direction.

THEOREM 1

Conformality of Mapping by Analytic Functions

The mapping $w = f(z)$ by an analytic function f is conformal, except at **critical points,** *that is, points at which the derivative f' is zero.*

PROOF $w = z^2$ has a critical point at $z = 0$, where $f'(z) = 2z = 0$ and the angles are doubled (see Fig. 375), so that conformality fails.

The idea of proof is to consider a curve

$$C: z(t) = x(t) + iy(t) \tag{2}$$

in the domain of $f(z)$ and to show that $w = f(z)$ rotates all tangents at a point z_0 (where $f'(z_0) \neq 0$) through the same angle. Now $\dot{z}(t) = dz/dt = \dot{x}(t) + i\,\dot{y}(t)$ is tangent to C in (2) because this is the limit of $(z_1 - z_0)/\Delta t$ (which has the direction of the secant $z_1 - z_0$

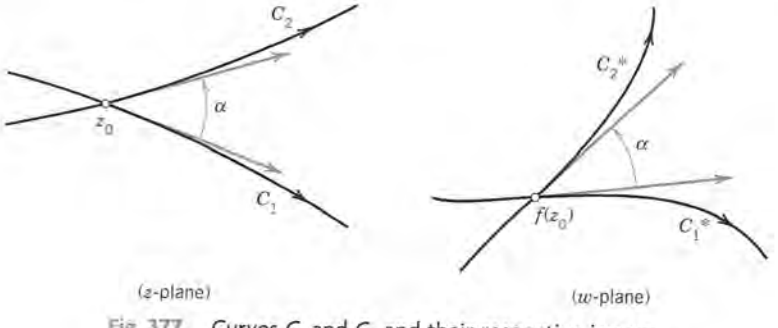

Fig. 377. Curves C_1 and C_2 and their respective images C_1^* and C_2^* under a conformal mapping $w = f(z)$

in Fig. 378) as z_1 approaches z_0 along C. The image C^* of C is $w = f(z(t))$. By the chain rule, $\dot{w} = f'(z(t))\dot{z}(t)$. Hence the tangent direction of C^* is given by the argument (use (9) in Sec. 13.2)

$$\arg \dot{w} = \arg f' + \arg \dot{z} \tag{3}$$

where $\arg \dot{z}$ gives the tangent direction of C. This shows that the mapping rotates *all* directions at a point z_0 in the domain of analyticity of f through the same angle $\arg f'(z_0)$, which exists as long as $f'(z_0) \neq 0$. But this means conformality, as Fig. 377 illustrates for an angle α between two curves, whose images C_1^* and C_2^* make the same angle (because of the rotation). ■

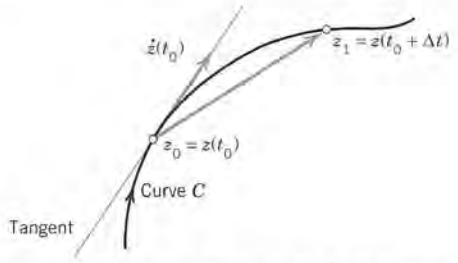

Fig. 378. Secant and tangent of the curve C

In the remainder of this section and in the next ones we shall consider various conformal mappings that are of practical interest, for instance, in modeling potential problems.

EXAMPLE 2 Conformality of $w = z^n$

The mapping $w = z^n$, $n = 2, 3, \cdots$, is conformal, except at $z = 0$, where $w' = nz^{n-1} = 0$. For $n = 2$ this is shown in Fig. 375; we see that at 0 the angles are doubled. For general n the angles at 0 are multiplied by a factor n under the mapping. Hence the sector $0 \leqq \theta \leqq \pi/n$ is mapped by z^n onto the upper half-plane $v \geqq 0$ (Fig. 379). ■

Fig. 379. Mapping by $w = z^n$

EXAMPLE 3 Mapping $w = z + 1/z$. Joukowski Airfoil

In terms of polar coordinates this mapping is

$$w = u + iv = r(\cos\theta + i\sin\theta) + \frac{1}{r}(\cos\theta - i\sin\theta).$$

By separating the real and imaginary parts we thus obtain

$$u = a\cos\theta, \qquad v = b\sin\theta \qquad \text{where} \qquad a = r + \frac{1}{r}, \quad b = r - \frac{1}{r}.$$

Hence circles $|z| = r = const \neq 1$ are mapped onto ellipses $x^2/a^2 + y^2/b^2 = 1$. The circle $r = 1$ is mapped onto the segment $-2 \leqq u \leqq 2$ of the u-axis. See Fig. 380.

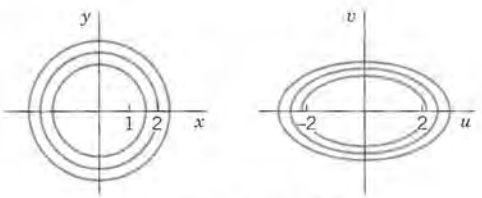

Fig. 380. Example 3

Now the derivative of w is

$$w' = 1 - \frac{1}{z^2} = \frac{(z+1)(z-1)}{z^2}$$

which is 0 at $z = \pm 1$. These are the points at which the mapping is not conformal. The two circles in Fig. 381 pass through $z = -1$. The larger is mapped onto a *Joukowski airfoil*. The dashed circle passes through both -1 and 1 and is mapped onto a curved segment.

Another interesting application of $w = z + 1/z$ (the flow around a cylinder) will be considered in Sec. 18.4. ■

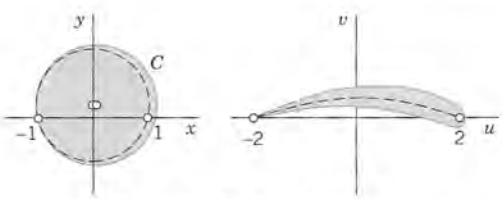

Fig. 381. Joukowski airfoil

EXAMPLE 4 Conformality of $w = e^z$

From (10) in Sec. 13.5 we have $|e^z| = e^x$ and Arg $z = y$. Hence e^z maps a vertical straight line $x = x_0 = const$ onto the circle $|w| = e^{x_0}$ and a horizontal straight line $y = y_0 = const$ onto the ray arg $w = y_0$. The rectangle in Fig. 382 is mapped onto a region bounded by circles and rays as shown.

The fundamental region $-\pi < \text{Arg } z \leqq \pi$ of e^z in the z-plane is mapped bijectively and conformally onto the entire w-plane without the origin $w = 0$ (because $e^z = 0$ for no z). Figure 383 shows that the upper half $0 < y \leqq \pi$ of the fundamental region is mapped onto the upper half-plane $0 < \arg w \leqq \pi$, the left half being mapped inside the unit disk $|w| \leqq 1$ and the right half outside (why?). ■

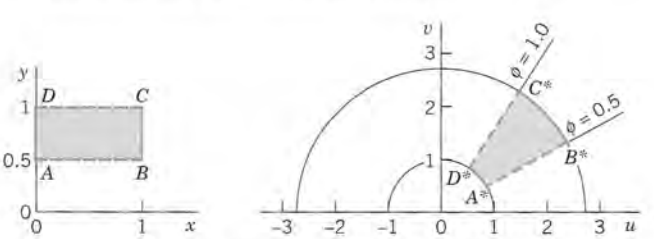

Fig. 382. Mapping by $w = e^z$

Fig. 383. Mapping by $w = e^z$

EXAMPLE 5 **Principle of Inverse Mapping. Mapping $w = \operatorname{Ln} z$**

Principle. *The mapping by the inverse $z = f^{-1}(w)$ of $w = f(z)$ is obtained by interchanging the roles of the z-plane and the w-plane in the mapping by $w = f(z)$.*

Now the principal value $w = f(z) = \operatorname{Ln} z$ of the natural logarithm has the inverse $z = f^{-1}(w) = e^w$. From Example 4 (with the notations z and w interchanged!) we know that $f^{-1}(w) = e^w$ maps the fundamental region of the exponential function onto the z-plane without $z = 0$ (because $e^w \neq 0$ for every w). Hence $w = f(z) = \operatorname{Ln} z$ maps the z-plane without the origin and cut along the negative real axis (where $\theta = \operatorname{Im} \operatorname{Ln} z$ jumps by 2π) conformally onto the horizontal strip $-\pi < v \leqq \pi$ of the w-plane, where $w = u + iv$.

Since the mapping $w = \operatorname{Ln} z + 2\pi i$ differs from $w = \operatorname{Ln} z$ by the translation $2\pi i$ (vertically upward), this function maps the z-plane (cut as before and 0 omitted) onto the strip $\pi < v \leqq 3\pi$. Similarly for each of the infinitely many mappings $w = \ln z = \operatorname{Ln} z \pm 2n\pi i$ ($n = 0, 1, 2, \cdots$). The corresponding horizontal strips of width 2π (images of the z-plane under these mappings) together cover the whole w-plane without overlapping. ■

Magnification Ratio. By the definition of the derivative we have

$$\lim_{z \to z_0} \left| \frac{f(z) - f(z_0)}{z - z_0} \right| = |f'(z_0)|. \tag{4}$$

Therefore, the mapping $w = f(z)$ magnifies (or shortens) the lengths of short lines by approximately the factor $|f'(z_0)|$. The image of a small figure ***conforms*** to the original figure in the sense that it has approximately the same shape. However, since $f'(z)$ varies from point to point, a *large* figure may have an image whose shape is quite different from that of the original figure.

More on the Condition $f'(z) \neq 0$. From (4) in Sec. 13.4 and the Cauchy–Riemann equations we obtain

$$|f'(z)|^2 = \left| \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \right|^2 = \left(\frac{\partial u}{\partial x} \right)^2 + \left(\frac{\partial v}{\partial x} \right)^2 = \frac{\partial u}{\partial x} \frac{\partial v}{\partial y} - \frac{\partial u}{\partial y} \frac{\partial v}{\partial x} \tag{5'}$$

that is,

$$|f'(z)|^2 = \begin{vmatrix} \dfrac{\partial u}{\partial x} & \dfrac{\partial u}{\partial y} \\ \dfrac{\partial v}{\partial x} & \dfrac{\partial v}{\partial y} \end{vmatrix} = \frac{\partial(u, v)}{\partial(x, y)}. \tag{5}$$

This determinant is the so-called **Jacobian** (Sec. 10.3) of the transformation $w = f(z)$ written in real form $u = u(x, y)$, $v = v(x, y)$. Hence $f'(z_0) \neq 0$ implies that the Jacobian is not 0 at z_0. This condition is sufficient that the mapping $w = f(z)$ in a sufficiently small neighborhood of z_0 is one-to-one or injective (different points have different images). See Ref. [GR4] in App. 1.

PROBLEM SET 17.1

1. Verify all calculations in Example 1.
2. Why do the images of the curves $|z| = const$ and $\arg z = const$ under a mapping by an analytic function $f(z)$ intersect at right angles, except at points at which $f'(z) = 0$?
3. Does the mapping $w = \bar{z} = x - iy$ preserve angles in size as well as in sense?

4–6 MAPPING OF CURVES

Find and sketch or graph the image of the given curves under the given mapping.

4. $x = 1, 2, 3, 4$, $y = 1, 2, 3, 4$; $w = z^2$
5. Curves as in Prob. 4, $w = iz$ **(Rotation)**
6. $|z| = 1/3, 1/2, 1, 2, 3$; $\operatorname{Arg} z = 0, \pm\pi/4, \pm\pi/2, \pm 3\pi/2, \pm\pi$; $w = 1/z$

7–15 MAPPING OF REGIONS

Find and sketch or graph the image of the given region under the given mapping.

7. $-\pi/4 < \operatorname{Arg} z < \pi/4$, $|z| < 1/2$, $w = z^3$

8. $x \geqq 1$, $w = 1/z$

9. $|z| > 1$, $w = 3z$

10. $\operatorname{Im} z > 0$, $w = 1 - z$

11. $x \geqq 0$, $y \geqq 0$, $|z| \leqq 4$; $w = z^2$

12. $-1 \leqq x \leqq 1$, $-\pi < y < \pi$; $w = e^z$

13. $\ln 3 < x < \ln 5$, $w = e^z$

14. $-\pi < y \leqq 3\pi$, $w = e^z$

15. $2 \leqq |z| \leqq 3$, $\pi/4 \leqq \theta \leqq \pi/2$; $w = \operatorname{Ln} z$

16. CAS EXPERIMENT. Orthogonal Nets. Graph the orthogonal net of the two families of level curves $\operatorname{Re} f(z) = const$ and $\operatorname{Im} f(z) = const$, where (a) $f(z) = z^4$, (b) $f(z) = 1/z$, (c) $f(z) = 1/z^2$, (d) $f(z) = (z + i)/(1 + iz)$. Why do these curves generally intersect at right angles? In your work, experiment to get the best possible graphs. Also do the same for other functions of your own choice. Observe and record shortcomings of your CAS and means to overcome such deficiencies.

17–23 FAILURE OF CONFORMALITY

Find all points at which the following mappings are not conformal.

17. $z(z^4 - 5)$

18. $z^2 + 1/z^2$

19. $\cos \pi z$

20. $\cosh 2z$

21. $z^2 + az + b$

22. $\exp(z^5 - 80z)$

23. $(z - a)^3$, $(z^3 - a)^2$

24–28 MAGNIFICATION RATIO, JACOBIAN

Find the magnification ratio M. Describe what it tells you about the mapping. Where is M equal to 1? Find the Jacobian J.

24. $w = \frac{1}{2}z^2$

25. $w = e^z$

26. $w = z^3$

27. $w = \operatorname{Ln} z$

28. $w = 1/z$

29. Magnification of Angles. Let $f(z)$ be analytic at z_0. Suppose that $f'(z_0) = 0, \cdots, f^{(k-1)}(z_0) = 0$. Then the mapping $w = f(z)$ magnifies angles with vertex at z_0 by a factor k. Illustrate this with examples for $k = 2, 3, 4$.

30. Prove the statement in Prob. 29 for general $k = 1, 2, \cdots$. *Hint.* Use the Taylor series.

17.2 Linear Fractional Transformations

Conformal mappings can help in modeling and solving boundary value problems by first mapping regions conformally onto another. We shall explain this for standard regions (disks, half-planes, strips) in the next section. For this it is useful to know properties of special basic mappings. Accordingly, let us begin with the following very important class.

Linear fractional transformations (or **Möbius transformations**) are mappings

$$(1) \qquad w = \frac{az + b}{cz + d} \qquad (ad - bc \neq 0)$$

where a, b, c, d are complex or real numbers. Differentiation gives

$$(2) \qquad w' = \frac{a(cz + d) - c(az + b)}{(cz + d)^2} = \frac{ad - bc}{(cz + d)^2}.$$

This motivates our requirement $ad - bc \neq 0$. It implies conformality for all z and excludes the totally uninteresting case $w' \equiv 0$ once and for all. Special cases of (1) are

$$(3) \qquad \begin{aligned} &w = z + b && \textit{(Translations)} \\ &w = az \quad \text{with } |a| = 1 && \textit{(Rotations)} \\ &w = az + b && \textit{(Linear transformations)} \\ &w = 1/z && \textit{(Inversion in the unit circle).} \end{aligned}$$

EXAMPLE 1 **Properties of the Inversion $w = 1/z$ (Fig. 384)**

In polar forms $z = re^{i\theta}$ and $w = Re^{i\phi}$ the inversion $w = 1/z$ is

$$Re^{i\phi} = \frac{1}{re^{i\theta}} = \frac{1}{r}\,e^{-i\theta} \qquad \text{and gives} \qquad R = \frac{1}{r}, \qquad \phi = -\theta.$$

Hence the unit circle $|z| = r = 1$ is mapped onto the unit circle $|w| = R = 1$; $w = e^{i\phi} = e^{-i\theta}$. For a general z the image $w = 1/z$ can be found geometrically by marking $|w| = R = 1/r$ on the segment from 0 to z and then reflecting the mark in the real axis. (Make a sketch.)

Figure 384 shows that $w = 1/z$ maps horizontal and vertical straight lines onto circles or straight lines. Even the following is true.

$w = 1/z$ maps every straight line or circle onto a circle or straight line.

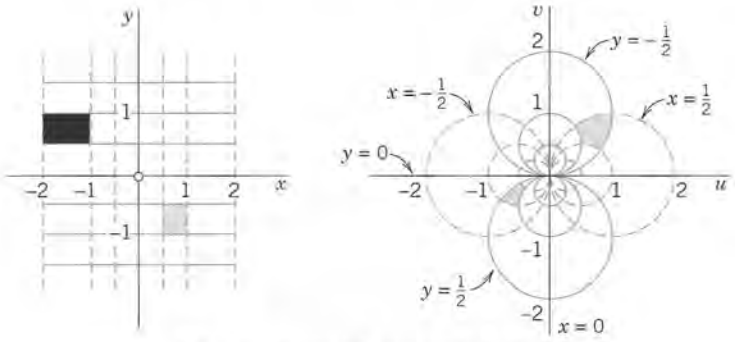

Fig. 384. Mapping (Inversion) $w = 1/z$

Proof. Every straight line or circle in the z-plane can be written

$$A(x^2 + y^2) + Bx + Cy + D = 0 \qquad (A, B, C, D \text{ real}).$$

$A = 0$ gives a straight line and $A \neq 0$ a circle. In terms of z and $\bar{z}$ this equation becomes

$$Az\bar{z} + B\frac{z + \bar{z}}{2} + C\frac{z - \bar{z}}{2i} + D = 0.$$

Now $w = 1/z$. Substitution of $z = 1/w$ and multiplication by $w\bar{w}$ gives the equation

$$A + B\frac{\bar{w} + w}{2} + C\frac{\bar{w} - w}{2i} + Dw\bar{w} = 0$$

or, in terms of u and v,

$$A + Bu - Cv + D(u^2 + v^2) = 0.$$

This represents a circle (if $D \neq 0$) or a straight line (if $D = 0$) in the w-plane. ■

The proof in this example suggests the use of z and $\bar{z}$ instead of x and y, a ***general principle*** that is often quite useful in practice.

Surprisingly, *every* linear fractional transformation has the property just proved:

THEOREM 1

Circles and Straight Lines

Every linear fractional transformation (1) *maps the totality of circles and straight lines in the z-plane onto the totality of circles and straight lines in the w-plane.*

PROOF This is trivial for a translation or rotation, fairly obvious for a uniform expansion or contraction, and true for $w = 1/z$, as just proved. Hence it also holds for composites of these special mappings. Now comes the key idea of the proof: represent (1) in terms of these special mappings. When $c = 0$, this is easy. When $c \neq 0$, the representation is

$$w = K\frac{1}{cz + d} + \frac{a}{c} \qquad \text{where} \qquad K = -\frac{ad - bc}{c}.$$

This can be verified by substituting K, taking the common denominator and simplifying; this yields (1). We can now set

$$w_1 = cz, \qquad w_2 = w_1 + d, \qquad w_3 = \frac{1}{w_2}, \qquad w_4 = Kw_3,$$

and see from the previous formula that then $w = w_4 + a/c$. This tells us that (1) is indeed a composite of those special mappings and completes the proof. ■

Extended Complex Plane

The extended complex plane (the complex plane together with the point ∞ in Sec. 16.2) can now be motivated even more naturally by linear fractional transformations as follows.

To each z for which $cz + d \neq 0$ there corresponds a unique w in (1). Now let $c \neq 0$. Then for $z = -d/c$ we have $cz + d = 0$, so that no w corresponds to this z. This suggests that we let $w = \infty$ be the image of $z = -d/c$.

Also, the **inverse mapping** of (1) is obtained by solving (1) for z; this gives again a linear fractional transformation

$$\textbf{(4)} \qquad z = \frac{dw - b}{-cw + a}.$$

When $c \neq 0$, then $cw - a = 0$ for $w = a/c$, and we let a/c be the image of $z = \infty$. With these settings, the linear fractional transformation (1) is now a one-to-one mapping of the extended z-plane onto the extended w-plane. We also say that every linear fractional transformation maps "the extended complex plane in a one-to-one manner onto itself."

Our discussion suggests the following.

General Remark. If $z = \infty$, then the right side of (1) becomes the meaningless expression $(a \cdot \infty + b)/(c \cdot \infty + d)$. We assign to it the value $w = a/c$ if $c \neq 0$ and $w = \infty$ if $c = 0$.

Fixed Points

Fixed points of a mapping $w = f(z)$ are points that are mapped onto themselves, are "kept fixed" under the mapping. Thus they are obtained from

$$w = f(z) = z.$$

The **identity mapping** $w = z$ has every point as a fixed point. The mapping $w = \bar{z}$ has infinitely many fixed points, $w = 1/z$ has two, a rotation has one, and a translation none in the finite plane. (Find them in each case.) For (1), the fixed-point condition $w = z$ is

$$(5) \qquad z = \frac{az + b}{cz + d}, \qquad \text{thus} \qquad cz^2 - (a - d)z - b = 0.$$

This is a quadratic equation in z whose coefficients all vanish if and only if the mapping is the identity mapping $w = z$ (in this case, $a = d \neq 0$, $b = c = 0$). Hence we have

THEOREM 2

Fixed Points

A linear fractional transformation, not the identity, has at most two fixed points. If a linear fractional transformation is known to have three or more fixed points, it must be the identity mapping $w = z$.

To make our present general discussion of linear fractional transformations even more useful from a practical point of view, we extend it by further facts and typical examples, in the problem set as well as in the next section.

PROBLEM SET 17.2

1. Verify the calculations in the proof of Theorem 1.
2. **(Composition of LFTs)** Show that substituting a linear fractional transformation (LFT) into a LFT gives a LFT.
3. **(Matrices)** If you are familiar with 2×2 matrices, prove that the coefficient matrices of (1) and (4) are inverses of each other, provided $ad - bc = 1$, and that the composition of LFTs corresponds to the multiplication of the coefficient matrices.

4–7 INVERSE

Find the inverse $z = z(w)$. Check the result by solving $z(w)$ for w.

4. $w = \dfrac{4z + i}{-3iz + 1}$
5. $w = \dfrac{3z}{2z - i}$
6. $w = \dfrac{z + i}{z - i}$
7. $w = \dfrac{2z + 5i}{4z}$

8–14 FIXED POINTS

Find the fixed points.

8. $w = 81z^5$
9. $w = (4 + i)z$
10. $w = z + 4i$
11. $w = (z - i)^2$
12. $w = \dfrac{z - 1}{z + 1}$
13. $w = \dfrac{2iz - 1}{z + 2i}$
14. $w = \dfrac{3z + 2}{z - 1}$

15. Find a LFT whose (only) fixed points are -2 and 2.
16. Find a LFT (not $w = z$) with fixed points 0 and 1.
17. Find all LFTs with fixed points -1 and 1.
18. Find all LFTs whose only fixed point is 0.
19. Find all LFTs with fixed points 0 and ∞.
20. Find all LFTs without fixed points in the finite plane.

17.3 Special Linear Fractional Transformations

In this section we shall see how to determine linear fractional transformations

$$(1) \qquad w = \frac{az + b}{cz + d} \qquad (ad - bc \neq 0)$$

for mapping certain standard domains onto others and how to discuss properties of (1).

A mapping (1) is determined by a, b, c, d, actually by the ratios of three of these constants to the fourth because we can drop or introduce a common factor. This makes it plausible that three conditions determine a unique mapping (1):

THEOREM 1

Three Points and Their Images Given

Three given distinct points z_1, z_2, z_3 can always be mapped onto three prescribed distinct points w_1, w_2, w_3 by one, and only one, linear fractional transformation $w = f(z)$. This mapping is given implicitly by the equation

$$\frac{w - w_1}{w - w_3} \cdot \frac{w_2 - w_3}{w_2 - w_1} = \frac{z - z_1}{z - z_3} \cdot \frac{z_2 - z_3}{z_2 - z_1}. \tag{2}$$

(If one of these points is the point ∞, the quotient of the two differences containing this point must be replaced by 1.)

PROOF Equation (2) is of the form $F(w) = G(z)$ with linear fractional F and G. Hence $w = F^{-1}(G(z)) = f(z)$, where F^{-1} is the inverse of F and is linear fractional (see (4) in Sec. 17.2) and so is the composite $F^{-1}(G(z))$ (by Prob. 21), that is, $w = f(z)$ is linear fractional. Now if in (2) we set $w = w_1, w_2, w_3$ on the left and $z = z_1, z_2, z_3$ on the right, we see that

$$F(w_1) = 0, \qquad F(w_2) = 1, \qquad F(w_3) = \infty$$
$$G(z_1) = 0, \qquad G(z_2) = 1, \qquad G(z_3) = \infty.$$

From the first column, $F(w_1) = G(z_1)$, thus $w_1 = F^{-1}(G(z_1)) = f(z_1)$. Similarly, $w_2 = f(z_2)$, $w_3 = f(z_3)$. This proves the existence of the desired linear fractional transformation.

To prove uniqueness, let $w = g(z)$ be a linear fractional transformation, which also maps z_j onto w_j, $j = 1, 2, 3$. Thus $w_j = g(z_j)$. Hence $g^{-1}(w_j) = z_j$, where $w_j = f(z_j)$. Together, $g^{-1}(f(z_j)) = z_j$, a mapping with the three fixed points z_1, z_2, z_3. By Theorem 2 in Sec. 17.2, this is the identity mapping, $g^{-1}(f(z)) = z$ for all z. Thus $f(z) = g(z)$ for all z, the uniqueness.

The last statement of Theorem 1 follows from the General Remark in Sec. 17.2. ■

Mapping of Standard Domains by Theorem 1

Using Theorem 1, we can now find linear fractional transformations according to the following

Principle. Prescribe three boundary points z_1, z_2, z_3 of the domain D in the z-plane. Choose their images w_1, w_2, w_3 on the boundary of the image D^* of D in the w-plane. Obtain the mapping from (2). Make sure that D is mapped onto D^*, not onto its complement. In the latter case, interchange two w-points. (Why does this help?)

EXAMPLE 1 **Mapping of a Half-Plane onto a Disk (Fig. 385)**

Find the linear fractional transformation (1) that maps $z_1 = -1$, $z_2 = 0$, $z_3 = 1$ onto $w_1 = -1$, $w_2 = -i$, $w_3 = 1$, respectively.

Solution. From (2) we obtain

$$\frac{w - (-1)}{w - 1} \cdot \frac{-i - 1}{-i - (-1)} = \frac{z - (-1)}{z - 1} \cdot \frac{0 - 1}{0 - (-1)},$$

thus

$$w = \frac{z - i}{-iz + 1}.$$

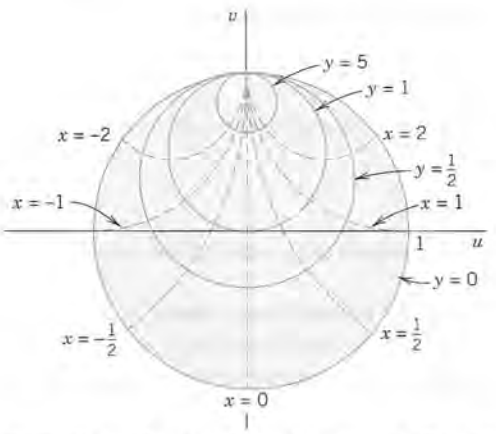

Fig. 385. Linear fractional transformation in Example 1

Let us show that we can determine the specific properties of such a mapping without much calculation. For $z = x$ we have $w = (x - i)/(-ix + 1)$, thus $|w| = 1$, so that the x-axis maps onto the unit circle. Since $z = i$ gives $w = 0$, the upper half-plane maps onto the interior of that circle and the lower half-plane onto the exterior. $z = 0, i, \infty$ go onto $w = -i, 0, i$, so that the positive imaginary axis maps onto the segment S: $u = 0$, $-1 \leqq v \leqq 1$. The vertical lines $x = const$ map onto circles (by Theorem 1, Sec. 17.2) through $w = i$ (the image of $z = \infty$) and perpendicular to $|w| = 1$ (by conformality; see Fig. 385). Similarly, the horizontal lines $y = const$ map onto circles through $w = i$ and perpendicular to S (by conformality). Figure 385 gives these circles for $y \geqq 0$, and for $y < 0$ they lie outside the unit disk shown. ■

EXAMPLE 2 Occurrence of ∞

Determine the linear fractional transformation that maps $z_1 = 0$, $z_2 = 1$, $z_3 = \infty$ onto $w_1 = -1$, $w_2 = -i$, $w_3 = 1$, respectively.

Solution. From (2) we obtain the desired mapping

$$w = \frac{z - i}{z + i}.$$

This is sometimes called the *Cayley transformation.*[2] In this case, (2) gave at first the quotient $(1 - \infty)/(z - \infty)$, which we had to replace by 1. ■

EXAMPLE 3 Mapping of a Disk onto a Half-Plane

Find the linear fractional transformation that maps $z_1 = -1$, $z_2 = i$, $z_3 = 1$ onto $w_1 = 0$, $w_2 = i$, $w_3 = \infty$, respectively, such that the unit disk is mapped onto the right half-plane. (Sketch disk and half-plane.)

Solution. From (2) we obtain, after replacing $(i - \infty)/(w - \infty)$ by 1,

$$w = -\frac{z + 1}{z - 1}. \quad ■$$

Mapping half-planes onto half-planes is another task of practical interest. For instance, we may wish to map the upper half-plane $y \geqq 0$ onto the upper half-plane $v \geqq 0$. Then the x-axis must be mapped onto the u-axis.

[2]ARTHUR CAYLEY (1821–1895), English mathematician and professor at Cambridge, is known for his important work in algebra, matrix theory, and differential equations.

EXAMPLE 4 Mapping of a Half-Plane onto a Half-Plane

Find the linear fractional transformation that maps $z_1 = -2$, $z_2 = 0$, $z_3 = 2$ onto $w_1 = \infty$, $w_2 = 1/4$, $w_3 = 3/8$, respectively.

Solution. You may verify that (2) gives the mapping function

$$w = \frac{z + 1}{2z + 4}$$

What is the image of the x-axis? Of the y-axis? ■

Mappings of disks onto disks is a third class of practical problems. We may readily verify that the unit disk in the z-plane is mapped onto the unit disk in the w-plane by the following function, which maps z_0 onto the center $w = 0$.

(3)
$$w = \frac{z - z_0}{cz - 1}, \qquad c = \bar{z}_0, \qquad |z_0| < 1.$$

To see this, take $|z| = 1$, obtaining, with $c = \bar{z}_0$ as in (3),

$$\begin{aligned} |z - z_0| &= |\bar{z} - c| \\ &= |z|\,|\bar{z} - c| \\ &= |z\bar{z} - cz| = |1 - cz| = |cz - 1|. \end{aligned}$$

Hence

$$|w| = |z - z_0|/|cz - 1| = 1$$

from (3), so that $|z| = 1$ maps onto $|w| = 1$, as claimed, with z_0 going onto 0, as the numerator in (3) shows.

Formula (3) is illustrated by the following example. Another interesting case will be given in Prob. 10 of Sec. 18.2.

EXAMPLE 5 Mapping of the Unit Disk onto the Unit Disk

Taking $z_0 = \frac{1}{2}$ in (3), we obtain (verify!)

$$w = \frac{2z - 1}{z - 2}$$ (Fig. 386). ■

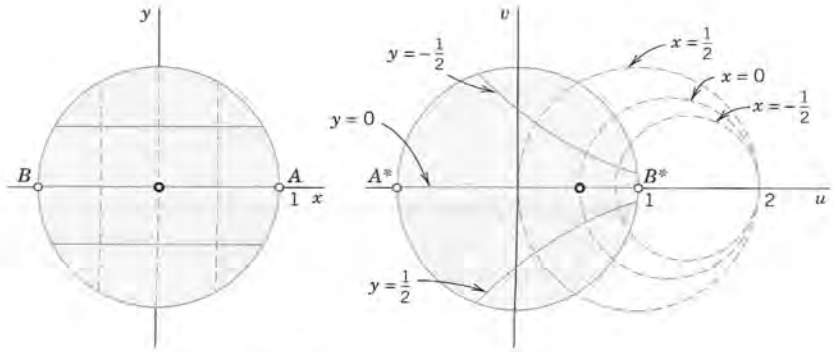

Fig. 386. Mapping in Example 5

EXAMPLE 6 Mapping of an Angular Region onto the Unit Disk

Certain mapping problems can be solved by combining linear fractional transformations with others. For instance, to map the angular region D: $-\pi/6 \leqq \arg z \leqq \pi/6$ (Fig. 387) onto the unit disk $|w| \leqq 1$, we may map D by $Z = z^3$ onto the right Z-half-plane and then the latter onto the disk $|w| \leqq 1$ by

$$w = i\,\frac{Z-1}{Z+1}, \qquad \text{combined} \qquad w = i\,\frac{z^3-1}{z^3+1}.$$

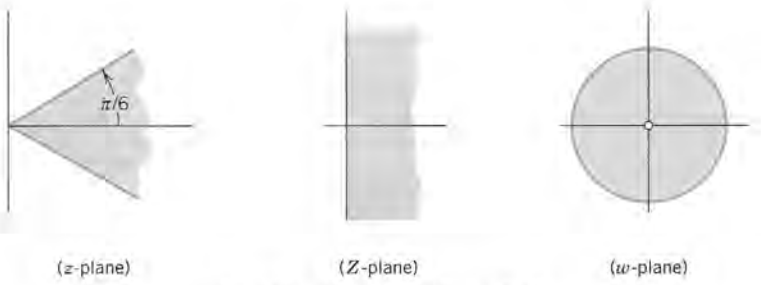

Fig. 387. Mapping in Example 6

This is the end of our discussion of linear fractional transformations. In the next section we turn to conformal mappings by other analytic functions (sine, cosine, etc.).

PROBLEM SET 17.3

1. Derive the mapping in Example 2 from (2).
2. **(Inverse)** Find the inverse of the mapping in Example 1. Show that under that inverse the lines $x = const$ are the images of circles in the w-plane with centers on the line $v = 1$.
3. Verify the formula (3) for disks.
4. Derive the mapping in Example 4 from (2). Find its inverse and prove by calculation that it has the same fixed points as the mapping itself. Is this surprising?
5. **(Inverse)** If $w = f(z)$ is any transformation that has an inverse, prove the (trivial!) fact that f and its inverse have the same fixed points.
6. **CAS EXPERIMENT. Linear Fractional Transformations (LFTs). (a)** Graph typical regions (squares, disks, etc.) and their images under the LFTs in Examples 1–5.
   (b) Make an experimental study of the continuous dependence of LFTs on their coefficients. For instance, change the LFT in Example 4 continuously and graph the changing image of a fixed region (applying animation if available).

7–15 LFTs FROM THREE POINTS AND THEIR IMAGES

Find the LFT that maps the given three points onto the three given points in the respective order.

7. $-1, 0, 1$ onto $-0.6 - 0.8i, -1, -0.6, + 0.8i$
8. $0, 1, 2$ onto $1, \frac{1}{2}, \frac{1}{3}$
9. $2i, -2i, 4$ onto $-4 + 2i, -4 - 2i, 0$
10. $i, -1, 1$ onto $-1, -i, i$
11. $0, 1, \infty$ onto $\infty, 1, 0$
12. $0, -i, i$ onto $-1, 0, \infty$
13. $2i, i, 0$ onto $\frac{5}{2}i, 2i, \infty$
14. $0, 2i, -2i$ onto $-1, 0, \infty$
15. $-1, 0, 1$ onto $0, 1, -1$

16. Find all LFTs $w(z)$ that map the x-axis onto the u-axis.
17. Find a LFT that maps $|z| \leqq 1$ onto $|w| \leqq 1$ so that $z = i/2$ is mapped onto $w = 0$. Sketch the images of the lines $x = const$ and $y = const$.
18. Find an analytic function that maps the second quadrant of the z-plane onto the interior of the unit circle in the w-plane.
19. Find an analytic function $w = f(z)$ that maps the region $0 \leqq \arg z \leqq \pi/4$ onto the unit disk $|w| \leqq 1$.
20. **(Composite)** Show that the composite of two LFTs is a LFT.

17.4 Conformal Mapping by Other Functions

So far we have discussed the mapping by z^n, e^z (Sec. 17.1) and linear fractional transformations (Secs. 17.2, 17.3), and we shall now turn to the mapping by trigonometric and hyperbolic analytic functions.

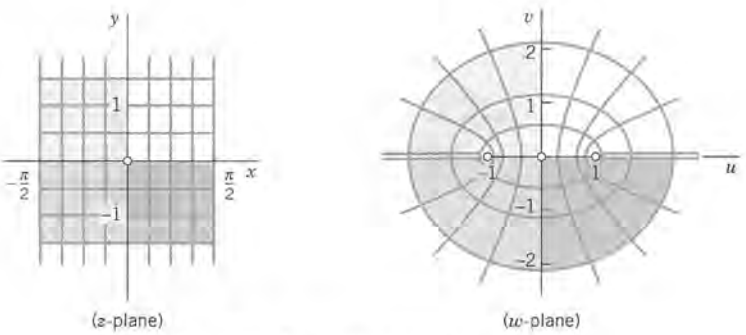

Fig. 388. Mapping $w = u + iv = \sin z$

Sine Function. Figure 388 shows the mapping by

$$w = u + iv = \sin z = \sin x \cosh y + i \cos x \sinh y \qquad \text{(Sec. 13.6)}. \tag{1}$$

Hence

$$u = \sin x \cosh y, \qquad v = \cos x \sinh y. \tag{2}$$

Since $\sin z$ is periodic with period 2π, the mapping is certainly not one-to-one if we consider it in the full z-plane. We restrict z to the vertical strip S: $-\frac{1}{2}\pi \leqq x \leqq \frac{1}{2}\pi$ in Fig. 388. Since $f'(z) = \cos z = 0$ at $z = \pm\frac{1}{2}\pi$, the mapping is not conformal at these two critical points. We claim that the rectangular net of straight lines $x = const$ and $y = const$ in Fig. 388 is mapped onto a net in the w-plane consisting of hyperbolas (the images of the vertical lines $x = const$) and ellipses (the images of the horizontal lines $y = const$) intersecting the hyperbolas at right angles (conformality!). Corresponding calculations are simple. From (2) and the relations $\sin^2 x + \cos^2 x = 1$ and $\cosh^2 y - \sinh^2 y = 1$ we obtain

$$\frac{u^2}{\sin^2 x} - \frac{v^2}{\cos^2 x} = \cosh^2 y - \sinh^2 y = 1 \qquad \text{(Hyperbolas)}$$

$$\frac{u^2}{\cosh^2 y} + \frac{v^2}{\sinh^2 y} = \sin^2 x + \cos^2 x = 1 \qquad \text{(Ellipses)}.$$

Exceptions are the vertical lines $x = \pm\frac{1}{2}\pi$, which are "folded" onto $u \leqq -1$ and $u \geqq 1$ $(v = 0)$, respectively.

Figure 389 illustrates this further. The upper and lower sides of the rectangle are mapped onto semi-ellipses and the vertical sides onto $-\cosh 1 \leqq u \leqq -1$ and $1 \leqq u \leqq \cosh 1$ $(v = 0)$, respectively. An application to a potential problem will be given in Prob. 5 of Sec. 18.2.

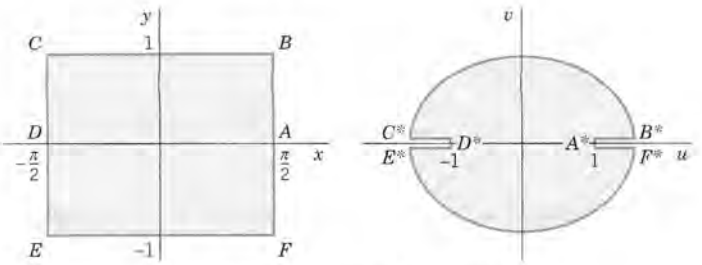

Fig. 389. Mapping by $w = \sin z$

Cosine Function. The mapping $w = \cos z$ could be discussed independently, but since

$$w = \cos z = \sin (z + \tfrac{1}{2}\pi), \tag{3}$$

we see at once that this is the same mapping as $\sin z$ preceded by a translation to the right through $\frac{1}{2}\pi$ units.

Hyperbolic Sine. Since

$$w = \sinh z = -i \sin (iz), \tag{4}$$

the mapping is a counterclockwise rotation $Z = iz$ through $\frac{1}{2}\pi$ (i.e., 90°), followed by the sine mapping $Z^* = \sin Z$, followed by a clockwise 90°-rotation $w = -iZ^*$.

Hyperbolic Cosine. This function

$$w = \cosh z = \cos (iz) \tag{5}$$

defines a mapping that is a rotation $Z = iz$ followed by the mapping $w = \cos Z$.

Figure 390 shows the mapping of a semi-infinite strip onto a half-plane by $w = \cosh z$. Since $\cosh 0 = 1$, the point $z = 0$ is mapped onto $w = 1$. For real $z = x \geqq 0$, $\cosh z$ is real and increases with increasing x in a monotone fashion, starting from 1. Hence the positive x-axis is mapped onto the portion $u \geqq 1$ of the u-axis.

For pure imaginary $z = iy$ we have $\cosh iy = \cos y$. Hence the left boundary of the strip is mapped onto the segment $1 \geqq u \geqq -1$ of the u-axis, the point $z = \pi i$ corresponding to

$$w = \cosh i\pi = \cos \pi = -1.$$

On the upper boundary of the strip, $y = \pi$, and since $\sin \pi = 0$ and $\cos \pi = -1$, it follows that this part of the boundary is mapped onto the portion $u \leqq -1$ of the u-axis. Hence the boundary of the strip is mapped onto the u-axis. It is not difficult to see that the interior of the strip is mapped onto the upper half of the w-plane, and the mapping is one-to-one.

This mapping in Fig. 390 has applications in potential theory, as we shall see in Prob. 12 of Sec. 18.3.

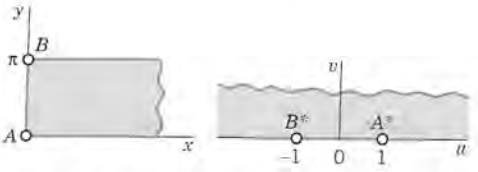

Fig. 390. Mapping by $w = \cosh z$

Tangent Function. Figure 391 shows the mapping of a vertical infinite strip onto the unit circle by $w = \tan z$, accomplished in three steps as suggested by the representation (Sec. 13.6)

$$w = \tan z = \frac{\sin z}{\cos z} = \frac{(e^{iz} - e^{-iz})/i}{e^{iz} + e^{-iz}} = \frac{(e^{2iz} - 1)/i}{e^{2iz} + 1}.$$

Hence if we set $Z = e^{2iz}$ and use $1/i = -i$, we have

$$(6) \qquad w = \tan z = -iW, \qquad W = \frac{Z - 1}{Z + 1}, \qquad Z = e^{2iz}.$$

We now see that $w = \tan z$ is a linear fractional transformation preceded by an exponential mapping (see Sec. 17.1) and followed by a clockwise rotation through an angle $\frac{1}{2}\pi$ (90°).

The strip is S: $-\frac{1}{4}\pi < x < \frac{1}{4}\pi$, and we show that it is mapped onto the unit disk in the w-plane. Since $Z = e^{2iz} = e^{-2y+2ix}$, we see from (10) in Sec. 13.5 that $|Z| = e^{-2y}$, $\operatorname{Arg} Z = 2x$. Hence the vertical lines $x = -\pi/4$, 0, $\pi/4$ are mapped onto the rays $\operatorname{Arg} Z = -\pi/2$, 0, $\pi/2$, respectively. Hence S is mapped onto the right Z-half-plane. Also $|Z| = e^{-2y} < 1$ if $y > 0$ and $|Z| > 1$ if $y < 0$. Hence the upper half of S is mapped inside the unit circle $|Z| = 1$ and the lower half of S outside $|Z| = 1$, as shown in Fig. 391.

Now comes the linear fractional transformation in (6), which we denote by $g(Z)$:

$$(7) \qquad W = g(Z) = \frac{Z - 1}{Z + 1}.$$

For real Z this is real. Hence the real Z-axis is mapped onto the real W-axis. Furthermore, the imaginary Z-axis is mapped onto the unit circle $|W| = 1$ because for pure imaginary $Z = iY$ we get from (7)

$$|W| = |g(iY)| = \left| \frac{iY - 1}{iY + 1} \right| = 1.$$

The right Z-half-plane is mapped inside this unit circle $|W| = 1$, not outside, because $Z = 1$ has its image $g(1) = 0$ inside that circle. Finally, the unit circle $|Z| = 1$ is mapped

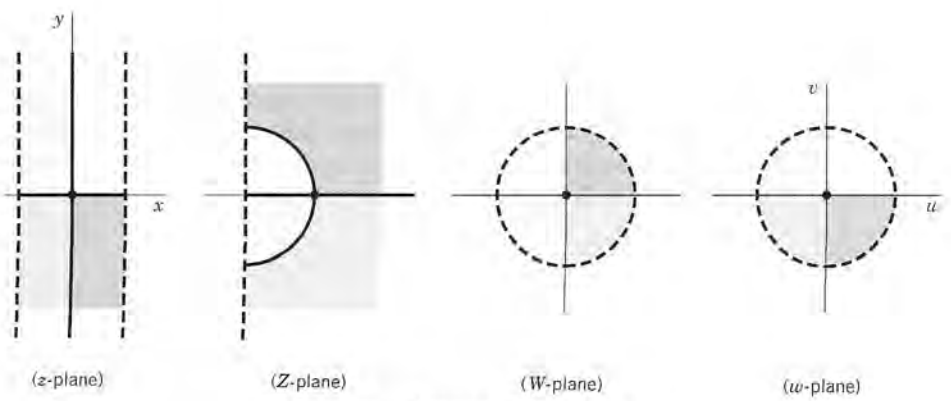

Fig. 391. Mapping by $w = \tan z$

onto the imaginary W-axis, because this circle is $Z = e^{i\phi}$, so that (7) gives a pure imaginary expression, namely,

$$g(e^{i\phi}) = \frac{e^{i\phi} - 1}{e^{i\phi} + 1} = \frac{e^{i\phi/2} - e^{-i\phi/2}}{e^{i\phi/2} + e^{-i\phi/2}} = \frac{i \sin(\phi/2)}{\cos(\phi/2)}.$$

From the W-plane we get to the w-plane simply by a clockwise rotation through $\pi/2$; see (6).

Together we have shown that $w = \tan z$ maps S: $-\pi/4 < \operatorname{Re} z < \pi/4$ onto the unit disk $|w| = 1$, with the four quarters of S mapped as indicated in Fig. 391. This mapping is conformal and one-to-one.

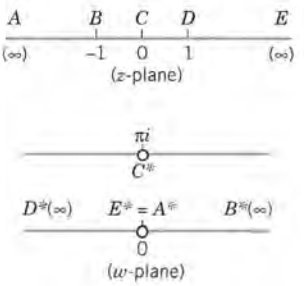
PROBLEM SET 17.4

1–7 CONFORMAL MAPPING $w = e^z$

Find and sketch the image of the given region under $w = e^z$.

1. $0 \leqq x \leqq 2$, $-\pi \leqq y \leqq \pi$
2. $-1 \leqq x \leqq 0$, $0 \leqq y \leqq \pi/2$
3. $-0.5 < x < 0.5$, $3\pi/4 < y < 5\pi/4$
4. $-3 < x < 3$, $\pi/4 < y < 3\pi/4$
5. $0 < x < 1$, $0 < y < \pi$
6. $x < 0$, $-\pi/2 < y < \pi/2$
7. x arbitrary, $0 \leqq y \leqq 2\pi$
8. **CAS EXPERIMENT. Conformal Mapping.** If your CAS can do conformal mapping, use it to solve Prob. 5. Then increase y beyond π, say, to 50π or 100π. State what you expected. See what you get as the image. Explain.

9–12 CONFORMAL MAPPING $w = \sin z$



Find and sketch or graph the image of the given region under $w = \sin z$.

9. $0 \leqq x \leqq \pi$, $0 \leqq y \leqq 1$
10. $0 < x < \pi/6$, y arbitrary
11. $0 < x < 2\pi$, $1 < y < 5$
12. $-\pi/4 < x < \pi/4$, $0 < y < 3$
13. Determine all points at which $w = \sin z$ is not conformal.
14. Find and sketch or graph the images of the lines $x = 0$, $\pm\pi/6$, $\pm\pi/3$, $\pm\pi/2$ under the mapping $w = \sin z$.
15. Find an analytic function that maps the region R bounded by the positive x- and y-axes and the hyperbola $xy = \pi/2$ in the first quadrant onto the upper half-plane. *Hint.* First map the region onto a horizontal strip.
16. Describe the mapping $w = \cosh z$ in terms of the mapping $w = \sin z$ and rotations and translations.
17. Find all points at which the mapping $w = \cosh \pi z$ is not conformal.

18–22 CONFORMAL MAPPING $w = \cos z$

Find and sketch or graph the image of the given region under $w = \cos z$.

18. $0 < x < \pi/2$, $0 < y < 2$
19. $0 < x < \pi$, $0 < y < 1$
20. $-1 \leqq x \leqq 1$, $0 \leqq y \leqq 1$
21. $\pi < x < 2\pi$, $y < 0$
22. $0 < x < 2\pi$, $1/2 < y < 1$
23. Find the images of the lines $y = c = const$ under the mapping $w = \cos z$.
24. Show that $w = \operatorname{Ln} \dfrac{z - 1}{z + 1}$ maps the upper half-plane onto the horizontal strip $0 \leqq \operatorname{Im} w \leqq \pi$ as shown in the figure.

Problem 24

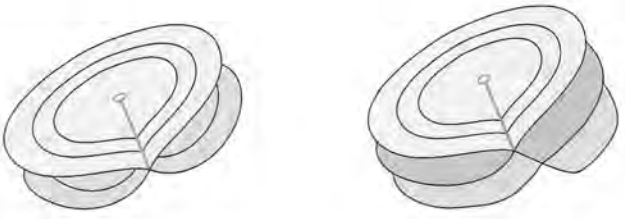
25. Find and sketch the image of R: $2 \leqq |z| \leqq 3$, $\pi/4 \leqq \theta \leqq \pi/2$ under the mapping $w = \operatorname{Ln} z$.

17.5 Riemann Surfaces. *Optional*

Riemann surfaces are surfaces on which multivalued relations, such as $w = \sqrt{z}$ or $w = \ln z$, become single-valued, that is, functions in the usual sense. We explain the idea, which is simple—but ingenious, one of the greatest in complex analysis.

The mapping given by

$$w = u + iv = z^2 \tag{1}$$ (Sec. 17.1)



is conformal, except at $z = 0$, where $w' = 2z = 0$. At $z = 0$, angles are doubled under the mapping. Thus the right z-half-plane (including the positive y-axis) is mapped onto the full w-plane, cut along the negative half of the u-axis; this mapping is one-to-one. Similarly for the left z-half-plane (including the negative y-axis). Hence the image of the full z-plane under $w = z^2$ "covers the w-plane twice" in the sense that every $w \neq 0$ is the image of two z-points; if z_1 is one, the other is $-z_1$. For example, $z = i$ and $-i$ are both mapped onto $w = -1$.

Now comes the crucial idea. We place those two copies of the cut w-plane upon each other so that the upper sheet is the image of the right half z-plane R and the lower sheet is the image of the left half z-plane L. We join the two sheets crosswise along the cuts (along the negative u-axis) so that if z moves from R to L, its image can move from the upper to the lower sheet. The two origins are fastened together because $w = 0$ is the image of just one z-point, $z = 0$. The surface obtained is called a **Riemann surface** (Fig. 392a). $w = 0$ is called a "winding point" or **branch point.** $w = z^2$ maps the full z-plane onto this surface in a one-to-one manner.

By interchanging the roles of the variables z and w it follows that the double-valued relation

$$w = \sqrt{z} \tag{2}$$ (Sec. 13.2)

becomes single-valued on the Riemann surface in Fig. 392a, that is, a function in the usual sense. We can let the upper sheet correspond to the principal value of $\sqrt{z}$. Its image is the right w-half-plane. The other sheet is then mapped onto the left w-half-plane.

(a) Riemann surface of $\sqrt{z}$ (b) Riemann surface of $\sqrt[3]{z}$

Fig. 392. Riemann surfaces

Similarly, the triple-valued relation $w = \sqrt[3]{z}$ becomes single-valued on the three-sheeted Riemann surface in Fig. 392b, which also has a branch point at $z = 0$.

The infinitely many-valued natural logarithm (Sec. 13.7)

$$w = \ln z = \operatorname{Ln} z + 2n\pi i \qquad (n = 0, \pm 1, \pm 2, \cdots)$$

becomes single-valued on a Riemann surface consisting of infinitely many sheets. $w = \operatorname{Ln} z$ corresponds to one of them. This sheet is cut along the negative x-axis and the upper edge of the slit is joined to the lower edge of the next sheet, which corresponds to the argument $\pi < \theta \leqq 3\pi$, that is, to

$$w = \operatorname{Ln} z + 2\pi i.$$

The principal value $\operatorname{Ln} z$ maps its sheet onto the horizontal strip $-\pi < v \leqq \pi$. The function $w = \operatorname{Ln} z + 2\pi i$ maps its sheet onto the neighboring strip $\pi < v \leqq 3\pi$, and so on. The mapping of the points $z \neq 0$ of the Riemann surface onto the points of the w-plane is one-to-one. See also Example 5 in Sec. 17.1.

PROBLEM SET 17.5

1. Consider $w = \sqrt{z}$. Find the path of the image point w of a point z that moves twice around the unit circle, starting from the initial position $z = 1$.
2. Show that the Riemann surface of $w = \sqrt[n]{z}$ consists of n sheets and has a branch point at $z = 0$.
3. Make a sketch, similar to Fig. 392, of the Riemann surface of $\sqrt[4]{z}$.
4. Show that the Riemann surface of $w = \sqrt{(z-1)(z-2)}$ has branch points at $z = 1$ and $z = 2$ and consists of two sheets that may be cut along the line segment from 1 to 2 and joined crosswise. *Hint.* Introduce polar coordinates $z - 1 = r_1 e^{i\theta_1}$, $z - 2 = r_2 e^{i\theta_2}$.

5–10 RIEMANN SURFACES

Find the branch points and the number of sheets of the Riemann surface.

5. $\sqrt{3z + 5}$
6. $\sqrt{(1 - z^2)(4 - z^2)}$
7. $5 + \sqrt[3]{2z + i}$
8. $\ln (3z - 4i)$
9. $e^{\sqrt{z}}$
10. $\sqrt{e^z}$

CHAPTER 17 REVIEW QUESTIONS AND PROBLEMS

1. How did we define the angle of intersection of two oriented curves, and what does it mean to say that a mapping is conformal?
2. At what points is a mapping $w = f(z)$ by an analytic function not conformal? Give examples.
3. What happens to angles at z_0 under a mapping $w = f(z)$ if $f'(z_0) = 0$, $f''(z_0) = 0$, $f'''(z_0) \neq 0$?
4. What do "surjective," "injective," and "bijective" mean?
5. What mapping gave the Joukowski airfoil?
6. What are linear fractional transformations (LFTs)? Why are they important in connection with the extended complex plane?
7. Why did we require that $ad - bc \neq 0$ for a LFT?
8. What are fixed points of a mapping? Give examples.
